Pivotal Greenplum 5.21.4 Release Notes

Updated: September, 2019

- Welcome to Pivotal Greenplum 5.21.4
- Changed Feature
- Resolved Issues
- Beta Features
- Deprecated Features
- Known Issues and Limitations
- Differences Compared to Open Source Greenplum Database
- Supported Platforms
- Pivotal Greenplum Tools and Extensions Compatibility
- Hadoop Distribution Compatibility
- Upgrading to Greenplum Database 5.21.4
- Migrating Data to Pivotal Greenplum 5.x
- Pivotal Greenplum on DCA Systems
- Update for gp_toolkit.gp_bloat_expected_pages Issue
- Update for gp_toolkit.gp_bloat_diag Issue
Welcome to Pivotal Greenplum 5.21.4

Pivotal Greenplum Database is a massively parallel processing (MPP) database server that supports next generation data warehousing and large-scale analytics processing. By automatically partitioning data and running parallel queries, it allows a cluster of servers to operate as a single database supercomputer performing tens or hundreds times faster than a traditional database. It supports SQL, MapReduce parallel processing, and data volumes ranging from hundreds of gigabytes, to hundreds of terabytes.

This document contains pertinent release information about Pivotal Greenplum Database 5.21.4. For previous versions of the release notes for Greenplum Database, go to Pivotal Greenplum Database Documentation. For information about Greenplum Database end of life, see the Pivotal Support Lifecycle Policy.

Pivotal Greenplum 5.x software is available for download from the Pivotal Greenplum page on Pivotal Network.

Pivotal Greenplum 5.x is based on the open source Greenplum Database project code.

**Important:** The Greenplum gpbackup and gprestore utilities are now distributed separately from Pivotal Greenplum Database, and are updated independently of the core Greenplum Database server. These utilities will not be updated in future Greenplum Database 5.x releases. You can upgrade to the latest gpbackup and gprestore versions by downloading and installing the latest Pivotal Greenplum Backup and Restore release from Pivotal Network.

**Important:** Pivotal Support does not provide support for open source versions of Greenplum Database. Only Pivotal Greenplum Database is supported by Pivotal Support.

Pivotal Greenplum 5.21.4 is a maintenance release that resolves issues.
Changed Feature

Greenplum Database 5.21.4 includes this changed feature.

- The Greenplum Database timezone files have been updated. This release includes Internet Assigned Numbers Authority (IANA) Time Zone Database version 2019b.

  Greenplum Database updates its list of available timezones as necessary. The Greenplum Database timezone files are based on the PostgreSQL IANA timezone database files.
Resolved Issues

The listed issues are resolved in Pivotal Greenplum Database 5.21.4.

For issues resolved in prior 5.x releases, refer to the corresponding release notes. Release notes are available from the Pivotal Greenplum page on Pivotal Network.

30081 - Postgres Planner
In some cases, cached query plan invalidation was not performed correctly. This caused Greenplum Database to return the error cached plan must not change result type. This issue has been resolved. Cached query plan invalidation has been improved and the error is no longer returned.

30071 - Catalog and Metadata
In some cases, an Exclusive lock was acquired on the system catalog table pg_class preventing concurrent updates to the table. This issue has been resolved. Now a Row Exclusive lock is used to update pg_class.

30070 - Vacuum
A mismatch in segment file state on the master and a segment during a VACUUM operation could cause a subsequent operation on the relation to return an error. The error occurred when the query executor (QE) did not update the segment file state appropriately when it could not acquire an exclusive lock on an AO/AOCO relation during the VACUUM. This issue has been resolved. The QE now waits for the lock, which ensures that the segment file state is consistent between master and segment.

29987 - Query Optimizer
GPORCA did not generate implied predicates for queries that contain a predicate on a CAST column that uses a list such as an IN clause and a join condition on the same column. This resulted in an inferior plan that scanned the whole table. This issue has been resolved, and GPORCA now produces an optimal plan that infers such predicates.
Beta Features

Because Pivotal Greenplum Database is based on the open source Greenplum Database project code, it includes several Beta features to allow interested developers to experiment with their use on development systems. Feedback will help drive development of these features, and they may become supported in future versions of the product.

Warning: Beta features are not supported for production deployments.

Greenplum Database 5.21.4 includes these Beta features:

- Storage plugin API for gpbackup and gprestore. Partners, customers, and OSS developers can develop plugins to use in conjunction with gpbackup and gprestore.
  For information about the storage plugin API, see Backup/Restore Storage Plugin API in the Pivotal Greenplum Database Documentation.
- Recursive WITH Queries (Common Table Expressions). See WITH Queries (Common Table Expressions) in the Pivotal Greenplum Database Documentation.
- Resource groups remain a Beta feature only on the SuSE 11 platform, due to limited cgroups functionality in the kernel.
  SuSE 12 resolves the Linux cgroup issues that caused the performance degradation when Greenplum Database resource groups are enabled.
- Using the Greenplum Platform Extension (PXF) connectors to write Parquet data is a Beta feature.
**Depreciated Features**

These Greenplum Database features are deprecated.

- The `gptransfer` utility will be removed in the next major release. The utility copies objects between Greenplum Database systems. The `gpcopy` utility provides `gptransfer` functionality.
- The `gphdfs` external table protocol will be removed in the next major release. Consider using the Greenplum Platform Extension Framework (PXF) `pxf` external table protocol to access data stored in an external Hadoop file system. Refer to *Accessing External Data with PXF* for more information.
Known Issues and Limitations

Pivotal Greenplum 5.x has these limitations:

- Upgrading a Greenplum Database 4.3.x release to Pivotal Greenplum 5.x is not supported. See Migrating Data to Pivotal Greenplum 5.x.
- Some features are works-in-progress and are considered to be Beta features. Pivotal does not support using Beta features in a production environment. See Beta Features.
- Greenplum Database 4.3.x packages are not compatible with Pivotal Greenplum 5.x.

The following table lists key known issues in Pivotal Greenplum 5.x.

Table 1: Key Known Issues in Pivotal Greenplum 5.x

<table>
<thead>
<tr>
<th>Issue</th>
<th>Category</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>29917</td>
<td>Segment Mirroring</td>
<td>A “read beyond eof” error has been observed with certain persistent tables during full recovery. The root cause of this problem has not yet been determined. Greenplum Database version 5.21 contains additional debug logging to help in determining the cause of this problem. The additional logging is enabled by default, and adds approximately 646 bytes to each persistent table entry file. If you want to disable the additional debug logging, set the debug_filerep_config_print configuration parameter &quot;false.&quot;</td>
</tr>
<tr>
<td>Issue</td>
<td>Category</td>
<td>Description</td>
</tr>
<tr>
<td>--------</td>
<td>-----------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>29861</td>
<td>gpstart</td>
<td>If a segment's data directory becomes inaccessible or the contents of the data directory are deleted, the segment goes offline and is marked as down in gp_segment_configuration. However, if you have temporary or transaction files in a separate filespace or if you stop and start the database, gpstart can fail with the error: 20190404:17:26:44:025089 gpstart:mdw:gpadmin-[ERROR]:-Multiple OIDs found in flat files 20190404:17:26:44:025089 gpstart:mdw:gpadmin-[ERROR]:-Filespaces are inconsistent. Abort Greenplum Database start. The error indicates that two files are missing from a segment directory, gp_temporary_files_filespace and gp_transaction_files_filespace. gpstart reports the error even if the segments have already been marked down. <strong>Workaround:</strong> To resolve this problem you must manually create the missing files in the segment directory using the segment's corresponding dbid, transaction file segment directory, and filespace oid. See the detailed instructions for creating these files in Article Number: 6784 gpstart fails with error &quot;Multiple OIDs found in flat files&quot; on the Pivotal Support site.</td>
</tr>
<tr>

<td>Description</td>
</tr>
<tr>
<td>---------</td>
<td>--------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>164671144</td>
<td>gpssh-exkeys</td>
<td>The <code>gpssh-exkeys</code> utility uses the Paramiko SSH library for Python, which has a dependency on the Python Cryptography Toolkit (PyCrypto) library. The following security vulnerabilities have been identified in some versions of PyCrypto.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• <a href="https://nvd.nist.gov/vuln/detail/CVE-2018-6594">https://nvd.nist.gov/vuln/detail/CVE-2018-6594</a> - lib/Crypto/PublicKey/ElGamal.py in PyCrypto through 2.6.1 generates weak ElGamal key parameters, which allows attackers to obtain sensitive information by reading ciphertext data (i.e., it does not have semantic security in face of a ciphertext-only attack). The Decisional Diffie-Hellman (DDH) assumption does not hold for PyCrypto's ElGamal implementation. Paramiko does not import this algorithm, so Greenplum Database is unaffected by this vulnerability.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• <a href="https://nvd.nist.gov/vuln/detail/CVE-2013-7459">https://nvd.nist.gov/vuln/detail/CVE-2013-7459</a> - Heap-based buffer overflow in the ALGnew function in block_templace.c in Python Cryptography Toolkit (aka pycrypto) allows remote attackers to execute arbitrary code as demonstrated by a crafted iv parameter to cryptmsg.py. This bug was introduced in PyCrypto 2.6. Greenplum Database has PyCrypto 2.0.1, and is unaffected by the vulnerability.</td>
</tr>
</tbody>
</table>
|         |              | • [https://nvd.nist.gov/vuln/detail/CVE-2013-1445](https://nvd.nist.gov/vuln/detail/CVE-2013-1445) - The Crypto.Random.atfork function in PyCrypto before 2.6.1 does not properly reseed the pseudo-random number generator (PRNG) before allowing a child process to access it, which makes it easier for context-dependent
<table>
<thead>
<tr>
<th>Issue</th>
<th>Category</th>
<th>Description</th>
</tr>
</thead>
</table>
|       |          | attackers to obtain sensitive information by leveraging a race condition in which a child process is created and accesses the PRNG within the same rate-limit period as another process. Paramiko version 1.7.6-9, used in Greenplum Database 4.x and 5.x, introduced a workaround to this bug. Paramiko version 1.18.4 in Greenplum Database 6 solves it in a more permanent way.  
• ![https://nvd.nist.gov/vuln/detail/CVE-2012-2417](CVE-2012-2417) - PyCrypto before 2.6 does not produce appropriate prime numbers when using an ElGamal scheme to generate a key, which reduces the signature space or public key space and makes it easier for attackers to conduct brute force attacks to obtain the private key.  
Paramiko does not import this algorithm, so Greenplum Database is unaffected by the vulnerability.  
Through testing and investigation, Pivotal has determined that these vulnerabilities do not affect Greenplum Database, and no actions are required for existing Greenplum Database 4.3 or 5.x releases. However, there may be additional unidentified vulnerabilities in the PyCrypto library, and users who install a later version of PyCrypto could be exposed to other vulnerabilities.  
The PyCrypto library will be removed from Greenplum Database 6.0.  
**Workaround:** Administrators can set up passwordless SSH between hosts in the Greenplum Database cluster without using the `gpssh-exkeys` utility. This must be done before initializing the Greenplum Database system. |

<td>An identified PostgreSQL security vulnerability (<a href="https://nvd.nist.gov/vuln/detail/CVE-2018-1058">https://nvd.nist.gov/vuln/detail/CVE-2018-1058</a>) also exists in Greenplum Database. The problem centers around the default public schema and how Greenplum Database uses the <code>search_path</code> setting. The ability to create objects with the same names in different schemas, combined with how Greenplum Database searches for objects within schemas, presents an opportunity for a user to modify the behavior of a query for other users. For example, a malicious user could insert a trojan-horse function that, when executed by a superuser, grants escalated privileges to the malicious user. There are methods to protect from this vulnerability. See <a href="https://www.postgresql.org/docs/current/vulnerability.html">A Guide to CVE-2018-1058: Protect Your Search Path</a> on the PostgreSQL wiki for a full explanation of the vulnerability and the steps you can take to protect your data.</td>

<td>ANALYZE</td>
<td>In Greenplum Database 5.15.1 and earlier 5.x releases, an ANALYZE command might return a error that states target lists can have at most 1664 entries when performing an ANALYZE operation on a table with a large number of columns (more than 800 columns). The error occurs because the in-memory sample table created by ANALYZE requires an additional column to indicate whether a column is NULL or is a truncated column for each variable length column being analyzed (such as varchar, text, and bpchar, numeric, arrays, and geometric datatype columns). The error is returned when ANALYZE attempts to create a sample table and the number of columns (table columns and indicator columns) exceeds the maximum number of columns allowed. In Greenplum Database 5.16.0 and later 5.x releases, the ANALYZE sample table does not require an additional column for variable length text columns such as varchar, text, and bpchar columns. <strong>WORKAROUND:</strong> To collect statistics on the table, perform ANALYZE operations on 2 or more sets of table columns.</td>

</tbody>
</table>
| 29523   | gptoolkit    | An upgrade between minor releases does not update the template0 database, and in some cases, using these views in the gp_toolkit schema might cause issues if you create a database using template0 as the template database after you upgrade to Greenplum Database 5.11.0 or later.  
• The gp_toolkit.gp_bloat_expected_pages view might incorrectly report that a root partition table is bloated even though root partition tables do not contain data if you upgrade from Greenplum Database 5.10.x or earlier.  
• The gp_toolkit.gp_bloat_diag view might return an integer out of range error in some cases if you upgrade from Greenplum Database 5.3.0 or earlier.  
For example, the issues might occur if you upgrade a Greenplum Database system from 5.3.0 or an earlier 5.x release and then run a gprestore operation with the --redirect-db option to create a new database. The utility creates a new database using template0 as the template database.  
**Workaround:** You can update the views in the gp_toolkit schema in the new database. For information about checking and updating gp_toolkit, see Update for gp_toolkit.gp_bloat_expected_pages Issue and Update for gp_toolkit.gp_bloat_diag Issue. |

<td>When a session creates temporary objects in a database, Greenplum Database might not drop temporary objects when the session ends if the session terminates abnormally or is terminated from an administrator command.</td>
</tr>
<tr>
<td>29496</td>
<td>gpconfig</td>
<td>For a small number of server configuration parameters such as log_min_messages, the command <code>gpconfig -s &lt;config_param&gt;</code> does not display the correct value of the parameter for the segment hosts when the value of the parameter on master is different than the value on the segments. For parameters with the set classification master, the utility displays the value set on the master for both master and segments (for information about set classifications, see Setting Parameters in the Pivotal Greenplum Database Documentation). For those parameters, the value on the master is passed as part of queries to segment instances. The SQL query that gpconfig runs to display the master and segment parameter values returns the master host value that is passed to the segment as part of the query. For a few parameters such as log_min_messages, segment instances use the segment host value specified in the postgresql.conf file at start up. The segment value can overridden for the scope of a query. Workaround: To display the parameter value specified in the postgresql.conf file on the master host and segment hosts, you can specify the gpconfig option <code>--file</code>.</td>

<th>Description</th>
</tr>
</thead>
</table>
| 158011506 | Catalog and Metadata | In some cases, the timezone used by Greenplum Database might be different than the host system timezone, or the Greenplum Database timezone set by a user. In some rare cases, times used and displayed by Greenplum Database might be slightly different than the host system time. The timezone used by Greenplum Database is selected from a set of internally stored PostgreSQL timezones. Greenplum Database selects the timezone by matching a PostgreSQL timezone with the user specified time zone, or the host system time zone. For example, when selecting a default timezone, Greenplum Database uses an algorithm to select a PostgreSQL timezones based on the host system timezone. If the system timezone includes leap second information, Greenplum Database cannot match the system timezone with a PostgreSQL timezone. Greenplum Database calculates a best match with a PostgreSQL timezone based on information from the host system.  

**Workaround:** Set the Greenplum Database and host system timezones to a timezone that is supported by both Greenplum Database and the host system. For example, you can show and set the Greenplum Database timezone with the `gpconfig` utility. These commands show the Greenplum Database timezone and set the timezone to `US/Pacific`.  

```bash
# gpconfig -s TimeZone

# gpconfig -c TimeZone -v 'US/Pacific'
```

You must restart Greenplum Database after changing the timezone. The command...

<tr>
<td>149789783</td>
<td>Resource Groups</td>
<td>Significant Pivotal Greenplum performance degradation has been observed when enabling resource group-based workload management on Red Hat 6.x, CentOS 6.x, and SuSE 11 systems. This issue is caused by a Linux cgroup kernel bug. This kernel bug has been fixed in CentOS 7.x and Red Hat 7.x systems. When resource groups are enabled on systems with an affected kernel, there can be a delay of 1 second or longer when starting a transaction or a query. The delay is caused by a Linux cgroup kernel bug where a synchronization mechanism called <code>synchronize_sched</code> is abused when a process is attached to a cgroup. See <a href="http://www.spinics.net/lists/cgroups/msg05708.html">http://www.spinics.net/lists/cgroups/msg05708.html</a> and <a href="https://lkml.org/lkml/2013/1/14/97">https://lkml.org/lkml/2013/1/14/97</a> for more information. The issue causes single attachment operations to take longer and also causes all concurrent attachments to be executed in sequence. For example, one process attachment could take about 0.01 second. When concurrently attaching 100 processes, the fastest process attachment takes 0.01 second and the slowest takes about 1 second. Pivotal Greenplum performs process attachments when a transaction or queries are started. So the performance degradation is dependent on concurrent started transactions or queries, and not related to concurrent running queries. Also Pivotal Greenplum has optimizations to bypass the rewriting when a QE is reused by multiple queries in the same session. <strong>Workaround:</strong> This bug does not affect CentOS 7.x and Red Hat 7.x systems.</td>

<td>Backup and Restore</td>
<td>Backups created on Greenplum Database versions before 4.3.33.0 or 5.1.19.0 may fail to restore to Greenplum Database versions 4.3.33.0 or 5.1.19.0 or later. In Greenplum Database 4.3.33.0 and 5.1.19.0, a check was introduced to ensure that the distribution key for a table is equal to the primary key or is a left-subset of the primary key. If you add a primary key to a table that contains no data, Greenplum Database automatically updates the distribution key to match the primary key. The index key for any unique index on a table must also match or be a left-subset of the distribution key. Earlier Greenplum Database versions did not enforce these policies. Restoring a table from an older backup that has a different distribution key causes errors because the backup data file on each segment contains data that was distributed using the original distribution key. Restoring a unique index with a key that does not match the distribution key will fail with an error when attempting to create the index. This issue affects the gprestore, gpdbrestore, and pg_restore utilities.</td>
</tr>
</tbody>
</table>
**Differences Compared to Open Source Greenplum Database**

Pivotal Greenplum 5.x includes all of the functionality in the open source *Greenplum Database project* and adds:

- Product packaging and installation script.
- Support for QuickLZ compression. QuickLZ compression is not provided in the open source version of Greenplum Database due to licensing restrictions.
- Support for managing Greenplum Database using Pivotal Greenplum Command Center.
- Support for full text search and text analysis using Pivotal GPText.
- Support for data connectors:
  - Greenplum-Spark Connector
  - Greenplum-Informatica Connector
  - Greenplum-Kafka Integration
  - Gemfire-Greenplum Connector
  - Greenplum Stream Server
- Data Direct ODBC/JDBC Drivers
- `gpcopy` utility for copying or migrating objects between Greenplum systems.
Supported Platforms

Pivotal Greenplum 5.21.4 runs on the following platforms:

- Red Hat Enterprise Linux 64-bit 7.x (See the following Note)
- Red Hat Enterprise Linux 64-bit 6.x (See the following Note)
- SuSE Linux Enterprise Server 64-bit 12 SP2 and SP3 with kernel version greater than 4.4.73-5. (See the following Note)
- SuSE Linux Enterprise Server 64-bit 11 SP4 (See the following Note)
- CentOS 64-bit 7.x
- CentOS 64-bit 6.x (See the following Note)
- Oracle Linux 64-bit 7.4, using the Red Hat Compatible Kernel (RHCK)

Note: For the supported Linux operating systems, Pivotal Greenplum Database is supported on system hosts using either AMD or Intel CPUs based on the x86-64 architecture. Pivotal recommends using a homogeneous set of hardware (system hosts) in a Greenplum Database system.

Important: Significant Greenplum Database performance degradation has been observed when enabling resource group-based workload management on Red Hat 6.x, CentOS 6.x, and SuSE 11 systems. This issue is caused by a Linux cgroup kernel bug. This kernel bug has been fixed in CentOS 7.x and Red Hat 7.x systems.

If you use Red Hat 6 and the performance with resource groups is acceptable for your use case, upgrade your kernel to version 2.6.32-696 or higher to benefit from other fixes to the cgroups implementation.

SuSE 11 does not have a kernel version that resolves this issue; resource groups are still considered to be a Beta feature on this platform. Resource groups are not supported on SuSE 11 for production use. See known issue 149789783.

Pivotal Greenplum on SuSE 12 supports resource groups for production use. SuSE 12 resolves the Linux cgroup kernel issues that caused the performance degradation when Greenplum Database resource groups are enabled.

Note: For Greenplum Database that is installed on Red Hat Enterprise Linux 7.x or CentOS 7.x prior to 7.3, an operating system issue might cause Greenplum Database that is running large workloads to hang in the workload. The Greenplum Database issue is caused by Linux kernel bugs. RHEL 7.3 and CentOS 7.3 resolves the issue.

Note: Greenplum Database on SuSE Linux Enterprise systems does not support these features.
- The PL/Perl procedural language
- The gpmapreduce tool
- The PL/Container language extension
- The Greenplum Platform Extension Framework (PXF)

Note: PL/Container is not supported on RHEL/CentOS 6.x systems, because those platforms do not officially support Docker.

Greenplum Database support on Dell EMC DCA.
- Pivotal Greenplum Database 5.21.4 is supported on DCA systems that are running DCA software version 3.4 or greater.
- Only Pivotal Greenplum Database is supported on DCA systems. Open source versions of Greenplum Database are not supported.
- FIPS is supported on DCA software version 3.4 and greater with Pivotal Greenplum Database 5.2.0 and greater.
**Note:** These Greenplum Database releases are not certified on DCA because of an incompatibility in configuring timezone information.

5.5.0, 5.6.0, 5.6.1, 5.7.0, 5.8.0

These Greenplum Database releases are certified on DCA.

5.7.1, 5.8.1, 5.9.0 and later releases, and 5.x releases prior to 5.5.0.

Pivotal Greenplum 5.21.4 supports these Java versions:

- 8.xxx
- 7.xxx

Greenplum Database 5.21.4 software that runs on Linux systems uses OpenSSL 1.0.2l (with FIPS 2.0.16), cURL 7.54, OpenLDAP 2.4.44, and Python 2.7.12.

Greenplum Database client software that runs on Windows and AIX systems uses OpenSSL 0.9.8zg.

The Greenplum Database s3 external table protocol supports these data sources:

- Amazon Simple Storage Service (Amazon S3)
- Dell EMC Elastic Cloud Storage (ECS), an Amazon S3 compatible service

Pivotal Greenplum 5.21.4 supports Data Domain Boost on Red Hat Enterprise Linux.

This table lists the versions of Data Domain Boost SDK and DDOS supported by Pivotal Greenplum 5.x.

</table>

**Note:** In addition to the DDOS versions listed in the previous table, Pivotal Greenplum 5.0.0 and later supports all minor patch releases (fourth digit releases) later than the certified version.

\(^1\)Support for Data Domain Boost 3.0.0.3 is deprecated. The DELL EMC end of Primary Support date is December 31, 2017.

\(^2\)The Greenplum Database utilities `gpbackup` and `gprestore` support Data Domain DD Boost File System Plugin (BoostFS) v1.1 with DDOS 6.0 or greater.

The `gpbackup` and `gprestore` utilities support using Dell EMC Data Domain Boost software with the DD Boost Storage Plugin.

**Note:** Pivotal Greenplum 5.21.4 does not support the ODBC driver for Cognos Analytics V11.

Connecting to IBM Cognos software with an ODBC driver is not supported. Greenplum Database supports connecting to IBM Cognos software with the DataDirect JDBC driver for Pivotal Greenplum. This driver is available as a download from Pivotal Network.

**Veritas NetBackup**

Pivotal Greenplum 5.21.4 supports backup with Veritas NetBackup version 7.7.3. See *Backing Up Databases with Veritas NetBackup.*
Supported Platform Notes

The following notes describe platform support for Pivotal Greenplum. Please send any questions or comments to Pivotal Support at https://support.pivotal.io.

- Pivotal Greenplum is supported using either IPV4 or IPV6 protocols.
- The only file system supported for running Greenplum Database is the XFS file system. All other file systems are explicitly not supported by Pivotal.
- Greenplum Database is supported on network or shared storage if the shared storage is presented as a block device to the servers running Greenplum Database and the XFS file system is mounted on the block device. Network file systems are not supported. When using network or shared storage, Greenplum Database mirroring must be used in the same way as with local storage, and no modifications may be made to the mirroring scheme or the recovery scheme of the segments. Other features of the shared storage such as de-duplication and/or replication are not directly supported by Pivotal Greenplum Database, but may be used with support of the storage vendor as long as they do not interfere with the expected operation of Greenplum Database at the discretion of Pivotal.
- Greenplum Database is supported when running on virtualized systems, as long as the storage is presented as block devices and the XFS file system is mounted for the storage of the segment directories.

Warning: Running Pivotal Greenplum on hyper-converged infrastructure (HCI) has known issues with performance, scalability, and stability and is not recommended as a scalable solution for Pivotal Greenplum and may not be supported by Pivotal if stability problems appear related to the infrastructure. HCI virtualizes all of the elements of conventional hardware systems and includes, at a minimum, virtualized computing, a virtualized SAN, and virtualized networking.

- A minimum of 10-gigabit network is required for a system configuration to be supported by Pivotal.
- Greenplum Database is supported on Amazon Web Services (AWS), Microsoft Azure, and Google Cloud Compute (GCP).

- **AWS** - For production workloads, r4.8xlarge and r4.16xlarge instance types with four 12TB ST1 EBS volumes for each segment host, or d2.8xlarge with ephemeral storage configured with 4 RAID 0 volumes, are supported. EBS storage is recommended. EBS storage is more reliable and provides more features than ephemeral storage. Note that Amazon has no provisions to replace a bad ephemeral drive; when a disk failure occurs, you must replace the node with the bad disk.

  Pivotal recommends using an Auto Scaling Group (ASG) to provision nodes in AWS. An ASG automatically replaces bad nodes, and you can add further automation to recover the Greenplum processes on the new nodes automatically.

  Deployments should be in a Placement Group within a single Availability Zone. Because Amazon recommends using the same instance type in a Placement Group, use a single instance type for all nodes, including the masters.

- **Azure** - For production workloads, Pivotal recommends configuring Standard_H8 instance type with 4 2TB disks and 2 segments per host and recommend using 8 2TB disks and 4 segments per host with Standard_H16 instance type. Standard_H16 uses 8 2TB disks and 4 segments per host. This means software RAID 0 is required so that the number of volumes do not exceed the number of segments.

  For Azure deployments, you must also configure the Greenplum Database system to not use port 65330. Add the following line to the `sysctl.conf` file on all Greenplum Database hosts.

  ```
  $net.ipv4.ip_local_reserved_ports=65330
  ```

- **GCP** - For all workloads, n1-standard-8 and n1-highmem-8 are supported which are relatively small instance types. This is because of the disk performance in GCP forces the configuration to have just 2 segments per host but with many hosts to scale. Use pd-standard disks and the size of the disk is recommended to be 6 TB. For performance perspective, use a factor of 8 when determining how
many nodes to deploy in GCP, so a 16 segment host cluster in AWS would require 128 nodes in GCP.

- For Red Hat Enterprise Linux 7.2 or CentOS 7.2, the default systemctl setting RemoveIPC=yes removes IPC connections when non-system users logout. This causes the Greenplum Database utility gpinit system to fail with semaphore errors. To avoid this issue, see "Setting the Greenplum Recommended OS Parameters" in the Greenplum Database Installation Guide.
Pivotal Greenplum Tools and Extensions Compatibility

- Client Tools
- Extensions
- Pivotal Greenplum Data Connectors
- Pivotal GPText Compatibility
- Pivotal Greenplum Command Center

Client Tools

Greenplum releases a number of client tool packages on various platforms that can be used to connect to Greenplum Database and the Greenplum Command Center management tool. The following table describes the compatibility of these packages with this Greenplum Database release.

Tool packages are available from Pivotal Network.

Table 3: Pivotal Greenplum 5.21.4 Tools Compatibility

<table>
<thead>
<tr>
<th>Tool</th>
<th>Description of Contents</th>
<th>Tool Version(s)</th>
<th>Server Version(s)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Pivotal Greenplum Clients</td>
<td>Greenplum Database Command-Line Interface (psql)</td>
<td>5.8</td>
<td>5.x</td>
</tr>
<tr>
<td>Pivotal Greenplum Loaders</td>
<td>Greenplum Database Parallel Data Loading Tools (gpfdist, gpload)</td>
<td>5.8</td>
<td>5.x</td>
</tr>
<tr>
<td>Pivotal Greenplum Command Center</td>
<td>Greenplum Database management tool</td>
<td>4.7</td>
<td>5.19 and later</td>
</tr>
<tr>
<td></td>
<td></td>
<td>4.0.0</td>
<td>5.7.0 and later</td>
</tr>
<tr>
<td></td>
<td></td>
<td>3.3.2</td>
<td>5.0.0 and later</td>
</tr>
<tr>

<td></td>
<td>3.2.2</td>
<td>5.0.0 - 5.2.x</td>
</tr>
<tr>
<td>Pivotal Greenplum Workload Manager¹</td>
<td>Greenplum Database query monitoring and management tool</td>
<td>1.8.0</td>
<td>5.0.0</td>
</tr>
</tbody>
</table>

The Greenplum Database Client Tools and Load Tools are supported on the following platforms:

- AIX 7.2 (64-bit) (Client and Load Tools only)²
- Red Hat Enterprise Linux x86_64 7.x (RHEL 7)
- Red Hat Enterprise Linux x86_64 6.x (RHEL 6)
- SuSE Linux Enterprise Server x86_64 SLES 11 SP4, or SLES 12 SP2/SP3
- Windows 10 (32-bit and 64-bit)
- Windows 8 (32-bit and 64-bit)
- Windows Server 2012 (32-bit and 64-bit)
- Windows Server 2012 R2 (32-bit and 64-bit)
- Windows Server 2008 R2 (32-bit and 64-bit)

Note: ¹For Pivotal Greenplum Command Center 4.0.0 and later, workload management is an integrated Command Center feature rather than the separate tool Pivotal Greenplum Workload Manager.
Extensions

Table 4: Pivotal Greenplum 5.21.4 Extensions Compatibility

<table>
<thead>
<tr>
<th>Pivotal Greenplum Extension</th>
<th>Versions</th>
</tr>
</thead>
<tbody>
<tr>
<td>MADlib machine learning for Greenplum Database 5.x(^1)</td>
<td>MADlib 1.16, 1.15.1, 1.15, 1.14</td>
</tr>
<tr>
<td>PL/Java for Greenplum Database 5.x</td>
<td>PL/Java 1.4.3(^2)</td>
</tr>
<tr>
<td>PL/R for Greenplum Database 5.x</td>
<td>2.3.3</td>
</tr>
<tr>
<td>PostGIS Spatial and Geographic Objects for Greenplum Database 5.x</td>
<td>2.1.5+pivotal.2</td>
</tr>
<tr>
<td>Python Data Science Module Package for Greenplum Database 5.x(^3)</td>
<td>1.1.1, 1.1.0, 1.0.0</td>
</tr>
<tr>
<td>R Data Science Library Package for Greenplum Database 5.x(^4)</td>
<td>1.0.1, 1.0.0</td>
</tr>
<tr>
<td>PL/Container for Greenplum Database 5.x</td>
<td>1.1(^5), 1.2(^6), 1.3, 1.4</td>
</tr>
</tbody>
</table>

Note:  
\(^1\) Pivotal recommends that you upgrade to the most recent version of MADlib. For information about MADlib support and upgrade information, see the [MADlib FAQ](#). For information on installing the MADlib extension in Greenplum Database, see [Greenplum MADlib Extension for Analytics](#) in the [Greenplum Database Reference Guide](#).

\(^2\) The PL/Java extension package version 1.4.3 is compatible only with Greenplum Database 5.11.0 and later, it is not compatible with 5.10.x or earlier. If you are upgrading from Greenplum Database 5.10.x or earlier and have installed PL/Java 1.4.2, you must upgrade the PL/Java extension to version 1.4.3.

\(^3\) For information about the Python package, including the modules provided, see the [Python Data Science Module Package](#) in the [Greenplum Database Documentation](#).

\(^4\) For information about the R package, including the libraries provided, see the [R Data Science Library Package](#) in the [Greenplum Database Documentation](#).

\(^5\) To upgrade from PL/Container 1.0 to PL/Container 1.1 and later, you must drop the PL/Container 1.0 language before registering the new version of PL/Container. For information on upgrading the PL/Container extension in Greenplum Database, see [PL/Container Language Extension](#) in the [Greenplum Database Reference Guide](#).

\(^6\) PL/Container version 1.2 can utilize the resource group capabilities that were introduced in Greenplum Database 5.8.0. If you downgrade to a Greenplum Database system that uses PL/Container 1.1 or earlier, you must use `plcontainer runtime-edit` to remove any `resource_group_id` settings from the PL/Container runtime configuration file. See [Upgrading from PL/Container 1.1](#).

These Greenplum Database extensions are installed with Pivotal Greenplum Database:

- Fuzzy String Match Extension
- PL/Python Extension
- pgcrypto Extension
**Pivotal Greenplum Data Connectors**

  
  **Note:** PXF is available only for supported Red Hat and CentOS platforms. PXF is not available for supported SuSE platforms.

- **Greenplum-Spark Connector** - The Pivotal Greenplum-Spark Connector supports high speed, parallel data transfer from Greenplum Database to an Apache Spark cluster. The Greenplum-Spark Connector is available as a separate download from Pivotal Network. Refer to the Greenplum-Spark Connector documentation for compatibility and usage information.

- **Greenplum-Informatica Connector** - The Pivotal Greenplum-Informatica connector supports high speed data transfer from an Informatica PowerCenter cluster to a Pivotal Greenplum Database cluster for batch and streaming ETL operations. See the Pivotal Greenplum-Informatica Connector Documentation.

- **Greenplum-Kafka Integration** - The Pivotal Greenplum-Kafka Integration provides high speed, parallel data transfer from a Kafka cluster to a Pivotal Greenplum Database cluster for batch and streaming ETL operations. Refer to the Pivotal Greenplum-Kafka Integration Documentation for more information about this feature.

- **Greenplum Stream Server** - The Pivotal Greenplum Stream Server is an ETL tool that provides high speed, parallel data transfer from Informatica, Kafka, and custom client data sources to a Pivotal Greenplum Database cluster. Refer to the Performing ETL Operations with the Pivotal Greenplum Stream Server Documentation for more information about this feature.

- **Gemfire-Greenplum Connector** - The Pivotal Gemfire-Greenplum Connector supports the transfer of data between a GemFire region and a Greenplum Database cluster. The Gemfire-Greenplum Connector is available as a separate download from Pivotal Network. Refer to the Gemfire-Greenplum Connector documentation for compatibility and usage information.

**Pivotal GPText Compatibility**

Pivotal Greenplum Database 5.21.4 is compatible with Pivotal GPText version 2.1.3 and later.

**Pivotal Greenplum Command Center**

See the Greenplum Command Center documentation for GPCC and Greenplum Workload Manager compatibility information, see the Pivotal Greenplum Command Center 3.x and 2.x Release Notes.

**Note:** For Pivotal Greenplum Command Center 4.0.0 and later, workload management is an integrated Command Center feature rather than the separate tool Pivotal Greenplum Workload Manager.
Hadoop Distribution Compatibility

Greenplum Database provides access to HDFS with gphdfs and the Greenplum Platform Extension Framework (PXF).

PXF Hadoop Distribution Compatibility

PXF supports the Cloudera, Hortonworks Data Platform, MapR, and generic Apache Hadoop distributions. If you plan to access JSON format data stored in a Cloudera Hadoop cluster, PXF requires a Cloudera version 5.8 or later Hadoop distribution.

gphdfs Hadoop Distribution Compatibility

The supported Hadoop distributions for gphdfs are listed below:

Table 5: Supported gphdfs Hadoop Distributions

<table>
<thead>
<tr>
<th>Hadoop Distribution</th>
<th>Version</th>
<th>gp_hadoop_target_version</th>
</tr>
</thead>
<tbody>
<tr>
<td>Cloudera</td>
<td>CDH 5.x</td>
<td>cdh</td>
</tr>
<tr>
<td>Hortonworks Data Platform</td>
<td>HDP 2.x</td>
<td>hdp</td>
</tr>
<tr>
<td>MapR</td>
<td>MapR 4.x, MapR 5.x</td>
<td>mpr</td>
</tr>
<tr>
<td>Apache Hadoop</td>
<td>2.x</td>
<td>hadoop</td>
</tr>
</tbody>
</table>

Note: MapR requires the MapR client.
Upgrading to Greenplum Database 5.21.4

The upgrade path supported for this release is Greenplum Database 5.x to Greenplum Database 5.21.4. Upgrading a Greenplum Database 4.3.x release to Pivotal Greenplum 5.x is not supported. See Migrating Data to Pivotal Greenplum 5.x.

**Note:** If you are upgrading Greenplum Database on a DCA system, see Pivotal Greenplum on DCA Systems.

**Important:** Pivotal recommends that customers set the Greenplum Database timezone to a value that is compatible with their host systems. Setting the Greenplum Database timezone prevents Greenplum Database from selecting a timezone each time the cluster is restarted and sets the timezone for the Greenplum Database master and segment instances. After you upgrade to this release and if you have not set a Greenplum Database timezone value, verify that the selected Greenplum Database timezone is acceptable for your deployment. See Configuring Timezone and Localization Settings for more information.

### Prerequisites

Before starting the upgrade process, Pivotal recommends performing the following checks.

- Verify the health of the Greenplum Database host hardware, and that you verify that the hosts meet the requirements for running Greenplum Database. The Greenplum Database `gpcheckperf` utility can assist you in confirming the host requirements.

  **Note:** If you need to run the `gpcheckcat` utility, Pivotal recommends running it a few weeks before the upgrade and that you run `gpcheckcat` during a maintenance period. If necessary, you can resolve any issues found by the utility before the scheduled upgrade.

  The utility is in `$GPHOME/bin`. Pivotal recommends that Greenplum Database be in restricted mode when you run `gpcheckcat` utility. See the Greenplum Database Utility Guide for information about the `gpcheckcat` utility.

  If `gpcheckcat` reports catalog inconsistencies, you can run `gpcheckcat` with the `--g` option to generate SQL scripts to fix the inconsistencies.

  After you run the SQL scripts, run `gpcheckcat` again. You might need to repeat the process of running `gpcheckcat` and creating SQL scripts to ensure that there are no inconsistencies. Pivotal recommends that the SQL scripts generated by `gpcheckcat` be run on a quiescent system. The utility might report false alerts if there is activity on the system.

  **Important:** If the `gpcheckcat` utility reports errors, but does not generate a SQL script to fix the errors, contact Pivotal support. Information for contacting Pivotal Support is at https://support.pivotal.io.

- During the migration process from Greenplum Database 5.0.0, a backup is made of some files and directories in `$MASTER_DATA_DIRECTORY`. Pivotal recommends that files and directories that are not used by Greenplum Database be backed up, if necessary, and removed from the `$MASTER_DATA_DIRECTORY` before migration. For information about the Greenplum Database migration utilities, see the Greenplum Database Documentation.

For information about supported versions of Greenplum Database extensions, see Pivotal Greenplum Tools and Extensions Compatibility.

If you are utilizing Data Domain Boost, you have to re-enter your DD Boost credentials after upgrading to Greenplum Database 5.21.4 as follows:

```
gpcrondump --ddboost-host ddboost_hostname --ddboost-user ddboost_user --ddboost-backupdir backup_directory
```
**Note:** If you do not reenter your login credentials after an upgrade, your backup will never start because the Greenplum Database cannot connect to the Data Domain system. You will receive an error advising you to check your login credentials.

If you have configured the Greenplum Platform Extension Framework (PXF) in your previous Greenplum Database installation, you must stop the PXF service, and you might need to back up PXF configuration files before upgrading to a new version of Greenplum Database. Refer to [PXF Pre-Upgrade Actions](#) for instructions.

If you do not plan to use PXF, or you have not yet configured PXF, no action is necessary.

### Upgrading from 5.x to 5.21.4

An upgrade from 5.x to 5.21.4 involves stopping Greenplum Database, updating the Greenplum Database software binaries, upgrading and restarting Greenplum Database. If you are using Greenplum Database extension packages there are additional requirements. See [Prerequisites](#) in the previous section.

**Note:** If you are upgrading from Greenplum Database 5.10.x or earlier and have installed the PL/Java extension, you must upgrade the PL/Java extension to extension package version 1.4.3. Previous releases of the PL/Java extension are not compatible with Greenplum Database 5.11.0 and later. For information about the PL/Java extension package, see [Pivotal Greenplum Tools and Extensions Compatibility](#).

**Note:** If you have databases that were created with Greenplum Database 5.10.x or an earlier 5.x release, upgrade the `gp_bloat_expected_pages` view in the `gp_toolkit` schema. For information about the issue and how check a database for the issue, see [Update for `gp_toolkit.gp_bloat_expected_pages` Issue](#).

**Note:** If you are upgrading from Greenplum Database 5.7.0 or an earlier 5.x release and have configured PgBouncer in your Greenplum Database installation, you must migrate to the new PgBouncer when you upgrade Greenplum Database. Refer to [Migrating PgBouncer](#) for specific migration instructions.

**Note:** If you have databases that were created with Greenplum Database 5.3.0 or an earlier 5.x release, upgrade the `gp_bloat_diag` function and view in the `gp_toolkit` schema. For information about the issue and how check a database for the issue, see [Update for `gp_toolkit.gp_bloat_diag` Issue](#).

**Note:** If the Greenplum Command Center database `gpperfmon` is installed in your Greenplum Database system, the migration process changes the distribution key of the Greenplum Database `log_alert_`* tables to the `logtime` column. The redistribution of the table data might take some time the first time you start Greenplum Database after migration. The change occurs only the first time you start Greenplum Database after a migration.

1. Log in to your Greenplum Database master host as the Greenplum administrative user:

   ```
   $ su - gpadmin
   ```

2. Perform a smart shutdown of your current Greenplum Database 5.x system (there can be no active connections to the database). This example uses the `-a` option to disable confirmation prompts:

   ```
   $ gpstop -a
   ```

3. Run the binary installer for 5.21.4 on the Greenplum Database master host.

   When prompted, choose an installation location in the same base directory as your current installation. For example:

   ```
   /usr/local/greenplum-db-5.21.4
   ```

   If you install Greenplum Database with the `rpm` (as `root`), the installation directory is `/usr/local/greenplum-db-5.21.4`. 

---

53
For the rpm installation, update the permissions for the new installation. For example, run this command as root to change user and group of the installed files to gpadmin.

```
# chown -R gpadmin:gpadmin /usr/local/greenplum*
```

4. If needed, update the `greenplum_path.sh` file for use with your specific installation. These are some examples.

   - If Greenplum Database uses LDAP authentication, edit the `greenplum_path.sh` file to add the line:

     ```
     export LDAPCONF=/etc/openldap/ldap.conf
     ```

   - If Greenplum Database uses PL/Java, you might need to set or update the environment variables JAVA_HOME and LD_LIBRARY_PATH in `greenplum_path.sh`.

     **Note:** When comparing the previous and new `greenplum_path.sh` files, be aware that installing some Greenplum Database extensions also updates the `greenplum_path.sh` file. The `greenplum_path.sh` from the previous release might contain updates that were the result of those extensions. See step 9 for installing Greenplum Database extensions.

5. Edit the environment of the Greenplum Database superuser (gpadmin) and make sure you are sourcing the `greenplum_path.sh` file for the new installation. For example change the following line in `.bashrc` or your chosen profile file:

   ```
   source /usr/local/greenplum-db-5.0.0/greenplum_path.sh
   ```

   to:

   ```
   source /usr/local/greenplum-db-5.21.4/greenplum_path.sh
   ```

   Or if you are sourcing a symbolic link (/usr/local/greenplum-db) in your profile files, update the link to point to the newly installed version. For example:

   ```
   $ rm /usr/local/greenplum-db
   $ ln -s /usr/local/greenplum-db-5.21.4 /usr/local/greenplum-db
   ```

6. Source the environment file you just edited. For example:

   ```
   $ source ~/.bashrc
   ```

7. Run the `gpseginstall` utility to install the 5.21.4 binaries on all the segment hosts specified in the `hostfile`. For example:

   ```
   $ gpseginstall -f hostfile
   ```

   **Note:** The `gpseginstall` utility copies the installed files from the current host to the remote hosts. It does not use rpm to install Greenplum Database on the remote hosts, even if you used rpm to install Greenplum Database on the current host.

8. Use the Greenplum Database `gppkg` utility to install Greenplum Database extensions. If you were previously using any Greenplum Database extensions such as pgcrypto, PL/R, PL/Java, PL/Perl, and PostGIS, download the corresponding packages from Pivotal Network, and install using this utility. See the Greenplum Database Documentation for `gppkg` usage details.

   Also copy any additional files that are used by the extensions (such as JAR files, shared object files, and libraries) from the previous version installation directory to the new version installation directory on the master and segment host systems.

9. If you are upgrading from Greenplum Database 5.7 or an earlier 5.x release and have configured PgBouncer in your Greenplum Database installation, you must migrate to the new PgBouncer when you upgrade Greenplum Database. Refer to Migrating PgBouncer for specific migration instructions.
10. After all segment hosts have been upgraded, you can log in as the gpadmin user and restart your Greenplum Database system:

```
# su - gpadmin
$ gpstart
```

11. If you are utilizing Data Domain Boost, you have to re-enter your DD Boost credentials after upgrading from Greenplum Database to 5.21.4 as follows:

```
gpcrondump --ddboost-host ddboost_hostname --ddboost-user ddboost_user --ddboost-backupdir backup_directory
```

**Note:** If you do not reenter your login credentials after an upgrade, your backup will never start because the Greenplum Database cannot connect to the Data Domain system. You will receive an error advising you to check your login credentials.

12. If you configured PXF in your previous Greenplum Database installation, you must re-initialize the PXF service after you upgrade Greenplum Database. Refer to [Upgrading PXF](#) for instructions.

After upgrading Greenplum Database, ensure features work as expected. For example, you should test that backup and restore perform as expected, and Greenplum Database features such as user-defined functions, and extensions such as MADlib and PostGIS perform as expected.

**Troubleshooting a Failed Upgrade**

If you experience issues during the migration process and have active entitlements for Greenplum Database that were purchased through Pivotal, contact Pivotal Support. Information for contacting Pivotal Support is at [https://support.pivotal.io](https://support.pivotal.io).

Be prepared to provide the following information:

- A completed Upgrade Procedure.
- Log output from gpcheckcat (located in ~/gpAdminLogs)
Migrating Data to Pivotal Greenplum 5.x

Upgrading a Pivotal Greenplum Database 4.x system directly to Pivotal Greenplum Database 5.x is not supported.

You can migrate existing data to Greenplum Database 5.x using standard backup and restore procedures (gpcrondump and gpdbrestore) or by using gptransfer. The gpcopy utility can be used to migrate data from Greenplum Database 4.3.26 or later to 5.9 or later.

Follow these general guidelines for migrating data:

- Make sure that you have a complete backup of all data in the Greenplum Database 4.3.x cluster, and that you can successfully restore the Greenplum Database 4.3.x cluster if necessary.
- You must install and initialize a new Greenplum Database 5.x cluster using the version 5.x gpinit-system utility.

**Note:** Unless you modify file locations manually, gpdbrestore only supports restoring data to a cluster that has an identical number of hosts and an identical number of segments per host, with each segment having the same content_id as the segment in the original cluster. If you initialize the Greenplum Database 5.x cluster using a configuration that is different from the version 4.3 cluster, then follow the steps outlined in *Restoring to a Different Greenplum System Configuration* to manually update the file locations.

**Important:** For Greenplum Database 5.x, Pivotal recommends that customers set the Greenplum Database timezone to a value that is compatible with the host systems. Setting the Greenplum Database timezone prevents Greenplum Database from selecting a timezone each time the cluster is restarted and sets the timezone for the Greenplum Database master and segment instances. See *Configuring Timezone and Localization Settings* for more information.

- If you intend to install Greenplum Database 5.x on the same hardware as your 4.3.x system, you will need enough disk space to accommodate over 5 times the original data set (2 full copies of the primary and mirror data sets, plus the original backup data in ASCII format) in order to migrate data with gpcrondump and gpdbrestore. Keep in mind that the ASCII backup data will require more disk space than the original data, which may be stored in compressed binary format. Offline backup solutions such as Dell EMC Data Domain or Veritas NetBackup can reduce the required disk space on each host.

If you attempt to migrate your data on the same hardware but run out of free space, gpcopy provides the --truncate-source-after option to truncate each source table after copying the table to the destination cluster and validating the copy succeeded. This reduces the amount of free space needed to migrate clusters that reside on the same hardware. See *Migrating Data with gpcopy* for more information.

- Use the version 5.x gpdbrestore utility to load the 4.3.x backup data into the new cluster.
- If the Greenplum Database 5.x cluster resides on separate hardware from the 4.3.x cluster, and the clusters have different numbers of segments, you can optionally use the version 5.x gptransfer utility to migrate the 4.3.x data. You must initiate the gptransfer operation from the version 5.x cluster, pulling the older data into the newer system.

On a Greenplum Database system with FIPS enabled, validating table data with MD5 (specifying the gptransfer option --validate=md5) is not available. Use the option sha256 to validate table data.

Validating table data with SHA-256 (specifying the option --validate=sha256) requires the Greenplum Database pgcrypto extension. The extension is included with Pivotal Greenplum 5.x. The extension package must be installed on supported Pivotal Greenplum 4.3.x systems. Support for pgcrypto functions in a Greenplum 4.3.x database is not required.

- Greenplum Database 5.x removes automatic implicit casts between the text type and other data types. After you migrate from Greenplum Database version 4.3.x to version 5.x, this change in behavior may impact existing applications and queries. Refer to *About Implicit Text Casting in Greenplum Database* in...
the *Greenplum Database Installation Guide* for information, including a discussion about supported and unsupported workarounds.

- After migrating data you may need to modify SQL scripts, administration scripts, and user-defined functions as necessary to account for changes in Greenplum Database version 5.x. Look for **Upgrade Action Required** entries in the *Pivotal Greenplum 5.0.0 Release Notes* for features that may necessitate post-migration tasks.

- If you are migrating from Greenplum Database 4.3.27 or an earlier 4.3.x release and have configured PgBouncer in your Greenplum Database installation, you must migrate to the new PgBouncer when you upgrade Greenplum Database. Refer to *Migrating PgBouncer* for specific migration instructions.
Pivotal Greenplum on DCA Systems

On supported Dell EMC DCA systems, you can install Pivotal Greenplum 5.21.4, or you can upgrade from Pivotal Greenplum 5.x to 5.21.4.

Only Pivotal Greenplum Database is supported on DCA systems. Open source versions of Greenplum Database are not supported.

- Installing the Pivotal Greenplum 5.21.4 Software Binaries on DCA Systems
- Upgrading from 5.x to 5.21.4 on DCA Systems

**Important:** Upgrading Pivotal Greenplum Database 4.3.x to Pivotal Greenplum 5.21.4 is not supported. See [Migrating Data to Pivotal Greenplum 5.x](#).

**Note:** These Greenplum Database releases are not certified on DCA because of an incompatibility in configuring timezone information.

5.5.0, 5.6.0, 5.6.1, 5.7.0, 5.8.0

These Greenplum Database releases are certified on DCA.

5.7.1, 5.8.1, 5.9.0 and later releases, and 5.x releases prior to 5.5.0.

### Installing the Pivotal Greenplum 5.21.4 Software Binaries on DCA Systems

**Important:** This section is for installing Pivotal Greenplum 5.21.4 only on DCA systems. Also, see the information on the [DELL EMC support site](#) (requires login).

For information about installing Pivotal Greenplum on non-DCA systems, see the [Greenplum Database Installation Guide](#).

**Prerequisites**

- Ensure your DCA system supports Pivotal Greenplum 5.21.4. See [Supported Platforms](#).
- Ensure Greenplum Database 4.3.x is not installed on your system.

Installing Pivotal Greenplum 5.21.4 on a DCA system with an existing Greenplum Database 4.3.x installation is not supported. For information about uninstalling Greenplum Database software, see your Dell EMC DCA documentation.

### Installing Pivotal Greenplum 5.21.4

1. Download or copy the Greenplum Database DCA installer file `greenplum-db-appliance-5.21.4-RHEL6-x86_64.bin` to the Greenplum Database master host.
2. As root, run the DCA installer for 5.21.4 on the Greenplum Database master host and specify the file `hostfile` that lists all hosts in the cluster, one host name per line. If necessary, copy `hostfile` to the directory containing the installer before running the installer.

   This example command runs the installer for Greenplum Database 5.21.4.

   ```bash
   # ./greenplum-db-appliance-5.21.4-RHEL6-x86_64.bin hostfile
   ```

### Upgrading from 5.x to 5.21.4 on DCA Systems

Upgrading Pivotal Greenplum from 5.x to 5.21.4 on a Dell EMC DCA system involves stopping Greenplum Database, updating the Greenplum Database software binaries, and restarting Greenplum Database.
**Important:** This section is only for upgrading to Pivotal Greenplum 5.21.4 on DCA systems. For information about upgrading on non-DCA systems, see Upgrading to Greenplum Database 5.21.4.

**Note:** If you are upgrading from Greenplum Database 5.10.x or earlier and have installed the PL/Java extension, you must upgrade the PL/Java extension to extension package version 1.4.3. Previous releases of the PL/Java extension are not compatible with Greenplum Database 5.11.0 and later. For information about the PL/Java extension package, see Pivotal Greenplum Tools and Extensions Compatibility.

**Note:** If you have databases that were created with Greenplum Database 5.10.x or an earlier 5.x release, upgrade the `gp_bloat_expected_pages` view in the `gp_toolkit` schema. For information about the issue and how check a database for the issue, see Update for `gp_toolkit.gp_bloat_expected_pages` Issue.

**Note:** If you are upgrading from Greenplum Database 5.7.0 or an earlier 5.x release and have configured PgBouncer in your Greenplum Database installation, you must migrate to the new PgBouncer when you upgrade Greenplum Database. Refer to Migrating PgBouncer for specific migration instructions.

**Note:** If you have databases that were created with Greenplum Database 5.3.0 or an earlier 5.x release, upgrade the `gp_bloat_diag` function and view in the `gp_toolkit` schema. For information about the issue and how check a database for the issue, see Update for `gp_toolkit.gp_bloat_diag` Issue.

---

1. Log in to your Greenplum Database master host as the Greenplum administrative user (`gpadmin`):
   ```bash
   # su - gpadmin
   ```

2. Download or copy the installer file `greenplum-db-appliance-5.21.4-RHEL6-x86_64.bin` to the Greenplum Database master host.

3. Perform a smart shutdown of your current Greenplum Database 5.x system (there can be no active connections to the database). This example uses the `-a` option to disable confirmation prompts:
   ```bash
   $ gpstop -a
   ```

4. As root, run the Greenplum Database DCA installer for 5.21.4 on the Greenplum Database master host and specify the file `hostfile` that lists all hosts in the cluster. If necessary, copy `hostfile` to the directory containing the installer before running the installer.
   This example command runs the installer for Greenplum Database 5.21.4 for Red Hat Enterprise Linux 6.x.
   ```bash
   # ./greenplum-db-appliance-5.21.4-RHEL6-x86_64.bin hostfile
   ```

   The file `hostfile` is a text file that lists all hosts in the cluster, one host name per line.

5. If needed, update the `greenplum_path.sh` file for use with your specific installation. These are some examples.
   - If Greenplum Database uses LDAP authentication, edit the `greenplum_path.sh` file to add the line:
     ```bash
     export LDAPCONF=/etc/openldap/ldap.conf
     ```
   - If Greenplum Database uses PL/Java, you might need to set or update the environment variables `JAVA_HOME` and `LD_LIBRARY_PATH` in `greenplum_path.sh`.

     **Note:** When comparing the previous and new `greenplum_path.sh` files, be aware that installing some Greenplum Database extensions also updates the `greenplum_path.sh` file. The `greenplum_path.sh` from the previous release might contain updates that were the result of those extensions. See step 6 for installing Greenplum Database extensions.
6. Install Greenplum Database extension packages. For information about installing a Greenplum Database extension package, see `gppkg` in the *Greenplum Database Utility Guide*.

   Also migrate any additional files that are used by the extensions (such as JAR files, shared object files, and libraries) from the previous version installation directory to the new version installation directory.

7. After all segment hosts have been upgraded, you can log in as the `gpadmin` user and restart your Greenplum Database system:

   ```
   # su - gpadmin
   $ gpstart
   ```

8. If you are utilizing Data Domain Boost, you have to re-enter your DD Boost credentials after upgrading to Greenplum Database 5.21.4 as follows:

   `gpcrondump --ddboost-host ddboost_hostname --ddboost-user ddboost_user --ddboost-backupdir backup_directory`

   **Note:** If you do not reenter your login credentials after an upgrade, your backup will never start because the Greenplum Database cannot connect to the Data Domain system. You will receive an error advising you to check your login credentials.

   After upgrading Greenplum Database, ensure features work as expected. For example, you should test that backup and restore perform as expected, and Greenplum Database features such as user-defined functions, and extensions such as MADlib and PostGIS perform as expected.
Update for gp_toolkit.gp_bloat_expected_pages Issue

In Greenplum Database 5.10.x and earlier 5.x releases, the Greenplum Database view gp_toolkit.gp_bloat_expected_pages view might incorrectly report that a root partition table is bloated even though root partition tables do not contain data. This information could cause a user to run a VACUUM FULL operation on the partitioned table when the operation was not required. The issue was resolved in Greenplum Database 5.11.0 (resolved issue 29523).

When updating Greenplum Database, the gp_toolkit.gp_bloat_expected_pages view must be updated in databases created with a Greenplum Database 5.10.x or an earlier 5.x release. This issue has been fixed in databases created with Greenplum Database 5.11.0 and later. For information about using template0 as the template database after upgrading from Greenplum Database 5.10.x or an earlier 5.x release, see known issue 29523.

To check whether the gp_toolkit.gp_bloat_expected_pages view in a database requires an update, run the psql command \d+ to display the view definition.

\d+ gp_toolkit.gp_bloat_expected_pages

The updated view definition contains this predicate.

AND NOT EXISTS
  ( SELECT parrelid
    FROM pg_partition
    WHERE parrelid = pgc.oid )

Perform the following steps as the gpadmin user to update the view on each database that was created with Greenplum Database 5.11.0 or an earlier 5.x release.

1. Copy the script into a text file on the Greenplum Database master.
2. Run the script on each database that requires the update.

   This example updates gp_toolkit.gp_bloat_expected_pages view in the database mytest and assumes that the script is in the gp_bloat_expected_pages in the gpadmin home directory.

   
   psql -f /home/gpadmin/gp_bloat_expected_pages.sql -d mytest

Run the script during a low activity period. Running the script during a high activity period does not affect database functionality but might affect performance.

Script to Update gp_toolkit.gp_bloat_expected_pages View

BEGIN;
CREATE OR REPLACE VIEW gp_toolkit.gp_bloat_expected_pages
AS
  SELECT
    btdrelid,
    btdrelpages,
    CASE WHEN btdexppages < numsegments
    THEN numsegments
    ELSE btdexppages
    END as btdexppages
  FROM
    ( SELECT
        oid as btdrelid,
        pgc.relpages as btdrelpages,
        CEIL((pgc.reltuples * (25 + width))::numeric /
          current_setting('block_size')::numeric) AS btdexppages,
(SELECT numsegments FROM gp_toolkit.__gp_number_of_segments) AS numsegments
FROM
  ( SELECT pgc.oid, pgc.reltuples, pgc.relpages
    FROM pg_class pgc
    WHERE NOT EXISTS
      ( SELECT iaooid
        FROM gp_toolkit.__gp_is_append_only
        WHERE iaooid = pgc.oid AND iaotype = 't' )
    AND NOT EXISTS
      ( SELECT parrelid
        FROM pg_partition
        WHERE parrelid = pgc.oid ) ) AS pgc
LEFT OUTER JOIN
  ( SELECT starelid, SUM(stawidth * (1.0 - stanullfrac)) AS width
    FROM pg_statistic pgs
    GROUP BY 1 ) AS btwcols
ON pgc.oid = btwcols.starelid
WHERE starelid IS NOT NULL) AS subq;

GRANT SELECT ON TABLE gp_toolkit.gp_bloat_expected_pages TO public;
COMMIT;
Update for gp_toolkit.gp_bloat_diag Issue

In Greenplum Database 5.3.0 or an earlier 5.x release, Greenplum Database returned an integer out of range error in some cases when performing a query against the gp_toolkit.gp_bloat_diag view. The issue was resolved in Greenplum Database 5.4.0 (resolved issue 26518).

When updating Greenplum Database, the gp_toolkit.gp_bloat_diag function and view must be updated in databases created with a Greenplum Database 5.3.0 or an earlier 5.x release. This issue has been fixed in databases created with Greenplum Database 5.4.0 and later. For information about upgrading from Greenplum Database 5.3.0 or an earlier 5.x release and then using template0 as the template database, see known issue 29523.

To check whether the gp_toolkit.gp_bloat_diag function and view in a database requires an update, run the psql command \df to display information about the gp_toolkit.gp_bloat_diag function.

```
\df gp_toolkit.gp_bloat_diag
```

If the data type for btdexppages is integer, an update is required. If the data type is numeric an update is not required. In this example, the btdexppages data type is integer and requires an update.

<table>
<thead>
<tr>
<th>List of functions</th>
<th>-------</th>
</tr>
</thead>
</table>
| - [ RECORD 1 ]----
| +-------------------
| Schema | gp_toolkit
| Name | gp_bloat_diag
| Result data type | record
| Argument data types | btdrelpages integer, btdexppages integer, aotable boolean, OUT bltidx integer, OUT bltdiag text
| Type | normal

Perform the following steps as the gpadmin user to update the function and view to fix the issue on each database that was created with Greenplum Database 5.3.0 or an earlier 5.x release.

1. Copy the script into a text file on the Greenplum Database master.
2. Run the script on each database that requires the update.

   This example updates gp_toolkit.gp_bloat_diag function and view in the database mytest and assumes that the script is in the update_bloat_diag.sql in the gpadmin home directory.

```
psql -f /home/gpadmin/update_bloat_diag.sql -d mytest
```

Run the script during a low activity period. Running the script during a high activity period does not affect database functionality but might affect performance.

Script to Update gp_toolkit.gp_bloat_diag Function and View

```sql
BEGIN;
CREATE OR REPLACE FUNCTION gp_toolkit.gp_bloat_diag(btdrelpages int,
btdexppages numeric, aotable bool,
OUT bltidx int, OUT bltdiag text)
AS $$
SELECT
  blotidx,
CASE
  WHEN blotidx = 0
    THEN 'no bloat detected':text
  WHEN blotidx = 1
    THEN 'bloat detected'
END
$$;
```
THEN 'moderate amount of bloat suspected'::text
WHEN bloatidx = 2
THEN 'significant amount of bloat suspected'::text
WHEN bloatidx = -1
THEN 'diagnosis inconclusive or no bloat suspected'::text
END AS bloatdiag
FROM
(
    SELECT
        CASE
            WHEN $3 = 't' THEN 0
            WHEN $1 < 10 AND $2 = 0 THEN -1
            WHEN $2 = 0 THEN 2
            WHEN $1 < $2 THEN 0
            WHEN ($1/$2)::numeric > 10 THEN 2
            WHEN ($1/$2)::numeric > 3 THEN 1
            ELSE -1
        END AS bloatidx
    ) AS bloatmapping
$$
LANGUAGE SQL READS SQL DATA;

GRANT EXECUTE ON FUNCTION gp_toolkit.gp_bloat_diag(int, numeric, bool, OUT int, OUT text) TO public;

CREATE OR REPLACE VIEW gp_toolkit.gp_bloat_diag
AS
    SELECT
        btdrelid AS bdirelid,
        fnnspname AS bdinspname,
        fnrelname AS bdirelname,
        btdrelpages AS bdirelpages,
        btdexppages AS bdiexppages,
        bltdiag(bd) AS bdidiag
    FROM
        (SELECT
            fn.*, beg.*,
            gp_toolkit.gp_bloat_diag(btdrelpages::int, btdexppages::numeric, iao.iaotype::bool) AS bd
        FROM
            gp_toolkit.gp_bloat_expected_pages beg,
            pg_catalog.pg_class pgc,
            gp_toolkit.__gp_fullname fn,
            gp_toolkit.__gp_is_append_only iao
        WHERE beg.btdrelid = pgc.oid
        AND pgc.oid = fn.fnoid
        AND iao.iaoid = pgc.oid
    ) as bloatsummary
WHERE bltidx(bd) > 0;

Pivotal Greenplum 5.21.3 Release Notes

Updated: August, 2019

- Welcome to Pivotal Greenplum 5.21.3
- Changed Feature
- Resolved Issues
- Beta Features
- Deprecated Features
- Known Issues and Limitations
- Differences Compared to Open Source Greenplum Database
- Supported Platforms
- Pivotal Greenplum Tools and Extensions Compatibility
- Hadoop Distribution Compatibility
- Upgrading to Greenplum Database 5.21.3
- Migrating Data to Pivotal Greenplum 5.x
- Pivotal Greenplum on DCA Systems
- Update for gp_toolkit.gp_bloat_expected_pages Issue
- Update for gp_toolkit.gp_bloat_diag Issue
Welcome to Pivotal Greenplum 5.21.3

Pivotal Greenplum Database is a massively parallel processing (MPP) database server that supports next generation data warehousing and large-scale analytics processing. By automatically partitioning data and running parallel queries, it allows a cluster of servers to operate as a single database supercomputer performing tens or hundreds times faster than a traditional database. It supports SQL, MapReduce parallel processing, and data volumes ranging from hundreds of gigabytes, to hundreds of terabytes.

This document contains pertinent release information about Pivotal Greenplum Database 5.21.3. For previous versions of the release notes for Greenplum Database, go to Pivotal Greenplum Database Documentation. For information about Greenplum Database end of life, see the Pivotal Support Lifecycle Policy.

Pivotal Greenplum 5.x software is available for download from the Pivotal Greenplum page on Pivotal Network.

Pivotal Greenplum 5.x is based on the open source Greenplum Database project code.

**Important:** The Greenplum gpbackup and gprestore utilities are now distributed separately from Pivotal Greenplum Database, and are updated independently of the core Greenplum Database server. These utilities will not be updated in future Greenplum Database 5.x releases. You can upgrade to the latest gpbackup and gprestore versions by downloading and installing the latest Pivotal Greenplum Backup and Restore release from Pivotal Network.

**Important:** Pivotal Support does not provide support for open source versions of Greenplum Database. Only Pivotal Greenplum Database is supported by Pivotal Support.

Pivotal Greenplum 5.21.3 is a maintenance release that resolves issues.
Changed Feature

Greenplum Database 5.21.3 includes this changed feature.

- The Greenplum Database timezone files have been updated. This release includes Internet Assigned Numbers Authority (IANA) Time Zone Database version 2019a.

  Greenplum Database updates its list of available timezones as necessary. The Greenplum Database timezone files are based on the PostgreSQL IANA timezone database files.
Resolved Issues

The listed issues are resolved in Pivotal Greenplum Database 5.21.3.

For issues resolved in prior 5.x releases, refer to the corresponding release notes. Release notes are available from the Pivotal Greenplum page on Pivotal Network.

29981 - Optimizer
A query plan that used a HashJoin with a skewed redistribute motion beneath it could fail to complete due to the combined poor performance of the hashing and redistribute operations. GPORCA was modified to penalize the local cost of the HashJoin in this situation, to prefer a more efficient broadcast motion. Note that GPORCA’s default behavior is preserved in this release; in order to prefer the broadcast motion for such queries, you must set the optimizer_penalize_skew configuration parameter to true at the query, database, or system level.

29985 - Transaction Management
In some cases, a Greenplum Database backend process could hang with the waiting_reason column in the pg_stat_activity table listed replication for the process. This issue might occur when a temporary table was created by the backend process and the process received a pg_terminate_backend() request while handling a SIGUSR1 signal. This issue has been resolved, now the backend process exits properly in the specified situation.

30006 - Greenplum Stream Server
In some cases, the Greenplum Stream Server (GPSS) immediately terminated a Kafka load operation when it encountered a record with a null value. This issue is resolved. GPSS now writes each null value it encounters to the error log and applies it to the segment reject limit, and then continues reading the Kafka data.

30008 - Greenplum Stream Server
The Greenplum Stream Server did not take the system timezone into account when it loaded timestamp-type data. This behaviour resulted in an incorrect timestamp value when a client such as the Greenplum-Informatica Connector loaded data from Informatica into Greenplum Database. This issue is resolved; GPSS now localizes a timestamp to the timezone of the gpss session before loading the data.

30019 - MPP: Locking, Signals, Processing
If there were inconsistencies between global and local locks, the master process could panic because of corrupted local or global lock tables. This issue was resolved by ensuring that a query fails immediately after a lock inconsistency is detected.

30020 - Postgres Planner
A query caused a panic when an upper-level predicate was pushed down into a subquery that was not pushdown-safe because the predicate referenced a set-returning function in a subquery output column. The planner failed to detect the subquery was not pushdown-safe because of nested unions or intersections. This has been fixed.

30034 - Optimizer
GPORCA did not consider unsupported predicates when calculating statistics during dynamic partition elimination, which could result in over costing the query plan. GPORCA was modified to convert unsupported predicates to a filter, so that partition elimination can be used. The default GPORCA behavior is unchanged; you can enable the modified behavior (to convert predicates to a filter and use partition elimination) by setting the optimizer_dpe_stats configuration parameter to on.

30057 - Query Optimizer
Certain queries on partitioned tables with subqueries could encounter this error:

```
ERROR: type <some type> is not composite
```

The cause of this error was that the subquery transformation introduced additional columns that were not available in the dynamic table scan. This issue has been resolved.

**30058 - Query Execution**

Running `EXPLAIN ANALYZE` on some queries generates a Greenplum Database PANIC. The error occurs when an analyze operation was dispatched to a query executor (QE). This issue has been fixed; analyze operations can be dispatched to a QE.

**30059 - Documentation**

The `gpsd` and `minirepro` utilities were modified to display a warning that indicates they may collect sensitive data: WARNING: This tool collects statistics about your data, including most common values, which requires some data elements to be included in the output file. Please review output file to ensure it is within corporate policy to transport the output file. The documentation for `pg_statistic` was also updated to warn that the table’s contents are collected with `gpsd` and `minirepro`.

**30068 - Executor**

Greenplum did not correctly populate a subplan attribute in a dynamic table scan, which could lead to a crash when executing an affected query. The code was modified to populate the subplan attribute in the same way it does for dynamic index and bitmap scans, which resolves the problem.

**167365033 - Interconnect**

Greenplum Database would sometimes reset a connection when a query failed to create its backend process. The issue was resolved by updating the interconnect cleanup code to properly handle process creation failures.

**167577666 - Optimizer**

GPORCA was modified to fix a problem that could lead to wrong results with materialized skip-level correlated queries.

**167699864 - Interconnect**

A query with multiple slices could return with a delay of several seconds because of an internal data retransmission bug in the interconnect module. The issue was fixed by properly handling the data retransmission condition.

**167888881 - COPY**

When a segment has more than 2,147,483,647 rows, the `COPY` command would load the data correctly but the validation count overflowed the `int32` variable. This issue was resolved by using an `int64` data type.
Beta Features

Because Pivotal Greenplum Database is based on the open source Greenplum Database project code, it includes several Beta features to allow interested developers to experiment with their use on development systems. Feedback will help drive development of these features, and they may become supported in future versions of the product.

**Warning:** Beta features are not supported for production deployments.

Greenplum Database 5.21.3 includes these Beta features:

- **Storage plugin API for** `gpbackup` **and** `gprestore`. Partners, customers, and OSS developers can develop plugins to use in conjunction with `gpbackup` and `gprestore`.
  
  For information about the storage plugin API, see [Backup/Restore Storage Plugin API in the Pivotal Greenplum Database Documentation](#).

- **Recursive WITH Queries (Common Table Expressions).** See [WITH Queries (Common Table Expressions) in the Pivotal Greenplum Database Documentation](#).

- Resource groups remain a Beta feature only on the SuSE 11 platform, due to limited cgroups functionality in the kernel.
  
  SuSE 12 resolves the Linux cgroup issues that caused the performance degradation when Greenplum Database resource groups are enabled.

- Using the Greenplum Platform Extension (PXF) connectors to write Parquet data is a Beta feature.
Deprecation Features

These Greenplum Database features are deprecated.

- The `gptransfer` utility will be removed in the next major release. The utility copies objects between Greenplum Database systems. The `gpcopy` utility provides `gptransfer` functionality.
- The `gphdfs` external table protocol will be removed in the next major release. Consider using the Greenplum Platform Extension Framework (PXF) `pxf` external table protocol to access data stored in an external Hadoop file system. Refer to Accessing External Data with PXF for more information.
Known Issues and Limitations

Pivotal Greenplum 5.x has these limitations:

- Upgrading a Greenplum Database 4.3.x release to Pivotal Greenplum 5.x is not supported. See Migrating Data to Pivotal Greenplum 5.x.
- Some features are works-in-progress and are considered to be Beta features. Pivotal does not support using Beta features in a production environment. See Beta Features.
- Greenplum Database 4.3.x packages are not compatible with Pivotal Greenplum 5.x.

The following table lists key known issues in Pivotal Greenplum 5.x.

Table 6: Key Known Issues in Pivotal Greenplum 5.x

<table>
<thead>
<tr>
<th>Issue</th>
<th>Category</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>29917</td>
<td>Segment Mirroring</td>
<td>A &quot;read beyond eof&quot; error has been observed with certain persistent tables during full recovery. The root cause of this problem has not yet been determined. Greenplum Database version 5.21 contains additional debug logging to help in determining the cause of this problem. The additional logging is enabled by default, and adds approximately 646 bytes to each persistent table entry file. If you want to disable the additional debug logging, set the debug_filerep_config_print configuration parameter &quot;false.&quot;</td>
</tr>
<tr>
<td>Issue</td>
<td>Category</td>
<td>Description</td>
</tr>
<tr>
<td>--------</td>
<td>--------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
</tbody>
</table>
| 29861  | gpstart      | If a segment’s data directory becomes inaccessible or the contents of the data directory are deleted, the segment goes offline and is marked as down in gp_segment_configuration. However, if you have temporary or transaction files in a separate filespace or if you stop and start the database, gpstart can fail with the error:  

```
20190404:17:26:44:025089
gpstart:mdw:gpadmin-[ERROR]:-Multiple OIDs found in flat files
20190404:17:26:44:025089
gpstart:mdw:gpadmin-[ERROR]:-Filespaces are inconsistent. Abort Greenplum Database start.
```

The error indicates that two files are missing from a segment directory, gp_temporary_files_filespace and gp_transaction_files_filespace. gpstart reports the error even if the segments have already been marked down.  

**Workaround:** To resolve this problem you must manually create the missing files in the segment directory using the segment’s corresponding dbid, transaction file segment directory, and filespace oid. See the detailed instructions for creating these files in Article Number: 6784 gpstart fails with error "Multiple OIDs found in flat files” on the Pivotal Support site. |

|       |          | attackers to obtain sensitive information by leveraging a race condition in which a child process is created and accesses the PRNG within the same rate-limit period as another process.  
Paramiko version 1.7.6-9, used in Greenplum Database 4.x and 5.x, introduced a workaround to this bug.  
Paramiko version 1.18.4 in Greenplum Database 6 solves it in a more permanent way.  
• [https://nvd.nist.gov/vuln/detail/CVE-2012-2417](https://nvd.nist.gov/vuln/detail/CVE-2012-2417) - PyCrypto before 2.6 does not produce appropriate prime numbers when using an ElGamal scheme to generate a key, which reduces the signature space or public key space and makes it easier for attackers to conduct brute force attacks to obtain the private key.  
Paramiko does not import this algorithm, so Greenplum Database is unaffected by the vulnerability.  
Through testing and investigation, Pivotal has determined that these vulnerabilities do not affect Greenplum Database, and no actions are required for existing Greenplum Database 4.3 or 5.x releases. However, there may be additional unidentified vulnerabilities in the PyCrypto library, and users who install a later version of PyCrypto could be exposed to other vulnerabilities.  
The PyCrypto library will be removed from Greenplum Database 6.0.  
**Workaround:** Administrators can set up passwordless SSH between hosts in the Greenplum Database cluster without using the `gpssh-exkeys` utility. This must be done before initializing the Greenplum Database system. |

<td>search_path</td>
<td>An identified PostgreSQL security vulnerability (<a href="https://nvd.nist.gov/vuln/detail/CVE-2018-1058">https://nvd.nist.gov/vuln/detail/CVE-2018-1058</a>) also exists in Greenplum Database. The problem centers around the default <code>public</code> schema and how Greenplum Database uses the <code>search_path</code> setting. The ability to create objects with the same names in different schemas, combined with how Greenplum Database searches for objects within schemas, presents an opportunity for a user to modify the behavior of a query for other users. For example, a malicious user could insert a trojan-horse function that, when executed by a superuser, grants escalated privileges to the malicious user. There are methods to protect from this vulnerability. See <em>A Guide to CVE-2018-1058: Protect Your Search Path</em> on the PostgreSQL wiki for a full explanation of the vulnerability and the steps you can take to protect your data.</td>

<td>ANALYZE</td>
<td>In Greenplum Database 5.15.1 and earlier 5.x releases, an ANALYZE command might return a error that states target lists can have at most 1664 entries when performing an ANALYZE operation on a table with a large number of columns (more than 800 columns). The error occurs because the in-memory sample table created by ANALYZE requires an additional column to indicate whether a column is NULL or is a truncated column for each variable length column being analyzed (such as varchar, text, and bpchar, numeric, arrays, and geometric datatype columns). The error is returned when ANALYZE attempts to create a sample table and the number of columns (table columns and indicator columns) exceeds the maximum number of columns allowed. In Greenplum Database 5.16.0 and later 5.x releases, the ANALYZE sample table does not require an additional column for variable length text columns such as varchar, text, and bpchar columns. <strong>WORKAROUND:</strong> To collect statistics on the table, perform ANALYZE operations on 2 or more sets of table columns.</td>

<td>When a session creates temporary objects in a database, Greenplum Database might not drop temporary objects when the session ends if the session terminates abnormally or is terminated from an administrator command.</td>
</tr>
<tr>
<td>29496</td>
<td>gpconfig</td>
<td>For a small number of server configuration parameters such as <code>log_min_messages</code>, the command <code>gpconfig -s &lt;config_param&gt;</code> does not display the correct value of the parameter for the segment hosts when the value of the parameter on master is different than the value on the segments. For parameters with the set classification <code>master</code>, the utility displays the value set on the master for both master and segments (for information about set classifications, see Setting Parameters in the Pivotal Greenplum Database Documentation). For those parameters, the value on the master is passed as part of queries to segment instances. The SQL query that <code>gpconfig</code> runs to display the master and segment parameter values returns the master host value that is passed to the segment as part of the query. For a few parameters such as <code>log_min_messages</code>, segment instances use the segment host value specified in the <code>postgresql.conf</code> file at start up. The segment value can overridden for the scope of a query. <strong>Workaround:</strong> To display the parameter value specified in the <code>postgresql.conf</code> file on the master host and segment hosts, you can specify the <code>gpconfig</code> option <code>--file</code>.</td>

<tr>
<td>149789783</td>
<td>Resource Groups</td>
<td>Significant Pivotal Greenplum performance degradation has been observed when enabling resource group-based workload management on Red Hat 6.x, CentOS 6.x, and SuSE 11 systems. This issue is caused by a Linux cgroup kernel bug. This kernel bug has been fixed in CentOS 7.x and Red Hat 7.x systems. When resource groups are enabled on systems with an affected kernel, there can be a delay of 1 second or longer when starting a transaction or a query. The delay is caused by a Linux cgroup kernel bug where a synchronization mechanism called <code>synchronize_sched</code> is abused when a process is attached to a cgroup. See <a href="http://www.spinics.net/lists/cgroups/msg05708.html">http://www.spinics.net/lists/cgroups/msg05708.html</a> and <a href="https://lkml.org/lkml/2013/1/14/97">https://lkml.org/lkml/2013/1/14/97</a> for more information. The issue causes single attachment operations to take longer and also causes all concurrent attachments to be executed in sequence. For example, one process attachment could take about 0.01 second. When concurrently attaching 100 processes, the fastest process attachment takes 0.01 second and the slowest takes about 1 second. Pivotal Greenplum performs process attachments when a transaction or queries are started. So the performance degradation is dependent on concurrent started transactions or queries, and not related to concurrent running queries. Also Pivotal Greenplum has optimizations to bypass the rewriting when a QE is reused by multiple queries in the same session. <strong>Workaround:</strong> This bug does not affect CentOS 7.x and Red Hat 7.x systems.</td>

</table>
| 168142530 | Backup and Restore  | Backups created on Greenplum Database versions before 4.3.33.0 or 5.1.19.0 may fail to restore to Greenplum Database versions 4.3.33.0 or 5.1.19.0 or later.  
In Greenplum Database 4.3.33.0 and 5.1.19.0, a check was introduced to ensure that the distribution key for a table is equal to the primary key or is a left-subset of the primary key. If you add a primary key to a table that contains no data, Greenplum Database automatically updates the distribution key to match the primary key.  
The index key for any unique index on a table must also match or be a left-subset of the distribution key.  
Earlier Greenplum Database versions did not enforce these policies.  
Restoring a table from an older backup that has a different distribution key causes errors because the backup data file on each segment contains data that was distributed using the original distribution key.  
Restoring a unique index with a key that does not match the distribution key will fail with an error when attempting to create the index.  
This issue affects the gprestore, gpdbrestore, and pg_restore utilities. |
Differences Compared to Open Source Greenplum Database

Pivotal Greenplum 5.x includes all of the functionality in the open source Greenplum Database project and adds:

- Product packaging and installation script.
- Support for QuickLZ compression. QuickLZ compression is not provided in the open source version of Greenplum Database due to licensing restrictions.
- Support for managing Greenplum Database using Pivotal Greenplum Command Center.
- Support for full text search and text analysis using Pivotal GPText.
- Support for data connectors:
  - Greenplum-Spark Connector
  - Greenplum-Informatica Connector
  - Greenplum-Kafka Integration
  - Gemfire-Greenplum Connector
  - Greenplum Stream Server
- Data Direct ODBC/JDBC Drivers
- `gpcopy` utility for copying or migrating objects between Greenplum systems.
**Supported Platforms**

Pivotal Greenplum 5.21.3 runs on the following platforms:

- Red Hat Enterprise Linux 64-bit 7.x (See the following Note)
- Red Hat Enterprise Linux 64-bit 6.x (See the following Note)
- SuSE Linux Enterprise Server 64-bit 12 SP2 and SP3 with kernel version greater than 4.4.73-5. (See the following Note)
- SuSE Linux Enterprise Server 64-bit 11 SP4 (See the following Note)
- CentOS 64-bit 7.x
- CentOS 64-bit 6.x (See the following Note)
- Oracle Linux 64-bit 7.4, using the Red Hat Compatible Kernel (RHCK)

**Note:** For the supported Linux operating systems, Pivotal Greenplum Database is supported on system hosts using either AMD or Intel CPUs based on the x86-64 architecture. Pivotal recommends using a homogeneous set of hardware (system hosts) in a Greenplum Database system.

**Important:** Significant Greenplum Database performance degradation has been observed when enabling resource group-based workload management on Red Hat 6.x, CentOS 6.x, and SuSE 11 systems. This issue is caused by a Linux cgroup kernel bug. This kernel bug has been fixed in CentOS 7.x and Red Hat 7.x systems.

If you use Red Hat 6 and the performance with resource groups is acceptable for your use case, upgrade your kernel to version 2.6.32-696 or higher to benefit from other fixes to the cgroups implementation.

SuSE 11 does not have a kernel version that resolves this issue; resource groups are still considered to be a Beta feature on this platform. Resource groups are not supported on SuSE 11 for production use. See known issue 149789783.

Pivotal Greenplum on SuSE 12 supports resource groups for production use. SuSE 12 resolves the Linux cgroup kernel issues that caused the performance degradation when Greenplum Database resource groups are enabled.

**Note:** For Greenplum Database that is installed on Red Hat Enterprise Linux 7.x or CentOS 7.x prior to 7.3, an operating system issue might cause Greenplum Database that is running large workloads to hang in the workload. The Greenplum Database issue is caused by Linux kernel bugs. RHEL 7.3 and CentOS 7.3 resolves the issue.

**Note:** Greenplum Database on SuSE Linux Enterprise systems does not support these features.

- The PL/Perl procedural language
- The gpmapreduce tool
- The PL/Container language extension
- The Greenplum Platform Extension Framework (PXF)

**Note:** PL/Container is not supported on RHEL/CentOS 6.x systems, because those platforms do not officially support Docker.

Greenplum Database support on Dell EMC DCA.

- Pivotal Greenplum Database 5.21.3 is supported on DCA systems that are running DCA software version 3.4 or greater.
- Only Pivotal Greenplum Database is supported on DCA systems. Open source versions of Greenplum Database are not supported.
- FIPS is supported on DCA software version 3.4 and greater with Pivotal Greenplum Database 5.2.0 and greater.
**Note:** These Greenplum Database releases are not certified on DCA because of an incompatibility in configuring timezone information.

5.5.0, 5.6.0, 5.6.1, 5.7.0, 5.8.0

These Greenplum Database releases are certified on DCA.

5.7.1, 5.8.1, 5.9.0 and later releases, and 5.x releases prior to 5.5.0.

Pivotal Greenplum 5.21.3 supports these Java versions:

- 8.xxx
- 7.xxx

Greenplum Database 5.21.3 software that runs on Linux systems uses OpenSSL 1.0.2l (with FIPS 2.0.16), cURL 7.54, OpenLDAP 2.4.44, and Python 2.7.12.

Greenplum Database client software that runs on Windows and AIX systems uses OpenSSL 0.9.8zg.

The Greenplum Database s3 external table protocol supports these data sources:

- Amazon Simple Storage Service (Amazon S3)
- Dell EMC Elastic Cloud Storage (ECS), an Amazon S3 compatible service

Pivotal Greenplum 5.21.3 supports Data Domain Boost on Red Hat Enterprise Linux.

This table lists the versions of Data Domain Boost SDK and DDOS supported by Pivotal Greenplum 5.x.

</table>

Note: In addition to the DDOS versions listed in the previous table, Pivotal Greenplum 5.0.0 and later supports all minor patch releases (fourth digit releases) later than the certified version.

1 Support for Data Domain Boost 3.0.0.3 is deprecated. The DELL EMC end of Primary Support date is December 31, 2017.

2 The Greenplum Database utilities `gpbackup` and `gprestore` support Data Domain DD Boost File System Plugin (BoostFS) v1.1 with DDOS 6.0 or greater.

The `gpbackup` and `gprestore` utilities support using Dell EMC Data Domain Boost software with the DD Boost Storage Plugin.

Note: Pivotal Greenplum 5.21.3 does not support the ODBC driver for Cognos Analytics V11.

Connecting to IBM Cognos software with an ODBC driver is not supported. Greenplum Database supports connecting to IBM Cognos software with the DataDirect JDBC driver for Pivotal Greenplum. This driver is available as a download from Pivotal Network.

**Veritas NetBackup**

Pivotal Greenplum 5.21.3 supports backup with Veritas NetBackup version 7.7.3. See Backing Up Databases with Veritas NetBackup.
Supported Platform Notes

The following notes describe platform support for Pivotal Greenplum. Please send any questions or comments to Pivotal Support at https://support.pivotal.io.

• Pivotal Greenplum is supported using either IPV4 or IPV6 protocols.
• The only file system supported for running Greenplum Database is the XFS file system. All other file systems are explicitly not supported by Pivotal.
• Greenplum Database is supported on network or shared storage if the shared storage is presented as a block device to the servers running Greenplum Database and the XFS file system is mounted on the block device. Network file systems are not supported. When using network or shared storage, Greenplum Database mirroring must be used in the same way as with local storage, and no modifications may be made to the mirroring scheme or the recovery scheme of the segments. Other features of the shared storage such as de-duplication and/or replication are not directly supported by Pivotal Greenplum Database, but may be used with support of the storage vendor as long as they do not interfere with the expected operation of Greenplum Database at the discretion of Pivotal.
• Greenplum Database is supported when running on virtualized systems, as long as the storage is presented as block devices and the XFS file system is mounted for the storage of the segment directories.

Warning: Running Pivotal Greenplum on hyper-converged infrastructure (HCI) has known issues with performance, scalability, and stability and is not recommended as a scalable solution for Pivotal Greenplum and may not be supported by Pivotal if stability problems appear related to the infrastructure. HCI virtualizes all of the elements of conventional hardware systems and includes, at a minimum, virtualized computing, a virtualised SAN, and virtualized networking.

• A minimum of 10-gigabit network is required for a system configuration to be supported by Pivotal.
• Greenplum Database is supported on Amazon Web Services (AWS), Microsoft Azure, and Google Cloud Compute (GCP).

• AWS - For production workloads, r4.8xlarge and r4.16xlarge instance types with four 12TB ST1 EBS volumes for each segment host, or d2.8xlarge with ephemeral storage configured with 4 RAID 0 volumes, are supported. EBS storage is recommended. EBS storage is more reliable and provides more features than ephemeral storage. Note that Amazon has no provisions to replace a bad ephemeral drive; when a disk failure occurs, you must replace the node with the bad disk.

Pivotal recommends using an Auto Scaling Group (ASG) to provision nodes in AWS. An ASG automatically replaces bad nodes, and you can add further automation to recover the Greenplum processes on the new nodes automatically.

Deployments should be in a Placement Group within a single Availability Zone. Because Amazon recommends using the same instance type in a Placement Group, use a single instance type for all nodes, including the masters.

• Azure - For production workloads, Pivotal recommends configuring Standard_H8 instance type with 4 2TB disks and 2 segments per host and recommend using 8 2TB disks and 4 segments per host with Standard_H16 instance type. Standard_H16 uses 8 2TB disks and 4 segments per host. This means software RAID 0 is required so that the number of volumes do not exceed the number of segments.

For Azure deployments, you must also configure the Greenplum Database system to not use port 65330. Add the following line to the sysctl.conf file on all Greenplum Database hosts.

```
$net.ipv4.ip_local_reserved_ports=65330
```

• GCP - For all workloads, n1-standard-8 and n1-highmem-8 are supported which are relatively small instance types. This is because of the disk performance in GCP forces the configuration to have just 2 segments per host but with many hosts to scale. Use pd-standard disks and the size of the disk is recommended to be 6 TB. For performance perspective, use a factor of 8 when determining how
many nodes to deploy in GCP, so a 16 segment host cluster in AWS would require 128 nodes in GCP.

- For Red Hat Enterprise Linux 7.2 or CentOS 7.2, the default `systemd` setting `RemoveIPC=yes` removes IPC connections when non-system users logout. This causes the Greenplum Database utility `gpinit系统` to fail with semaphore errors. To avoid this issue, see "Setting the Greenplum Recommended OS Parameters" in the *Greenplum Database Installation Guide*. 
Pivotal Greenplum Tools and Extensions Compatibility

- **Client Tools**
- **Extensions**
- **Pivotal Greenplum Data Connectors**
- **Pivotal GPTText Compatibility**
- **Pivotal Greenplum Command Center**

**Client Tools**

Greenplum releases a number of client tool packages on various platforms that can be used to connect to Greenplum Database and the Greenplum Command Center management tool. The following table describes the compatibility of these packages with this Greenplum Database release.

Tool packages are available from Pivotal Network.

**Table 8: Pivotal Greenplum 5.21.3 Tools Compatibility**

<table>
<thead>
<tr>
<th>Tool</th>
<th>Description of Contents</th>
<th>Tool Version(s)</th>
<th>Server Version(s)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Pivotal Greenplum Clients</td>
<td>Greenplum Database Command-Line Interface (psql)</td>
<td>5.8</td>
<td>5.x</td>
</tr>
<tr>
<td>Pivotal Greenplum Loaders</td>
<td>Greenplum Database Parallel Data Loading Tools (gpfdist, gpload)</td>
<td>5.8</td>
<td>5.x</td>
</tr>
<tr>
<td>Pivotal Greenplum Command Center</td>
<td>Greenplum Database management tool</td>
<td>4.7</td>
<td>5.19 and later</td>
</tr>
<tr>
<td></td>
<td></td>
<td>4.0.0</td>
<td>5.7.0 and later</td>
</tr>
<tr>
<td></td>
<td></td>
<td>3.3.2</td>
<td>5.0.0 and later</td>
</tr>
<tr>
<td></td>
<td></td>
<td>3.2.2</td>
<td>5.0.0 - 5.2.x</td>
</tr>
<tr>
<td>Pivotal Greenplum Workload Manager¹</td>
<td>Greenplum Database query monitoring and management tool</td>
<td>1.8.0</td>
<td>5.0.0</td>
</tr>
</tbody>
</table>

The Greenplum Database Client Tools and Load Tools are supported on the following platforms:

- AIX 7.2 (64-bit) (Client and Load Tools only)²
- Red Hat Enterprise Linux x86_64 7.x (RHEL 7)
- Red Hat Enterprise Linux x86_64 6.x (RHEL 6)
- SuSE Linux Enterprise Server x86_64 SLES 11 SP4, or SLES 12 SP2/SP3
- Windows 10 (32-bit and 64-bit)
- Windows 8 (32-bit and 64-bit)
- Windows Server 2012 (32-bit and 64-bit)
- Windows Server 2012 R2 (32-bit and 64-bit)
- Windows Server 2008 R2 (32-bit and 64-bit)

**Note:** ¹For Pivotal Greenplum Command Center 4.0.0 and later, workload management is an integrated Command Center feature rather than the separate tool Pivotal Greenplum Workload Manager.
For Greenplum Database 5.4.1 and earlier 5.x releases, download the AIX Client and Load Tools package either from the Greenplum Database 5.11.1 file collection or the Greenplum Database 5.0.0 file collection on Pivotal Network.

**Extensions**

Table 9: Pivotal Greenplum 5.21.3 Extensions Compatibility

<table>
<thead>
<tr>
<th>Pivotal Greenplum Extension</th>
<th>Versions</th>
</tr>
</thead>
<tbody>
<tr>
<td>MADlib machine learning for Greenplum Database 5.x</td>
<td>MADlib 1.16, 1.15.1, 1.15, 1.14</td>
</tr>
<tr>
<td>PL/Java for Greenplum Database 5.x</td>
<td>PL/Java 1.4.3¹</td>
</tr>
<tr>
<td>PL/R for Greenplum Database 5.x</td>
<td>2.3.3</td>
</tr>
<tr>
<td>PostGIS Spatial and Geographic Objects for Greenplum Database 5.x</td>
<td>2.1.5+pivotal.2</td>
</tr>
<tr>
<td>Python Data Science Module Package for Greenplum Database 5.x</td>
<td>1.1.1, 1.1.0, 1.0.0</td>
</tr>
<tr>
<td>R Data Science Library Package for Greenplum Database 5.x</td>
<td>1.0.1, 1.0.0</td>
</tr>
<tr>
<td>PL/Container for Greenplum Database 5.x</td>
<td>1.1⁵, 1.2⁶, 1.3, 1.4</td>
</tr>
</tbody>
</table>

**Note:** ¹Pivotal recommends that you upgrade to the most recent version of MADlib. For information about MADlib support and upgrade information, see the MADlib FAQ. For information on installing the MADlib extension in Greenplum Database, see Greenplum MADlib Extension for Analytics in the Greenplum Database Reference Guide.

²The PL/Java extension package version 1.4.3 is compatible only with Greenplum Database 5.11.0 and later, it is not compatible with 5.10.x or earlier. If you are upgrading from Greenplum Database 5.10.x or earlier and have installed PL/Java 1.4.2, you must upgrade the PL/Java extension to version 1.4.3.

³For information about the Python package, including the modules provided, see the Python Data Science Module Package in the Greenplum Database Documentation.

⁴For information about the R package, including the libraries provided, see the R Data Science Library Package in the Greenplum Database Documentation.

⁵To upgrade from PL/Container 1.0 to PL/Container 1.1 and later, you must drop the PL/Container 1.0 language before registering the new version of PL/Container. For information on upgrading the PL/Container extension in Greenplum Database, see PL/Container Language Extension in the Greenplum Database Reference Guide.

⁶PL/Container version 1.2 can utilize the resource group capabilities that were introduced in Greenplum Database 5.8.0. If you downgrade to a Greenplum Database system that uses PL/Container 1.1 or earlier, you must use plcontainer runtime-edit to remove any resource_group_id settings from the PL/Container runtime configuration file. See Upgrading from PL/Container 1.1.

These Greenplum Database extensions are installed with Pivotal Greenplum Database

- Fuzzy String Match Extension
- PL/Python Extension
- pgcrypto Extension
Pivotal Greenplum Data Connectors

- Greenplum Platform Extension Framework (PXF) - PXF, integrated with Greenplum Database, provides access to HDFS, Hive, HBase, and SQL external data stores. Refer to Accessing External Data with PXF in the Greenplum Database Administrator Guide for PXF configuration and usage information.
  
  **Note:** PXF is available only for supported Red Hat and CentOS platforms. PXF is not available for supported SuSE platforms.

- Greenplum-Spark Connector - The Pivotal Greenplum-Spark Connector supports high speed, parallel data transfer from Greenplum Database to an Apache Spark cluster. The Greenplum-Spark Connector is available as a separate download from Pivotal Network. Refer to the Greenplum-Spark Connector documentation for compatibility and usage information.

- Greenplum-Informatica Connector - The Pivotal Greenplum-Informatica connector supports high speed data transfer from an Informatica PowerCenter cluster to a Pivotal Greenplum Database cluster for batch and streaming ETL operations. See the Pivotal Greenplum-Informatica Connector Documentation.

- Greenplum-Kafka Integration - The Pivotal Greenplum-Kafka Integration provides high speed, parallel data transfer from a Kafka cluster to a Pivotal Greenplum Database cluster for batch and streaming ETL operations. Refer to the Pivotal Greenplum-Kafka Integration Documentation for more information about this feature.

- Greenplum Stream Server - The Pivotal Greenplum Stream Server is an ETL tool that provides high speed, parallel data transfer from Informatica, Kafka, and custom client data sources to a Pivotal Greenplum Database cluster. Refer to the Performing ETL Operations with the Pivotal Greenplum Stream Server Documentation for more information about this feature.

- Gemfire-Greenplum Connector - The Pivotal Gemfire-Greenplum Connector supports the transfer of data between a GemFire region and a Greenplum Database cluster. The Gemfire-Greenplum Connector is available as a separate download from Pivotal Network. Refer to the Gemfire-Greenplum Connector documentation for compatibility and usage information.

Pivotal GPText Compatibility

Pivotal Greenplum Database 5.21.3 is compatible with Pivotal GPText version 2.1.3 and later.

Pivotal Greenplum Command Center

See the Greenplum Command Center documentation for GPCC and Greenplum Workload Manager compatibility information, see the Pivotal Greenplum Command Center 3.x and 2.x Release Notes.

**Note:** For Pivotal Greenplum Command Center 4.0.0 and later, workload management is an integrated Command Center feature rather than the separate tool Pivotal Greenplum Workload Manager.
Hadoop Distribution Compatibility

Greenplum Database provides access to HDFS with `gphdfs` and the Greenplum Platform Extension Framework (PXF).

**PXF Hadoop Distribution Compatibility**

PXF supports the Cloudera, Hortonworks Data Platform, MapR, and generic Apache Hadoop distributions.

If you plan to access JSON format data stored in a Cloudera Hadoop cluster, PXF requires a Cloudera version 5.8 or later Hadoop distribution.

**gphdfs Hadoop Distribution Compatibility**

The supported Hadoop distributions for `gphdfs` are listed below:

Table 10: Supported `gphdfs` Hadoop Distributions

<table>
<thead>
<tr>
<th>Hadoop Distribution</th>
<th>Version</th>
<th>gp_hadoop_target_version</th>
</tr>
</thead>
<tbody>
<tr>
<td>Cloudera</td>
<td>CDH 5.x</td>
<td>cdh</td>
</tr>
<tr>
<td>Hortonworks Data Platform</td>
<td>HDP 2.x</td>
<td>hdp</td>
</tr>
<tr>
<td>MapR</td>
<td>MapR 4.x, MapR 5.x</td>
<td>mpr</td>
</tr>
<tr>
<td>Apache Hadoop</td>
<td>2.x</td>
<td>hadoop</td>
</tr>
</tbody>
</table>

*Note:* MapR requires the MapR client.
Upgrading to Greenplum Database 5.21.3

The upgrade path supported for this release is Greenplum Database 5.x to Greenplum Database 5.21.3. Upgrading a Greenplum Database 4.3.x release to Pivotal Greenplum 5.x is not supported. See Migrating Data to Pivotal Greenplum 5.x.

Note: If you are upgrading Greenplum Database on a DCA system, see Pivotal Greenplum on DCA Systems.

Important: Pivotal recommends that customers set the Greenplum Database timezone to a value that is compatible with their host systems. Setting the Greenplum Database timezone prevents Greenplum Database from selecting a timezone each time the cluster is restarted and sets the timezone for the Greenplum Database master and segment instances. After you upgrade to this release and if you have not set a Greenplum Database timezone value, verify that the selected Greenplum Database timezone is acceptable for your deployment. See Configuring Timezone and Localization Settings for more information.

Prerequisites

Before starting the upgrade process, Pivotal recommends performing the following checks.

• Verify the health of the Greenplum Database host hardware, and that you verify that the hosts meet the requirements for running Greenplum Database. The Greenplum Database `gpcheckperf` utility can assist you in confirming the host requirements.

  Note: If you need to run the `gpcheckcat` utility, Pivotal recommends running it a few weeks before the upgrade and that you run `gpcheckcat` during a maintenance period. If necessary, you can resolve any issues found by the utility before the scheduled upgrade.

  The utility is in `$GPHOME/bin`. Pivotal recommends that Greenplum Database be in restricted mode when you run `gpcheckcat` utility. See the Greenplum Database Utility Guide for information about the `gpcheckcat` utility.

  If `gpcheckcat` reports catalog inconsistencies, you can run `gpcheckcat` with the `--g` option to generate SQL scripts to fix the inconsistencies.

  After you run the SQL scripts, run `gpcheckcat` again. You might need to repeat the process of running `gpcheckcat` and creating SQL scripts to ensure that there are no inconsistencies. Pivotal recommends that the SQL scripts generated by `gpcheckcat` be run on a quiescent system. The utility might report false alerts if there is activity on the system.

  Important: If the `gpcheckcat` utility reports errors, but does not generate a SQL script to fix the errors, contact Pivotal support. Information for contacting Pivotal Support is at https://support.pivotal.io.

• During the migration process from Greenplum Database 5.0.0, a backup is made of some files and directories in `$MASTER_DATA_DIRECTORY`. Pivotal recommends that files and directories that are not used by Greenplum Database be backed up, if necessary, and removed from the `$MASTER_DATA_DIRECTORY` before migration. For information about the Greenplum Database migration utilities, see the Greenplum Database Documentation.

For information about supported versions of Greenplum Database extensions, see Pivotal Greenplum Tools and Extensions Compatibility.

If you are utilizing Data Domain Boost, you have to re-enter your DD Boost credentials after upgrading to Greenplum Database 5.21.3 as follows:

```
gpcrondump --ddboost-host ddboost_hostname --ddboost-user ddboost_user
            --ddboost-backupdir backup_directory
```
**Note:** If you do not reenter your login credentials after an upgrade, your backup will never start because the Greenplum Database cannot connect to the Data Domain system. You will receive an error advising you to check your login credentials.

If you have configured the Greenplum Platform Extension Framework (PXF) in your previous Greenplum Database installation, you must stop the PXF service, and you might need to back up PXF configuration files before upgrading to a new version of Greenplum Database. Refer to PXF Pre-Upgrade Actions for instructions.

If you do not plan to use PXF, or you have not yet configured PXF, no action is necessary.

### Upgrading from 5.x to 5.21.3

An upgrade from 5.x to 5.21.3 involves stopping Greenplum Database, updating the Greenplum Database software binaries, upgrading and restarting Greenplum Database. If you are using Greenplum Database extension packages there are additional requirements. See Prerequisites in the previous section.

**Note:** If you are upgrading from Greenplum Database 5.10.x or earlier and have installed the PL/Java extension, you must upgrade the PL/Java extension to extension package version 1.4.3. Previous releases of the PL/Java extension are not compatible with Greenplum Database 5.11.0 and later. For information about the PL/Java extension package, see Pivotal Greenplum Tools and Extensions Compatibility.

**Note:** If you have databases that were created with Greenplum Database 5.10.x or an earlier 5.x release, upgrade the `gp_bloat_expected_pages` view in the `gp_toolkit` schema. For information about the issue and how check a database for the issue, see Update for `gp_toolkit.gp_bloat_expected_pages` Issue.

**Note:** If you are upgrading from Greenplum Database 5.7.0 or an earlier 5.x release and have configured PgBouncer in your Greenplum Database installation, you must migrate to the new PgBouncer when you upgrade Greenplum Database. Refer to Migrating PgBouncer for specific migration instructions.

**Note:** If you have databases that were created with Greenplum Database 5.3.0 or an earlier 5.x release, upgrade the `gp_bloat_diag` function and view in the `gp_toolkit` schema. For information about the issue and how check a database for the issue, see Update for `gp_toolkit.gp_bloat_diag` Issue.

**Note:** If the Greenplum Command Center database `gpperfmon` is installed in your Greenplum Database system, the migration process changes the distribution key of the Greenplum Database `log_alert_*` tables to the `logtime` column. The redistribution of the table data might take some time the first time you start Greenplum Database after migration. The change occurs only the first time you start Greenplum Database after a migration.

1. Log in to your Greenplum Database master host as the Greenplum administrative user:

   ```
   $ su - gpadmin
   ```

2. Perform a smart shutdown of your current Greenplum Database 5.x system (there can be no active connections to the database). This example uses the `-a` option to disable confirmation prompts:

   ```
   $ gpstop -a
   ```

3. Run the binary installer for 5.21.3 on the Greenplum Database master host.

   When prompted, choose an installation location in the same base directory as your current installation. For example:

   ```
   /usr/local/greenplum-db-5.21.3
   ```

   If you install Greenplum Database with the rpm (as root), the installation directory is `/usr/local/greenplum-db-5.21.3`. 

   ```
   ```
For the rpm installation, update the permissions for the new installation. For example, run this command as root to change user and group of the installed files to gpadmin.

# chown -R gpadmin:gpadmin /usr/local/greenplum*

4. If needed, update the `greenplum_path.sh` file for use with your specific installation. These are some examples.

- If Greenplum Database uses LDAP authentication, edit the `greenplum_path.sh` file to add the line:

  ```bash
  export LDAPCONF=/etc/openldap/ldap.conf
  ```

- If Greenplum Database uses PL/Java, you might need to set or update the environment variables `JAVA_HOME` and `LD_LIBRARY_PATH` in `greenplum_path.sh`.

  **Note:** When comparing the previous and new `greenplum_path.sh` files, be aware that installing some Greenplum Database extensions also updates the `greenplum_path.sh` file. The `greenplum_path.sh` from the previous release might contain updates that were the result of those extensions. See step 9 for installing Greenplum Database extensions.

5. Edit the environment of the Greenplum Database superuser (gpadmin) and make sure you are sourcing the `greenplum_path.sh` file for the new installation. For example change the following line in `.bashrc` or your chosen profile file:

```bash
source /usr/local/greenplum-db-5.0.0/greenplum_path.sh
```

to:

```bash
source /usr/local/greenplum-db-5.21.3/greenplum_path.sh
```

Or if you are sourcing a symbolic link (`/usr/local/greenplum-db`) in your profile files, update the link to point to the newly installed version. For example:

```bash
$ rm /usr/local/greenplum-db
$ ln -s /usr/local/greenplum-db-5.21.3 /usr/local/greenplum-db
```

6. Source the environment file you just edited. For example:

```bash
$ source ~/.bashrc
```

7. Run the `gpseginstall` utility to install the 5.21.3 binaries on all the segment hosts specified in the `hostfile`. For example:

```bash
$ gpseginstall -f hostfile
```

  **Note:** The `gpseginstall` utility copies the installed files from the current host to the remote hosts. It does not use `rpm` to install Greenplum Database on the remote hosts, even if you used `rpm` to install Greenplum Database on the current host.

8. Use the Greenplum Database `gppkg` utility to install Greenplum Database extensions. If you were previously using any Greenplum Database extensions such as pgcrypto, PL/R, PL/Java, PL/Perl, and PostGIS, download the corresponding packages from Pivotal Network, and install using this utility. See the Greenplum Database Documentation for `gppkg` usage details.

   Also copy any additional files that are used by the extensions (such as JAR files, shared object files, and libraries) from the previous version installation directory to the new version installation directory on the master and segment host systems.

9. If you are upgrading from Greenplum Database 5.7 or an earlier 5.x release and have configured PgBouncer in your Greenplum Database installation, you must migrate to the new PgBouncer when you upgrade Greenplum Database. Refer to `Migrating PgBouncer` for specific migration instructions.
10. After all segment hosts have been upgraded, you can log in as the `gpadmin` user and restart your Greenplum Database system:

```bash
# su - gpadmin
$ gpstart
```

11. If you are utilizing Data Domain Boost, you have to re-enter your DD Boost credentials after upgrading from Greenplum Database to 5.21.3 as follows:

```
gpcrondump --ddboost-host ddboost_hostname --ddboost-user ddboost_user --ddboost-backupdir backup_directory
```

**Note:** If you do not reenter your login credentials after an upgrade, your backup will never start because the Greenplum Database cannot connect to the Data Domain system. You will receive an error advising you to check your login credentials.

12. If you configured PXF in your previous Greenplum Database installation, you must re-initialize the PXF service after you upgrade Greenplum Database. Refer to *Upgrading PXF* for instructions.

After upgrading Greenplum Database, ensure features work as expected. For example, you should test that backup and restore perform as expected, and Greenplum Database features such as user-defined functions, and extensions such as MADlib and PostGIS perform as expected.

**Troubleshooting a Failed Upgrade**

If you experience issues during the migration process and have active entitlements for Greenplum Database that were purchased through Pivotal, contact Pivotal Support. Information for contacting Pivotal Support is at [https://support.pivotal.io](https://support.pivotal.io).

Be prepared to provide the following information:

- A completed *Upgrade Procedure*.
- Log output from `gpcheckcat` (located in `~/gpAdminLogs`)
Migrating Data to Pivotal Greenplum 5.x

Upgrading a Pivotal Greenplum Database 4.x system directly to Pivotal Greenplum Database 5.x is not supported.

You can migrate existing data to Greenplum Database 5.x using standard backup and restore procedures (gpcrondump and gpdbrestore) or by using gptransfer. The gpcopy utility can be used to migrate data from Greenplum Database 4.3.26 or later to 5.9 or later.

Follow these general guidelines for migrating data:

- Make sure that you have a complete backup of all data in the Greenplum Database 4.3.x cluster, and that you can successfully restore the Greenplum Database 4.3.x cluster if necessary.
- You must install and initialize a new Greenplum Database 5.x cluster using the version 5.x gpinitx system utility.

Note: Unless you modify file locations manually, gpdbrestore only supports restoring data to a cluster that has an identical number of hosts and an identical number of segments per host, with each segment having the same content_id as the segment in the original cluster. If you initialize the Greenplum Database 5.x cluster using a configuration that is different from the version 4.3 cluster, then follow the steps outlined in Restoring to a Different Greenplum System Configuration to manually update the file locations.

Important: For Greenplum Database 5.x, Pivotal recommends that customers set the Greenplum Database timezone to a value that is compatible with the host systems. Setting the Greenplum Database timezone prevents Greenplum Database from selecting a timezone each time the cluster is restarted and sets the timezone for the Greenplum Database master and segment instances. See Configuring Timezone and Localization Settings for more information.

- If you intend to install Greenplum Database 5.x on the same hardware as your 4.3.x system, you will need enough disk space to accommodate over 5 times the original data set (2 full copies of the primary and mirror data sets, plus the original backup data in ASCII format) in order to migrate data with gpcrondump and gpdbrestore. Keep in mind that the ASCII backup data will require more disk space than the original data, which may be stored in compressed binary format. Offline backup solutions such as Dell EMC Data Domain or Veritas NetBackup can reduce the required disk space on each host.

If you attempt to migrate your data on the same hardware but run out of free space, gpcopy provides the --truncate-source-after option to truncate each source table after copying the table to the destination cluster and validating the copy succeeded. This reduces the amount of free space needed to migrate clusters that reside on the same hardware. See Migrating Data with gpcopy for more information.

- Use the version 5.x gpdbrestore utility to load the 4.3.x backup data into the new cluster.
- If the Greenplum Database 5.x cluster resides on separate hardware from the 4.3.x cluster, and the clusters have different numbers of segments, you can optionally use the version 5.x gptransfer utility to migrate the 4.3.x data. You must initiate the gptransfer operation from the version 5.x cluster, pulling the older data into the newer system.

On a Greenplum Database system with FIPS enabled, validating table data with MD5 (specifying the gptransfer option --validate=md5) is not available. Use the option sha256 to validate table data.

Validating table data with SHA-256 (specifying the option --validate=sha256) requires the Greenplum Database pgcrypto extension. The extension is included with Pivotal Greenplum 5.x. The extension package must be installed on supported Pivotal Greenplum 4.3.x systems. Support for pgcrypto functions in a Greenplum 4.3.x database is not required.

- Greenplum Database 5.x removes automatic implicit casts between the text type and other data types. After you migrate from Greenplum Database version 4.3.x to version 5.x, this change in behavior may impact existing applications and queries. Refer to About Implicit Text Casting in Greenplum Database in
the *Greenplum Database Installation Guide* for information, including a discussion about supported and unsupported workarounds.

- After migrating data you may need to modify SQL scripts, administration scripts, and user-defined functions as necessary to account for changes in Greenplum Database version 5.x. Look for **Upgrade Action Required** entries in the *Pivotal Greenplum 5.0.0 Release Notes* for features that may necessitate post-migration tasks.

- If you are migrating from Greenplum Database 4.3.27 or an earlier 4.3.x release and have configured PgBouncer in your Greenplum Database installation, you must migrate to the new PgBouncer when you upgrade Greenplum Database. Refer to *Migrating PgBouncer* for specific migration instructions.
Pivotal Greenplum on DCA Systems

On supported Dell EMC DCA systems, you can install Pivotal Greenplum 5.21.3, or you can upgrade from Pivotal Greenplum 5.x to 5.21.3.

Only Pivotal Greenplum Database is supported on DCA systems. Open source versions of Greenplum Database are not supported.

- Installing the Pivotal Greenplum 5.21.3 Software Binaries on DCA Systems
- Upgrading from 5.x to 5.21.3 on DCA Systems

**Important:** Upgrading Pivotal Greenplum Database 4.3.x to Pivotal Greenplum 5.21.3 is not supported. See *Migrating Data to Pivotal Greenplum 5.x*.

**Note:** These Greenplum Database releases are not certified on DCA because of an incompatibility in configuring timezone information.

5.5.0, 5.6.0, 5.6.1, 5.7.0, 5.8.0

These Greenplum Database releases are certified on DCA.

5.7.1, 5.8.1, 5.9.0 and later releases, and 5.x releases prior to 5.5.0.

**Installing the Pivotal Greenplum 5.21.3 Software Binaries on DCA Systems**

**Important:** This section is for installing Pivotal Greenplum 5.21.3 only on DCA systems. Also, see the information on the DELL EMC support site (requires login).

For information about installing Pivotal Greenplum on non-DCA systems, see the *Greenplum Database Installation Guide*.

**Prerequisites**

- Ensure your DCA system supports Pivotal Greenplum 5.21.3. See *Supported Platforms*.
- Ensure Greenplum Database 4.3.x is not installed on your system.

Installing Pivotal Greenplum 5.21.3 on a DCA system with an existing Greenplum Database 4.3.x installation is not supported. For information about uninstalling Greenplum Database software, see your Dell EMC DCA documentation.

**Installing Pivotal Greenplum 5.21.3**

1. Download or copy the Greenplum Database DCA installer file `greenplum-db-appliance-5.21.3-RHEL6-x86_64.bin` to the Greenplum Database master host.
2. As root, run the DCA installer for 5.21.3 on the Greenplum Database master host and specify the file *hostfile* that lists all hosts in the cluster, one host name per line. If necessary, copy *hostfile* to the directory containing the installer before running the installer.

   This example command runs the installer for Greenplum Database 5.21.3.

   ```
   # ./greenplum-db-appliance-5.21.3-RHEL6-x86_64.bin hostfile
   ```

**Upgrading from 5.x to 5.21.3 on DCA Systems**

Upgrading Pivotal Greenplum from 5.x to 5.21.3 on a Dell EMC DCA system involves stopping Greenplum Database, updating the Greenplum Database software binaries, and restarting Greenplum Database.
**Important:** This section is only for upgrading to Pivotal Greenplum 5.21.3 on DCA systems. For information about upgrading on non-DCA systems, see *Upgrading to Greenplum Database 5.21.3*.

**Note:** If you are upgrading from Greenplum Database 5.10.x or earlier and have installed the PL/Java extension, you must upgrade the PL/Java extension to extension package version 1.4.3. Previous releases of the PL/Java extension are not compatible with Greenplum Database 5.11.0 and later. For information about the PL/Java extension package, see *Pivotal Greenplum Tools and Extensions Compatibility*.

**Note:** If you have databases that were created with Greenplum Database 5.10.x or an earlier 5.x release, upgrade the `gp_bloat_expected_pages` view in the `gp_toolkit` schema. For information about the issue and how check a database for the issue, see *Update for gp_toolkit.gp_bloat_expected_pages Issue*.

**Note:** If you are upgrading from Greenplum Database 5.7.0 or an earlier 5.x release and have configured PgBouncer in your Greenplum Database installation, you must migrate to the new PgBouncer when you upgrade Greenplum Database. Refer to *Migrating PgBouncer* for specific migration instructions.

**Note:** If you have databases that were created with Greenplum Database 5.3.0 or an earlier 5.x release, upgrade the `gp_bloat_diag` function and view in the `gp_toolkit` schema. For information about the issue and how check a database for the issue, see *Update for gp_toolkit.gp_bloat_diag Issue*.

1. Log in to your Greenplum Database master host as the Greenplum administrative user (`gpadmin`):

   ```
   # su - gpadmin
   ```

2. Download or copy the installer file `greenplum-db-appliance-5.21.3-RHEL6-x86_64.bin` to the Greenplum Database master host.

3. Perform a smart shutdown of your current Greenplum Database 5.x system (there can be no active connections to the database). This example uses the `-a` option to disable confirmation prompts:

   ```
   $ gpstop -a
   ```

4. As root, run the Greenplum Database DCA installer for 5.21.3 on the Greenplum Database master host and specify the file `hostfile` that lists all hosts in the cluster. If necessary, copy `hostfile` to the directory containing the installer before running the installer.

   This example command runs the installer for Greenplum Database 5.21.3 for Red Hat Enterprise Linux 6.x.

   ```
   # ./greenplum-db-appliance-5.21.3-RHEL6-x86_64.bin hostfile
   ```

   The file `hostfile` is a text file that lists all hosts in the cluster, one host name per line.

5. If needed, update the `greenplum_path.sh` file for use with your specific installation. These are some examples.

   - If Greenplum Database uses LDAP authentication, edit the `greenplum_path.sh` file to add the line:

     ```
     export LDAPCONF=/etc/openldap/ldap.conf
     ```

   - If Greenplum Database uses PL/Java, you might need to set or update the environment variables `JAVA_HOME` and `LD_LIBRARY_PATH` in `greenplum_path.sh`.

     **Note:** When comparing the previous and new `greenplum_path.sh` files, be aware that installing some Greenplum Database extensions also updates the `greenplum_path.sh` file. The `greenplum_path.sh` from the previous release might contain updates that were the result of those extensions. See step 6 for installing Greenplum Database extensions.
6. Install Greenplum Database extension packages. For information about installing a Greenplum Database extension package, see gppkg in the Greenplum Database Utility Guide.

Also migrate any additional files that are used by the extensions (such as JAR files, shared object files, and libraries) from the previous version installation directory to the new version installation directory.

7. After all segment hosts have been upgraded, you can log in as the gpadmin user and restart your Greenplum Database system:

```
# su - gpadmin
$ gpstart
```

8. If you are utilizing Data Domain Boost, you have to re-enter your DD Boost credentials after upgrading to Greenplum Database 5.21.3 as follows:

```
gpcrondump --ddboost-host ddboost_hostname --ddboost-user ddboost_user
--ddboost-backupdir backup_directory
```

**Note:** If you do not reenter your login credentials after an upgrade, your backup will never start because the Greenplum Database cannot connect to the Data Domain system. You will receive an error advising you to check your login credentials.

After upgrading Greenplum Database, ensure features work as expected. For example, you should test that backup and restore perform as expected, and Greenplum Database features such as user-defined functions, and extensions such as MADlib and PostGIS perform as expected.
**Update for gp_toolkit.gp_bloat_expected_pages Issue**

In Greenplum Database 5.10.x and earlier 5.x releases, the Greenplum Database view `gp_toolkit.gp_bloat_expected_pages` view might incorrectly report that a root partition table is bloated even though root partition tables do not contain data. This information could cause a user to run a `VACUUM FULL` operation on the partitioned table when the operation was not required. The issue was resolved in Greenplum Database 5.11.0 (resolved issue 29523).

When updating Greenplum Database, the `gp_toolkit.gp_bloat_expected_pages` view must be updated in databases created with a Greenplum Database 5.10.x or an earlier 5.x release. This issue has been fixed in databases created with Greenplum Database 5.11.0 and later. For information about using `template0` as the template database after upgrading from Greenplum Database 5.10.x or an earlier 5.x release, see known issue 29523.

To check whether the `gp_toolkit.gp_bloat_expected_pages` view in a database requires an update, run the `psql` command `\d+` to display the view definition.

```bash
\d+ gp_toolkit.gp_bloat_expected_pages
```

The updated view definition contains this predicate.

```sql
AND NOT EXISTS
(SELECT parrelid
 FROM pg_partition
 WHERE parrelid = pgc.oid )
```

Perform the following steps as the `gpadmin` user to update the view on each database that was created with Greenplum Database 5.11.0 or an earlier 5.x release.

1. Copy the script into a text file on the Greenplum Database master.
2. Run the script on each database that requires the update.

   This example updates `gp_toolkit.gp_bloat_expected_pages` view in the database `mytest` and assumes that the script is in the `gp_bloat_expected_pages` in the `gpadmin` home directory.

```bash
psql -f /home/gpadmin/gp_bloat_expected_pages.sql -d mytest
```

Run the script during a low activity period. Running the script during a high activity period does not affect database functionality but might affect performance.

**Script to Update gp_toolkit.gp_bloat_expected_pages View**

```sql
BEGIN;
CREATE OR REPLACE VIEW gp_toolkit.gp_bloat_expected_pages AS
SELECT
  btdrelid,
  btdrelpages,
  CASE WHEN btdexppages < numsegments
    THEN numsegments
    ELSE btdexppages
  END as btdexppages
FROM
 ( SELECT
    oid as btdrelid,
    pgc.relpages as btdrelpages,
    CEIL((pgc.reltuples * (25 + width))/current_setting('block_size'))::numeric / current_setting('block_size')::numeric ) AS btdexppages,
```

```sql
END;```
| (SELECT numsegments FROM gp_toolkit.__gp_number_of_segments) AS numsegments FROM |
| ( SELECT pgc.oid, pgc.reltuples, pgc.relpages |
| FROM pg_class pgc |
| WHERE NOT EXISTS |
| ( SELECT iaooid |
| FROM gp_toolkit.__gp_is_append_only |
| WHERE iaooid = pgc.oid AND iaotype = 't' ) |
| AND NOT EXISTS |
| ( SELECT parrelid |
| FROM pg_partition |
| WHERE parrelid = pgc.oid ) ) AS pgc |
| LEFT OUTER JOIN |
| ( SELECT starelid, SUM(stawidth * (1.0 - stanullfrac)) AS width |
| FROM pg_statistic pgs |
| GROUP BY 1 ) AS btwcols |
| ON pgc.oid = btwcols.starelid |
| WHERE starelid IS NOT NULL ) AS subq; |

GRANT SELECT ON TABLE gp_toolkit.gp_bloat_expected_pages TO public;
COMMIT;
Update for gp_toolkit.gp_bloat_diag Issue

In Greenplum Database 5.3.0 or an earlier 5.x release, Greenplum Database returned an integer out of range error in some cases when performing a query against the gp_toolkit.gp_bloat_diag view. The issue was resolved in Greenplum Database 5.4.0 (resolved issue 26518).

When updating Greenplum Database, the gp_toolkit.gp_bloat_diag function and view must be updated in databases created with a Greenplum Database 5.3.0 or an earlier 5.x release. This issue has been fixed in databases created with Greenplum Database 5.4.0 and later. For information about upgrading from Greenplum Database 5.3.0 or an earlier 5.x release and then using template0 as the template database, see known issue 29523.

To check whether the gp_toolkit.gp_bloat_diag function and view in a database requires an update, run the psql command \df to display information about the gp_toolkit.gp_bloat_diag function.

\df gp_toolkit.gp_bloat_diag

If the data type for btdexppages is integer, an update is required. If the data type is numeric an update is not required. In this example, the btdexppages data type is integer and requires an update.

List of functions

<table>
<thead>
<tr>
<th>Schema</th>
<th>gp_toolkit</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>gp_bloat_diag</td>
</tr>
<tr>
<td>Result data type</td>
<td>record</td>
</tr>
<tr>
<td>Argument data types</td>
<td>btdrelpages integer, btdexppages integer, aotable boolean, OUT bltidx integer, OUT bltdiag text</td>
</tr>
<tr>
<td>Type</td>
<td>normal</td>
</tr>
</tbody>
</table>

Perform the following steps as the gpadmin user to update the function and view to fix the issue on each database that was created with Greenplum Database 5.3.0 or an earlier 5.x release.

1. Copy the script into a text file on the Greenplum Database master.
2. Run the script on each database that requires the update.

This example updates gp_toolkit.gp_bloat_diag function and view in the database mytest and assumes that the script is in the update_bloat_diag.sql in the gpadmin home directory.

psql -f /home/gpadmin/update_bloat_diag.sql -d mytest

Run the script during a low activity period. Running the script during a high activity period does not affect database functionality but might affect performance.

Script to Update gp_toolkit.gp_bloat_diag Function and View

BEGIN;
CREATE OR REPLACE FUNCTION gp_toolkit.gp_bloat_diag(btdrelpages int,
btdexppages numeric, aotable bool,
OUT bltidx int, OUT bltdiag text)
AS $$
SELECT
  bltidx,
  CASE
    WHEN bltidx = 0
    THEN 'no bloat detected'::text

Pivotal Greenplum 5.21.2 Release Notes

Updated: August, 2019

- Welcome to Pivotal Greenplum 5.21.2
- Resolved Issues
- Beta Features
- Deprecated Features
- Known Issues and Limitations
- Differences Compared to Open Source Greenplum Database
- Supported Platforms
- Pivotal Greenplum Tools and Extensions Compatibility
- Hadoop Distribution Compatibility
- Upgrading to Greenplum Database 5.21.2
- Migrating Data to Pivotal Greenplum 5.x
- Pivotal Greenplum on DCA Systems
- Update for gp_toolkit.gp_bloat_expected_pages Issue
- Update for gp_toolkit.gp_bloat_diag Issue
Welcome to Pivotal Greenplum 5.21.2

Pivotal Greenplum Database is a massively parallel processing (MPP) database server that supports next generation data warehousing and large-scale analytics processing. By automatically partitioning data and running parallel queries, it allows a cluster of servers to operate as a single database supercomputer performing tens or hundreds times faster than a traditional database. It supports SQL, MapReduce parallel processing, and data volumes ranging from hundreds of gigabytes, to hundreds of terabytes.

This document contains pertinent release information about Pivotal Greenplum Database 5.21.2. For previous versions of the release notes for Greenplum Database, go to Pivotal Greenplum Database Documentation. For information about Greenplum Database end of life, see the Pivotal Support Lifecycle Policy.

Pivotal Greenplum 5.x software is available for download from the Pivotal Greenplum page on Pivotal Network.

Pivotal Greenplum 5.x is based on the open source Greenplum Database project code.

**Important:** Pivotal Support does **not** provide support for open source versions of Greenplum Database. Only Pivotal Greenplum Database is supported by Pivotal Support.

Pivotal Greenplum 5.21.2 is a maintenance release that resolves issues.

**Note:** Starting with Greenplum version 5.21.2, the gpcopy utility is provided as a separate download on Pivotal Network. See the Pivotal Greenplum gpcopy Documentation for more information.

**Important:** The Greenplum gpbackup and gprestore utilities are now distributed separately from Pivotal Greenplum Database, and are updated independently of the core Greenplum Database server. These utilities will not be updated in future Greenplum Database 5.x releases. You can upgrade to the latest gpbackup and gprestore versions by downloading and installing the latest Pivotal Greenplum Backup and Restore release from Pivotal Network.
Resolved Issues

The listed issues are resolved in Pivotal Greenplum Database 5.21.2.

For issues resolved in prior 5.x releases, refer to the corresponding release notes. Release notes are available from the Pivotal Greenplum page on Pivotal Network.

30043 - Server: Execution
Setting the server configuration parameter `gp_gpperfmon_send_interval` as a non-superuser generated a Greenplum Database panic on the master host. This has been fixed, now the parameter can be set only by a database superuser.

30033 - Resource Management
Some queries that use hash aggregation might have executed more slowly or return an out of memory error when resource groups are enabled and a group is allocating a small memory quota. This was due to issue with hash aggregation that prevented spilling to disk for some queries. This issue has been resolved.

30016 - Server: Execution
When Greenplum Database resource groups are enabled, some queries that perform hash aggregation of a large amount of data performed poorly. Resource groups did not manage spilling query data to disk correctly. Resource group management of query data has been improved.

29969 - Functions and Languages
In some cases, incorrect results were returned when a cached query plan was executed after the `search_path` was changed. Now cached a query plan is invalidated and a new plan is generated when the `search_path` changes.

29934 - Query Optimizer
For some queries against tables that contain an index that is not on a distribution key, GPORCA performance was slower than the Postgres Planner. GPORCA performance has been improved for the specified type of query.

29997 - Process Management
In some cases, the database entered recovery mode when the process management module incorrectly destroyed resources when the InitPlan for a query completed. This issue has been resolved. The process management module now correctly sets the process state and properly reuses backend processes.

29996 - Query Optimizer
For some queries against partitioned tables where the tables were defined with a bitmap index, the ORCA query plan did not use the bitmap index. GPORCA did not properly handle left outer index joins on partitioned tables. This issue has been resolved.

29991 - Server
`ALTER TABLE ... DROP COLUMN` followed by an `ALTER TABLE ... SET WITH (REORGANIZE=true)` in some cases may lose the column encoding settings of the dropped column. This problem manifested itself later as a block version mismatch error when the table was further altered. This issue is resolved. The Greenplum Database server now preserves column encoding settings for dropped columns when redistributing the data.

8213 - PXF
PXF did not propagate external table format options consistently across supported profiles. This issue has been resolved. PXF now consistently passes format options from Greenplum Database to the PXF server for all profiles. As a side effect of this fix, the PXF...
Hive connector no longer requires or supports providing a `DELIMITER=<delim>` option in the `LOCATION` URI when you create an external table that specifies the `HiveText` or `HiveRC` profiles. If you have previously created any PXF external tables with a `DELIMITER` in the `LOCATION` URI, you will no longer be able to query these tables. You must drop and recreate the external tables after you migrate to Greenplum Database 5.21.2. Refer to *Upgrading PXF* for more information.
Beta Features

Because Pivotal Greenplum Database is based on the open source Greenplum Database project code, it includes several Beta features to allow interested developers to experiment with their use on development systems. Feedback will help drive development of these features, and they may become supported in future versions of the product.

**Warning:** Beta features are not supported for production deployments.

Greenplum Database 5.21.2 includes these Beta features:

- **Storage plugin API for gpbackup and gprestore.** Partners, customers, and OSS developers can develop plugins to use in conjunction with gpbackup and gprestore.
  
  For information about the storage plugin API, see [Backup/Restore Storage Plugin API](#) in the Pivotal Greenplum Database Documentation.

- **RecursiveWITH Queries (Common Table Expressions).** See [WITH Queries (Common Table Expressions)](#) in the Pivotal Greenplum Database Documentation.

- **Resource groups remain a Beta feature only on the SuSE 11 platform, due to limited cgroups functionality in the kernel.**

  SuSE 12 resolves the Linux cgroup issues that caused the performance degradation when Greenplum Database resource groups are enabled.

- **Using the Greenplum Platform Extension (PXF) connectors to write Parquet data is a Beta feature.**
Deprecation Features

These Greenplum Database features are deprecated.

- The `gptransfer` utility will be removed in the next major release. The utility copies objects between Greenplum Database systems. The `gpcopy` utility provides `gptransfer` functionality.
- The `gphdfs` external table protocol will be removed in the next major release. Consider using the Greenplum Platform Extension Framework (PXF) `pxf` external table protocol to access data stored in an external Hadoop file system. Refer to *Accessing External Data with PXF* for more information.
Known Issues and Limitations

Pivotal Greenplum 5.x has these limitations:

- Upgrading a Greenplum Database 4.3.x release to Pivotal Greenplum 5.x is not supported. See Migrating Data to Pivotal Greenplum 5.x.
- Some features are works-in-progress and are considered to be Beta features. Pivotal does not support using Beta features in a production environment. See Beta Features.
- Greenplum Database 4.3.x packages are not compatible with Pivotal Greenplum 5.x.

The following table lists key known issues in Pivotal Greenplum 5.x.

Table 11: Key Known Issues in Pivotal Greenplum 5.x

<table>
<thead>
<tr>
<th>Issue</th>
<th>Category</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>29917</td>
<td>Segment Mirroring</td>
<td>A “read beyond eof” error has been observed with certain persistent tables during full recovery. The root cause of this problem has not yet been determined. Greenplum Database version 5.21 contains additional debug logging to help in determining the cause of this problem. The additional logging is enabled by default, and adds approximately 646 bytes to each persistent table entry file. If you want to disable the additional debug logging, set the debug_filerep_config_print configuration parameter &quot;false.&quot;</td>
</tr>
<tr>
<td>Issue</td>
<td>Category</td>
<td>Description</td>
</tr>
<tr>
<td>--------</td>
<td>----------</td>
<td>-------------</td>
</tr>
<tr>
<td>29861</td>
<td>gpstart</td>
<td>If a segment’s data directory becomes inaccessible or the contents of the data directory are deleted, the segment goes offline and is marked as down in <code>gp_segment_configuration</code>. However, if you have temporary or transaction files in a separate filespace or if you stop and start the database, <code>gpstart</code> can fail with the error:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>The error indicates that two files are missing from a segment directory, <code>gp_temporary_files_filespace</code> and <code>gp_transaction_files_filespace</code>. <code>gpstart</code> reports the error even if the segments have already been marked down.</td>
</tr>
<tr>
<td></td>
<td></td>
<td><strong>Workaround</strong>: To resolve this problem you must manually create the missing files in the segment directory using the segment’s corresponding dbid, transaction file segment directory, and filespace oid. See the detailed instructions for creating these files in Article Number: 6784 <code>gpstart</code> fails with error “Multiple OIDs found in flat files” on the Pivotal Support site.</td>
</tr>
<tr>
<td>Issue</td>

<td>Description</td>
</tr>
<tr>
<td>------------</td>
<td>------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>164671144</td>
<td>gpssh-exkeys</td>
<td>The <code>gpssh-exkeys</code> utility uses the Paramiko SSH library for Python, which has a dependency on the Python Cryptography Toolkit (PyCrypto) library. The following security vulnerabilities have been identified in some versions of PyCrypto.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• <a href="https://nvd.nist.gov/vuln/detail/CVE-2018-6594">https://nvd.nist.gov/vuln/detail/CVE-2018-6594</a> - lib/Crypto/PublicKey/ElGamal.py in PyCrypto through 2.6.1 generates weak ElGamal key parameters, which allows attackers to obtain sensitive information by reading ciphertext data (i.e., it does not have semantic security in face of a ciphertext-only attack). The Decisional Diffie-Hellman (DDH) assumption does not hold for PyCrypto's ElGamal implementation. Paramiko does not import this algorithm, so Greenplum Database is unaffected by this vulnerability.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• <a href="https://nvd.nist.gov/vuln/detail/CVE-2013-7459">https://nvd.nist.gov/vuln/detail/CVE-2013-7459</a> - Heap-based buffer overflow in the ALGnew function in block_templace.c in Python Cryptography Toolkit (aka pycrypto) allows remote attackers to execute arbitrary code as demonstrated by a crafted iv parameter to cryptmsg.py. This bug was introduced in PyCrypto 2.6. Greenplum Database has PyCrypto 2.0.1, and is unaffected by the vulnerability.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• <a href="https://nvd.nist.gov/vuln/detail/CVE-2013-1445">https://nvd.nist.gov/vuln/detail/CVE-2013-1445</a> - The Crypto.Random.atfork function in PyCrypto before 2.6.1 does not properly reseed the pseudo-random number generator (PRNG) before allowing a child process to access it, which makes it easier for context-dependent</td>
</tr>
</tbody>
</table>
attackers to obtain sensitive information by leveraging a race condition in which a child process is created and accesses the PRNG within the same rate-limit period as another process.

Paramiko version 1.7.6-9, used in Greenplum Database 4.x and 5.x, introduced a workaround to this bug. Paramiko version 1.18.4 in Greenplum Database 6 solves it in a more permanent way.

- https://nvd.nist.gov/vuln/detail/CVE-2012-2417 - PyCrypto before 2.6 does not produce appropriate prime numbers when using an ElGamal scheme to generate a key, which reduces the signature space or public key space and makes it easier for attackers to conduct brute force attacks to obtain the private key.

Paramiko does not import this algorithm, so Greenplum Database is unaffected by the vulnerability.

Through testing and investigation, Pivotal has determined that these vulnerabilities do not affect Greenplum Database, and no actions are required for existing Greenplum Database 4.3 or 5.x releases. However, there may be additional unidentified vulnerabilities in the PyCrypto library, and users who install a later version of PyCrypto could be exposed to other vulnerabilities.

The PyCrypto library will be removed from Greenplum Database 6.0.

**Workaround:** Administrators can set up passwordless SSH between hosts in the Greenplum Database cluster without using the `gpssh-exkeys` utility. This must be done before initializing the Greenplum Database system.
<table>
<thead>
<tr>
<th>Issue</th>
<th>Category</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td>1. Create an SSH key for the <code>gpadmin</code> user on each host. For example, log in to each host as <code>gpadmin</code> and use the <code>ssh-keygen</code> command to generate an SSH key. Do not enter a passphrase.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>2. Add the public key for each host in the cluster to every other host in the cluster. For example, use the <code>ssh-copy-id</code> command from each host to copy the public key to every other host in the cluster.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>When adding new hosts to the Greenplum Database system, you must create a new SSH key for each new host and exchange keys between the existing hosts and new hosts.</td>
</tr>
<tr>
<td>165434975</td>
<td>search_path</td>
<td>An identified PostgreSQL security vulnerability (<a href="https://nvd.nist.gov/vuln/detail/CVE-2018-1058">https://nvd.nist.gov/vuln/detail/CVE-2018-1058</a>) also exists in Greenplum Database. The problem centers around the default public schema and how Greenplum Database uses the <code>search_path</code> setting. The ability to create objects with the same names in different schemas, combined with how Greenplum Database searches for objects within schemas, presents an opportunity for a user to modify the behavior of a query for other users. For example, a malicious user could insert a trojan-horse function that, when executed by a superuser, grants escalated privileges to the malicious user.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>There are methods to protect from this vulnerability. See <a href="https://www.postgresql.org/docs/current/security-vuln.html">A Guide to CVE-2018-1058: Protect Your Search Path</a> on the PostgreSQL wiki for a full explanation of the vulnerability and the steps you can take to protect your data.</td>

<tr>
<td>29699</td>
<td>ANALYZE</td>
<td>In Greenplum Database 5.15.1 and earlier 5.x releases, an ANALYZE command might return an error that states target lists can have at most 1664 entries when performing an ANALYZE operation on a table with a large number of columns (more than 800 columns). The error occurs because the in-memory sample table created by ANALYZE requires an additional column to indicate whether a column is NULL or is a truncated column for each variable length column being analyzed (such as varchar, text, and bpchar, numeric, arrays, and geometric datatype columns). The error is returned when ANALYZE attempts to create a sample table and the number of columns (table columns and indicator columns) exceeds the maximum number of columns allowed. In Greenplum Database 5.16.0 and later 5.x releases, the ANALYZE sample table does not require an additional column for variable length text columns such as varchar, text, and bpchar columns. <strong>WORKAROUND:</strong> To collect statistics on the table, perform ANALYZE operations on 2 or more sets of table columns.</td>
</tr>

</tr>
</tbody>
</table>
| 29496   | gpconfig                      | For a small number of server configuration parameters such as `log_min_messages`, the command `gpconfig -s <config_param>` does not display the correct value of the parameter for the segment hosts when the value of the parameter on master is different than the value on the segments. For parameters with the set classification `master`, the utility displays the value set on the master for both master and segments (for information about set classifications, see Setting Parameters in the Pivotal Greenplum Database Documentation). For those parameters, the value on the master is passed as part of queries to segment instances. The SQL query that `gpconfig` runs to display the master and segment parameter values returns the master host value that is passed to the segment as part of the query.

For a few parameters such as `log_min_messages`, segment instances use the segment host value specified in the `postgresql.conf` file at start up. The segment value can overridden for the scope of a query.

**Workaround**: To display the parameter value specified in the `postgresql.conf` file on the master host and segment hosts, you can specify the `gpconfig` option `--file`. |

</tr>
<tr>
<td></td>
<td></td>
<td><strong>Workaround:</strong> Use only in-range values for the <code>money</code> data type (32-bit for Greenplum Database 4.x, or 64-bit for Greenplum Database 5.x). Or, use an alternative data type such as <code>numeric</code> or <code>decimal</code>.</td>
</tr>
<tr>
<td>Issue</td>
<td>Category</td>
<td>Description</td>
</tr>
<tr>
<td>-------</td>
<td>----------</td>
<td>-------------</td>
</tr>
<tr>
<td>3290</td>
<td>JSON</td>
<td>The <code>to_json()</code> function is not implemented as a callable function. Attempting to call the function results in an error. For example:</td>
</tr>
</tbody>
</table>

```sql
tutorial=# select to_json('Fred said "Hi. "':::text);
ERROR: function to_json(text) does not exist
LINE 1: select to_json('Fred said "Hi. "':::text);
```

**HINT:** No function matches the given name and argument types. You might need to add explicit type casts.

**Workaround:** Greenplum Database invokes `to_json()` internally when casting to the json data type, so perform a cast instead. For example: `SELECT '{"foo":"bar"}':::json;` Greenplum Database also provides the `array_to_json()` and `row_to_json()` functions.

<th>Issue</th>
<th>Category</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>149789783</td>
<td>Resource Groups</td>
<td>Significant Pivotal Greenplum performance degradation has been observed when enabling resource group-based workload management on Red Hat 6.x, CentOS 6.x, and SuSE 11 systems. This issue is caused by a Linux cgroup kernel bug. This kernel bug has been fixed in CentOS 7.x and Red Hat 7.x systems. When resource groups are enabled on systems with an affected kernel, there can be a delay of 1 second or longer when starting a transaction or a query. The delay is caused by a Linux cgroup kernel bug where a synchronization mechanism called <code>synchronize_sched</code> is abused when a process is attached to a cgroup. See <a href="http://www.spinics.net/lists/cgroups/msg05708.html">http://www.spinics.net/lists/cgroups/msg05708.html</a> and <a href="https://lkml.org/lkml/2013/1/14/97">https://lkml.org/lkml/2013/1/14/97</a> for more information. The issue causes single attachment operations to take longer and also causes all concurrent attachments to be executed in sequence. For example, one process attachment could take about 0.01 second. When concurrently attaching 100 processes, the fastest process attachment takes 0.01 second and the slowest takes about 1 second. Pivotal Greenplum performs process attachments when a transaction or queries are started. So the performance degradation is dependent on concurrent started transactions or queries, and not related to concurrent running queries. Also Pivotal Greenplum has optimizations to bypass the rewriting when a QE is reused by multiple queries in the same session. <strong>Workaround:</strong> This bug does not affect CentOS 7.x and Red Hat 7.x systems.</td>
</tr>

</tbody>
</table>
Differences Compared to Open Source Greenplum Database

Pivotal Greenplum 5.x includes all of the functionality in the open source Greenplum Database project and adds:

- Product packaging and installation script.
- Support for QuickLZ compression. QuickLZ compression is not provided in the open source version of Greenplum Database due to licensing restrictions.
- Support for managing Greenplum Database using Pivotal Greenplum Command Center.
- Support for full text search and text analysis using Pivotal GPText.
- Support for data connectors:
  - Greenplum-Spark Connector
  - Greenplum-Informatica Connector
  - Greenplum-Kafka Integration
  - Gemfire-Greenplum Connector
  - Greenplum Stream Server
- Data Direct ODBC/JDBC Drivers
- `gpcopy` utility for copying or migrating objects between Greenplum systems.
Supported Platforms

Pivotal Greenplum 5.21.2 runs on the following platforms:

- Red Hat Enterprise Linux 64-bit 7.x (See the following Note)
- Red Hat Enterprise Linux 64-bit 6.x (See the following Note)
- SuSE Linux Enterprise Server 64-bit 12 SP2 and SP3 with kernel version greater than 4.4.73-5. (See the following Note)
- SuSE Linux Enterprise Server 64-bit 11 SP4 (See the following Note)
- CentOS 64-bit 7.x
- CentOS 64-bit 6.x (See the following Note)
- Oracle Linux 64-bit 7.4, using the Red Hat Compatible Kernel (RHCK)

Note: For the supported Linux operating systems, Pivotal Greenplum Database is supported on system hosts using either AMD or Intel CPUs based on the x86-64 architecture. Pivotal recommends using a homogeneous set of hardware (system hosts) in a Greenplum Database system.

Important: Significant Greenplum Database performance degradation has been observed when enabling resource group-based workload management on Red Hat 6.x, CentOS 6.x, and SuSE 11 systems. This issue is caused by a Linux cgroup kernel bug. This kernel bug has been fixed in CentOS 7.x and Red Hat 7.x systems.

If you use Red Hat 6 and the performance with resource groups is acceptable for your use case, upgrade your kernel to version 2.6.32-696 or higher to benefit from other fixes to the cgroups implementation.

SuSE 11 does not have a kernel version that resolves this issue; resource groups are still considered to be a Beta feature on this platform. Resource groups are not supported on SuSE 11 for production use. See known issue 149789783.

Pivotal Greenplum on SuSE 12 supports resource groups for production use. SuSE 12 resolves the Linux cgroup kernel issues that caused the performance degradation when Greenplum Database resource groups are enabled.

Note: For Greenplum Database that is installed on Red Hat Enterprise Linux 7.x or CentOS 7.x prior to 7.3, an operating system issue might cause Greenplum Database that is running large workloads to hang in the workload. The Greenplum Database issue is caused by Linux kernel bugs. RHEL 7.3 and CentOS 7.3 resolves the issue.

Note: Greenplum Database on SuSE Linux Enterprise systems does not support these features.

- The PL/Perl procedural language
- The gpmapreduce tool
- The PL/Container language extension
- The Greenplum Platform Extension Framework (PXF)

Note: PL/Container is not supported on RHEL/CentOS 6.x systems, because those platforms do not officially support Docker.

Greenplum Database support on Dell EMC DCA.

- Pivotal Greenplum Database 5.21.2 is supported on DCA systems that are running DCA software version 3.4 or greater.
- Only Pivotal Greenplum Database is supported on DCA systems. Open source versions of Greenplum Database are not supported.
- FIPS is supported on DCA software version 3.4 and greater with Pivotal Greenplum Database 5.2.0 and greater.
Note: These Greenplum Database releases are not certified on DCA because of an incompatibility in configuring timezone information.

5.5.0, 5.6.0, 5.6.1, 5.7.0, 5.8.0

These Greenplum Database releases are certified on DCA.

5.7.1, 5.8.1, 5.9.0 and later releases, and 5.x releases prior to 5.5.0.

Pivotal Greenplum 5.21.2 supports these Java versions:

- 8.xxx
- 7.xxx

Greenplum Database 5.21.2 software that runs on Linux systems uses OpenSSL 1.0.2l (with FIPS 2.0.16), cURL 7.54, OpenLDAP 2.4.44, and Python 2.7.12.

Greenplum Database client software that runs on Windows and AIX systems uses OpenSSL 0.9.8zg.

The Greenplum Database s3 external table protocol supports these data sources:

- Amazon Simple Storage Service (Amazon S3)
- Dell EMC Elastic Cloud Storage (ECS), an Amazon S3 compatible service

Pivotal Greenplum 5.21.2 supports Data Domain Boost on Red Hat Enterprise Linux.

This table lists the versions of Data Domain Boost SDK and DDOS supported by Pivotal Greenplum 5.x.
Table 12: Data Domain Boost Compatibility

</tbody>
</table>

Note: In addition to the DDOS versions listed in the previous table, Pivotal Greenplum 5.0.0 and later supports all minor patch releases (fourth digit releases) later than the certified version.

<sup>1</sup>Support for Data Domain Boost 3.0.0.3 is deprecated. The DELL EMC end of Primary Support date is December 31, 2017.

<sup>2</sup>The Greenplum Database utilities `gpbackup` and `gprestore` support Data Domain DD Boost File System Plugin (BoostFS) v1.1 with DDOS 6.0 or greater.

The `gpbackup` and `gprestore` utilities support using Dell EMC Data Domain Boost software with the DD Boost Storage Plugin.

Note: Pivotal Greenplum 5.21.2 does not support the ODBC driver for Cognos Analytics V11.

Connecting to IBM Cognos software with an ODBC driver is not supported. Greenplum Database supports connecting to IBM Cognos software with the DataDirect JDBC driver for Pivotal Greenplum. This driver is available as a download from Pivotal Network.

**Veritas NetBackup**

Pivotal Greenplum 5.21.2 supports backup with Veritas NetBackup version 7.7.3. See Backing Up Databases with Veritas NetBackup.
Supported Platform Notes

The following notes describe platform support for Pivotal Greenplum. Please send any questions or comments to Pivotal Support at https://support.pivotal.io.

- Pivotal Greenplum is supported using either IPV4 or IPV6 protocols.
- The only file system supported for running Greenplum Database is the XFS file system. All other file systems are explicitly not supported by Pivotal.
- Greenplum Database is supported on network or shared storage if the shared storage is presented as a block device to the servers running Greenplum Database and the XFS file system is mounted on the block device. Network file systems are not supported. When using network or shared storage, Greenplum Database mirroring must be used in the same way as with local storage, and no modifications may be made to the mirroring scheme or the recovery scheme of the segments. Other features of the shared storage such as de-duplication and/or replication are not directly supported by Pivotal Greenplum Database, but may be used with support of the storage vendor as long as they do not interfere with the expected operation of Greenplum Database at the discretion of Pivotal.
- Greenplum Database is supported when running on virtualized systems, as long as the storage is presented as block devices and the XFS file system is mounted for the storage of the segment directories.

Warning: Running Pivotal Greenplum on hyper-converged infrastructure (HCI) has known issues with performance, scalability, and stability and is not recommended as a scalable solution for Pivotal Greenplum and may not be supported by Pivotal if stability problems appear related to the infrastructure. HCI virtualizes all of the elements of conventional hardware systems and includes, at a minimum, virtualized computing, a virtualised SAN, and virtualized networking.

- A minimum of 10-gigabit network is required for a system configuration to be supported by Pivotal.
- Greenplum Database is supported on Amazon Web Services (AWS), Microsoft Azure, and Google Cloud Compute (GCP).
  - AWS - For production workloads, r4.8xlarge and r4.16xlarge instance types with four 12TB ST1 EBS volumes for each segment host, or d2.8xlarge with ephemeral storage configured with 4 RAID 0 volumes, are supported. EBS storage is recommended. EBS storage is more reliable and provides more features than ephemeral storage. Note that Amazon has no provisions to replace a bad ephemeral drive; when a disk failure occurs, you must replace the node with the bad disk.

  Pivotall recommends using an Auto Scaling Group (ASG) to provision nodes in AWS. An ASG automatically replaces bad nodes, and you can add further automation to recover the Greenplum processes on the new nodes automatically.

  Deployments should be in a Placement Group within a single Availability Zone. Because Amazon recommends using the same instance type in a Placement Group, use a single instance type for all nodes, including the masters.

  Azure - For production workloads, Pivotal recommends configuring Standard_H8 instance type with 4 2TB disks and 2 segments per host and recommend using 8 2TB disks and 4 segments per host with Standard_H16 instance type. Standard_H16 uses 8 2TB disks and 4 segments per host. This means software RAID 0 is required so that the number of volumes do not exceed the number of segments.

  For Azure deployments, you must also configure the Greenplum Database system to not use port 65330. Add the following line to the sysctl.conf file on all Greenplum Database hosts:

  $ net.ipv4.ip_local_reserved_ports=65330

  GCP - For all workloads, n1-standard-8 and n1-highmem-8 are supported which are relatively small instance types. This is because of the disk performance in GCP forces the configuration to have just 2 segments per host but with many hosts to scale. Use pd-standard disks and the size of the disk is recommended to be 6 TB. For performance perspective, use a factor of 8 when determining how
many nodes to deploy in GCP, so a 16 segment host cluster in AWS would require 128 nodes in GCP.

- For Red Hat Enterprise Linux 7.2 or CentOS 7.2, the default `systemd` setting `RemoveIPC=yes` removes IPC connections when non-system users logout. This causes the Greenplum Database utility `gpinitfsystem` to fail with semaphore errors. To avoid this issue, see "Setting the Greenplum Recommended OS Parameters" in the *Greenplum Database Installation Guide*. 
Pivotal Greenplum Tools and Extensions Compatibility

- **Client Tools**
- **Extensions**
- **Pivotal Greenplum Data Connectors**
- **Pivotal GPTText Compatibility**
- **Pivotal Greenplum Command Center**

### Client Tools

Greenplum releases a number of client tool packages on various platforms that can be used to connect to Greenplum Database and the Greenplum Command Center management tool. The following table describes the compatibility of these packages with this Greenplum Database release.

Tool packages are available from Pivotal Network.

**Table 13: Pivotal Greenplum 5.21.2 Tools Compatibility**

<table>
<thead>
<tr>
<th>Tool</th>
<th>Description of Contents</th>
<th>Tool Version(s)</th>
<th>Server Version(s)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Pivotal Greenplum Clients</td>
<td>Greenplum Database Command-Line Interface (psql)</td>
<td>5.8</td>
<td>5.x</td>
</tr>
<tr>
<td>Pivotal Greenplum Loaders</td>
<td>Greenplum Database Parallel Data Loading Tools (gpfdist, gpload)</td>
<td>5.8</td>
<td>5.x</td>
</tr>
<tr>
<td>Pivotal Greenplum Command Center</td>
<td>Greenplum Database management tool</td>
<td>4.7</td>
<td>5.19 and later</td>
</tr>
<tr>
<td></td>
<td></td>
<td>4.0.0</td>
<td>5.7.0 and later</td>
</tr>
<tr>
<td></td>
<td></td>
<td>3.3.2</td>
<td>5.0.0 and later</td>
</tr>
<tr>
<td></td>
<td></td>
<td>3.2.2</td>
<td>5.0.0 - 5.2.x</td>
</tr>
<tr>
<td>Pivotal Greenplum Workload Manager(^1)</td>
<td>Greenplum Database query monitoring and management tool</td>
<td>1.8.0</td>
<td>5.0.0</td>
</tr>
</tbody>
</table>

The Greenplum Database Client Tools and Load Tools are supported on the following platforms:
- AIX 7.2 (64-bit) (Client and Load Tools only)\(^2\)
- Red Hat Enterprise Linux x86_64 7.x (RHEL 7)
- Red Hat Enterprise Linux x86_64 6.x (RHEL 6)
- SuSE Linux Enterprise Server x86_64 SLES 11 SP4, or SLES 12 SP2/SP3
- Windows 10 (32-bit and 64-bit)
- Windows 8 (32-bit and 64-bit)
- Windows Server 2012 (32-bit and 64-bit)
- Windows Server 2012 R2 (32-bit and 64-bit)
- Windows Server 2008 R2 (32-bit and 64-bit)

**Note:**\(^1\) For Pivotal Greenplum Command Center 4.0.0 and later, workload management is an integrated Command Center feature rather than the separate tool Pivotal Greenplum Workload Manager.
For Greenplum Database 5.4.1 and earlier 5.x releases, download the AIX Client and Load Tools package either from the Greenplum Database 5.11.1 file collection or the Greenplum Database 5.0.0 file collection on Pivotal Network.

### Extensions

**Table 14: Pivotal Greenplum 5.21.2 Extensions Compatibility**

<table>
<thead>
<tr>
<th>Pivotal Greenplum Extension</th>
<th>Versions</th>
</tr>
</thead>
<tbody>
<tr>
<td>MADlib machine learning for Greenplum Database 5.x&lt;sup&gt;1&lt;/sup&gt;</td>
<td>MADlib 1.16, 1.15.1, 1.15, 1.14</td>
</tr>
<tr>
<td>PL/Java for Greenplum Database 5.x</td>
<td>PL/Java 1.4.3&lt;sup&gt;2&lt;/sup&gt;</td>
</tr>
<tr>
<td>PL/R for Greenplum Database 5.x</td>
<td>2.3.3</td>
</tr>
<tr>
<td>PostGIS Spatial and Geographic Objects for Greenplum Database 5.x</td>
<td>2.1.5+pivotal.2</td>
</tr>
<tr>
<td>Python Data Science Module Package for Greenplum Database 5.x&lt;sup&gt;3&lt;/sup&gt;</td>
<td>1.1.1, 1.1.0, 1.0.0</td>
</tr>
<tr>
<td>R Data Science Library Package for Greenplum Database 5.x&lt;sup&gt;4&lt;/sup&gt;</td>
<td>1.0.1, 1.0.0</td>
</tr>
<tr>
<td>PL/Container for Greenplum Database 5.x</td>
<td>1.1&lt;sup&gt;5&lt;/sup&gt;, 1.2&lt;sup&gt;6&lt;/sup&gt;, 1.3, 1.4</td>
</tr>
</tbody>
</table>

**Note:**

1. Pivotal recommends that you upgrade to the most recent version of MADlib. For information about MADlib support and upgrade information, see the [MADlib FAQ](#) in the [Greenplum Database Reference Guide](#).

2. The PL/Java extension package version 1.4.3 is compatible only with Greenplum Database 5.11.0 and later, it is not compatible with 5.10.x or earlier. If you are upgrading from Greenplum Database 5.10.x or earlier and have installed PL/Java 1.4.2, you must upgrade the PL/Java extension to version 1.4.3.

3. For information about the Python package, including the modules provided, see the [Python Data Science Module Package](#) in the [Greenplum Database Documentation](#).

4. For information about the R package, including the libraries provided, see the [R Data Science Library Package](#) in the [Greenplum Database Documentation](#).

5. To upgrade from PL/Container 1.0 to PL/Container 1.1 and later, you must drop the PL/Container 1.0 language before registering the new version of PL/Container. For information on upgrading the PL/Container extension in Greenplum Database, see [PL/Container Language Extension](#) in the [Greenplum Database Reference Guide](#).

6. PL/Container version 1.2 can utilize the resource group capabilities that were introduced in Greenplum Database 5.8.0. If you downgrade to a Greenplum Database system that uses PL/Container 1.1 or earlier, you must use `plcontainer runtime-edit` to remove any `resource_group_id` settings from the PL/Container runtime configuration file. See [Upgrading from PL/Container 1.1](#).

These Greenplum Database extensions are installed with Pivotal Greenplum Database

- Fuzzy String Match Extension
- PL/Python Extension
- pgcrypto Extension
**Pivotal Greenplum Data Connectors**

- **Greenplum Platform Extension Framework (PXF)** - PXF, integrated with Greenplum Database, provides access to HDFS, Hive, HBase, and SQL external data stores. Refer to *Accessing External Data with PXF* in the *Greenplum Database Administrator Guide* for PXF configuration and usage information.

  **Note:** PXF is available only for supported Red Hat and CentOS platforms. PXF is not available for supported SuSE platforms.

- **Greenplum-Spark Connector** - The Pivotal Greenplum-Spark Connector supports high speed, parallel data transfer from Greenplum Database to an Apache Spark cluster. The Greenplum-Spark Connector is available as a separate download from *Pivotal Network*. Refer to the *Greenplum-Spark Connector documentation* for compatibility and usage information.

- **Greenplum-Informatica Connector** - The Pivotal Greenplum-Informatica connector supports high speed data transfer from an Informatica PowerCenter cluster to a Pivotal Greenplum Database cluster for batch and streaming ETL operations. See the *Pivotal Greenplum-Informatica Connector Documentation*.

- **Greenplum-Kafka Integration** - The Pivotal Greenplum-Kafka Integration provides high speed, parallel data transfer from a Kafka cluster to a Pivotal Greenplum Database cluster for batch and streaming ETL operations. Refer to the *Pivotal Greenplum-Kafka Integration Documentation* for more information about this feature.

- **Greenplum Stream Server** - The Pivotal Greenplum Stream Server is an ETL tool that provides high speed, parallel data transfer from Informatica, Kafka, and custom client data sources to a Pivotal Greenplum Database cluster. Refer to the *Performing ETL Operations with the Pivotal Greenplum Stream Server Documentation* for more information about this feature.

- **Gemfire-Greenplum Connector** - The Pivotal Gemfire-Greenplum Connector supports the transfer of data between a GemFire region and a Greenplum Database cluster. The Gemfire-Greenplum Connector is available as a separate download from *Pivotal Network*. Refer to the *Gemfire-Greenplum Connector documentation* for compatibility and usage information.

---

**Pivotal GPText Compatibility**

Pivotal Greenplum Database 5.21.2 is compatible with Pivotal GPText version 2.1.3 and later.

---

**Pivotal Greenplum Command Center**

See the *Greenplum Command Center documentation* for GPCC and Greenplum Workload Manager compatibility information, see the Pivotal Greenplum Command Center 3.x and 2.x *Release Notes*.

**Note:** For Pivotal Greenplum Command Center 4.0.0 and later, workload management is an integrated Command Center feature rather than the separate tool Pivotal Greenplum Workload Manager.
Hadoop Distribution Compatibility

Greenplum Database provides access to HDFS with gphdfs and the Greenplum Platform Extension Framework (PXF).

PXF Hadoop Distribution Compatibility

PXF supports the Cloudera, Hortonworks Data Platform, MapR, and generic Apache Hadoop distributions.

If you plan to access JSON format data stored in a Cloudera Hadoop cluster, PXF requires a Cloudera version 5.8 or later Hadoop distribution.

gphdfs Hadoop Distribution Compatibility

The supported Hadoop distributions for gphdfs are listed below:

Table 15: Supported gphdfs Hadoop Distributions

<table>
<thead>
<tr>
<th>Hadoop Distribution</th>
<th>Version</th>
<th>gp_hadoop_target_version</th>
</tr>
</thead>
<tbody>
<tr>
<td>Cloudera</td>
<td>CDH 5.x</td>
<td>cdh</td>
</tr>
<tr>
<td>Hortonworks Data Platform</td>
<td>HDP 2.x</td>
<td>hdp</td>
</tr>
<tr>
<td>MapR</td>
<td>MapR 4.x, MapR 5.x</td>
<td>mpr</td>
</tr>
<tr>
<td>Apache Hadoop</td>
<td>2.x</td>
<td>hadoop</td>
</tr>
</tbody>
</table>

**Note:** MapR requires the MapR client.
Upgrading to Greenplum Database 5.21.2

The upgrade path supported for this release is Greenplum Database 5.x to Greenplum Database 5.21.2. Upgrading a Greenplum Database 4.3.x release to Pivotal Greenplum 5.x is not supported. See Migrating Data to Pivotal Greenplum 5.x.

**Note:** If you are upgrading Greenplum Database on a DCA system, see Pivotal Greenplum on DCA Systems.

**Important:** Pivotal recommends that customers set the Greenplum Database timezone to a value that is compatible with their host systems. Setting the Greenplum Database timezone prevents Greenplum Database from selecting a timezone each time the cluster is restarted and sets the timezone for the Greenplum Database master and segment instances. After you upgrade to this release and if you have not set a Greenplum Database timezone value, verify that the selected Greenplum Database timezone is acceptable for your deployment. See Configuring Timezone and Localization Settings for more information.

**Prerequisites**

Before starting the upgrade process, Pivotal recommends performing the following checks.

- Verify the health of the Greenplum Database host hardware, and that you verify that the hosts meet the requirements for running Greenplum Database. The Greenplum Database gpcheckperf utility can assist you in confirming the host requirements.

  **Note:** If you need to run the gpcheckcat utility, Pivotal recommends running it a few weeks before the upgrade and that you run gpcheckcat during a maintenance period. If necessary, you can resolve any issues found by the utility before the scheduled upgrade.

  The utility is in $GPHOME/bin. Pivotal recommends that Greenplum Database be in restricted mode when you run gpcheckcat utility. See the Greenplum Database Utility Guide for information about the gpcheckcat utility.

  If gpcheckcat reports catalog inconsistencies, you can run gpcheckcat with the --g option to generate SQL scripts to fix the inconsistencies.

  After you run the SQL scripts, run gpcheckcat again. You might need to repeat the process of running gpcheckcat and creating SQL scripts to ensure that there are no inconsistencies. Pivotal recommends that the SQL scripts generated by gpcheckcat be run on a quiescent system. The utility might report false alerts if there is activity on the system.

  **Important:** If the gpcheckcat utility reports errors, but does not generate a SQL script to fix the errors, contact Pivotal support. Information for contacting Pivotal Support is at https://support.pivotal.io.

- During the migration process from Greenplum Database 5.0.0, a backup is made of some files and directories in $MASTER_DATA_DIRECTORY. Pivotal recommends that files and directories that are not used by Greenplum Database be backed up, if necessary, and removed from the $MASTER_DATA_DIRECTORY before migration. For information about the Greenplum Database migration utilities, see the Greenplum Database Documentation.

For information about supported versions of Greenplum Database extensions, see Pivotal Greenplum Tools and Extensions Compatibility.

If you are utilizing Data Domain Boost, you have to re-enter your DD Boost credentials after upgrading to Greenplum Database 5.21.2 as follows:

```
gpcrondump --ddboost-host ddboost_hostname --ddboost-user ddboost_user
--ddboost-backupdir backup_directory
```

**Note:** If you do not reenter your login credentials after an upgrade, your backup will never start because the Greenplum Database cannot connect to the Data Domain system. You will receive an error advising you to check your login credentials.

If you have configured the Greenplum Platform Extension Framework (PXF) in your previous Greenplum Database installation, you must stop the PXF service, and you might need to back up PXF configuration files before upgrading to a new version of Greenplum Database. Refer to *PXF Pre-Upgrade Actions* for instructions.

If you do not plan to use PXF, or you have not yet configured PXF, no action is necessary.

### Upgrading from 5.x to 5.21.2

An upgrade from 5.x to 5.21.2 involves stopping Greenplum Database, updating the Greenplum Database software binaries, upgrading and restarting Greenplum Database. If you are using Greenplum Database extension packages there are additional requirements. See *Prerequisites* in the previous section.

**Note:** If you are upgrading from Greenplum Database 5.10.x or earlier and have installed the PL/Java extension, you must upgrade the PL/Java extension to extension package version 1.4.3. Previous releases of the PL/Java extension are not compatible with Greenplum Database 5.11.0 and later. For information about the PL/Java extension package, see *Pivotal Greenplum Tools and Extensions Compatibility*.

**Note:** If you have databases that were created with Greenplum Database 5.10.x or an earlier 5.x release, upgrade the `gp_bloat_expected_pages` view in the `gp_toolkit` schema. For information about the issue and how check a database for the issue, see *Update for gp_toolkit.gp_bloat_expected_pages Issue*.

**Note:** If you are upgrading from Greenplum Database 5.7.0 or an earlier 5.x release and have configured PgBouncer in your Greenplum Database installation, you must migrate to the new PgBouncer when you upgrade Greenplum Database. Refer to *Migrating PgBouncer* for specific migration instructions.

**Note:** If you have databases that were created with Greenplum Database 5.3.0 or an earlier 5.x release, upgrade the `gp_bloat_diag` function and view in the `gp_toolkit` schema. For information about the issue and how check a database for the issue, see *Update for gp_toolkit.gp_bloat_diag Issue*.

**Note:** If the Greenplum Command Center database `gpperfmon` is installed in your Greenplum Database system, the migration process changes the distribution key of the Greenplum Database `log_alert_*` tables to the `logtime` column. The redistribution of the table data might take some time the first time you start Greenplum Database after migration. The change occurs only the first time you start Greenplum Database after a migration.

1. Log in to your Greenplum Database master host as the Greenplum administrative user:

   ```
   $ su - gpadmin
   ```

2. Perform a smart shutdown of your current Greenplum Database 5.x system (there can be no active connections to the database). This example uses the `–a` option to disable confirmation prompts:

   ```
   $ gpstop -a
   ```

3. Run the binary installer for 5.21.2 on the Greenplum Database master host.

   When prompted, choose an installation location in the same base directory as your current installation. For example:

   ```
   /usr/local/greenplum-db-5.21.2
   ```

   If you install Greenplum Database with the `rpm` (as `root`), the installation directory is `/usr/local/greenplum-db-5.21.2`.
For the rpm installation, update the permissions for the new installation. For example, run this command as root to change user and group of the installed files to gpadmin.

```bash
# chown -R gpadmin:gpadmin /usr/local/greenplum*
```

4. If needed, update the `greenplum_path.sh` file for use with your specific installation. These are some examples.
   - If Greenplum Database uses LDAP authentication, edit the `greenplum_path.sh` file to add the line:
     ```bash
     export LDAPCONF=/etc/openldap/ldap.conf
     ```
   - If Greenplum Database uses PL/Java, you might need to set or update the environment variables `JAVA_HOME` and `LD_LIBRARY_PATH` in `greenplum_path.sh`.

     **Note:** When comparing the previous and new `greenplum_path.sh` files, be aware that installing some Greenplum Database extensions also updates the `greenplum_path.sh` file. The `greenplum_path.sh` from the previous release might contain updates that were the result of those extensions. See step 9 for installing Greenplum Database extensions.

5. Edit the environment of the Greenplum Database superuser (`gpadmin`) and make sure you are sourcing the `greenplum_path.sh` file for the new installation. For example change the following line in `.bashrc` or your chosen profile file:

   ```bash
   source /usr/local/greenplum-db-5.0.0/greenplum_path.sh
   ```

   to:

   ```bash
   source /usr/local/greenplum-db-5.21.2/greenplum_path.sh
   ```

   Or if you are sourcing a symbolic link (`/usr/local/greenplum-db`) in your profile files, update the link to point to the newly installed version. For example:

   ```bash
   $ rm /usr/local/greenplum-db
   $ ln -s /usr/local/greenplum-db-5.21.2 /usr/local/greenplum-db
   ```

6. Source the environment file you just edited. For example:

   ```bash
   $ source ~/.bashrc
   ```

7. Run the `gpseginstall` utility to install the 5.21.2 binaries on all the segment hosts specified in the `hostfile`. For example:

   ```bash
   $ gpseginstall -f hostfile
   ```

   **Note:** The `gpseginstall` utility copies the installed files from the current host to the remote hosts. It does not use `rpm` to install Greenplum Database on the remote hosts, even if you used `rpm` to install Greenplum Database on the current host.

8. Use the Greenplum Database `gppkg` utility to install Greenplum Database extensions. If you were previously using any Greenplum Database extensions such as pgcrypto, PL/R, PL/Java, PL/Perl, and PostGIS, download the corresponding packages from Pivotal Network, and install using this utility. See the Greenplum Database Documentation for `gppkg` usage details.

   Also copy any additional files that are used by the extensions (such as JAR files, shared object files, and libraries) from the previous version installation directory to the new version installation directory on the master and segment host systems.

9. If you are upgrading from Greenplum Database 5.7 or an earlier 5.x release and have configured PgBouncer in your Greenplum Database installation, you must migrate to the new PgBouncer when you upgrade Greenplum Database. Refer to Migrating PgBouncer for specific migration instructions.
10. After all segment hosts have been upgraded, you can log in as the `gpadmin` user and restart your Greenplum Database system:

```
# su - gpadmin
$ gpstart
```

11. If you are utilizing Data Domain Boost, you have to re-enter your DD Boost credentials after upgrading from Greenplum Database to 5.21.2 as follows:

```
gpcrondump --ddboost-host ddboost_hostname --ddboost-user ddboost_user
--ddboost-backupdir backup_directory
```

**Note:** If you do not reenter your login credentials after an upgrade, your backup will never start because the Greenplum Database cannot connect to the Data Domain system. You will receive an error advising you to check your login credentials.

12. If you configured PXF in your previous Greenplum Database installation, you must re-initialize the PXF service after you upgrade Greenplum Database. Refer to *Upgrading PXF* for instructions.

After upgrading Greenplum Database, ensure features work as expected. For example, you should test that backup and restore perform as expected, and Greenplum Database features such as user-defined functions, and extensions such as MADlib and PostGIS perform as expected.

**Troubleshooting a Failed Upgrade**

If you experience issues during the migration process and have active entitlements for Greenplum Database that were purchased through Pivotal, contact Pivotal Support. Information for contacting Pivotal Support is at [https://support.pivotal.io](https://support.pivotal.io).

Be prepared to provide the following information:

- A completed *Upgrade Procedure*.
- Log output from `gpcheckcat` (located in `~/gpAdminLogs`)

Migrating Data to Pivotal Greenplum 5.x

Upgrading a Pivotal Greenplum Database 4.x system directly to Pivotal Greenplum Database 5.x is not supported.

You can migrate existing data to Greenplum Database 5.x using standard backup and restore procedures (gpcrondump and gpdbrestore) or by using gptransfer. The gpcopy utility can be used to migrate data from Greenplum Database 4.3.26 or later to 5.9 or later.

Follow these general guidelines for migrating data:

• Make sure that you have a complete backup of all data in the Greenplum Database 4.3.x cluster, and that you can successfully restore the Greenplum Database 4.3.x cluster if necessary.
• You must install and initialize a new Greenplum Database 5.x cluster using the version 5.x gpinitsystem utility.

Note: Unless you modify file locations manually, gpdbrestore only supports restoring data to a cluster that has an identical number of hosts and an identical number of segments per host, with each segment having the same content_id as the segment in the original cluster. If you initialize the Greenplum Database 5.x cluster using a configuration that is different from the version 4.3 cluster, then follow the steps outlined in Restoring to a Different Greenplum System Configuration to manually update the file locations.

Important: For Greenplum Database 5.x, Pivotal recommends that customers set the Greenplum Database timezone to a value that is compatible with the host systems. Setting the Greenplum Database timezone prevents Greenplum Database from selecting a timezone each time the cluster is restarted and sets the timezone for the Greenplum Database master and segment instances. See Configuring Timezone and Localization Settings for more information.

• If you intend to install Greenplum Database 5.x on the same hardware as your 4.3.x system, you will need enough disk space to accommodate over 5 times the original data set (2 full copies of the primary and mirror data sets, plus the original backup data in ASCII format) in order to migrate data with gpcrondump and gpdbrestore. Keep in mind that the ASCII backup data will require more disk space than the original data, which may be stored in compressed binary format. Offline backup solutions such as Dell EMC Data Domain or Veritas NetBackup can reduce the required disk space on each host.

If you attempt to migrate your data on the same hardware but run out of free space, gpcopy provides the --truncate-source-after option to truncate each source table after copying the table to the destination cluster and validating the copy succeeded. This reduces the amount of free space needed to migrate clusters that reside on the same hardware. See Migrating Data with gpcopy for more information.

• Use the version 5.x gpdbrestore utility to load the 4.3.x backup data into the new cluster.
• If the Greenplum Database 5.x cluster resides on separate hardware from the 4.3.x cluster, and the clusters have different numbers of segments, you can optionally use the version 5.x gptransfer utility to migrate the 4.3.x data. You must initiate the gptransfer operation from the version 5.x cluster, pulling the older data into the newer system.

On a Greenplum Database system with FIPS enabled, validating table data with MD5 (specifying the gptransfer option --validate=md5) is not available. Use the option sha256 to validate table data.

Validating table data with SHA-256 (specifying the option --validate=sha256) requires the Greenplum Database pgcrypto extension. The extension is included with Pivotal Greenplum 5.x. The extension package must be installed on supported Pivotal Greenplum 4.3.x systems. Support for pgcrypto functions in a Greenplum 4.3.x database is not required.

• Greenplum Database 5.x removes automatic implicit casts between the text type and other data types. After you migrate from Greenplum Database version 4.3.x to version 5.x, this change in behavior may impact existing applications and queries. Refer to About Implicit Text Casting in Greenplum Database in
the Greenplum Database Installation Guide for information, including a discussion about supported and unsupported workarounds.

- After migrating data you may need to modify SQL scripts, administration scripts, and user-defined functions as necessary to account for changes in Greenplum Database version 5.x. Look for Upgrade Action Required entries in the Pivotal Greenplum 5.0.0 Release Notes for features that may necessitate post-migration tasks.

- If you are migrating from Greenplum Database 4.3.27 or an earlier 4.3.x release and have configured PgBouncer in your Greenplum Database installation, you must migrate to the new PgBouncer when you upgrade Greenplum Database. Refer to Migrating PgBouncer for specific migration instructions.
**Pivotal Greenplum on DCA Systems**

On supported Dell EMC DCA systems, you can install Pivotal Greenplum 5.21.2, or you can upgrade from Pivotal Greenplum 5.x to 5.21.2.

Only Pivotal Greenplum Database is supported on DCA systems. Open source versions of Greenplum Database are not supported.

- **Installing the Pivotal Greenplum 5.21.2 Software Binaries on DCA Systems**
- **Upgrading from 5.x to 5.21.2 on DCA Systems**

**Important:** Upgrading Pivotal Greenplum Database 4.3.x to Pivotal Greenplum 5.21.2 is not supported. See [Migrating Data to Pivotal Greenplum 5.x](#).

**Note:** These Greenplum Database releases are not certified on DCA because of an incompatibility in configuring timezone information.

5.5.0, 5.6.0, 5.6.1, 5.7.0, 5.8.0

These Greenplum Database releases are certified on DCA.

5.7.1, 5.8.1, 5.9.0 and later releases, and 5.x releases prior to 5.5.0.

**Installing the Pivotal Greenplum 5.21.2 Software Binaries on DCA Systems**

**Important:** This section is for installing Pivotal Greenplum 5.21.2 only on DCA systems. Also, see the information on the [DELL EMC support site](#) (requires login).

For information about installing Pivotal Greenplum on non-DCA systems, see the [Greenplum Database Installation Guide](#).

**Prerequisites**

- Ensure your DCA system supports Pivotal Greenplum 5.21.2. See [Supported Platforms](#).
- Ensure Greenplum Database 4.3.x is not installed on your system.

Installing Pivotal Greenplum 5.21.2 on a DCA system with an existing Greenplum Database 4.3.x installation is not supported. For information about uninstalling Greenplum Database software, see your Dell EMC DCA documentation.

**Installing Pivotal Greenplum 5.21.2**

1. Download or copy the Greenplum Database DCA installer file `greenplum-db-appliance-5.21.2-RHEL6-x86_64.bin` to the Greenplum Database master host.

2. As root, run the DCA installer for 5.21.2 on the Greenplum Database master host and specify the file `hostfile` that lists all hosts in the cluster, one host name per line. If necessary, copy `hostfile` to the directory containing the installer before running the installer.

   This example command runs the installer for Greenplum Database 5.21.2.

   ```
   # ./greenplum-db-appliance-5.21.2-RHEL6-x86_64.bin hostfile
   ```

**Upgrading from 5.x to 5.21.2 on DCA Systems**

Upgrading Pivotal Greenplum from 5.x to 5.21.2 on a Dell EMC DCA system involves stopping Greenplum Database, updating the Greenplum Database software binaries, and restarting Greenplum Database.
Important: This section is only for upgrading to Pivotal Greenplum 5.21.2 on DCA systems. For information about upgrading on non-DCA systems, see Upgrading to Greenplum Database 5.21.2.

Note: If you are upgrading from Greenplum Database 5.10.x or earlier and have installed the PL/Java extension, you must upgrade the PL/Java extension to extension package version 1.4.3. Previous releases of the PL/Java extension are not compatible with Greenplum Database 5.11.0 and later. For information about the PL/Java extension package, see Pivotal Greenplum Tools and Extensions Compatibility.

Note: If you have databases that were created with Greenplum Database 5.10.x or an earlier 5.x release, upgrade the `gp_bloat_expected_pages` view in the `gp_toolkit` schema. For information about the issue and how check a database for the issue, see Update for `gp_toolkit.gp_bloat_expected_pages` Issue.

Note: If you are upgrading from Greenplum Database 5.7.0 or an earlier 5.x release and have configured PgBouncer in your Greenplum Database installation, you must migrate to the new PgBouncer when you upgrade Greenplum Database. Refer to Migrating PgBouncer for specific migration instructions.

Note: If you have databases that were created with Greenplum Database 5.3.0 or an earlier 5.x release, upgrade the `gp_bloat_diag` function and view in the `gp_toolkit` schema. For information about the issue and how check a database for the issue, see Update for `gp_toolkit.gp_bloat_diag` Issue.

1. Log in to your Greenplum Database master host as the Greenplum administrative user (`gpadmin`):

   ```bash
   # su - gpadmin
   ```

2. Download or copy the installer file `greenplum-db-appliance-5.21.2-RHEL6-x86_64.bin` to the Greenplum Database master host.

3. Perform a smart shutdown of your current Greenplum Database 5.x system (there can be no active connections to the database). This example uses the `-a` option to disable confirmation prompts:

   ```bash
   $ gpstop -a
   ```

4. As root, run the Greenplum Database DCA installer for 5.21.2 on the Greenplum Database master host and specify the file `hostfile` that lists all hosts in the cluster. If necessary, copy `hostfile` to the directory containing the installer before running the installer.

   This example command runs the installer for Greenplum Database 5.21.2 for Red Hat Enterprise Linux 6.x.

   ```bash
   # ./greenplum-db-appliance-5.21.2-RHEL6-x86_64.bin hostfile
   ```

   The file `hostfile` is a text file that lists all hosts in the cluster, one host name per line.

5. If needed, update the `greenplum_path.sh` file for use with your specific installation. These are some examples.

   - If Greenplum Database uses LDAP authentication, edit the `greenplum_path.sh` file to add the line:

     ```bash
     export LDAPCONF=/etc/openldap/ldap.conf
     ```

   - If Greenplum Database uses PL/Java, you might need to set or update the environment variables `JAVA_HOME` and `LD_LIBRARY_PATH` in `greenplum_path.sh`.

     Note: When comparing the previous and new `greenplum_path.sh` files, be aware that installing some Greenplum Database extensions also updates the `greenplum_path.sh` file. The `greenplum_path.sh` from the previous release might contain updates that were the result of those extensions. See step 6 for installing Greenplum Database extensions.
6. Install Greenplum Database extension packages. For information about installing a Greenplum Database extension package, see `gppkg` in the *Greenplum Database Utility Guide*. Also migrate any additional files that are used by the extensions (such as JAR files, shared object files, and libraries) from the previous version installation directory to the new version installation directory.

7. After all segment hosts have been upgraded, you can log in as the `gpadmin` user and restart your Greenplum Database system:

```
# su - gpadmin
$ gpstart
```

8. If you are utilizing Data Domain Boost, you have to re-enter your DD Boost credentials after upgrading to Greenplum Database 5.21.2 as follows:

```
gpcrondump --ddboost-host ddboost_hostname --ddboost-user ddboost_user --ddboost-backupdir backup_directory
```

**Note:** If you do not reenter your login credentials after an upgrade, your backup will never start because the Greenplum Database cannot connect to the Data Domain system. You will receive an error advising you to check your login credentials.

After upgrading Greenplum Database, ensure features work as expected. For example, you should test that backup and restore perform as expected, and Greenplum Database features such as user-defined functions, and extensions such as MADlib and PostGIS perform as expected.
Update for gp_toolkit.gp_bloat_expected_pages Issue

In Greenplum Database 5.10.x and earlier 5.x releases, the Greenplum Database view gp_toolkit.gp_bloat_expected_pages view might incorrectly report that a root partition table is bloated even though root partition tables do not contain data. This information could cause a user to run a VACUUM FULL operation on the partitioned table when the operation was not required. The issue was resolved in Greenplum Database 5.11.0 (resolved issue 29523).

When updating Greenplum Database, the gp_toolkit.gp_bloat_expected_pages view must be updated in databases created with a Greenplum Database 5.10.x or an earlier 5.x release. This issue has been fixed in databases created with Greenplum Database 5.11.0 and later. For information about using template0 as the template database after upgrading from Greenplum Database 5.10.x or an earlier 5.x release, see known issue 29523.

To check whether the gp_toolkit.gp_bloat_expected_pages view in a database requires an update, run the psql command \d+ to display the view definition.

\d+ gp_toolkit.gp_bloat_expected_pages

The updated view definition contains this predicate.

AND NOT EXISTS
( SELECT parrelid
  FROM pg_partition
  WHERE parrelid = pgc.oid )

Perform the following steps as the gpadmin user to update the view on each database that was created with Greenplum Database 5.11.0 or an earlier 5.x release.

1. Copy the script into a text file on the Greenplum Database master.
2. Run the script on each database that requires the update.

This example updates gp_toolkit.gp_bloat_expected_pages view in the database mytest and assumes that the script is in the gp_bloat_expected_pages in the gpadmin home directory.

psql -f /home/gpadmin/gp_bloat_expected_pages.sql -d mytest

Run the script during a low activity period. Running the script during a high activity period does not affect database functionality but might affect performance.

Script to Update gp_toolkit.gp_bloat_expected_pages View

BEGIN;
CREATE OR REPLACE VIEW gp_toolkit.gp_bloat_expected_pages
AS
SELECT
  btdrelid,
  btdrelpages,
  CASE WHEN btdexppages < numsegments
    THEN numsegments
    ELSE btdexppages
  END as btdexppages
FROM
( SELECT
    oid as btdrelid,
    pgc.relpages as btdrelpages,
    CEIL((pgc.reltuples * (25 + width))::numeric / current_setting('block_size')::numeric) AS btdexppages,
(SELECT numsegments FROM gp_toolkit.__gp_number_of_segments) AS numsegments
FROM
  ( SELECT pgc.oid, pgc.reltuples, pgc.relpages
    FROM pg_class pgc
    WHERE NOT EXISTS
      ( SELECT iaooid
        FROM gp_toolkit.__gp_is_append_only
        WHERE iaooid = pgc.oid AND iaotype = 't' )
    AND NOT EXISTS
      ( SELECT parrelid
        FROM pg_partition
        WHERE parrelid = pgc.oid ) ) AS pgc
LEFT OUTER JOIN
  ( SELECT starelid, SUM(stawidth * (1.0 - stanullfrac)) AS width
    FROM pg_statistic pgs
    GROUP BY 1 ) AS btwcols
ON pgc.oid = btwcols.starelid
WHERE starelid IS NOT NULL) AS subq;

GRANT SELECT ON TABLE gp_toolkit.gp_bloat_expected_pages TO public;
COMMIT;
Update for gp_toolkit.gp_bloat_diag Issue

In Greenplum Database 5.3.0 or an earlier 5.x release, Greenplum Database returned an integer out of range error in some cases when performing a query against the gp_toolkit.gp_bloat_diag view. The issue was resolved in Greenplum Database 5.4.0 (resolved issue 26518).

When updating Greenplum Database, the gp_toolkit.gp_bloat_diag function and view must be updated in databases created with a Greenplum Database 5.3.0 or an earlier 5.x release. This issue has been fixed in databases created with Greenplum Database 5.4.0 and later. For information about upgrading from Greenplum Database 5.3.0 or an earlier 5.x release and then using template0 as the template database, see known issue 29523.

To check whether the gp_toolkit.gp_bloat_diag function and view in a database requires an update, run the psql command `\df` to display information about the gp_toolkit.gp_bloat_diag function.

```
\df gp_toolkit.gp_bloat_diag
```

If the data type for btdexppages is integer, an update is required. If the data type is numeric an update is not required. In this example, the btdexppages data type is integer and requires an update.

<table>
<thead>
<tr>
<th>List of functions</th>
</tr>
</thead>
<tbody>
<tr>
<td>[ RECORD 1 ]------</td>
</tr>
<tr>
<td>+------------------</td>
</tr>
<tr>
<td>Schema</td>
</tr>
<tr>
<td>Name</td>
</tr>
<tr>
<td>Result data type</td>
</tr>
<tr>
<td>Argument data types</td>
</tr>
<tr>
<td>Type</td>
</tr>
</tbody>
</table>

Perform the following steps as the gpadmin user to update the function and view to fix the issue on each database that was created with Greenplum Database 5.3.0 or an earlier 5.x release.

1. Copy the script into a text file on the Greenplum Database master.
2. Run the script on each database that requires the update.

   This example updates gp_toolkit.gp_bloat_diag function and view in the database mytest and assumes that the script is in the update_bloat_diag.sql in the gpadmin home directory.

   ```
   psql -f /home/gpadmin/update_bloat_diag.sql -d mytest
   ```

Run the script during a low activity period. Running the script during a high activity period does not affect database functionality but might affect performance.

**Script to Update gp_toolkit.gp_bloat_diag Function and View**

```
BEGIN;
CREATE OR REPLACE FUNCTION gp_toolkit.gp_bloat_diag(btdrelpages int,
  btdexppages numeric, aotable bool,
  OUT bltidx int, OUT bltdiag text)
AS $$
SELECT
  bltidx,
  CASE
    WHEN bltidx = 0
    THEN 'no bloat detected'::text
    WHEN bltidx = 1
```
THEN 'moderate amount of bloat suspected':::text
WHEN bloatidx = 2
THEN 'significant amount of bloat suspected':::text
WHEN bloatidx = -1
THEN 'diagnosis inconclusive or no bloat suspected':::text
END AS bloatdiag
FROM
(
    SELECT
        CASE
            WHEN $3 = 't' THEN 0
            WHEN $1 < 10 AND $2 = 0 THEN -1
            WHEN $2 = 0 THEN 2
            WHEN $1 < $2 THEN 0
            WHEN ($1/$2)::numeric > 10 THEN 2
            WHEN ($1/$2)::numeric > 3 THEN 1
            ELSE -1
        END AS bloatidx
    ) AS bloatmapping
$$
LANGUAGE SQL READS SQL DATA;

GRANT EXECUTE ON FUNCTION gp_toolkit.gp_bloat_diag(int, numeric, bool, OUT int, OUT text) TO public;

CREATE OR REPLACE VIEW gp_toolkit.gp_bloat_diag
AS
    SELECT
        btdrelid AS bdirelid,
        fnnspname AS bdinspname,
        fnrelname AS bdirelname,
        btdrelpages AS bdirelpages,
        btdexppages AS bdiexppages,
        bltdiag(bd) AS bdidiag
    FROM
    (
        SELECT
            fn.*, beg.*,
            gp_toolkit.gp_bloat_diag(btdrelpages::int, btdexppages::numeric, iao.iaotype::bool) AS bd
        FROM
            gp_toolkit.gp_bloat_expected_pages beg,

Pivotal Greenplum 5.21.1 Release Notes

Updated: July, 2019

- Welcome to Pivotal Greenplum 5.21.1
- Resolved Issues
- Beta Features
- Deprecated Features
- Known Issues and Limitations
- Differences Compared to Open Source Greenplum Database
- Supported Platforms
- Pivotal Greenplum Tools and Extensions Compatibility
- Hadoop Distribution Compatibility
- Upgrading to Greenplum Database 5.21.1
- Migrating Data to Pivotal Greenplum 5.x
- Pivotal Greenplum on DCA Systems
- Update for gp_toolkit.gp_bloat_expected_pages Issue
- Update for gp_toolkit.gp_bloat_diag Issue
Welcome to Pivotal Greenplum 5.21.1

Pivotal Greenplum Database is a massively parallel processing (MPP) database server that supports next generation data warehousing and large-scale analytics processing. By automatically partitioning data and running parallel queries, it allows a cluster of servers to operate as a single database supercomputer performing tens or hundreds times faster than a traditional database. It supports SQL, MapReduce parallel processing, and data volumes ranging from hundreds of gigabytes, to hundreds of terabytes.

This document contains pertinent release information about Pivotal Greenplum Database 5.21.1. For previous versions of the release notes for Greenplum Database, go to Pivotal Greenplum Database Documentation. For information about Greenplum Database end of life, see the Pivotal Support Lifecycle Policy.

Pivotal Greenplum 5.x software is available for download from the Pivotal Greenplum page on Pivotal Network.

Pivotal Greenplum 5.x is based on the open source Greenplum Database project code.

**Important:** The Greenplum gpbackup and gprestore utilities are now distributed separately from Pivotal Greenplum Database, and are updated independently of the core Greenplum Database server. These utilities will not be updated in future Greenplum Database 5.x releases. You can upgrade to the latest gpbackup and gprestore versions by downloading and installing the latest Pivotal Greenplum Backup and Restore release from Pivotal Network.

**Important:** Pivotal Support does not provide support for open source versions of Greenplum Database. Only Pivotal Greenplum Database is supported by Pivotal Support.

Pivotal Greenplum 5.21.1 is a maintenance release that resolves issues.
Resolved Issues

The listed issues are resolved in Pivotal Greenplum Database 5.21.1.

For issues resolved in prior 5.x releases, refer to the corresponding release notes. Release notes are available from the Pivotal Greenplum page on Pivotal Network.

29980 - Query Optimizer
GPORCA did not properly handle a query with a GROUP BY with only an outer reference in the group by column, causing a panic. This issue has been resolved. GPORCA now uses the outer reference as a grouping column.

29580 - Management & Monitoring
Greenplum no longer creates an extra, empty log file during log rotation.

30029 - Command Center
A stack overflow in the metrics collector extension could cause a segmentation fault on the Greenplum master when processing large queries. This problem was resolved by updating the metrics collector code in Greenplum 5.21.1.

29934 - Query Optimizer
The Pivotal Query Optimizer (GPORCA) generated a Greenplum Database PANIC when executing queries that contain a SELECT DISTINCT sub-query in an IN clause. This issue has been resolved.

167267884, 167267868 - gpcrondump
Increase the maximum value of the server configuration parameter extra_float_digits to 3 and enable gpcrondump to use that value. This fixes a problem where float4 columns used as distribution keys were not backed up with sufficient precision to match the original distribution hash when the backup was restored.

167300801 - Query Optimizer
In some cases, the Pivotal Query Optimizer (GPORCA) allocated memory for an object that it never used. GPORCA now allocates the memory only when needed; this greatly reduces memory usage for certain queries.

165835701 - Query Optimizer
GPORCA was originally written to optimize queries using multiple threads, but GPORCA did not actually use the threading. The multi-threading code has been removed from GPORCA, resulting in increased query and explain performance.

29887- Server
The query executor passed an incorrect address for the in-progress transaction array. This problem may have affected extended queries such as DECLARE ... CURSOR statements and RETURN and EXECUTE PL/pgSQL statements. This issue has been fixed.

29752 - Server
An INSERT operation on an append-optimized partitioned table returned an error when a concurrent VACUUM operation was performed on the table. The error occurred because INSERT did not lock the child partition tables. This issue has been resolved. Now INSERT locks the child partition tables.
Beta Features

Because Pivotal Greenplum Database is based on the open source Greenplum Database project code, it includes several Beta features to allow interested developers to experiment with their use on development systems. Feedback will help drive development of these features, and they may become supported in future versions of the product.

**Warning**: Beta features are not supported for production deployments.

Greenplum Database 5.21.1 includes these Beta features:

- **Storage plugin API for** `gpbackup` **and** `gprestore`. Partners, customers, and OSS developers can develop plugins to use in conjunction with `gpbackup` and `gprestore`. For information about the storage plugin API, see *Backup/Restore Storage Plugin API* in the Pivotal Greenplum Database Documentation.

- **Recursive WITH Queries (Common Table Expressions)**. See *WITH Queries (Common Table Expressions)* in the Pivotal Greenplum Database Documentation.

- **Resource groups remain a Beta feature only on the SuSE 11 platform, due to limited cgroups functionality in the kernel.**

  SuSE 12 resolves the Linux cgroup issues that caused the performance degradation when Greenplum Database resource groups are enabled.

- **Using the Greenplum Platform Extension (PXF) connectors to write Parquet data is a Beta feature.**
**Deprecated Features**

These Greenplum Database features are deprecated.

- The `gptransfer` utility will be removed in the next major release. The utility copies objects between Greenplum Database systems. The `gpcopy` utility provides `gptransfer` functionality.
- The `gphdfs` external table protocol will be removed in the next major release. Consider using the Greenplum Platform Extension Framework (PXF) `pxf` external table protocol to access data stored in an external Hadoop file system. Refer to *Accessing External Data with PXF* for more information.
Known Issues and Limitations

Pivotal Greenplum 5.x has these limitations:

- Upgrading a Greenplum Database 4.3.x release to Pivotal Greenplum 5.x is not supported. See Migrating Data to Pivotal Greenplum 5.x.
- Some features are works-in-progress and are considered to be Beta features. Pivotal does not support using Beta features in a production environment. See Beta Features.
- Greenplum Database 4.3.x packages are not compatible with Pivotal Greenplum 5.x.

The following table lists key known issues in Pivotal Greenplum 5.x.

Table 16: Key Known Issues in Pivotal Greenplum 5.x

<table>
<thead>
<tr>
<th>Issue</th>
<th>Category</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>29917</td>
<td>Segment Mirroring</td>
<td>A “read beyond eof” error has been observed with certain persistent tables during full recovery. The root cause of this problem has not yet been determined. Greenplum Database version 5.21 contains additional debug logging to help in determining the cause of this problem. The additional logging is enabled by default, and adds approximately 646 bytes to each persistent table entry file. If you want to disable the additional debug logging, set the debug_filerep_config_print configuration parameter &quot;false.&quot;</td>
</tr>
<tr>
<td>Issue</td>
<td>Category</td>
<td>Description</td>
</tr>
<tr>
<td>--------</td>
<td>----------</td>
<td>-------------</td>
</tr>
</tbody>
</table>
| 29861  | gpstart  | If a segment's data directory becomes inaccessible or the contents of the data directory are deleted, the segment goes offline and is marked as down in gp_segment_configuration. However, if you have temporary or transaction files in a separate filespace or if you stop and start the database, gpstart can fail with the error:  

```
20190404:17:26:44:025089
gpstart:mdw:gpadmin-[ERROR]:-Multiple OIDs found in flat files
20190404:17:26:44:025089
gpstart:mdw:gpadmin-[ERROR]:-Filespaces are inconsistent. Abort Greenplum Database start.
```

The error indicates that two files are missing from a segment directory, gp_temporary_files_filespace and gp_transaction_files_filespace. gpstart reports the error even if the segments have already been marked down.  

**Workaround:** To resolve this problem you must manually create the missing files in the segment directory using the segment's corresponding dbid, transaction file segment directory, and filespace oid. See the detailed instructions for creating these files in Article Number: 6784 gpstart fails with error "Multiple OIDs found in flat files" on the Pivotal Support site.

<thead>
<tr>
<th>Issue</th>
<th>Category</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>164671144</td>
<td>gpssh-exkeys</td>
<td>The <code>gpssh-exkeys</code> utility uses the Paramiko SSH library for Python, which has a dependency on the Python Cryptography Toolkit (PyCrypto) library. The following security vulnerabilities have been identified in some versions of PyCrypto.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• <a href="https://nvd.nist.gov/vuln/detail/CVE-2018-6594">https://nvd.nist.gov/vuln/detail/CVE-2018-6594</a> - lib/Crypto/PublicKey/ElGamal.py in PyCrypto through 2.6.1 generates weak ElGamal key parameters, which allows attackers to obtain sensitive information by reading ciphertext data (i.e., it does not have semantic security in face of a ciphertext-only attack). The Decisional Diffie-Hellman (DDH) assumption does not hold for PyCrypto's ElGamal implementation. Paramiko does not import this algorithm, so Greenplum Database is unaffected by this vulnerability.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• <a href="https://nvd.nist.gov/vuln/detail/CVE-2013-7459">https://nvd.nist.gov/vuln/detail/CVE-2013-7459</a> - Heap-based buffer overflow in the ALGnew function in block_template.c in Python Cryptography Toolkit (aka pycrypto) allows remote attackers to execute arbitrary code as demonstrated by a crafted iv parameter to cryptmsg.py. This bug was introduced in Py Crypto 2.6. Greenplum Database has Py Crypto 2.0.1, and is unaffected by the vulnerability.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• <a href="https://nvd.nist.gov/vuln/detail/CVE-2013-1445">https://nvd.nist.gov/vuln/detail/CVE-2013-1445</a> - The Crypto.Random.atfork function in PyCrypto before 2.6.1 does not properly reseed the pseudo-random number generator (PRNG) before allowing a child process to access it, which makes it easier for context-dependent</td>
</tr>
</tbody>
</table>
attackers to obtain sensitive information by leveraging a race condition in which a child process is created and accesses the PRNG within the same rate-limit period as another process.

Paramiko version 1.7.6-9, used in Greenplum Database 4.x and 5.x, introduced a workaround to this bug. Paramiko version 1.18.4 in Greenplum Database 6 solves it in a more permanent way.

Paramiko does not import this algorithm, so Greenplum Database is unaffected by the vulnerability.

Through testing and investigation, Pivotal has determined that these vulnerabilities do not affect Greenplum Database, and no actions are required for existing Greenplum Database 4.3 or 5.x releases. However, there may be additional unidentified vulnerabilities in the PyCrypto library, and users who install a later version of PyCrypto could be exposed to other vulnerabilities.

The PyCrypto library will be removed from Greenplum Database 6.0.

**Workaround:** Administrators can set up passwordless SSH between hosts in the Greenplum Database cluster without using the `gpssh-exkeys` utility. This must be done before initializing the Greenplum Database system.
<table>
<thead>
<tr>
<th>Issue</th>
<th>Category</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td>1. Create an SSH key for the <em>gpadmin</em> user on each host. For example, log in to each host as <em>gpadmin</em> and use the <code>ssh-keygen</code> command to generate an SSH key. Do not enter a passphrase.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>2. Add the public key for each host in the cluster to every other host in the cluster. For example, use the <code>ssh-copy-id</code> command from each host to copy the public key to every other host in the cluster.</td>
</tr>
<tr>
<td>165434975</td>
<td>search_path</td>
<td>An identified PostgreSQL security vulnerability (<a href="https://nvd.nist.gov/vuln/detail/CVE-2018-1058">https://nvd.nist.gov/vuln/detail/CVE-2018-1058</a>) also exists in Greenplum Database. The problem centers around the default public schema and how Greenplum Database uses the <code>search_path</code> setting. The ability to create objects with the same names in different schemas, combined with how Greenplum Database searches for objects within schemas, presents an opportunity for a user to modify the behavior of a query for other users. For example, a malicious user could insert a trojan-horse function that, when executed by a superuser, grants escalated privileges to the malicious user.</td>
</tr>
<tr>
<td></td>
<td></td>

<td>ANALYZE</td>
<td>In Greenplum Database 5.15.1 and earlier 5.x releases, an ANALYZE command might return an error that states target lists can have at most 1664 entries when performing an ANALYZE operation on a table with a large number of columns (more than 800 columns). The error occurs because the in-memory sample table created by ANALYZE requires an additional column to indicate whether a column is NULL or is a truncated column for each variable length column being analyzed (such as varchar, text, and bpchar, numeric, arrays, and geometric datatype columns). The error is returned when ANALYZE attempts to create a sample table and the number of columns (table columns and indicator columns) exceeds the maximum number of columns allowed. In Greenplum Database 5.16.0 and later 5.x releases, the ANALYZE sample table does not require an additional column for variable length text columns such as varchar, text, and bpchar columns. <strong>WORKAROUND:</strong> To collect statistics on the table, perform ANALYZE operations on 2 or more sets of table columns.</td>
</tr>
<tr>

</table>
| 29674 | VACUUM   | Performing parallel VACUUM operations on a catalog table such as `pg_class`, `gp_relation_node`, `pg_type` and another table causes a deadlock and blocks connections to the database.  
**Workaround:** Avoid performing parallel VACUUM operations on catalog tables and user tables. |
| 29139 | DML      | In some cases for an append-optimized partitioned table, Greenplum Database acquires a **ROW EXCLUSIVE** lock on all leaf partitions of the table when inserting data directly into one of the leaf partitions of the table. The locks are acquired the first time Greenplum Database performs validation on the leaf partitions. When inserting data into one leaf partition, the locks are not acquired on the other leaf partitions as long as the validation information remains in memory.  
The issue does not occur for heap-storage partitioned tables. |
<table>
<thead>
<tr>
<th>Issue</th>
<th>Category</th>
<th>Description</th>
</tr>
</thead>
</table>
| 29523 | gptoolkit | An upgrade between minor releases does not update the template0 database, and in some cases, using these views in the gp_toolkit schema might cause issues if you create a database using template0 as the template database after you upgrade to Greenplum Database 5.11.0 or later.  
  - The gp_toolkit.gp_bloat_expected_pages view might incorrectly report that a root partition table is bloated even though root partition tables do not contain data if you upgrade from Greenplum Database 5.10.x or earlier.  
  - The gp_toolkit.gp_bloat_diag view might return an integer out of range error in some cases if you upgrade from Greenplum Database 5.3.0 or earlier.  

For example, the issues might occur if you upgrade a Greenplum Database system from 5.3.0 or an earlier 5.x release and then run a gprestore operation with the --redirect-db option to create a new database. The utility creates a new database using template0 as the template database.  

**Workaround:** You can update the views in the gp_toolkit schema in the new database. For information about checking and updating gp_toolkit, see [Update for gp_toolkit.gp_bloat_expected_pages Issue](#) and [Update for gp_toolkit.gp_bloat_diag Issue](#).

<td>Catalog and Metadata</td>
<td>When a session creates temporary objects in a database, Greenplum Database might not drop temporary objects when the session ends if the session terminates abnormally or is terminated from an administrator command.</td>
</tr>
</tbody>
</table>
| 29496  | gpconfig            | For a small number of server configuration parameters such as `log_min_messages`, the command `gpconfig -s <config_param>` does not display the correct value of the parameter for the segment hosts when the value of the parameter on master is different than the value on the segments.  
For parameters with the set classification `master`, the utility displays the value set on the master for both master and segments (for information about set classifications, see [Setting Parameters in the Pivotal Greenplum Database Documentation](#)). For those parameters, the value on the master is passed as part of queries to segment instances. The SQL query that `gpconfig` runs to display the master and segment parameter values returns the master host value that is passed to the segment as part of the query.  
For a few parameters such as `log_min_messages`, segment instances use the segment host value specified in the `postgresql.conf` file at start up. The segment value can overridden for the scope of a query.  
**Workaround:** To display the parameter value specified in the `postgresql.conf` file on the master host and segment hosts, you can specify the `gpconfig` option `--file`. |

</tbody>
</table>
| 158011506 | Catalog and Metadata | In some cases, the timezone used by Greenplum Database might be different than the host system timezone, or the Greenplum Database timezone set by a user. In some rare cases, times used and displayed by Greenplum Database might be slightly different than the host system time.  

The timezone used by Greenplum Database is selected from a set of internally stored PostgreSQL timezones. Greenplum Database selects the timezone by matching a PostgreSQL timezone with the user specified time zone, or the host system time zone. For example, when selecting a default timezone, Greenplum Database uses an algorithm to select a PostgreSQL timezones based on the host system timezone. If the system timezone includes leap second information, Greenplum Database cannot match the system timezone with a PostgreSQL timezone. Greenplum Database calculates a best match with a PostgreSQL timezone based on information from the host system.  

**Workaround:** Set the Greenplum Database and host system timezones to a timezone that is supported by both Greenplum Database and the host system. For example, you can show and set the Greenplum Database timezone with the `gpconfig` utility. These commands show the Greenplum Database timezone and set the timezone to US/Pacific.  

```
# gpconfig -s TimeZone
# gpconfig -c TimeZone -v 'US/Pacific'
```

You must restart Greenplum Database after changing the timezone. The command

<tr>
<td>149789783</td>
<td>Resource Groups</td>
<td>Significant Pivotal Greenplum performance degradation has been observed when enabling resource group-based workload management on Red Hat 6.x, CentOS 6.x, and SuSE 11 systems. This issue is caused by a Linux cgroup kernel bug. This kernel bug has been fixed in CentOS 7.x and Red Hat 7.x systems. When resource groups are enabled on systems with an affected kernel, there can be a delay of 1 second or longer when starting a transaction or a query. The delay is caused by a Linux cgroup kernel bug where a synchronization mechanism called synchronize_sched is abused when a process is attached to a cgroup. See <a href="http://www.spinics.net/lists/cgroups/msg05708.html">http://www.spinics.net/lists/cgroups/msg05708.html</a> and <a href="https://lkml.org/lkml/2013/1/14/97">https://lkml.org/lkml/2013/1/14/97</a> for more information. The issue causes single attachment operations to take longer and also causes all concurrent attachments to be executed in sequence. For example, one process attachment could take about 0.01 second. When concurrently attaching 100 processes, the fastest process attachment takes 0.01 second and the slowest takes about 1 second. Pivotal Greenplum performs process attachments when a transaction or queries are started. So the performance degradation is dependent on concurrent started transactions or queries, and not related to concurrent running queries. Also Pivotal Greenplum has optimizations to bypass the rewriting when a QE is reused by multiple queries in the same session. <strong>Workaround:</strong> This bug does not affect CentOS 7.x and Red Hat 7.x systems.</td>

Differences Compared to Open Source Greenplum Database

Pivotal Greenplum 5.x includes all of the functionality in the open source Greenplum Database project and adds:

- Product packaging and installation script.
- Support for QuickLZ compression. QuickLZ compression is not provided in the open source version of Greenplum Database due to licensing restrictions.
- Support for managing Greenplum Database using Pivotal Greenplum Command Center.
- Support for full text search and text analysis using Pivotal GPText.
- Support for data connectors:
  - Greenplum-Spark Connector
  - Greenplum-Informatica Connector
  - Greenplum-Kafka Integration
  - Gemfire-Greenplum Connector
  - Greenplum Stream Server
- Data Direct ODBC/JDBC Drivers
- `gpcopy` utility for copying or migrating objects between Greenplum systems.
Pivotal Greenplum 5.21.1 runs on the following platforms:

- Red Hat Enterprise Linux 64-bit 7.x (See the following Note)
- Red Hat Enterprise Linux 64-bit 6.x (See the following Note)
- SuSE Linux Enterprise Server 64-bit 12 SP2 and SP3 with kernel version greater than 4.4.73-5. (See the following Note)
- SuSE Linux Enterprise Server 64-bit 11 SP4 (See the following Note)
- CentOS 64-bit 7.x
- CentOS 64-bit 6.x (See the following Note)
- Oracle Linux 64-bit 7.4, using the Red Hat Compatible Kernel (RHCK)

**Note:** For the supported Linux operating systems, Pivotal Greenplum Database is supported on system hosts using either AMD or Intel CPUs based on the x86-64 architecture. Pivotal recommends using a homogeneous set of hardware (system hosts) in a Greenplum Database system.

**Important:** Significant Greenplum Database performance degradation has been observed when enabling resource group-based workload management on Red Hat 6.x, CentOS 6.x, and SuSE 11 systems. This issue is caused by a Linux cgroup kernel bug. This kernel bug has been fixed in CentOS 7.x and Red Hat 7.x systems.

If you use Red Hat 6 and the performance with resource groups is acceptable for your use case, upgrade your kernel to version 2.6.32-696 or higher to benefit from other fixes to the cgroups implementation.

SuSE 11 does not have a kernel version that resolves this issue; resource groups are still considered to be a Beta feature on this platform. Resource groups are not supported on SuSE 11 for production use. See known issue 149789783.

Pivotal Greenplum on SuSE 12 supports resource groups for production use. SuSE 12 resolves the Linux cgroup kernel issues that caused the performance degradation when Greenplum Database resource groups are enabled.

**Note:** For Greenplum Database that is installed on Red Hat Enterprise Linux 7.x or CentOS 7.x prior to 7.3, an operating system issue might cause Greenplum Database that is running large workloads to hang in the workload. The Greenplum Database issue is caused by Linux kernel bugs. RHEL 7.3 and CentOS 7.3 resolves the issue.

**Note:** Greenplum Database on SuSE Linux Enterprise systems does not support these features.

- The PL/Perl procedural language
- The gpmapreduce tool
- The PL/Container language extension
- The Greenplum Platform Extension Framework (PXF)

**Note:** PL/Container is not supported on RHEL/CentOS 6.x systems, because those platforms do not officially support Docker.

Greenplum Database support on Dell EMC DCA.

- Pivotal Greenplum Database 5.21.1 is supported on DCA systems that are running DCA software version 3.4 or greater.
- Only Pivotal Greenplum Database is supported on DCA systems. Open source versions of Greenplum Database are not supported.
- FIPS is supported on DCA software version 3.4 and greater with Pivotal Greenplum Database 5.2.0 and greater.
Note: These Greenplum Database releases are not certified on DCA because of an incompatibility in configuring timezone information.

5.5.0, 5.6.0, 5.6.1, 5.7.0, 5.8.0

These Greenplum Database releases are certified on DCA.

5.7.1, 5.8.1, 5.9.0 and later releases, and 5.x releases prior to 5.5.0.

Pivotal Greenplum 5.21.1 supports these Java versions:

- 8.xxx
- 7.xxx

Greenplum Database 5.21.1 software that runs on Linux systems uses OpenSSL 1.0.2l (with FIPS 2.0.16), cURL 7.54, OpenLDAP 2.4.44, and Python 2.7.12.

Greenplum Database client software that runs on Windows and AIX systems uses OpenSSL 0.9.8zg.

The Greenplum Database s3 external table protocol supports these data sources:

- Amazon Simple Storage Service (Amazon S3)
- Dell EMC Elastic Cloud Storage (ECS), an Amazon S3 compatible service

Pivotal Greenplum 5.21.1 supports Data Domain Boost on Red Hat Enterprise Linux.

This table lists the versions of Data Domain Boost SDK and DDOS supported by Pivotal Greenplum 5.x.
### Table 17: Data Domain Boost Compatibility

<td></td>
<td></td>
</tr>
</tbody>
</table>

**Note:** In addition to the DDOS versions listed in the previous table, Pivotal Greenplum 5.0.0 and later supports all minor patch releases (fourth digit releases) later than the certified version.

<sup>1</sup>Support for Data Domain Boost 3.0.0.3 is deprecated. The DELL EMC end of Primary Support date is December 31, 2017.

<sup>2</sup>The Greenplum Database utilities `gpbackup` and `gprestore` support Data Domain DD Boost File System Plugin (BoostFS) v1.1 with DDOS 6.0 or greater.

The `gpbackup` and `gprestore` utilities support using Dell EMC Data Domain Boost software with the DD Boost Storage Plugin.

**Note:** Pivotal Greenplum 5.21.1 does not support the ODBC driver for Cognos Analytics V11.

Connecting to IBM Cognos software with an ODBC driver is not supported. Greenplum Database supports connecting to IBM Cognos software with the DataDirect JDBC driver for Pivotal Greenplum. This driver is available as a download from Pivotal Network.

**Veritas NetBackup**

Pivotal Greenplum 5.21.1 supports backup with Veritas NetBackup version 7.7.3. See [Backing Up Databases with Veritas NetBackup](#).
Supported Platform Notes

The following notes describe platform support for Pivotal Greenplum. Please send any questions or comments to Pivotal Support at https://support.pivotal.io.

- Pivotal Greenplum is supported using either IPV4 or IPV6 protocols.
- The only file system supported for running Greenplum Database is the XFS file system. All other file systems are explicitly not supported by Pivotal.
- Greenplum Database is supported on network or shared storage if the shared storage is presented as a block device to the servers running Greenplum Database and the XFS file system is mounted on the block device. Network file systems are not supported. When using network or shared storage, Greenplum Database mirroring must be used in the same way as with local storage, and no modifications may be made to the mirroring scheme or the recovery scheme of the segments. Other features of the shared storage such as de-duplication and/or replication are not directly supported by Pivotal Greenplum Database, but may be used with support of the storage vendor as long as they do not interfere with the expected operation of Greenplum Database at the discretion of Pivotal.
- Greenplum Database is supported when running on virtualized systems, as long as the storage is presented as block devices and the XFS file system is mounted for the storage of the segment directories.

Warning: Running Pivotal Greenplum on hyper-converged infrastructure (HCI) has known issues with performance, scalability, and stability and is not recommended as a scalable solution for Pivotal Greenplum and may not be supported by Pivotal if stability problems appear related to the infrastructure. HCI virtualizes all of the elements of conventional hardware systems and includes, at a minimum, virtualized computing, a virtualised SAN, and virtualized networking.

- A minimum of 10-gigabit network is required for a system configuration to be supported by Pivotal.
- Greenplum Database is supported on Amazon Web Services (AWS), Microsoft Azure, and Google Cloud Compute (GCP).
  - **AWS** - For production workloads, r4.8xlarge and r4.16xlarge instance types with four 12TB ST1 EBS volumes for each segment host, or d2.8xlarge with ephemeral storage configured with 4 RAID 0 volumes, are supported. EBS storage is recommended. EBS storage is more reliable and provides more features than ephemeral storage. Note that Amazon has no provisions to replace a bad ephemeral drive; when a disk failure occurs, you must replace the node with the bad disk.
    Pivotal recommends using an Auto Scaling Group (ASG) to provision nodes in AWS. An ASG automatically replaces bad nodes, and you can add further automation to recover the Greenplum processes on the new nodes automatically.
    Deployments should be in a Placement Group within a single Availability Zone. Because Amazon recommends using the same instance type in a Placement Group, use a single instance type for all nodes, including the masters.
  - **Azure** - For production workloads, Pivotal recommends configuring Standard_H8 instance type with 4 2TB disks and 2 segments per host and recommend using 8 2TB disks and 4 segments per host with Standard_H16 instance type. Standard_H16 uses 8 2TB disks and 4 segments per host. This means software RAID 0 is required so that the number of volumes do not exceed the number of segments.
    For Azure deployments, you must also configure the Greenplum Database system to not use port 65330. Add the following line to the sysctl.conf file on all Greenplum Database hosts.
    ```
    $net.ipv4.ip_local_reserved_ports=65330
    ```
  - **GCP** - For all workloads, n1-standard-8 and n1-highmem-8 are supported which are relatively small instance types. This is because of the disk performance in GCP forces the configuration to have just 2 segments per host but with many hosts to scale. Use pd-standard disks and the size of the disk is recommended to be 6 TB. For performance perspective, use a factor of 8 when determining how...
many nodes to deploy in GCP, so a 16 segment host cluster in AWS would require 128 nodes in GCP.

• For Red Hat Enterprise Linux 7.2 or CentOS 7.2, the default `systemd` setting `RemoveIPC=yes` removes IPC connections when non-system users logout. This causes the Greenplum Database utility `gpinitsystem` to fail with semaphore errors. To avoid this issue, see "Setting the Greenplum Recommended OS Parameters" in the *Greenplum Database Installation Guide*. 
Pivotal Greenplum Tools and Extensions Compatibility

- Client Tools
- Extensions
- Pivotal Greenplum Data Connectors
- Pivotal GPText Compatibility
- Pivotal Greenplum Command Center

Client Tools

Greenplum releases a number of client tool packages on various platforms that can be used to connect to Greenplum Database and the Greenplum Command Center management tool. The following table describes the compatibility of these packages with this Greenplum Database release.

Tool packages are available from Pivotal Network.

Table 18: Pivotal Greenplum 5.21.1 Tools Compatibility

The Greenplum Database Client Tools and Load Tools are supported on the following platforms:

- AIX 7.2 (64-bit) (Client and Load Tools only)²
- Red Hat Enterprise Linux x86_64 7.x (RHEL 7)
- Red Hat Enterprise Linux x86_64 6.x (RHEL 6)
- SuSE Linux Enterprise Server x86_64 SLES 11 SP4, or SLES 12 SP2/SP3
- Windows 10 (32-bit and 64-bit)
- Windows 8 (32-bit and 64-bit)
- Windows Server 2012 (32-bit and 64-bit)
- Windows Server 2012 R2 (32-bit and 64-bit)
- Windows Server 2008 R2 (32-bit and 64-bit)

Note: ¹For Pivotal Greenplum Command Center 4.0.0 and later, workload management is an integrated Command Center feature rather than the separate tool Pivotal Greenplum Workload Manager.
For Greenplum Database 5.4.1 and earlier 5.x releases, download the AIX Client and Load Tools package either from the Greenplum Database 5.11.1 file collection or the Greenplum Database 5.0.0 file collection on Pivotal Network.

Extensions

Table 19: Pivotal Greenplum 5.21.1 Extensions Compatibility

<table>
<thead>
<tr>
<th>Pivotal Greenplum Extension</th>
<th>Versions</th>
</tr>
</thead>
<tbody>
<tr>
<td>MADlib machine learning for Greenplum Database 5.x(^1)</td>
<td>MADlib 1.16, 1.15.1, 1.15, 1.14</td>
</tr>
<tr>
<td>PL/Java for Greenplum Database 5.x</td>
<td>PL/Java 1.4.3(^2)</td>
</tr>
<tr>
<td>PL/R for Greenplum Database 5.x</td>
<td>2.3.3</td>
</tr>
<tr>
<td>PostGIS Spatial and Geographic Objects for Greenplum Database 5.x</td>
<td>2.1.5+pivotal.2</td>
</tr>
<tr>
<td>Python Data Science Module Package for Greenplum Database 5.x(^3)</td>
<td>1.1.1, 1.1.0, 1.0.0</td>
</tr>
<tr>
<td>R Data Science Library Package for Greenplum Database 5.x(^4)</td>
<td>1.0.1, 1.0.0</td>
</tr>
<tr>
<td>PL/Container for Greenplum Database 5.x</td>
<td>1.1(^5), 1.2(^6), 1.3, 1.4</td>
</tr>
</tbody>
</table>

**Note:**

\(^1\) Pivotal recommends that you upgrade to the most recent version of MADlib. For information about MADlib support and upgrade information, see the [MADlib FAQ](#) in the Greenplum Database Reference Guide.

\(^2\) The PL/Java extension package version 1.4.3 is compatible only with Greenplum Database 5.11.0 and later, it is not compatible with 5.10.x or earlier. If you are upgrading from Greenplum Database 5.10.x or earlier and have installed PL/Java 1.4.2, you must upgrade the PL/Java extension to version 1.4.3.

\(^3\) For information about the Python package, including the modules provided, see the [Python Data Science Module Package](#) in the Greenplum Database Documentation.

\(^4\) For information about the R package, including the libraries provided, see the [R Data Science Library Package](#) in the Greenplum Database Documentation.

\(^5\) To upgrade from PL/Container 1.0 to PL/Container 1.1 and later, you must drop the PL/Container 1.0 language before registering the new version of PL/Container. For information on upgrading the PL/Container extension in Greenplum Database, see [PL/Container Language Extension](#) in the Greenplum Database Reference Guide.

\(^6\) PL/Container version 1.2 can utilize the resource group capabilities that were introduced in Greenplum Database 5.8.0. If you downgrade to a Greenplum Database system that uses PL/Container 1.1 or earlier, you must use `plcontainer runtime-edit` to remove any resource group settings from the PL/Container runtime configuration file. See Upgrading from PL/Container 1.1.

These Greenplum Database extensions are installed with Pivotal Greenplum Database

- Fuzzy String Match Extension
- PL/Python Extension
- pgcrypto Extension
**Pivotal Greenplum Data Connectors**

- **Greenplum Platform Extension Framework (PXF)** - PXF, integrated with Greenplum Database, provides access to HDFS, Hive, HBase, and SQL external data stores. Refer to *Accessing External Data with PXF* in the *Greenplum Database Administrator Guide* for PXF configuration and usage information.

  **Note:** PXF is available only for supported Red Hat and CentOS platforms. PXF is not available for supported SuSE platforms.

- **Greenplum-Spark Connector** - The Pivotal Greenplum-Spark Connector supports high speed, parallel data transfer from Greenplum Database to an Apache Spark cluster. The Greenplum-Spark Connector is available as a separate download from *Pivotal Network*. Refer to the *Greenplum-Spark Connector documentation* for compatibility and usage information.

- **Greenplum-Informatica Connector** - The Pivotal Greenplum-Informatica connector supports high speed data transfer from an Informatica PowerCenter cluster to a Pivotal Greenplum Database cluster for batch and streaming ETL operations. See the *Pivotal Greenplum-Informatica Connector Documentation*.

- **Greenplum-Kafka Integration** - The Pivotal Greenplum-Kafka Integration provides high speed, parallel data transfer from a Kafka cluster to a Pivotal Greenplum Database cluster for batch and streaming ETL operations. Refer to the *Pivotal Greenplum-Kafka Integration Documentation* for more information about this feature.

- **Greenplum Stream Server** - The Pivotal Greenplum Stream Server is an ETL tool that provides high speed, parallel data transfer from Informatica, Kafka, and custom client data sources to a Pivotal Greenplum Database cluster. Refer to the *Performing ETL Operations with the Pivotal Greenplum Stream Server Documentation* for more information about this feature.

- **Gemfire-Greenplum Connector** - The Pivotal Gemfire-Greenplum Connector supports the transfer of data between a GemFire region and a Greenplum Database cluster. The Gemfire-Greenplum Connector is available as a separate download from *Pivotal Network*. Refer to the *Gemfire-Greenplum Connector documentation* for compatibility and usage information.

**Pivotal GPText Compatibility**

Pivotal Greenplum Database 5.21.1 is compatible with Pivotal GPText version 2.1.3 and later.

**Pivotal Greenplum Command Center**

See the *Greenplum Command Center documentation* for GPCC and Greenplum Workload Manager compatibility information, see the Pivotal Greenplum Command Center 3.x and 2.x *Release Notes*.

**Note:** For Pivotal Greenplum Command Center 4.0.0 and later, workload management is an integrated Command Center feature rather than the separate tool Pivotal Greenplum Workload Manager.
Hadoop Distribution Compatibility

Greenplum Database provides access to HDFS with gphdfs and the Greenplum Platform Extension Framework (PXF).

PXF Hadoop Distribution Compatibility

PXF supports the Cloudera, Hortonworks Data Platform, MapR, and generic Apache Hadoop distributions.

If you plan to access JSON format data stored in a Cloudera Hadoop cluster, PXF requires a Cloudera version 5.8 or later Hadoop distribution.

gphdfs Hadoop Distribution Compatibility

The supported Hadoop distributions for gphdfs are listed below:

Table 20: Supported gphdfs Hadoop Distributions

<table>
<thead>
<tr>
<th>Hadoop Distribution</th>
<th>Version</th>
<th>gp_hadoop_target_version</th>
</tr>
</thead>
<tbody>
<tr>
<td>Cloudera</td>
<td>CDH 5.x</td>
<td>cdh</td>
</tr>
<tr>
<td>Hortonworks Data Platform</td>
<td>HDP 2.x</td>
<td>hdp</td>
</tr>
<tr>
<td>MapR</td>
<td>MapR 4.x, MapR 5.x</td>
<td>mpr</td>
</tr>
<tr>
<td>Apache Hadoop</td>
<td>2.x</td>
<td>hadoop</td>
</tr>
</tbody>
</table>

Note: MapR requires the MapR client.
Upgrading to Greenplum Database 5.21.1

The upgrade path supported for this release is Greenplum Database 5.x to Greenplum Database 5.21.1. Upgrading a Greenplum Database 4.3.x release to Pivotal Greenplum 5.x is not supported. See Migrating Data to Pivotal Greenplum 5.x.

**Note:** If you are upgrading Greenplum Database on a DCA system, see Pivotal Greenplum on DCA Systems.

**Important:** Pivotal recommends that customers set the Greenplum Database timezone to a value that is compatible with their host systems. Setting the Greenplum Database timezone prevents Greenplum Database from selecting a timezone each time the cluster is restarted and sets the timezone for the Greenplum Database master and segment instances. After you upgrade to this release and if you have not set a Greenplum Database timezone value, verify that the selected Greenplum Database timezone is acceptable for your deployment. See Configuring Timezone and Localization Settings for more information.

**Prerequisites**

Before starting the upgrade process, Pivotal recommends performing the following checks.

- Verify the health of the Greenplum Database host hardware, and that you verify that the hosts meet the requirements for running Greenplum Database. The Greenplum Database gpcheckperf utility can assist you in confirming the host requirements.

  **Note:** If you need to run the gpcheckcat utility, Pivotal recommends running it a few weeks before the upgrade and that you run gpcheckcat during a maintenance period. If necessary, you can resolve any issues found by the utility before the scheduled upgrade.

  The utility is in $GPHOME/bin. Pivotal recommends that Greenplum Database be in restricted mode when you run gpcheckcat utility. See the Greenplum Database Utility Guide for information about the gpcheckcat utility.

  If gpcheckcat reports catalog inconsistencies, you can run gpcheckcat with the --g option to generate SQL scripts to fix the inconsistencies.

  After you run the SQL scripts, run gpcheckcat again. You might need to repeat the process of running gpcheckcat and creating SQL scripts to ensure that there are no inconsistencies. Pivotal recommends that the SQL scripts generated by gpcheckcat be run on a quiescent system. The utility might report false alerts if there is activity on the system.

  **Important:** If the gpcheckcat utility reports errors, but does not generate a SQL script to fix the errors, contact Pivotal support. Information for contacting Pivotal Support is at https://support.pivotal.io.

- During the migration process from Greenplum Database 5.0.0, a backup is made of some files and directories in $MASTER_DATA_DIRECTORY. Pivotal recommends that files and directories that are not used by Greenplum Database be backed up, if necessary, and removed from the $MASTER_DATA_DIRECTORY before migration. For information about the Greenplum Database migration utilities, see the Greenplum Database Documentation.

For information about supported versions of Greenplum Database extensions, see Pivotal Greenplum Tools and Extensions Compatibility.

If you are utilizing Data Domain Boost, you have to re-enter your DD Boost credentials after upgrading to Greenplum Database 5.21.1 as follows:

```
gpcrondump --ddboost-host ddboost_hostname --ddboost-user ddboost_user
--ddboost-backupdir backup_directory
```
**Note:** If you do not reenter your login credentials after an upgrade, your backup will never start because the Greenplum Database cannot connect to the Data Domain system. You will receive an error advising you to check your login credentials.

If you have configured the Greenplum Platform Extension Framework (PXF) in your previous Greenplum Database installation, you must stop the PXF service, and you might need to back up PXF configuration files before upgrading to a new version of Greenplum Database. Refer to PXF Pre-Upgrade Actions for instructions.

If you do not plan to use PXF, or you have not yet configured PXF, no action is necessary.

## Upgrading from 5.x to 5.21.1

An upgrade from 5.x to 5.21.1 involves stopping Greenplum Database, updating the Greenplum Database software binaries, upgrading and restarting Greenplum Database. If you are using Greenplum Database extension packages there are additional requirements. See Prerequisites in the previous section.

**Note:** If you are upgrading from Greenplum Database 5.10.x or earlier and have installed the PL/Java extension, you must upgrade the PL/Java extension to extension package version 1.4.3. Previous releases of the PL/Java extension are not compatible with Greenplum Database 5.11.0 and later. For information about the PL/Java extension package, see Pivotal Greenplum Tools and Extensions Compatibility.

**Note:** If you have databases that were created with Greenplum Database 5.10.x or an earlier 5.x release, upgrade the `gp_bloat_expected_pages` view in the `gp_toolkit` schema. For information about the issue and how check a database for the issue, see Update for `gp_toolkit.gp_bloat_expected_pages` Issue.

**Note:** If you are upgrading from Greenplum Database 5.7.0 or an earlier 5.x release and have configured PgBouncer in your Greenplum Database installation, you must migrate to the new PgBouncer when you upgrade Greenplum Database. Refer to Migrating PgBouncer for specific migration instructions.

**Note:** If you have databases that were created with Greenplum Database 5.3.0 or an earlier 5.x release, upgrade the `gp_bloat_diag` function and view in the `gp_toolkit` schema. For information about the issue and how check a database for the issue, see Update for `gp_toolkit.gp_bloat_diag` Issue.

**Note:** If the Greenplum Command Center database `gpperfmon` is installed in your Greenplum Database system, the migration process changes the distribution key of the Greenplum Database `log_alert_*` tables to the `logtime` column. The redistribution of the table data might take some time the first time you start Greenplum Database after migration. The change occurs only the first time you start Greenplum Database after a migration.

1. Log in to your Greenplum Database master host as the Greenplum administrative user:

   ```
   $ su - gpadmin
   ```

2. Perform a smart shutdown of your current Greenplum Database 5.x system (there can be no active connections to the database). This example uses the `--a` option to disable confirmation prompts:

   ```
   $ gpstop --a
   ```

3. Run the binary installer for 5.21.1 on the Greenplum Database master host.

   When prompted, choose an installation location in the same base directory as your current installation. For example:

   ```
   /usr/local/greenplum-db-5.21.1
   ```

   If you install Greenplum Database with the `rpm` (as root), the installation directory is `/usr/local/greenplum-db-5.21.1`.  

198
For the rpm installation, update the permissions for the new installation. For example, run this command as root to change user and group of the installed files to gpadmin.

```bash
# chown -R gpadmin:gpadmin /usr/local/greenplum*
```

4. If needed, update the `greenplum_path.sh` file for use with your specific installation. These are some examples.
   - If Greenplum Database uses LDAP authentication, edit the `greenplum_path.sh` file to add the line:

     ```bash
     export LDAPCONF=/etc/openldap/ldap.conf
     ```

   - If Greenplum Database uses PL/Java, you might need to set or update the environment variables `JAVA_HOME` and `LD_LIBRARY_PATH` in `greenplum_path.sh`.

     **Note:** When comparing the previous and new `greenplum_path.sh` files, be aware that installing some Greenplum Database extensions also updates the `greenplum_path.sh` file. The `greenplum_path.sh` from the previous release might contain updates that were the result of those extensions. See step 9 for installing Greenplum Database extensions.

5. Edit the environment of the Greenplum Database superuser (`gpadmin`) and make sure you are sourcing the `greenplum_path.sh` file for the new installation. For example change the following line in `.bashrc` or your chosen profile file:

   ```bash
   source /usr/local/greenplum-db-5.0.0/greenplum_path.sh
   ```

   to:

   ```bash
   source /usr/local/greenplum-db-5.21.1/greenplum_path.sh
   ```

   Or if you are sourcing a symbolic link (`/usr/local/greenplum-db`) in your profile files, update the link to point to the newly installed version. For example:

   ```bash
   $ rm /usr/local/greenplum-db
   $ ln -s /usr/local/greenplum-db-5.21.1 /usr/local/greenplum-db
   ```

6. Source the environment file you just edited. For example:

   ```bash
   $ source ~/.bashrc
   ```

7. Run the `gpseginstall` utility to install the 5.21.1 binaries on all the segment hosts specified in the `hostfile`. For example:

   ```bash
   $ gpseginstall -f hostfile
   ```

   **Note:** The `gpseginstall` utility copies the installed files from the current host to the remote hosts. It does not use `rpm` to install Greenplum Database on the remote hosts, even if you used `rpm` to install Greenplum Database on the current host.

8. Use the Greenplum Database `gppkg` utility to install Greenplum Database extensions. If you were previously using any Greenplum Database extensions such as `pgcrypto`, PL/R, PL/Java, PL/Perl, and PostGIS, download the corresponding packages from Pivotal Network, and install using this utility. See the Greenplum Database Documentation for `gppkg` usage details.

   Also copy any additional files that are used by the extensions (such as JAR files, shared object files, and libraries) from the previous version installation directory to the new version installation directory on the master and segment host systems.

9. If you are upgrading from Greenplum Database 5.7 or an earlier 5.x release and have configured PgBouncer in your Greenplum Database installation, you must migrate to the new PgBouncer when you upgrade Greenplum Database. Refer to Migrating PgBouncer for specific migration instructions.
10. After all segment hosts have been upgraded, you can log in as the `gpadmin` user and restart your Greenplum Database system:

```
# su - gpadmin
$ gpstart
```

11. If you are utilizing Data Domain Boost, you have to re-enter your DD Boost credentials after upgrading from Greenplum Database to 5.21.1 as follows:

```
gpcrondump --ddboost-host ddboost_hostname --ddboost-user ddboost_user --ddboost-backupdir backup_directory
```

**Note:** If you do not reenter your login credentials after an upgrade, your backup will never start because the Greenplum Database cannot connect to the Data Domain system. You will receive an error advising you to check your login credentials.

12. If you configured PXF in your previous Greenplum Database installation, you must re-initialize the PXF service after you upgrade Greenplum Database. Refer to *Upgrading PXF* for instructions.

After upgrading Greenplum Database, ensure features work as expected. For example, you should test that backup and restore perform as expected, and Greenplum Database features such as user-defined functions, and extensions such as MADlib and PostGIS perform as expected.

**Troubleshooting a Failed Upgrade**

If you experience issues during the migration process and have active entitlements for Greenplum Database that were purchased through Pivotal, contact Pivotal Support. Information for contacting Pivotal Support is at [https://support.pivotal.io](https://support.pivotal.io).

Be prepared to provide the following information:

- A completed *Upgrade Procedure*.
- Log output from `gpcheckcat` (located in `~/gpAdminLogs`)
Migrating Data to Pivotal Greenplum 5.x

Upgrading a Pivotal Greenplum Database 4.x system directly to Pivotal Greenplum Database 5.x is not supported.

You can migrate existing data to Greenplum Database 5.x using standard backup and restore procedures (gpcrondump and gpdbrestore) or by using gptransfer. The gpcopy utility can be used to migrate data from Greenplum Database 4.3.26 or later to 5.9 or later.

Follow these general guidelines for migrating data:

- Make sure that you have a complete backup of all data in the Greenplum Database 4.3.x cluster, and that you can successfully restore the Greenplum Database 4.3.x cluster if necessary.
- You must install and initialize a new Greenplum Database 5.x cluster using the version 5.x gpinit system utility.

**Note:** Unless you modify file locations manually, gpdbrestore only supports restoring data to a cluster that has an identical number of hosts and an identical number of segments per host, with each segment having the same content_id as the segment in the original cluster. If you initialize the Greenplum Database 5.x cluster using a configuration that is different from the version 4.3 cluster, then follow the steps outlined in Restoring to a Different Greenplum System Configuration to manually update the file locations.

**Important:** For Greenplum Database 5.x, Pivotal recommends that customers set the Greenplum Database timezone to a value that is compatible with the host systems. Setting the Greenplum Database timezone prevents Greenplum Database from selecting a timezone each time the cluster is restarted and sets the timezone for the Greenplum Database master and segment instances. See Configuring Timezone and Localization Settings for more information.

- If you intend to install Greenplum Database 5.x on the same hardware as your 4.3.x system, you will need enough disk space to accommodate over 5 times the original data set (2 full copies of the primary and mirror data sets, plus the original backup data in ASCII format) in order to migrate data with gpcrondump and gpdbrestore. Keep in mind that the ASCII backup data will require more disk space than the original data, which may be stored in compressed binary format. Offline backup solutions such as Dell EMC Data Domain or Veritas NetBackup can reduce the required disk space on each host.

  If you attempt to migrate your data on the same hardware but run out of free space, gpcopy provides the --truncate-source-after option to truncate each source table after copying the table to the destination cluster and validating the copy succeeded. This reduces the amount of free space needed to migrate clusters that reside on the same hardware. See Migrating Data with gpcopy for more information.

- Use the version 5.x gpdbrestore utility to load the 4.3.x backup data into the new cluster.

- If the Greenplum Database 5.x cluster resides on separate hardware from the 4.3.x cluster, and the clusters have different numbers of segments, you can optionally use the version 5.x gptransfer utility to migrate the 4.3.x data. You must initiate the gptransfer operation from the version 5.x cluster, pulling the older data into the newer system.

On a Greenplum Database system with FIPS enabled, validating table data with MD5 (specifying the gptransfer option --validate=md5) is not available. Use the option sha256 to validate table data.

Validating table data with SHA-256 (specifying the option --validate=sha256) requires the Greenplum Database pgcrypto extension. The extension is included with Pivotal Greenplum 5.x. The extension package must be installed on supported Pivotal Greenplum 4.3.x systems. Support for pgcrypto functions in a Greenplum 4.3.x database is not required.

- Greenplum Database 5.x removes automatic implicit casts between the text type and other data types. After you migrate from Greenplum Database version 4.3.x to version 5.x, this change in behavior may impact existing applications and queries. Refer to About Implicit Text Casting in Greenplum Database in
the Greenplum Database Installation Guide for information, including a discussion about supported and unsupported workarounds.

- After migrating data you may need to modify SQL scripts, administration scripts, and user-defined functions as necessary to account for changes in Greenplum Database version 5.x. Look for Upgrade Action Required entries in the Pivotal Greenplum 5.0.0 Release Notes for features that may necessitate post-migration tasks.

- If you are migrating from Greenplum Database 4.3.27 or an earlier 4.3.x release and have configured PgBouncer in your Greenplum Database installation, you must migrate to the new PgBouncer when you upgrade Greenplum Database. Refer to Migrating PgBouncer for specific migration instructions.
Pivotal Greenplum on DCA Systems

On supported Dell EMC DCA systems, you can install Pivotal Greenplum 5.21.1, or you can upgrade from Pivotal Greenplum 5.x to 5.21.1.

Only Pivotal Greenplum Database is supported on DCA systems. Open source versions of Greenplum Database are not supported.

• Installing the Pivotal Greenplum 5.21.1 Software Binaries on DCA Systems
• Upgrading from 5.x to 5.21.1 on DCA Systems

Important: Upgrading Pivotal Greenplum Database 4.3.x to Pivotal Greenplum 5.21.1 is not supported. See Migrating Data to Pivotal Greenplum 5.x.

Note: These Greenplum Database releases are not certified on DCA because of an incompatibility in configuring timezone information.

5.5.0, 5.6.0, 5.6.1, 5.7.0, 5.8.0
These Greenplum Database releases are certified on DCA.
5.7.1, 5.8.1, 5.9.0 and later releases, and 5.x releases prior to 5.5.0.

Installing the Pivotal Greenplum 5.21.1 Software Binaries on DCA Systems

Important: This section is for installing Pivotal Greenplum 5.21.1 only on DCA systems. Also, see the information on the DELL EMC support site (requires login).

For information about installing Pivotal Greenplum on non-DCA systems, see the Greenplum Database Installation Guide.

Prerequisites

• Ensure your DCA system supports Pivotal Greenplum 5.21.1. See Supported Platforms.
• Ensure Greenplum Database 4.3.x is not installed on your system.

Installing Pivotal Greenplum 5.21.1 on a DCA system with an existing Greenplum Database 4.3.x installation is not supported. For information about uninstalling Greenplum Database software, see your Dell EMC DCA documentation.

Installing Pivotal Greenplum 5.21.1

1. Download or copy the Greenplum Database DCA installer file greenplum-db-appliance-5.21.1-RHEL6-x86_64.bin to the Greenplum Database master host.
2. As root, run the DCA installer for 5.21.1 on the Greenplum Database master host and specify the file hostfile that lists all hosts in the cluster, one host name per line. If necessary, copy hostfile to the directory containing the installer before running the installer.

This example command runs the installer for Greenplum Database 5.21.1.

# ./greenplum-db-appliance-5.21.1-RHEL6-x86_64.bin hostfile

Upgrading from 5.x to 5.21.1 on DCA Systems

Upgrading Pivotal Greenplum from 5.x to 5.21.1 on a Dell EMC DCA system involves stopping Greenplum Database, updating the Greenplum Database software binaries, and restarting Greenplum Database.
Important: This section is only for upgrading to Pivotal Greenplum 5.21.1 on DCA systems. For information about upgrading on non-DCA systems, see Upgrading to Greenplum Database 5.21.1.

Note: If you are upgrading from Greenplum Database 5.10.x or earlier and have installed the PL/Java extension, you must upgrade the PL/Java extension to extension package version 1.4.3. Previous releases of the PL/Java extension are not compatible with Greenplum Database 5.11.0 and later. For information about the PL/Java extension package, see Pivotal Greenplum Tools and Extensions Compatibility.

Note: If you have databases that were created with Greenplum Database 5.10.x or an earlier 5.x release, upgrade the gp_bloat_expected_pages view in the gp_toolkit schema. For information about the issue and how check a database for the issue, see Update for gp_toolkit.gp_bloat_expected_pages Issue.

Note: If you are upgrading from Greenplum Database 5.7.0 or an earlier 5.x release and have configured PgBouncer in your Greenplum Database installation, you must migrate to the new PgBouncer when you upgrade Greenplum Database. Refer to Migrating PgBouncer for specific migration instructions.

Note: If you have databases that were created with Greenplum Database 5.3.0 or an earlier 5.x release, upgrade the gp_bloat_diag function and view in the gp_toolkit schema. For information about the issue and how check a database for the issue, see Update for gp_toolkit.gp_bloat_diag Issue.

1. Log in to your Greenplum Database master host as the Greenplum administrative user (gpadmin):

```
# su - gpadmin
```

2. Download or copy the installer file greenplum-db-appliance-5.21.1-RHEL6-x86_64.bin to the Greenplum Database master host.

3. Perform a smart shutdown of your current Greenplum Database 5.x system (there can be no active connections to the database). This example uses the –a option to disable confirmation prompts:

```
$ gpstop -a
```

4. As root, run the Greenplum Database DCA installer for 5.21.1 on the Greenplum Database master host and specify the file hostfile that lists all hosts in the cluster. If necessary, copy hostfile to the directory containing the installer before running the installer.

   This example command runs the installer for Greenplum Database 5.21.1 for Red Hat Enterprise Linux 6.x.

```
# ./greenplum-db-appliance-5.21.1-RHEL6-x86_64.bin hostfile
```

The file hostfile is a text file that lists all hosts in the cluster, one host name per line.

5. If needed, update the greenplum_path.sh file for use with your specific installation. These are some examples.

   • If Greenplum Database uses LDAP authentication, edit the greenplum_path.sh file to add the line:

   ```
   export LDAPCONF=/etc/openldap/ldap.conf
   ```

   • If Greenplum Database uses PL/Java, you might need to set or update the environment variables JAVA_HOME and LD_LIBRARY_PATH in greenplum_path.sh.

   Note: When comparing the previous and new greenplum_path.sh files, be aware that installing some Greenplum Database extensions also updates the greenplum_path.sh file. The greenplum_path.sh from the previous release might contain updates that were the result of those extensions. See step 6 for installing Greenplum Database extensions.
6. Install Greenplum Database extension packages. For information about installing a Greenplum Database extension package, see `gppkg` in the *Greenplum Database Utility Guide*.

   Also migrate any additional files that are used by the extensions (such as JAR files, shared object files, and libraries) from the previous version installation directory to the new version installation directory.

7. After all segment hosts have been upgraded, you can log in as the `gpadmin` user and restart your Greenplum Database system:

   ```
   # su - gpadmin
   $ gpstart
   ```

8. If you are utilizing Data Domain Boost, you have to re-enter your DD Boost credentials after upgrading to Greenplum Database 5.21.1 as follows:

   ```
   gpcrondump --ddboost-host ddboost_hostname --ddboost-user ddboost_user
               --ddboost-backupdir backup_directory
   ```

   **Note:** If you do not reenter your login credentials after an upgrade, your backup will never start because the Greenplum Database cannot connect to the Data Domain system. You will receive an error advising you to check your login credentials.

After upgrading Greenplum Database, ensure features work as expected. For example, you should test that backup and restore perform as expected, and Greenplum Database features such as user-defined functions, and extensions such as MADlib and PostGIS perform as expected.
Update for gp_toolkit.gp_bloat_expected_pages Issue

In Greenplum Database 5.10.x and earlier 5.x releases, the Greenplum Database view gp_toolkit.gp_bloat_expected_pages view might incorrectly report that a root partition table is bloated even though root partition tables do not contain data. This information could cause a user to run a vacuum full operation on the partitioned table when the operation was not required. The issue was resolved in Greenplum Database 5.11.0 (resolved issue 29523).

When updating Greenplum Database, the gp_toolkit.gp_bloat_expected_pages view must be updated in databases created with a Greenplum Database 5.10.x or an earlier 5.x release. This issue has been fixed in databases created with Greenplum Database 5.11.0 and later. For information about using template0 as the template database after upgrading from Greenplum Database 5.10.x or an earlier 5.x release, see known issue 29523.

To check whether the gp_toolkit.gp_bloat_expected_pages view in a database requires an update, run the psql command \d+ to display the view definition.

```
\d+ gp_toolkit.gp_bloat_expected_pages
```

The updated view definition contains this predicate.

```
AND NOT EXISTS
  ( SELECT parrelid
    FROM pg_partition
    WHERE parrelid = pgc.oid )
```

Perform the following steps as the gpadmin user to update the view on each database that was created with Greenplum Database 5.11.0 or an earlier 5.x release.

1. Copy the script into a text file on the Greenplum Database master.
2. Run the script on each database that requires the update.

   This example updates gp_toolkit.gp_bloat_expected_pages view in the database mytest and assumes that the script is in the gp_bloat_expected_pages in the gpadmin home directory.

```
psql -f /home/gpadmin/gp_bloat_expected_pages.sql -d mytest
```

Run the script during a low activity period. Running the script during a high activity period does not affect database functionality but might affect performance.

Script to Update gp_toolkit.gp_bloat_expected_pages View

```
BEGIN;
CREATE OR REPLACE VIEW gp_toolkit.gp_bloat_expected_pages AS
  SELECT
    btdrelid,
    btdrelpages,
    CASE WHEN btdexppages < numsegments
      THEN numsegments
      ELSE btdexppages
      END AS btdexppages
  FROM
    ( SELECT
      oid as btdrelid,
      pgc.relpages as btdrelpages,
      CEIL((pgc.reltuples * (25 + width))::numeric / current_setting('block_size')::numeric) AS btdexppages,
```

```
(SELECT numsegments FROM gp_toolkit.__gp_number_of_segments) AS numsegments
FROM
  ( SELECT pgc.oid, pgc.reltuples, pgc.relpages
    FROM pg_class pgc
    WHERE NOT EXISTS
      ( SELECT iaooid
        FROM gp_toolkit.__gp_is_append_only
        WHERE iaooid = pgc.oid AND iaotype = 't' )
    AND NOT EXISTS
      ( SELECT parrelid
        FROM pg_partition
        WHERE parrelid = pgc.oid ) ) AS pgc
LEFT OUTER JOIN
  ( SELECT starelid, SUM(stawidth * (1.0 - stanullfrac)) AS width
    FROM pg_statistic pgs
    GROUP BY 1 ) AS btwcols
ON pgc.oid = btwcols.starelid
WHERE starelid IS NOT NULL) AS subq;

GRANT SELECT ON TABLE gp_toolkit.gp_bloat_expected_pages TO public;
COMMIT;
Update for gp_toolkit.gp_bloat_diag Issue

In Greenplum Database 5.3.0 or an earlier 5.x release, Greenplum Database returned an integer out of range error in some cases when performing a query against the gp_toolkit.gp_bloat_diag view. The issue was resolved in Greenplum Database 5.4.0 (resolved issue 26518).

When updating Greenplum Database, the gp_toolkit.gp_bloat_diag function and view must be updated in databases created with a Greenplum Database 5.3.0 or an earlier 5.x release. This issue has been fixed in databases created with Greenplum Database 5.4.0 and later. For information about upgrading from Greenplum Database 5.3.0 or an earlier 5.x release and then using template0 as the template database, see known issue 29523.

To check whether the gp_toolkit.gp_bloat_diag function and view in a database requires an update, run the psql command \df to display information about the gp_toolkit.gp_bloat_diag function.

\df gp_toolkit.gp_bloat_diag

If the data type for btdexppages is integer, an update is required. If the data type is numeric an update is not required. In this example, the btdexppages data type is integer and requires an update.

List of functions
- [ RECORD 1 ]--------
+-----------------------
| Schema | gp_toolkit |
| Name   | gp_bloat_diag |
| Result data type | record |
| Argument data types | btdrelpages integer, btdexppages integer, aotable boolean, OUT bltidx integer, OUT bltdiag text |
| Type | normal |

Perform the following steps as the gpadmin user to update the function and view to fix the issue on each database that was created with Greenplum Database 5.3.0 or an earlier 5.x release.

1. Copy the script into a text file on the Greenplum Database master.
2. Run the script on each database that requires the update.

This example updates gp_toolkit.gp_bloat_diag function and view in the database mytest and assumes that the script is in the update_bloat_diag.sql in the gpadmin home directory.

psql -f /home/gpadmin/update_bloat_diag.sql -d mytest

Run the script during a low activity period. Running the script during a high activity period does not affect database functionality but might affect performance.

Script to Update gp_toolkit.gp_bloat_diag Function and View

BEGIN;
CREATE OR REPLACE FUNCTION gp_toolkit.gp_bloat_diag(btdrelpages int,
          btdexppages numeric, aotable bool,
          OUT bltidx int, OUT bltdiag text)
AS
$$
SELECT
  bltidx,
  CASE
    WHEN bltidx = 0
    THEN 'no bloat detected':::text
    WHEN bltidx = 1
  END
$$
THEN 'moderate amount of bloat suspected'::text
WHEN bloatidx = 2
THEN 'significant amount of bloat suspected'::text
WHEN bloatidx = -1
THEN 'diagnosis inconclusive or no bloat suspected'::text
END AS bloatdiag
FROM
(
SELECT
CASE
WHEN $3 = 't' THEN 0
WHEN $1 < 10 AND $2 = 0 THEN -1
WHEN $2 = 0 THEN 2
WHEN $1 < $2 THEN 0
WHEN ($1/$2)::numeric > 10 THEN 2
WHEN ($1/$2)::numeric > 3 THEN 1
ELSE -1
END AS bloatidx
) AS bloatmapping
$$
LANGUAGE SQL READS SQL DATA;

GRANT EXECUTE ON FUNCTION gp_toolkit.gp_bloat_diag(int, numeric, bool, OUT int, OUT text) TO public;

CREATE OR REPLACE VIEW gp_toolkit.gp_bloat_diag
AS
SELECT
btdrelid AS bdirelid,
fnnspname AS bdinspname,
fnrelname AS bdirelname,
btdrelpages AS bdirelpages,
btdexppages AS bdiexppages,
bltdiag(bd) AS bdidiag
FROM
(
SELECT
fn.*, beg.*,
gp_toolkit.gp_bloat_diag(btdrelpages::int, btdexppages::numeric, iao.iaotype::bool) AS bd
FROM
  gp_toolkit.gp_bloat_expected_pages beg,
  pg_catalog.pg_class pgc,
  gp_toolkit.__gp_fullname fn,
  gp_toolkit.__gp_is_append_only iao
WHERE beg.btdrelid = pgc.oid
AND pgc.oid = fn.fnoid
AND iao.iaooid = pgc.oid
) AS bloatsummary
WHERE bltidx(bd) > 0;

GRANT SELECT ON TABLE gp_toolkit.gp_bloat_diag TO public;
COMMIT;

Pivotal Greenplum 5.21.0 Release Notes

Updated: July, 2019

- Welcome to Pivotal Greenplum 5.21.0
- New Features
- Resolved Issues
- Beta Features
- Deprecated Features
- Known Issues and Limitations
- Differences Compared to Open Source Greenplum Database
- Supported Platforms
- Pivotal Greenplum Tools and Extensions Compatibility
- Hadoop Distribution Compatibility
- Upgrading to Greenplum Database 5.21.0
- Migrating Data to Pivotal Greenplum 5.x
- Pivotal Greenplum on DCA Systems
- Update for gp_toolkit.gp_bloat_expected_pages Issue
- Update for gp_toolkit.gp_bloat_diag Issue
Welcome to Pivotal Greenplum 5.21.0

Pivotal Greenplum Database is a massively parallel processing (MPP) database server that supports next generation data warehousing and large-scale analytics processing. By automatically partitioning data and running parallel queries, it allows a cluster of servers to operate as a single database supercomputer performing tens or hundreds times faster than a traditional database. It supports SQL, MapReduce parallel processing, and data volumes ranging from hundreds of gigabytes, to hundreds of terabytes.

This document contains pertinent release information about Pivotal Greenplum Database 5.21.0. For previous versions of the release notes for Greenplum Database, go to Pivotal Greenplum Database Documentation. For information about Greenplum Database end of life, see the Pivotal Support Lifecycle Policy.

Pivotal Greenplum 5.x software is available for download from the Pivotal Greenplum page on Pivotal Network.

Pivotal Greenplum 5.x is based on the open source Greenplum Database project code.

Important: The Greenplum gpbackup and gprestore utilities are now distributed separately from Pivotal Greenplum Database, and are updated independently of the core Greenplum Database server. These utilities will not be updated in future Greenplum Database 5.x releases. You can upgrade to the latest gpbackup and gprestore versions by downloading and installing the latest Pivotal Greenplum Backup and Restore release from Pivotal Network.

Important: Pivotal Support does not provide support for open source versions of Greenplum Database. Only Pivotal Greenplum Database is supported by Pivotal Support.

Pivotal Greenplum 5.21.0 is a minor release that changes features and resolves issues.
New Features

Greenplum Database 5.21.0 includes the following new features:

- Additional debug logging was added for persistent tables during segment recovery, to help in determining the cause of known issue 29917. The additional logging is enabled by default, and adds approximately 646 bytes to each persistent table entry file. If you want to disable the additional logging, set the `debug_filerep_config_print` configuration parameter "false."
- PXF version 5.7.0 is included, which introduces several new and changed features and bug fixes. See PXF Version 5.7.0 below.
- GPORCA performance enhancement for some queries that perform a comparison against a NULL value. The performance was not optimal because of incorrect cardinality estimation. The cardinality estimates for the specified type of comparisons have been improved.
- UDP interconnect enhancement - the server now returns backend processes to the process pool and reuses these processes in the same order as previous queries in the same session. This helps reduce the network flow count on certain cloud platforms.
- Greenplum Database 5.21.0 is compatible with MADlib 1.16, with support for deep learning. MADlib is provided as a separate download with Pivotal Greenplum 5.21. See Greenplum MADlib Extension for Analytics in the Greenplum Database Reference Guide.

PXF Version 5.7.0

PXF New Features

PXF includes the following new features:

- The PXF JDBC Connector now supports JDBC connection pooling, and exposes properties that you can set to configure pool connection reuse and timeouts. Refer to About JDBC Connection Pooling.

PXF Changed Features

PXF includes the following changes:

- PXF now supports JDBC named queries that are specified both with and without an ending semicolon. PXF previously required that you not specify the ending semicolon.
- PXF includes a newer version of the PostgreSQL JDBC driver JAR file, `postgresql-42.2.5.jar`.
- The PXF JDBC Connector now uses the PARTITION_BY, RANGE, and INTERVAL partition settings to aid in partition construction, and always returns the complete dataset. PXF previously returned only the data set identified by the RANGE, and did not include NULLs or the RANGE end value.
- PXF now solely uses the com.fasterxml.jackson JSON parser library for Java. PXF previously used both the fastersxml.jackson JSON parser library and the org.codehaus.jackson libraries.

PXF Resolved Issues

PXF includes the following resolved issues:

166491258 - PXF

PXF returned an error when it encountered a query configured in a JDBC named query file that ended in a semicolon.

This issue has been resolved. PXF now supports JDBC named queries that are specified both with and without an ending semicolon.

170 - PXF
When a PARTITION_BY column, and partition RANGE and INTERVAL were specified, the PXF JDBC Connector did not include NULL values or the RANGE end value in the query constraints. Additionally, the Connector returned only the data set identified by the RANGE.

This issue has been resolved. PXF now uses the JDBC partition options as a hint when it constructs partitions. PXF generates fragments with the contraints necessary to read the complete data set, including NULLs and the RANGE end value.

29973 - PXF

PXF did not return an error when an external table specifying the JSON profile was used to read JSON-format data into an integer field, but the data was a non-numeric type. PXF converted the non-numeric type to the integer 0.

This issue has been resolved. PXF now recognizes malformed JSON and data type mismatches, and returns an error.

167077097 - PXF

PXF returned an error when a writable external table with a LOCATION clause that specified a compression codec alias (rather than the complete class name) was used to INSERT parquet data.

This issue has been resolved. PXF now correctly supports compression codec aliases when writing parquet data.
Resolved Issues

The listed issues are resolved in Pivotal Greenplum Database 5.21.0.

For issues resolved in prior 5.x releases, refer to the corresponding release notes. Release notes are available from the Pivotal Greenplum page on Pivotal Network.

165690728 - Query Optimizer
In some cases, GPORCA produced a suboptimal plan when the JOIN condition was on a boolean-type NULL value.

This problem has been resolved. GPORCA now produces an optimal plan in this situation.

30011 - ANALYZE
Fixes the problem where an error was returned during an ANALYZE operation on a query that contains a table with a large number of numeric columns. The error states that target lists can have at most 1664 entries. Now ANALYZE can analyze a query that contains a table with more than 830 numeric columns.

29976 - GPORCA
In rare cases, GPORCA would generate a panic while trying to simplify predicates when a query contained equality predicates between char and varchar data types. This has been fixed by suppressing the simplification step in the cases that caused the panic.

29972 - Query Optimizer
Fixed a problem where a plan GPORCA generated for a query containing a join with an expression in the form f(a) = b could not complete.

29933 - Segment Mirroring
Greenplum 5.21 fixes a deadlock that could occur between gprecoverseg and the file transfer service (FTS) probe when gprecoverseg added or removed segment mirrors.

29580 - Management & Monitoring
Fixes the problem where Greenplum Database incorrectly created an extra log file during log file rotation. The timestamp in the file name of the extra log file was later than the current time and the file was not used.

8094 (29999) - UDP Interconnect
Greenplum 5.21 fixes a resource error related to the number of send/receive port pairs open in a given time period that manifests itself on certain cloud platforms. The server now retains the same order when reusing associated backend processes.

8092, 8095 (29999) - TCP Interconnect
Greenplum 5.21 fixes a TCP interconnect problem where a query might hang when one backend process cannot bind to a port because of an error handling bug in a motion module. Unnecessary bind operations have been removed, and the server now properly checks for this error scenario.

7946 - Query Optimizer
In some cases, GPORCA, the Pivotal Query Optimizer, generated an incorrect query result when the target list included a correlated subquery.

This problem has been resolved. GPORCA now returns the correct query results in this situation.

26225 - gpcheckcat
The gpcheckcat utility failed to generate a summary report if there was an orphan TOAST table entry in one of the segments. This is fixed. The string "N/A" is reported when there is no relation oid to report.
Beta Features

Because Pivotal Greenplum Database is based on the open source Greenplum Database project code, it includes several Beta features to allow interested developers to experiment with their use on development systems. Feedback will help drive development of these features, and they may become supported in future versions of the product.

**Warning:** Beta features are not supported for production deployments.

Greenplum Database 5.21.0 includes these Beta features:

- **Storage plugin API for `gpbackup` and `gprestore`**. Partners, customers, and OSS developers can develop plugins to use in conjunction with `gpbackup` and `gprestore`.
  
  For information about the storage plugin API, see [Backup/Restore Storage Plugin API](https://docs��plum.com) in the OpenGreenplum Database Documentation.

- **Recursive WITH Queries (Common Table Expressions)**. See [WITH Queries (Common Table Expressions)](https://docs.greenplum.com) in the Pivotal Greenplum Database Documentation.

- **Resource groups remain a Beta feature only on the SuSE 11 platform**, due to limited cgroups functionality in the kernel.
  
  SuSE 12 resolves the Linux cgroup issues that caused the performance degradation when Greenplum Database resource groups are enabled.

- **Using the Greenplum Platform Extension (PXF) connectors to write Parquet data** is a Beta feature.
**Deprecated Features**

These Greenplum Database features are deprecated.

- The `gptransfer` utility will be removed in the next major release. The utility copies objects between Greenplum Database systems. The `gpcopy` utility provides `gptransfer` functionality.
- The `gphdfs` external table protocol will be removed in the next major release. Consider using the Greenplum Platform Extension Framework (PXF) `pxf` external table protocol to access data stored in an external Hadoop file system. Refer to *Accessing External Data with PXF* for more information.
Known Issues and Limitations

Pivotal Greenplum 5.x has these limitations:

- Upgrading a Greenplum Database 4.3.x release to Pivotal Greenplum 5.x is not supported. See [Migrating Data to Pivotal Greenplum 5.x](#).
- Some features are works-in-progress and are considered to be Beta features. Pivotal does not support using Beta features in a production environment. See [Beta Features](#).
- Greenplum Database 4.3.x packages are not compatible with Pivotal Greenplum 5.x.

The following table lists key known issues in Pivotal Greenplum 5.x.

<table>
<thead>
<tr>
<th>Issue</th>
<th>Category</th>
<th>Description</th>
</tr>
</thead>
</table>
| 30029 | metrics_collector | A PL/pgSQL function with a `RAISE EXCEPTION` message longer than 1024 bytes can cause an overflow in the `metrics_collector` extension, leading to a segmentation fault on the Greenplum master. Workarounds:  
  - Shorten `RAISE EXCEPTION` messages to under 1024 bytes.  
  - Set the `gpcc.enable_send_query_info server configuration parameter to `off` before running queries that have long `RAISE EXCEPTION` messages.  
  
  ```sql
  SET gpcc.enable_send_query_info= "off";
  ```  
  This parameter can be set in the session, and will prevent the `metrics_collector` extension from calling the code that produces the error.  
  This issue is fixed in Greenplum Database version 5.21.1. |

| 29861  | gpstart  | If a segment’s data directory becomes inaccessible or the contents of the data directory are deleted, the segment goes offline and is marked as down in gp_segment_configuration. However, if you have temporary or transaction files in a separate filespace or if you stop and start the database, gpstart can fail with the error:  

```
20190404:17:26:44:025089 gpstart:mdw:gpadmin-[ERROR]:-Multiple OIDs found in flat files
```

The error indicates that two files are missing from a segment directory, gp_temporary_files_filespace and gp_transaction_files_filespace. gpstart reports the error even if the segments have already been marked down.  

**Workaround:** To resolve this problem you must manually create the missing files in the segment directory using the segment's corresponding dbid, transaction file segment directory, and filespace oid. See the detailed instructions for creating these files in Article Number: 6784 gpstart fails with error "Multiple OIDs found in flat files" on the Pivotal Support site.

<tbody>
<tr>
<td>164671144</td>
<td>gpssh-exkeys</td>
<td>The <code>gpssh-exkeys</code> utility uses the Paramiko SSH library for Python, which has a dependency on the Python Cryptography Toolkit (PyCrypto) library. The following security vulnerabilities have been identified in some versions of PyCrypto.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• <a href="https://nvd.nist.gov/vuln/detail/CVE-2018-6594">https://nvd.nist.gov/vuln/detail/CVE-2018-6594</a> - <code>lib/Crypto/PublicKey/ElGamal.py</code> in PyCrypto through 2.6.1 generates weak ElGamal key parameters, which allows attackers to obtain sensitive information by reading ciphertext data (i.e., it does not have semantic security in face of a ciphertext-only attack). The Decisional Diffie-Hellman (DDH) assumption does not hold for PyCrypto’s ElGamal implementation. Paramiko does not import this algorithm, so Greenplum Database is unaffected by this vulnerability.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• <a href="https://nvd.nist.gov/vuln/detail/CVE-2013-7459">https://nvd.nist.gov/vuln/detail/CVE-2013-7459</a> - Heap-based buffer overflow in the ALGnew function in block_templace.c in Python Cryptography Toolkit (aka pycrypto) allows remote attackers to execute arbitrary code as demonstrated by a crafted iv parameter to cryptmsg.py. This bug was introduced in PyCrypto 2.6. Greenplum Database has PyCrypto 2.0.1, and is unaffected by the vulnerability.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• <a href="https://nvd.nist.gov/vuln/detail/CVE-2013-1445">https://nvd.nist.gov/vuln/detail/CVE-2013-1445</a> - The Crypto.Random.atfork function in PyCrypto before 2.6.1 does not properly reseed the pseudo-random number generator (PRNG) before allowing a child process to access it, which makes it easier for context-dependent</td>
</tr>
<tr>
<td>Issue</td>
<td>Category</td>
<td>Description</td>
</tr>
<tr>
<td>-------</td>
<td>----------</td>
<td>-------------</td>
</tr>
</tbody>
</table>

attackers to obtain sensitive information by leveraging a race condition in which a child process is created and accesses the PRNG within the same rate-limit period as another process.

Paramiko version 1.7.6-9, used in Greenplum Database 4.x and 5.x, introduced a workaround to this bug. Paramiko version 1.18.4 in Greenplum Database 6 solves it in a more permanent way.

- [https://nvd.nist.gov/vuln/detail/CVE-2012-2417](https://nvd.nist.gov/vuln/detail/CVE-2012-2417) - PyCrypto before 2.6 does not produce appropriate prime numbers when using an ElGamal scheme to generate a key, which reduces the signature space or public key space and makes it easier for attackers to conduct brute force attacks to obtain the private key.

Paramiko does not import this algorithm, so Greenplum Database is unaffected by the vulnerability.

Through testing and investigation, Pivotal has determined that these vulnerabilities do not affect Greenplum Database, and no actions are required for existing Greenplum Database 4.3 or 5.x releases. However, there may be additional unidentified vulnerabilities in the PyCrypto library, and users who install a later version of PyCrypto could be exposed to other vulnerabilities.

The PyCrypto library will be removed from Greenplum Database 6.0.

**Workaround**: Administrators can set up passwordless SSH between hosts in the Greenplum Database cluster without using the `gpssh-exkeys` utility. This must be done before initializing the Greenplum Database system.

<tr>
<td>165434975</td>
<td>search_path</td>
<td>An identified PostgreSQL security vulnerability (<a href="https://nvd.nist.gov/vuln/detail/CVE-2018-1058">https://nvd.nist.gov/vuln/detail/CVE-2018-1058</a>) also exists in Greenplum Database. The problem centers around the default public schema and how Greenplum Database uses the <code>search_path</code> setting. The ability to create objects with the same names in different schemas, combined with how Greenplum Database searches for objects within schemas, presents an opportunity for a user to modify the behavior of a query for other users. For example, a malicious user could insert a trojan-horse function that, when executed by a superuser, grants escalated privileges to the malicious user. There are methods to protect from this vulnerability. See <em>A Guide to CVE-2018-1058: Protect Your Search Path</em> on the PostgreSQL wiki for a full explanation of the vulnerability and the steps you can take to protect your data.</td>

<td>ANALYZE</td>
<td>In Greenplum Database 5.15.1 and earlier 5.x releases, an ANALYZE command might return a error that states target lists can have at most 1664 entries when performing an ANALYZE operation on a table with a large number of columns (more than 800 columns). The error occurs because the in-memory sample table created by ANALYZE requires an additional column to indicate whether a column is NULL or is a truncated column for each variable length column being analyzed (such as varchar, text, and bpchar, numeric, arrays, and geometric datatype columns). The error is returned when ANALYZE attempts to create a sample table and the number of columns (table columns and indicator columns) exceeds the maximum number of columns allowed. In Greenplum Database 5.16.0 and later 5.x releases, the ANALYZE sample table does not require an additional column for variable length text columns such as varchar, text, and bpchar columns. <strong>WORKAROUND:</strong> To collect statistics on the table, perform ANALYZE operations on 2 or more sets of table columns.</td>
</tr>
<tr>
<td>162317340</td>
<td>Client Tools</td>
<td>On Pivotal Network in the file listings for Greenplum Database releases between 5.7.1 and 5.14.0, the Greenplum Database AIX Client Tools download file is incorrectly labeled as <em>Loaders for AIX 7</em>. The file you download is the correct AIX 7 Client Tools file.</td>

<td>VACUUM</td>
<td>Performing parallel VACUUM operations on a catalog table such as <code>pg_class</code>, <code>gp_relation_node</code>, <code>pg_type</code> and another table causes a deadlock and blocks connections to the database. <strong>Workaround:</strong> Avoid performing parallel VACUUM operations on catalog tables and user tables.</td>
</tr>
<tr>
<td>29139</td>
<td>DML</td>
<td>In some cases for an append-optimized partitioned table, Greenplum Database acquires a <code>ROW EXCLUSIVE</code> lock on all leaf partitions of the table when inserting data directly into one of the leaf partitions of the table. The locks are acquired the first time Greenplum Database performs validation on the leaf partitions. When inserting data into one leaf partition, the locks are not acquired on the other leaf partitions as long as the validation information remains in memory. The issue does not occur for heap-storage partitioned tables.</td>

<td>Catalog and Metadata</td>
<td>When a session creates temporary objects in a database, Greenplum Database might not drop temporary objects when the session ends if the session terminates abnormally or is terminated from an administrator command.</td>
</tr>
<tr>
<td>29496</td>
<td>gpconfig</td>
<td>For a small number of server configuration parameters such as <code>log_min_messages</code>, the command <code>gpconfig -s &lt;config_param&gt;</code> does not display the correct value of the parameter for the segment hosts when the value of the parameter on master is different than the value on the segments. For parameters with the set classification <code>master</code>, the utility displays the value set on the master for both master and segments (for information about set classifications, see Setting Parameters in the Pivotal Greenplum Database Documentation). For those parameters, the value on the master is passed as part of queries to segment instances. The SQL query that <code>gpconfig</code> runs to display the master and segment parameter values returns the master host value that is passed to the segment as part of the query. For a few parameters such as <code>log_min_messages</code>, segment instances use the segment host value specified in the <code>postgresql.conf</code> file at start up. The segment value can overridden for the scope of a query. <strong>Workaround:</strong> To display the parameter value specified in the <code>postgresql.conf</code> file on the master host and segment hosts, you can specify the <code>gpconfig</code> option <code>--file</code>.</td>

</tbody>
</table>
| 158011506  | Catalog and Metadata    | In some cases, the timezone used by Greenplum Database might be different than the host system timezone, or the Greenplum Database timezone set by a user. In some rare cases, times used and displayed by Greenplum Database might be slightly different than the host system time. The timezone used by Greenplum Database is selected from a set of internally stored PostgreSQL timezones. Greenplum Database selects the timezone by matching a PostgreSQL timezone with the user specified time zone, or the host system time zone. For example, when selecting a default timezone, Greenplum Database uses an algorithm to select a PostgreSQL timezones based on the host system timezone. If the system timezone includes leap second information, Greenplum Database cannot match the system timezone with a PostgreSQL timezone. Greenplum Database calculates a best match with a PostgreSQL timezone based on information from the host system. **Workaround:** Set the Greenplum Database and host system timezones to a timezone that is supported by both Greenplum Database and the host system. For example, you can show and set the Greenplum Database timezone with the `gpconfig` utility. These commands show the Greenplum Database timezone and set the timezone to US/Pacific.  

```bash
# gpconfig -s TimeZone
# gpconfig -c TimeZone -v 'US/Pacific'
```

You must restart Greenplum Database after changing the timezone. The command

<td>----------</td>
<td>-------------</td>
</tr>
<tr>
<td>3290</td>
<td>JSON</td>
<td>The <code>to_json()</code> function is not implemented as a callable function. Attempting to call the function results in an error. For example:</td>
</tr>
</tbody>
</table>

```
tutorial=# select to_json('Fred said "Hi. "':text);
ERROR: function to_json(text) does not exist
LINE 1: select to_json('Fred said "Hi. ".':text);
^  
HINT: No function matches the given name and argument types. You might need to add explicit type casts.
```

**Workaround:** Greenplum Database invokes `to_json()` internally when casting to the `json` data type, so perform a cast instead. For example: `SELECT '{"foo":"bar"}'::json;` Greenplum Database also provides the `array_to_json()` and `row_to_json()` functions.

<tbody>
<tr>
<td>149789783</td>
<td>Resource Groups</td>
<td>Significant Pivotal Greenplum performance degradation has been observed when enabling resource group-based workload management on Red Hat 6.x, CentOS 6.x, and SuSE 11 systems. This issue is caused by a Linux cgroup kernel bug. This kernel bug has been fixed in CentOS 7.x and Red Hat 7.x systems. When resource groups are enabled on systems with an affected kernel, there can be a delay of 1 second or longer when starting a transaction or a query. The delay is caused by a Linux cgroup kernel bug where a synchronization mechanism called <code>synchronize_sched</code> is abused when a process is attached to a cgroup. See <a href="http://www.spinics.net/lists/cgroups/msg05708.html">http://www.spinics.net/lists/cgroups/msg05708.html</a> and <a href="https://lkml.org/lkml/2013/1/14/97">https://lkml.org/lkml/2013/1/14/97</a> for more information. The issue causes single attachment operations to take longer and also causes all concurrent attachments to be executed in sequence. For example, one process attachment could take about 0.01 second. When concurrently attaching 100 processes, the fastest process attachment takes 0.01 second and the slowest takes about 1 second. Pivotal Greenplum performs process attachments when a transaction or queries are started. So the performance degradation is dependent on concurrent started transactions or queries, and not related to concurrent running queries. Also Pivotal Greenplum has optimizations to bypass the rewriting when a QE is reused by multiple queries in the same session. <strong>Workaround:</strong> This bug does not affect CentOS 7.x and Red Hat 7.x systems.</td>

</table>
Pivotal Greenplum 5.x includes all of the functionality in the open source Greenplum Database project and adds:

- Product packaging and installation script.
- Support for QuickLZ compression. QuickLZ compression is not provided in the open source version of Greenplum Database due to licensing restrictions.
- Support for managing Greenplum Database using Pivotal Greenplum Command Center.
- Support for full text search and text analysis using Pivotal GPText.
- Support for data connectors:
  - Greenplum-Spark Connector
  - Greenplum-Informatica Connector
  - Greenplum-Kafka Integration
  - Gemfire-Greenplum Connector
  - Greenplum Stream Server
- Data Direct ODBC/JDBC Drivers
- `gpcopy` utility for copying or migrating objects between Greenplum systems.
Supported Platforms

Pivotal Greenplum 5.21.0 runs on the following platforms:

- Red Hat Enterprise Linux 64-bit 7.x (See the following Note)
- Red Hat Enterprise Linux 64-bit 6.x (See the following Note)
- SuSE Linux Enterprise Server 64-bit 12 SP2 and SP3 with kernel version greater than 4.4.73-5. (See the following Note)
- SuSE Linux Enterprise Server 64-bit 11 SP4 (See the following Note)
- CentOS 64-bit 7.x
- CentOS 64-bit 6.x (See the following Note)
- Oracle Linux 64-bit 7.4, using the Red Hat Compatible Kernel (RHCK)

**Note:** For the supported Linux operating systems, Pivotal Greenplum Database is supported on system hosts using either AMD or Intel CPUs based on the x86-64 architecture. Pivotal recommends using a homogeneous set of hardware (system hosts) in a Greenplum Database system.

**Important:** Significant Greenplum Database performance degradation has been observed when enabling resource group-based workload management on Red Hat 6.x, CentOS 6.x, and SuSE 11 systems. This issue is caused by a Linux cgroup kernel bug. This kernel bug has been fixed in CentOS 7.x and Red Hat 7.x systems.

If you use Red Hat 6 and the performance with resource groups is acceptable for your use case, upgrade your kernel to version 2.6.32-696 or higher to benefit from other fixes to the cgroups implementation.

SuSE 11 does not have a kernel version that resolves this issue; resource groups are still considered to be a Beta feature on this platform. Resource groups are not supported on SuSE 11 for production use. See known issue 149789783.

Pivotal Greenplum on SuSE 12 supports resource groups for production use. SuSE 12 resolves the Linux cgroup kernel issues that caused the performance degradation when Greenplum Database resource groups are enabled.

**Note:** For Greenplum Database that is installed on Red Hat Enterprise Linux 7.x or CentOS 7.x prior to 7.3, an operating system issue might cause Greenplum Database that is running large workloads to hang in the workload. The Greenplum Database issue is caused by Linux kernel bugs.

RHEL 7.3 and CentOS 7.3 resolves the issue.

**Note:** Greenplum Database on SuSE Linux Enterprise systems does not support these features.

- The PL/Perl procedural language
- The gpmapreduce tool
- The PL/Container language extension
- The Greenplum Platform Extension Framework (PXF)

**Note:** PL/Container is not supported on RHEL/CentOS 6.x systems, because those platforms do not officially support Docker.

Greenplum Database support on Dell EMC DCA.

- Pivotal Greenplum Database 5.21.0 is supported on DCA systems that are running DCA software version 3.4 or greater.
- Only Pivotal Greenplum Database is supported on DCA systems. Open source versions of Greenplum Database are not supported.
- FIPS is supported on DCA software version 3.4 and greater with Pivotal Greenplum Database 5.2.0 and greater.
**Note:** These Greenplum Database releases are not certified on DCA because of an incompatibility in configuring timezone information.

5.5.0, 5.6.0, 5.6.1, 5.7.0, 5.8.0

These Greenplum Database releases are certified on DCA.

5.7.1, 5.8.1, 5.9.0 and later releases, and 5.x releases prior to 5.5.0.

Pivotal Greenplum 5.21.0 supports these Java versions:

- 8.xxx
- 7.xxx

Greenplum Database 5.21.0 software that runs on Linux systems uses OpenSSL 1.0.2l (with FIPS 2.0.16), cURL 7.54, OpenLDAP 2.4.44, and Python 2.7.12.

Greenplum Database client software that runs on Windows and AIX systems uses OpenSSL 0.9.8zg.

The Greenplum Database s3 external table protocol supports these data sources:

- Amazon Simple Storage Service (Amazon S3)
- *Dell EMC Elastic Cloud Storage* (ECS), an Amazon S3 compatible service

Pivotal Greenplum 5.21.0 supports Data Domain Boost on Red Hat Enterprise Linux.

This table lists the versions of Data Domain Boost SDK and DDOS supported by Pivotal Greenplum 5.x.
Table 22: Data Domain Boost Compatibility

</tbody>
</table>

**Note:** In addition to the DDOS versions listed in the previous table, Pivotal Greenplum 5.0.0 and later supports all minor patch releases (fourth digit releases) later than the certified version.

$^1$Support for Data Domain Boost 3.0.0.3 is deprecated. The DELL EMC end of Primary Support date is December 31, 2017.

$^2$The Greenplum Database utilities `gpbackup` and `gprestore` support Data Domain DD Boost File System Plugin (BoostFS) v1.1 with DDOS 6.0 or greater.

The `gpbackup` and `gprestore` utilities support using Dell EMC Data Domain Boost software with the DD Boost Storage Plugin.

**Note:** Pivotal Greenplum 5.21.0 does not support the ODBC driver for Cognos Analytics V11.

Connecting to IBM Cognos software with an ODBC driver is not supported. Greenplum Database supports connecting to IBM Cognos software with the DataDirect JDBC driver for Pivotal Greenplum. This driver is available as a download from Pivotal Network.

**Veritas NetBackup**

Pivotal Greenplum 5.21.0 supports backup with Veritas NetBackup version 7.7.3. See Backing Up Databases with Veritas NetBackup.
Supported Platform Notes

The following notes describe platform support for Pivotal Greenplum. Please send any questions or comments to Pivotal Support at https://support.pivotal.io.

• Pivotal Greenplum is supported using either IPV4 or IPV6 protocols.
• The only file system supported for running Greenplum Database is the XFS file system. All other file systems are explicitly not supported by Pivotal.
• Greenplum Database is supported on network or shared storage if the shared storage is presented as a block device to the servers running Greenplum Database and the XFS file system is mounted on the block device. Network file systems are not supported. When using network or shared storage, Greenplum Database mirroring must be used in the same way as with local storage, and no modifications may be made to the mirroring scheme or the recovery scheme of the segments. Other features of the shared storage such as de-duplication and/or replication are not directly supported by Pivotal Greenplum Database, but may be used with support of the storage vendor as long as they do not interfere with the expected operation of Greenplum Database at the discretion of Pivotal.
• Greenplum Database is supported when running on virtualized systems, as long as the storage is presented as block devices and the XFS file system is mounted for the storage of the segment directories.

Warning: Running Pivotal Greenplum on hyper-converged infrastructure (HCI) has known issues with performance, scalability, and stability and is not recommended as a scalable solution for Pivotal Greenplum and may not be supported by Pivotal if stability problems appear related to the infrastructure. HCI virtualizes all of the elements of conventional hardware systems and includes, at a minimum, virtualized computing, a virtualised SAN, and virtualized networking.

• A minimum of 10-gigabit network is required for a system configuration to be supported by Pivotal.
• Greenplum Database is supported on Amazon Web Services (AWS), Microsoft Azure, and Google Cloud Compute (GCP).
• AWS - For production workloads, r4.8xlarge and r4.16xlarge instance types with four 12TB ST1 EBS volumes for each segment host, or d2.8xlarge with ephemeral storage configured with 4 RAID 0 volumes, are supported. EBS storage is recommended. EBS storage is more reliable and provides more features than ephemeral storage. Note that Amazon has no provisions to replace a bad ephemeral drive; when a disk failure occurs, you must replace the node with the bad disk.

Pivotal recommends using an Auto Scaling Group (ASG) to provision nodes in AWS. An ASG automatically replaces bad nodes, and you can add further automation to recover the Greenplum processes on the new nodes automatically.

Deployments should be in a Placement Group within a single Availability Zone. Because Amazon recommends using the same instance type in a Placement Group, use a single instance type for all nodes, including the masters.
• Azure - For production workloads, Pivotal recommends configuring Standard_H8 instance type with 4 2TB disks and 2 segments per host and recommend using 8 2TB disks and 4 segments per host with Standard_H16 instance type. Standard_H16 uses 8 2TB disks and 4 segments per host. This means software RAID 0 is required so that the number of volumes do not exceed the number of segments.

For Azure deployments, you must also configure the Greenplum Database system to not use port 65330. Add the following line to the sysctl.conf file on all Greenplum Database hosts.

$net.ipv4.ip_local_reserved_ports=65330

• GCP - For all workloads, n1-standard-8 and n1-highmem-8 are supported which are relatively small instance types. This is because of the disk performance in GCP forces the configuration to have just 2 segments per host but with many hosts to scale. Use pd-standard disks and the size of the disk is recommended to be 6 TB. For performance perspective, use a factor of 8 when determining how
many nodes to deploy in GCP, so a 16 segment host cluster in AWS would require 128 nodes in GCP.

- For Red Hat Enterprise Linux 7.2 or CentOS 7.2, the default `systemd` setting `RemoveIPC=yes` removes IPC connections when non-system users logout. This causes the Greenplum Database utility `gpinsystem` to fail with semaphore errors. To avoid this issue, see "Setting the Greenplum Recommended OS Parameters" in the *Greenplum Database Installation Guide*. 
Pivotal Greenplum Tools and Extensions Compatibility

- **Client Tools**
- **Extensions**
- **Pivotal Greenplum Data Connectors**
- **Pivotal GPText Compatibility**
- **Pivotal Greenplum Command Center**

**Client Tools**

Greenplum releases a number of client tool packages on various platforms that can be used to connect to Greenplum Database and the Greenplum Command Center management tool. The following table describes the compatibility of these packages with this Greenplum Database release.

Tool packages are available from *Pivotal Network*.

**Table 23: Pivotal Greenplum 5.21.0 Tools Compatibility**

- Red Hat Enterprise Linux x86_64 7.x (RHEL 7)
- Red Hat Enterprise Linux x86_64 6.x (RHEL 6)
- SuSE Linux Enterprise Server x86_64 SLES 11 SP4, or SLES 12 SP2/SP3
- Windows 10 (32-bit and 64-bit)
- Windows 8 (32-bit and 64-bit)
- Windows Server 2012 (32-bit and 64-bit)
- Windows Server 2012 R2 (32-bit and 64-bit)
- Windows Server 2008 R2 (32-bit and 64-bit)

**Note:** \(^1\)For Pivotal Greenplum Command Center 4.0.0 and later, workload management is an integrated Command Center feature rather than the separate tool Pivotal Greenplum Workload Manager.

\(^2\)For Pivotal Greenplum Command Center 4.0.0 and later, workload management is an integrated Command Center feature rather than the separate tool Pivotal Greenplum Workload Manager.
For Greenplum Database 5.4.1 and earlier 5.x releases, download the AIX Client and Load Tools package either from the Greenplum Database 5.11.1 file collection or the Greenplum Database 5.0.0 file collection on Pivotal Network.

## Extensions

### Table 24: Pivotal Greenplum 5.21.0 Extensions Compatibility

<table>
<thead>
<tr>
<th>Pivotal Greenplum Extension</th>
<th>Versions</th>
</tr>
</thead>
<tbody>
<tr>
<td>MADlib machine learning for Greenplum Database 5.x</td>
<td>MADlib 1.16, 1.15.1, 1.15, 1.14</td>
</tr>
<tr>
<td>PL/Java for Greenplum Database 5.x</td>
<td>PL/Java 1.4.3²</td>
</tr>
<tr>
<td>PL/R for Greenplum Database 5.x</td>
<td>2.3.3</td>
</tr>
<tr>
<td>PostGIS Spatial and Geographic Objects for Greenplum Database 5.x</td>
<td>2.1.5+pivotal.2</td>
</tr>
<tr>
<td>Python Data Science Module Package for Greenplum Database 5.x</td>
<td>1.1.1, 1.1.0, 1.0.0</td>
</tr>
<tr>
<td>R Data Science Library Package for Greenplum Database 5.x</td>
<td>1.0.1, 1.0.0</td>
</tr>
<tr>
<td>PL/Container for Greenplum Database 5.x</td>
<td>1.1⁵, 1.2⁶, 1.3, 1.4</td>
</tr>
</tbody>
</table>

**Note:**

1. Pivotal recommends that you upgrade to the most recent version of MADlib. For information about MADlib support and upgrade information, see the [MADlib FAQ](#). For information on installing the MADlib extension in Greenplum Database, see [Greenplum MADlib Extension for Analytics](#) in the [Greenplum Database Reference Guide](#).

2. The PL/Java extension package version 1.4.3 is compatible only with Greenplum Database 5.11.0 and later, it is not compatible with 5.10.x or earlier. If you are upgrading from Greenplum Database 5.10.x or earlier and have installed PL/Java 1.4.2, you must upgrade the PL/Java extension to version 1.4.3.

3. For information about the Python package, including the modules provided, see the [Python Data Science Module Package](#) in the [Greenplum Database Documentation](#).

4. For information about the R package, including the libraries provided, see the [R Data Science Library Package](#) in the [Greenplum Database Documentation](#).

5. To upgrade from PL/Container 1.0 to PL/Container 1.1 and later, you must drop the PL/Container 1.0 language before registering the new version of PL/Container. For information on upgrading the PL/Container extension in Greenplum Database, see [PL/Container Language Extension](#) in the [Greenplum Database Reference Guide](#).

6. PL/Container version 1.2 can utilize the resource group capabilities that were introduced in Greenplum Database 5.8.0. If you downgrade to a Greenplum Database system that uses PL/Container 1.1 or earlier, you must use `plcontainer runtime-edit` to remove any `resource_group_id` settings from the PL/Container runtime configuration file. See [Upgrading from PL/Container 1.1](#).

These Greenplum Database extensions are installed with Pivotal Greenplum Database

- Fuzzy String Match Extension
- PL/Python Extension
- pgcrypto Extension
**Pivotal Greenplum Data Connectors**

- Greenplum Platform Extension Framework (PXF) - PXF, integrated with Greenplum Database, provides access to HDFS, Hive, HBase, and SQL external data stores. Refer to Accessing External Data with PXF in the Greenplum Database Administrator Guide for PXF configuration and usage information.
  
  **Note:** PXF is available only for supported Red Hat and CentOS platforms. PXF is not available for supported SuSE platforms.

- Greenplum-Spark Connector - The Pivotal Greenplum-Spark Connector supports high speed, parallel data transfer from Greenplum Database to an Apache Spark cluster. The Greenplum-Spark Connector is available as a separate download from Pivotal Network. Refer to the Greenplum-Spark Connector documentation for compatibility and usage information.

- Greenplum-Informatica Connector - The Pivotal Greenplum-Informatica connector supports high speed data transfer from an Informatica PowerCenter cluster to a Pivotal Greenplum Database cluster for batch and streaming ETL operations. See the Pivotal Greenplum-Informatica Connector Documentation.

- Greenplum-Kafka Integration - The Pivotal Greenplum-Kafka Integration provides high speed, parallel data transfer from a Kafka cluster to a Pivotal Greenplum Database cluster for batch and streaming ETL operations. Refer to the Pivotal Greenplum-Kafka Integration Documentation for more information about this feature.

- Greenplum Stream Server - The Pivotal Greenplum Stream Server is an ETL tool that provides high speed, parallel data transfer from Informatica, Kafka, and custom client data sources to a Pivotal Greenplum Database cluster. Refer to the Performing ETL Operations with the Pivotal Greenplum Stream Server Documentation for more information about this feature.

- Gemfire-Greenplum Connector - The Pivotal Gemfire-Greenplum Connector supports the transfer of data between a GemFire region and a Greenplum Database cluster. The Gemfire-Greenplum Connector is available as a separate download from Pivotal Network. Refer to the Gemfire-Greenplum Connector documentation for compatibility and usage information.

**Pivotal GPText Compatibility**

Pivotal Greenplum Database 5.21.0 is compatible with Pivotal GPText version 2.1.3 and later.

**Pivotal Greenplum Command Center**

See the Greenplum Command Center documentation for GPCC and Greenplum Workload Manager compatibility information, see the Pivotal Greenplum Command Center 3.x and 2.x Release Notes.

**Note:** For Pivotal Greenplum Command Center 4.0.0 and later, workload management is an integrated Command Center feature rather than the separate tool Pivotal Greenplum Workload Manager.
Hadoop Distribution Compatibility

Greenplum Database provides access to HDFS with `gphdfs` and the Greenplum Platform Extension Framework (PXF).

**PXF Hadoop Distribution Compatibility**

PXF supports the Cloudera, Hortonworks Data Platform, MapR, and generic Apache Hadoop distributions.

If you plan to access JSON format data stored in a Cloudera Hadoop cluster, PXF requires a Cloudera version 5.8 or later Hadoop distribution.

**gphdfs Hadoop Distribution Compatibility**

The supported Hadoop distributions for `gphdfs` are listed below:

<table>
<thead>
<tr>
<th>Hadoop Distribution</th>
<th>Version</th>
<th>gp_hadoop_target_version</th>
</tr>
</thead>
<tbody>
<tr>
<td>Cloudera</td>
<td>CDH 5.x</td>
<td>cdh</td>
</tr>
<tr>
<td>Hortonworks Data Platform</td>
<td>HDP 2.x</td>
<td>hdp</td>
</tr>
<tr>
<td>MapR</td>
<td>MapR 4.x, MapR 5.x</td>
<td>mpr</td>
</tr>
<tr>
<td>Apache Hadoop</td>
<td>2.x</td>
<td>hadoop</td>
</tr>
</tbody>
</table>

**Note:** MapR requires the MapR client.
Upgrading to Greenplum Database 5.21.0

The upgrade path supported for this release is Greenplum Database 5.x to Greenplum Database 5.21.0. Upgrading a Greenplum Database 4.3.x release to Pivotal Greenplum 5.x is not supported. See Migrating Data to Pivotal Greenplum 5.x.

Note: If you are upgrading Greenplum Database on a DCA system, see Pivotal Greenplum on DCA Systems.

Important: Pivotal recommends that customers set the Greenplum Database timezone to a value that is compatible with their host systems. Setting the Greenplum Database timezone prevents Greenplum Database from selecting a timezone each time the cluster is restarted and sets the timezone for the Greenplum Database master and segment instances. After you upgrade to this release and if you have not set a Greenplum Database timezone value, verify that the selected Greenplum Database timezone is acceptable for your deployment. See Configuring Timezone and Localization Settings for more information.

Prerequisites

Before starting the upgrade process, Pivotal recommends performing the following checks.

- Verify the health of the Greenplum Database host hardware, and that you verify that the hosts meet the requirements for running Greenplum Database. The Greenplum Database gpcheckperf utility can assist you in confirming the host requirements.

  Note: If you need to run the gpcheckcat utility, Pivotal recommends running it a few weeks before the upgrade and that you run gpcheckcat during a maintenance period. If necessary, you can resolve any issues found by the utility before the scheduled upgrade.

The utility is in $GPHOME/bin. Pivotal recommends that Greenplum Database be in restricted mode when you run gpcheckcat utility. See the Greenplum Database Utility Guide for information about the gpcheckcat utility.

If gpcheckcat reports catalog inconsistencies, you can run gpcheckcat with the \( \text{-g} \) option to generate SQL scripts to fix the inconsistencies.

After you run the SQL scripts, run gpcheckcat again. You might need to repeat the process of running gpcheckcat and creating SQL scripts to ensure that there are no inconsistencies. Pivotal recommends that the SQL scripts generated by gpcheckcat be run on a quiescent system. The utility might report false alerts if there is activity on the system.

Important: If the gpcheckcat utility reports errors, but does not generate a SQL script to fix the errors, contact Pivotal support. Information for contacting Pivotal Support is at https://support.pivotal.io.

- During the migration process from Greenplum Database 5.0.0, a backup is made of some files and directories in $MASTER_DATA_DIRECTORY. Pivotal recommends that files and directories that are not used by Greenplum Database be backed up, if necessary, and removed from the $MASTER_DATA_DIRECTORY before migration. For information about the Greenplum Database migration utilities, see the Greenplum Database Documentation.

For information about supported versions of Greenplum Database extensions, see Pivotal Greenplum Tools and Extensions Compatibility.

If you are utilizing Data Domain Boost, you have to re-enter your DD Boost credentials after upgrading to Greenplum Database 5.21.0 as follows:

```
gpcrondump --ddboost-host ddboost_hostname --ddboost-user ddboost_user --ddboost-backupdir backup_directory
```
**Note:** If you do not reenter your login credentials after an upgrade, your backup will never start because the Greenplum Database cannot connect to the Data Domain system. You will receive an error advising you to check your login credentials.

If you have configured the Greenplum Platform Extension Framework (PXF) in your previous Greenplum Database installation, you must stop the PXF service, and you might need to back up PXF configuration files before upgrading to a new version of Greenplum Database. Refer to *PXF Pre-Upgrade Actions* for instructions.

If you do not plan to use PXF, or you have not yet configured PXF, no action is necessary.

---

**Upgrading from 5.x to 5.21.0**

An upgrade from 5.x to 5.21.0 involves stopping Greenplum Database, updating the Greenplum Database software binaries, upgrading and restarting Greenplum Database. If you are using Greenplum Database extension packages there are additional requirements. See *Prerequisites* in the previous section.

**Note:** If you are upgrading from Greenplum Database 5.10.x or earlier and have installed the PL/Java extension, you must upgrade the PL/Java extension to extension package version 1.4.3. Previous releases of the PL/Java extension are not compatible with Greenplum Database 5.11.0 and later. For information about the PL/Java extension package, see *Pivotal Greenplum Tools and Extensions Compatibility*.

**Note:** If you have databases that were created with Greenplum Database 5.10.x or an earlier 5.x release, upgrade the `gp_bloat_expected_pages` view in the `gp_toolkit` schema. For information about the issue and how check a database for the issue, see *Update for gp_toolkit.gp_bloat_expected_pages Issue*.

**Note:** If you are upgrading from Greenplum Database 5.7.0 or an earlier 5.x release and have configured PgBouncer in your Greenplum Database installation, you must migrate to the new PgBouncer when you upgrade Greenplum Database. Refer to *Migrating PgBouncer* for specific migration instructions.

**Note:** If you have databases that were created with Greenplum Database 5.3.0 or an earlier 5.x release, upgrade the `gp_bloat_diag` function and view in the `gp_toolkit` schema. For information about the issue and how check a database for the issue, see *Update for gp_toolkit.gp_bloat_diag Issue*.

**Note:** If the Greenplum Command Center database `gpperfmon` is installed in your Greenplum Database system, the migration process changes the distribution key of the Greenplum Database `log_alert_*` tables to the `logtime` column. The redistribution of the table data might take some time the first time you start Greenplum Database after migration. The change occurs only the first time you start Greenplum Database after a migration.

---

1. Log in to your Greenplum Database master host as the Greenplum administrative user:

   ```
   $ su - gpadmin
   ```

2. Perform a smart shutdown of your current Greenplum Database 5.x system (there can be no active connections to the database). This example uses the `-a` option to disable confirmation prompts:

   ```
   $ gpstop -a
   ```

3. Run the binary installer for 5.21.0 on the Greenplum Database master host.

   When prompted, choose an installation location in the same base directory as your current installation. For example:

   ```
   /usr/local/greenplum-db-5.21.0
   ```

   If you install Greenplum Database with the rpm (as root), the installation directory is `/usr/local/greenplum-db-5.21.0`. 

For the rpm installation, update the permissions for the new installation. For example, run this command as root to change user and group of the installed files to gpadmin.

```bash
# chown -R gpadmin:gpadmin /usr/local/greenplum*
```

4. If needed, update the `greenplum_path.sh` file for use with your specific installation. These are some examples.

   - If Greenplum Database uses LDAP authentication, edit the `greenplum_path.sh` file to add the line:

     ```bash
     export LDAPCONF=/etc/openldap/ldap.conf
     ```

   - If Greenplum Database uses PL/Java, you might need to set or update the environment variables `JAVA_HOME` and `LD_LIBRARY_PATH` in `greenplum_path.sh`.

     **Note:** When comparing the previous and new `greenplum_path.sh` files, be aware that installing some Greenplum Database extensions also updates the `greenplum_path.sh` file. The `greenplum_path.sh` from the previous release might contain updates that were the result of those extensions. See step 9 for installing Greenplum Database extensions.

5. Edit the environment of the Greenplum Database superuser (`gpadmin`) and make sure you are sourcing the `greenplum_path.sh` file for the new installation. For example change the following line in `.bashrc` or your chosen profile file:

```bash
source /usr/local/greenplum-db-5.0.0/greenplum_path.sh
```

   to:

   ```bash
   source /usr/local/greenplum-db-5.21.0/greenplum_path.sh
   ```

   Or if you are sourcing a symbolic link (`/usr/local/greenplum-db`) in your profile files, update the link to point to the newly installed version. For example:

   ```bash
   $ rm /usr/local/greenplum-db
   $ ln -s /usr/local/greenplum-db-5.21.0 /usr/local/greenplum-db
   ```

6. Source the environment file you just edited. For example:

   ```bash
   $ source ~/.bashrc
   ```

7. Run the `gpseginstall` utility to install the 5.21.0 binaries on all the segment hosts specified in the `hostfile`. For example:

   ```bash
   $ gpseginstall -f hostfile
   ```

     **Note:** The `gpseginstall` utility copies the installed files from the current host to the remote hosts. It does not use `rpm` to install Greenplum Database on the remote hosts, even if you used `rpm` to install Greenplum Database on the current host.

8. Use the Greenplum Database `gppkg` utility to install Greenplum Database extensions. If you were previously using any Greenplum Database extensions such as pgcrypto, PL/R, PL/Java, PL/Perl, and PostGIS, download the corresponding packages from Pivotal Network, and install using this utility. See the Greenplum Database Documentation for `gppkg` usage details.

   Also copy any additional files that are used by the extensions (such as JAR files, shared object files, and libraries) from the previous version installation directory to the new version installation directory on the master and segment host systems.

9. If you are upgrading from Greenplum Database 5.7 or an earlier 5.x release and have configured PgBouncer in your Greenplum Database installation, you must migrate to the new PgBouncer when you upgrade Greenplum Database. Refer to Migrating PgBouncer for specific migration instructions.
10. After all segment hosts have been upgraded, you can log in as the gpadmin user and restart your Greenplum Database system:

```bash
# su - gpadmin
$ gpstart
```

11. If you are utilizing Data Domain Boost, you have to re-enter your DD Boost credentials after upgrading from Greenplum Database to 5.21.0 as follows:

```bash
gpcrondump --ddboost-host ddboost_hostname --ddboost-user ddboost_user --ddboost-backupdir backup_directory
```

**Note:** If you do not reenter your login credentials after an upgrade, your backup will never start because the Greenplum Database cannot connect to the Data Domain system. You will receive an error advising you to check your login credentials.

12. If you configured PXF in your previous Greenplum Database installation, you must re-initialize the PXF service after you upgrade Greenplum Database. Refer to Upgrading PXF for instructions.

After upgrading Greenplum Database, ensure features work as expected. For example, you should test that backup and restore perform as expected, and Greenplum Database features such as user-defined functions, and extensions such as MADlib and PostGIS perform as expected.

---

**Troubleshooting a Failed Upgrade**

If you experience issues during the migration process and have active entitlements for Greenplum Database that were purchased through Pivotal, contact Pivotal Support. Information for contacting Pivotal Support is at [https://support.pivotal.io](https://support.pivotal.io).

Be prepared to provide the following information:

- A completed Upgrade Procedure.
- Log output from gpcheckcat (located in ~/gpAdminLogs)
Migrating Data to Pivotal Greenplum 5.x

Upgrading a Pivotal Greenplum Database 4.x system directly to Pivotal Greenplum Database 5.x is not supported.

You can migrate existing data to Greenplum Database 5.x using standard backup and restore procedures (gpcrondump and gpdbrestore) or by using gptransfer. The gcopy utility can be used to migrate data from Greenplum Database 4.3.26 or later to 5.9 or later.

Follow these general guidelines for migrating data:

- Make sure that you have a complete backup of all data in the Greenplum Database 4.3.x cluster, and that you can successfully restore the Greenplum Database 4.3.x cluster if necessary.
- You must install and initialize a new Greenplum Database 5.x cluster using the version 5.x gpinit system utility.

**Note:** Unless you modify file locations manually, gpdbrestore only supports restoring data to a cluster that has an identical number of hosts and an identical number of segments per host, with each segment having the same content_id as the segment in the original cluster. If you initialize the Greenplum Database 5.x cluster using a configuration that is different from the version 4.3 cluster, then follow the steps outlined in *Restoring to a Different Greenplum System Configuration* to manually update the file locations.

**Important:** For Greenplum Database 5.x, Pivotal recommends that customers set the Greenplum Database timezone to a value that is compatible with the host systems. Setting the Greenplum Database timezone prevents Greenplum Database from selecting a timezone each time the cluster is restarted and sets the timezone for the Greenplum Database master and segment instances. See *Configuring Timezone and Localization Settings* for more information.

- If you intend to install Greenplum Database 5.x on the same hardware as your 4.3.x system, you will need enough disk space to accommodate over 5 times the original data set (2 full copies of the primary and mirror data sets, plus the original backup data in ASCII format) in order to migrate data with gpcrondump and gpdbrestore. Keep in mind that the ASCII backup data will require more disk space than the original data, which may be stored in compressed binary format. Offline backup solutions such as Dell EMC Data Domain or Veritas NetBackup can reduce the required disk space on each host.

If you attempt to migrate your data on the same hardware but run out of free space, gcopy provides the --truncate-source-after option to truncate each source table after copying the table to the destination cluster and validating the copy succeeded. This reduces the amount of free space needed to migrate clusters that reside on the same hardware. See *Migrating Data with gcopy* for more information.

- Use the version 5.x gpdbrestore utility to load the 4.3.x backup data into the new cluster.
- If the Greenplum Database 5.x cluster resides on separate hardware from the 4.3.x cluster, and the clusters have different numbers of segments, you can optionally use the version 5.x gptransfer utility to migrate the 4.3.x data. You must initiate the gptransfer operation from the version 5.x cluster, pulling the older data into the newer system.

On a Greenplum Database system with FIPS enabled, validating table data with MD5 (specifying the gptransfer option --validate-md5) is not available. Use the option sha256 to validate table data.

Validating table data with SHA-256 (specifying the option --validate=sha256) requires the Greenplum Database pgcrypto extension. The extension is included with Pivotal Greenplum 5.x. The extension package must be installed on supported Pivotal Greenplum 4.3.x systems. Support for pgcrypto functions in a Greenplum 4.3.x database is not required.

- Greenplum Database 5.x removes automatic implicit casts between the text type and other data types. After you migrate from Greenplum Database version 4.3.x to version 5.x, this change in behavior may impact existing applications and queries. Refer to *About Implicit Text Casting in Greenplum Database* in...
the Greenplum Database Installation Guide for information, including a discussion about supported and unsupported workarounds.

- After migrating data you may need to modify SQL scripts, administration scripts, and user-defined functions as necessary to account for changes in Greenplum Database version 5.x. Look for Upgrade Action Required entries in the Pivotal Greenplum 5.0.0 Release Notes for features that may necessitate post-migration tasks.

- If you are migrating from Greenplum Database 4.3.27 or an earlier 4.3.x release and have configured PgBouncer in your Greenplum Database installation, you must migrate to the new PgBouncer when you upgrade Greenplum Database. Refer to Migrating PgBouncer for specific migration instructions.
Pivotal Greenplum on DCA Systems

On supported Dell EMC DCA systems, you can install Pivotal Greenplum 5.21.0, or you can upgrade from Pivotal Greenplum 5.x to 5.21.0.

Only Pivotal Greenplum Database is supported on DCA systems. Open source versions of Greenplum Database are not supported.

- Installing the Pivotal Greenplum 5.21.0 Software Binaries on DCA Systems
- Upgrading from 5.x to 5.21.0 on DCA Systems

**Important:** Upgrading Pivotal Greenplum Database 4.3.x to Pivotal Greenplum 5.21.0 is not supported. See Migrating Data to Pivotal Greenplum 5.x.

**Note:** These Greenplum Database releases are not certified on DCA because of an incompatibility in configuring timezone information.

- 5.5.0, 5.6.0, 5.6.1, 5.7.0, 5.8.0
- 5.7.1, 5.8.1, 5.9.0 and later releases, and 5.x releases prior to 5.5.0.

**Installing the Pivotal Greenplum 5.21.0 Software Binaries on DCA Systems**

**Important:** This section is for installing Pivotal Greenplum 5.21.0 only on DCA systems. Also, see the information on the DELL EMC support site (requires login).

For information about installing Pivotal Greenplum on non-DCA systems, see the Greenplum Database Installation Guide.

**Prerequisites**

- Ensure your DCA system supports Pivotal Greenplum 5.21.0. See Supported Platforms.
- Ensure Greenplum Database 4.3.x is not installed on your system.

Installing Pivotal Greenplum 5.21.0 on a DCA system with an existing Greenplum Database 4.3.x installation is not supported. For information about uninstalling Greenplum Database software, see your Dell EMC DCA documentation.

**Installing Pivotal Greenplum 5.21.0**

1. Download or copy the Greenplum Database DCA installer file `greenplum-db-appliance-5.21.0-RHEL6-x86_64.bin` to the Greenplum Database master host.
2. As root, run the DCA installer for 5.21.0 on the Greenplum Database master host and specify the file `hostfile` that lists all hosts in the cluster, one host name per line. If necessary, copy `hostfile` to the directory containing the installer before running the installer.

   This example command runs the installer for Greenplum Database 5.21.0.

   ```
   # ./greenplum-db-appliance-5.21.0-RHEL6-x86_64.bin hostfile
   ```

**Upgrading from 5.x to 5.21.0 on DCA Systems**

Upgrading Pivotal Greenplum from 5.x to 5.21.0 on a Dell EMC DCA system involves stopping Greenplum Database, updating the Greenplum Database software binaries, and restarting Greenplum Database.
**Important:** This section is only for upgrading to Pivotal Greenplum 5.21.0 on DCA systems. For information about upgrading on non-DCA systems, see *Upgrading to Greenplum Database 5.21.0*.

**Note:** If you are upgrading from Greenplum Database 5.10.x or earlier and have installed the PL/Java extension, you must upgrade the PL/Java extension to extension package version 1.4.3. Previous releases of the PL/Java extension are not compatible with Greenplum Database 5.11.0 and later. For information about the PL/Java extension package, see *Pivotal Greenplum Tools and Extensions Compatibility*.

**Note:** If you have databases that were created with Greenplum Database 5.10.x or an earlier 5.x release, upgrade the `gp_bloat_expected_pages` view in the `gp_toolkit` schema. For information about the issue and how check a database for the issue, see *Update for gp_toolkit.gp_bloat_expected_pages Issue*.

**Note:** If you are upgrading from Greenplum Database 5.7.0 or an earlier 5.x release and have configured PgBouncer in your Greenplum Database installation, you must migrate to the new PgBouncer when you upgrade Greenplum Database. Refer to *Migrating PgBouncer* for specific migration instructions.

**Note:** If you have databases that were created with Greenplum Database 5.3.0 or an earlier 5.x release, upgrade the `gp_bloat_diag` function and view in the `gp_toolkit` schema. For information about the issue and how check a database for the issue, see *Update for gp_toolkit.gp_bloat_diag Issue*.

1. Log in to your Greenplum Database master host as the Greenplum administrative user (`gpadmin`):

   ```bash
   # su - gpadmin
   ``

2. Download or copy the installer file `greenplum-db-appliance-5.21.0-RHEL6-x86_64.bin` to the Greenplum Database master host.

3. Perform a smart shutdown of your current Greenplum Database 5.x system (there can be no active connections to the database). This example uses the `-a` option to disable confirmation prompts:

   ```bash
   $ gpstop -a
   ``

4. As root, run the Greenplum Database DCA installer for 5.21.0 on the Greenplum Database master host and specify the file `hostfile` that lists all hosts in the cluster. If necessary, copy `hostfile` to the directory containing the installer before running the installer.

   This example command runs the installer for Greenplum Database 5.21.0 for Red Hat Enterprise Linux 6.x.

   ```bash
   # ./greenplum-db-appliance-5.21.0-RHEL6-x86_64.bin hostfile
   ``

   The file `hostfile` is a text file that lists all hosts in the cluster, one host name per line.

5. If needed, update the `greenplum_path.sh` file for use with your specific installation. These are some examples.

   - If Greenplum Database uses LDAP authentication, edit the `greenplum_path.sh` file to add the line:

     ```bash
     export LDAPCONF=/etc/openldap/ldap.conf
     ```

   - If Greenplum Database uses PL/Java, you might need to set or update the environment variables `JAVA_HOME` and `LD_LIBRARY_PATH` in `greenplum_path.sh`.

     **Note:** When comparing the previous and new `greenplum_path.sh` files, be aware that installing some Greenplum Database extensions also updates the `greenplum_path.sh` file. The `greenplum_path.sh` from the previous release might contain updates that were the result of those extensions. See step 6 for installing Greenplum Database extensions.
6. Install Greenplum Database extension packages. For information about installing a Greenplum Database extension package, see gppkg in the Greenplum Database Utility Guide.

   Also migrate any additional files that are used by the extensions (such as JAR files, shared object files, and libraries) from the previous version installation directory to the new version installation directory.

7. After all segment hosts have been upgraded, you can log in as the gpadmin user and restart your Greenplum Database system:

   # su - gpadmin
   $ gpstart

8. If you are utilizing Data Domain Boost, you have to re-enter your DD Boost credentials after upgrading to Greenplum Database 5.21.0 as follows:

   gpcrondump --ddboost-host ddboost_hostname --ddboost-user ddboost_user
              --ddboost-backupdir backup_directory

   **Note:** If you do not reenter your login credentials after an upgrade, your backup will never start because the Greenplum Database cannot connect to the Data Domain system. You will receive an error advising you to check your login credentials.

After upgrading Greenplum Database, ensure features work as expected. For example, you should test that backup and restore perform as expected, and Greenplum Database features such as user-defined functions, and extensions such as MADlib and PostGIS perform as expected.
Update for gp_toolkit.gp_bloat_expected_pages Issue

In Greenplum Database 5.10.x and earlier 5.x releases, the Greenplum Database view gp_toolkit.gp_bloat_expected_pages view might incorrectly report that a root partition table is bloated even though root partition tables do not contain data. This information could cause a user to run a VACUUM FULL operation on the partitioned table when the operation was not required. The issue was resolved in Greenplum Database 5.11.0 (resolved issue 29523).

When updating Greenplum Database, the gp_toolkit.gp_bloat_expected_pages view must be updated in databases created with a Greenplum Database 5.10.x or an earlier 5.x release. This issue has been fixed in databases created with Greenplum Database 5.11.0 and later. For information about using template0 as the template database after upgrading from Greenplum Database 5.10.x or an earlier 5.x release, see known issue 29523.

To check whether the gp_toolkit.gp_bloat_expected_pages view in a database requires an update, run the psql command \d+ to display the view definition.

\d+ gp_toolkit.gp_bloat_expected_pages

The updated view definition contains this predicate.

AND NOT EXISTS
( SELECT parrelid
  FROM pg_partition
  WHERE parrelid = pgc.oid )

Perform the following steps as the gpadmin user to update the view on each database that was created with Greenplum Database 5.11.0 or an earlier 5.x release.

1. Copy the script into a text file on the Greenplum Database master.
2. Run the script on each database that requires the update.

   This example updates gp_toolkit.gp_bloat_expected_pages view in the database mytest and assumes that the script is in the gp_bloat_expected_pages in the gpadmin home directory.

   psql -f /home/gpadmin/gp_bloat_expected_pages.sql -d mytest

Run the script during a low activity period. Running the script during a high activity period does not affect database functionality but might affect performance.

Script to Update gp_toolkit.gp_bloat_expected_pages View

BEGIN;
CREATE OR REPLACE VIEW gp_toolkit.gp_bloat_expected_pages
AS
SELECT
  btdrelid,
  btdrelpages,
  CASE WHEN btdexppages < numsegments
       THEN numsegments
       ELSE btdexppages
  END as btdexppages
FROM
  ( SELECT
      oid as btdrelid,
      pgc.relpages as btdrelpages,
      CEIL((pgc.reltuples * (25 + width))::numeric / current_setting('block_size')::numeric) AS btdexppages,
      ... )
(SELECT numsegments FROM gp_toolkit.__gp_number_of_segments) AS numsegments
FROM
( SELECT pgc.oid, pgc.reltuples, pgc.relpages
FROM pg_class pgc
WHERE NOT EXISTS
( SELECT iaoid
  FROM gp_toolkit.__gp_is_append_only
  WHERE iaoid = pgc.oid AND iaotype = 't' )
AND NOT EXISTS
( SELECT parrelid
  FROM pg_partition
  WHERE parrelid = pgc.oid ) ) AS pgc
LEFT OUTER JOIN
( SELECT starelid, SUM(stawidth * (1.0 - stanullfrac)) AS width
  FROM pg_statistic pgs
  GROUP BY 1 ) AS btwcols
ON pgc.oid = btwcols.starelid
WHERE starelid IS NOT NULL) AS subq;

GRANT SELECT ON TABLE gp_toolkit.gp_bloat_expected_pages TO public;
COMMIT;
Update for gp_toolkit.gp_bloat_diag Issue

In Greenplum Database 5.3.0 or an earlier 5.x release, Greenplum Database returned an integer out of range error in some cases when performing a query against the gp_toolkit.gp_bloat_diag view. The issue was resolved in Greenplum Database 5.4.0 (resolved issue 26518).

When updating Greenplum Database, the gp_toolkit.gp_bloat_diag function and view must be updated in databases created with a Greenplum Database 5.3.0 or an earlier 5.x release. This issue has been fixed in databases created with Greenplum Database 5.4.0 and later. For information about upgrading from Greenplum Database 5.3.0 or an earlier 5.x release and then using template0 as the template database, see known issue 29523.

To check whether the gp_toolkit.gp_bloat_diag function and view in a database requires an update, run the psql command \df to display information about the gp_toolkit.gp_bloat_diag function.

\df gp_toolkit.gp_bloat_diag

If the data type for btdexppages is integer, an update is required. If the data type is numeric an update is not required. In this example, the btdexppages data type is integer and requires an update.

<table>

Chapter 6

Greenplum Database Installation Guide

Information about installing and configuring Greenplum Database software and configuring Greenplum Database host machines.
**Introduction to Greenplum**

High-level overview of the Greenplum Database system architecture.

Greenplum Database stores and processes large amounts of data by distributing the load across several servers or hosts. A logical database in Greenplum is an array of individual PostgreSQL databases working together to present a single database image. The master is the entry point to the Greenplum Database system. It is the database instance to which users connect and submit SQL statements. The master coordinates the workload across the other database instances in the system, called segments, which handle data processing and storage. The segments communicate with each other and the master over the interconnect, the networking layer of Greenplum Database.

Greenplum Database is a software-only solution; the hardware and database software are not coupled. Greenplum Database runs on a variety of commodity server platforms from Greenplum-certified hardware vendors. Performance depends on the hardware on which it is installed. Because the database is distributed across multiple machines in a Greenplum Database system, proper selection and configuration of hardware is vital to achieving the best possible performance.

This chapter describes the major components of a Greenplum Database system and the hardware considerations and concepts associated with each component: The Greenplum Master, The Segments and The Interconnect. Additionally, a system may have optional ETL Hosts for Data Loading and Greenplum Performance Monitoring for monitoring query workload and performance.

**The Greenplum Master**

The master is the entry point to the Greenplum Database system. It is the database server process that accepts client connections and processes the SQL commands that system users issue. Users connect to Greenplum Database through the master using a PostgreSQL-compatible client program such as psql or ODBC.

The master maintains the system catalog (a set of system tables that contain metadata about the Greenplum Database system itself), however the master does not contain any user data. Data resides only on the segments. The master authenticates client connections, processes incoming SQL commands, distributes the work load between segments, coordinates the results returned by each segment, and presents the final results to the client program.

Because the master does not contain any user data, it has very little disk load. The master needs a fast, dedicated CPU for data loading, connection handling, and query planning because extra space is often necessary for landing load files and backup files, especially in production environments. Customers may decide to also run ETL and reporting tools on the master, which requires more disk space and processing power.

**Master Redundancy**

You may optionally deploy a backup or mirror of the master instance. A backup master host serves as a warm standby if the primary master host becomes nonoperational. You can deploy the standby master on a designated redundant master host or on one of the segment hosts.

The standby master is kept up to date by a transaction log replication process, which runs on the standby master host and synchronizes the data between the primary and standby master hosts. If the primary master fails, the log replication process shuts down, and an administrator can activate the standby master in its place. When an the standby master is active, the replicated logs are used to reconstruct the state of the master host at the time of the last successfully committed transaction.
Since the master does not contain any user data, only the system catalog tables need to be synchronized between the primary and backup copies. When these tables are updated, changes automatically copy over to the standby master so it is always synchronized with the primary.

Figure 1: Master Mirroring in Greenplum Database

The Segments

In Greenplum Database, the segments are where data is stored and where most query processing occurs. User-defined tables and their indexes are distributed across the available segments in the Greenplum Database system; each segment contains a distinct portion of the data. Segment instances are the database server processes that serve segments. Users do not interact directly with the segments in a Greenplum Database system, but do so through the master.

In the reference Greenplum Database hardware configurations, the number of segment instances per segment host is determined by the number of effective CPUs or CPU core. For example, if your segment hosts have two dual-core processors, you may have two or four primary segments per host. If your segment hosts have three quad-core processors, you may have three, six or twelve segments per host. Performance testing will help decide the best number of segments for a chosen hardware platform.

Segment Redundancy

When you deploy your Greenplum Database system, you have the option to configure mirror segments. Mirror segments allow database queries to fail over to a backup segment if the primary segment becomes unavailable. Mirroring is a requirement for Pivotal-supported production Greenplum Database systems.

A mirror segment must always reside on a different host than its primary segment. Mirror segments can be arranged across the hosts in the system in one of two standard configurations, or in a custom configuration you design. The default configuration, called group mirroring, places the mirror segments for all primary segments on a host on one other host. Another option, called spread mirroring, spreads mirrors for each host's primary segments over the remaining hosts. Spread mirroring requires that there be more hosts in the system than there are primary segments on the host. On hosts with multiple network interfaces, the primary and mirror segments are distributed equally among the interfaces. Figure 2: Data Mirroring in Greenplum Database shows how table data is distributed across the segments when the default group mirroring option is configured.

Figure 2: Data Mirroring in Greenplum Database

Segment Failover and Recovery

When mirroring is enabled in a Greenplum Database system, the system automatically fails over to the mirror copy if a primary copy becomes unavailable. A Greenplum Database system can remain operational if a segment instance or host goes down only if all portions of data are available on the remaining active segments.

If the master cannot connect to a segment instance, it marks that segment instance as invalid in the Greenplum Database system catalog. The segment instance remains invalid and out of operation until an administrator brings that segment back online. An administrator can recover a failed segment while the system is up and running. The recovery process copies over only the changes that were missed while the segment was nonoperational.

If you do not have mirroring enabled and a segment becomes invalid, the system automatically shuts down. An administrator must recover all failed segments before operations can continue.
Example Segment Host Hardware Stack

Regardless of the hardware platform you choose, a production Greenplum Database processing node (a segment host) is typically configured as described in this section.

The segment hosts do the majority of database processing, so the segment host servers are configured in order to achieve the best performance possible from your Greenplum Database system. Greenplum Database's performance will be as fast as the slowest segment server in the array. Therefore, it is important to ensure that the underlying hardware and operating systems that are running Greenplum Database are all running at their optimal performance level. It is also advised that all segment hosts in a Greenplum Database array have identical hardware resources and configurations.

Segment hosts should also be dedicated to Greenplum Database operations only. To get the best query performance, you do not want Greenplum Database competing with other applications for machine or network resources.

The following diagram shows an example Greenplum Database segment host hardware stack. The number of effective CPUs on a host is the basis for determining how many primary Greenplum Database segment instances to deploy per segment host. This example shows a host with two effective CPUs (one dual-core CPU). Note that there is one primary segment instance (or primary/mirror pair if using mirroring) per CPU core.

![Figure 3: Example Greenplum Database Segment Host Configuration](image)

Example Segment Disk Layout

Each CPU is typically mapped to a logical disk. A logical disk consists of one primary file system (and optionally a mirror file system) accessing a pool of physical disks through an I/O channel or disk controller. The logical disk and file system are provided by the operating system. Most operating systems provide the ability for a logical disk drive to use groups of physical disks arranged in RAID arrays.

![Figure 4: Logical Disk Layout in Greenplum Database](image)

Depending on the hardware platform you choose, different RAID configurations offer different performance and capacity levels. Greenplum supports and certifies a number of reference hardware platforms and operating systems. Check with your sales account representative for the recommended configuration on your chosen platform.

The Interconnect

The *interconnect* is the networking layer of Greenplum Database. When a user connects to a database and issues a query, processes are created on each of the segments to handle the work of that query. The *interconnect* refers to the inter-process communication between the segments, as well as the network infrastructure on which this communication relies. The interconnect uses a standard 10 Gigabit Ethernet switching fabric.

By default, Greenplum Database interconnect uses UDP (User Datagram Protocol) with flow control for interconnect traffic to send messages over the network. The Greenplum software does the additional packet verification and checking not performed by UDP, so the reliability is equivalent to TCP (Transmission Control Protocol), and the performance and scalability exceeds that of TCP. For information about the types of interconnect supported by Greenplum Database, see server configuration parameter `gp_interconnect_type` in the *Greenplum Database Reference Guide*. 
Interconnect Redundancy

A highly available interconnect can be achieved by deploying dual 10 Gigabit Ethernet switches on your network, and redundant 10 Gigabit connections to the Greenplum Database master and segment host servers.

Network Interface Configuration

A segment host typically has multiple network interfaces designated to Greenplum interconnect traffic. The master host typically has additional external network interfaces in addition to the interfaces used for interconnect traffic.

Depending on the number of interfaces available, you will want to distribute interconnect network traffic across the number of available interfaces. This is done by assigning segment instances to a particular network interface and ensuring that the primary segments are evenly balanced over the number of available interfaces.

This is done by creating separate host address names for each network interface. For example, if a host has four network interfaces, then it would have four corresponding host addresses, each of which maps to one or more primary segment instances. The `/etc/hosts` file should be configured to contain not only the host name of each machine, but also all interface host addresses for all of the Greenplum Database hosts (master, standby master, segments, and ETL hosts).

With this configuration, the operating system automatically selects the best path to the destination. Greenplum Database automatically balances the network destinations to maximize parallelism.

Figure 5: Example Network Interface Architecture

Switch Configuration

When using multiple 10 Gigabit Ethernet switches within your Greenplum Database array, evenly divide the number of subnets between each switch. In this example configuration, if we had two switches, NICs 1 and 2 on each host would use switch 1 and NICs 3 and 4 on each host would use switch 2. For the master host, the host name bound to NIC 1 (and therefore using switch 1) is the effective master host name for the array. Therefore, if deploying a warm standby master for redundancy purposes, the standby master should map to a NIC that uses a different switch than the primary master.

Figure 6: Example Switch Configuration

ETL Hosts for Data Loading

Greenplum supports fast, parallel data loading with its external tables feature. By using external tables in conjunction with Greenplum Database's parallel file server (`gpfdist`), administrators can achieve maximum parallelism and load bandwidth from their Greenplum Database system. Many production systems deploy designated ETL servers for data loading purposes. These machines run the Greenplum parallel file server (`gpfdist`), but not Greenplum Database instances.

One advantage of using the `gpfdist` file server program is that it ensures that all of the segments in your Greenplum Database system are fully utilized when reading from external table data files.

The `gpfdist` program can serve data to the segment instances at an average rate of about 350 MB/s for delimited text formatted files and 200 MB/s for CSV formatted files. Therefore, you should consider the following options when running `gpfdist` in order to maximize the network bandwidth of your ETL systems:
• If your ETL machine is configured with multiple network interface cards (NICs) as described in Network Interface Configuration, run one instance of gpfdist on your ETL host and then define your external table definition so that the host name of each NIC is declared in the LOCATION clause (see CREATE EXTERNAL TABLE in the Greenplum Database Reference Guide). This allows network traffic between your Greenplum segment hosts and your ETL host to use all NICs simultaneously.

Figure 7: External Table Using Single gpfdist Instance with Multiple NICs

• Run multiple gpfdist instances on your ETL host and divide your external data files equally between each instance. For example, if you have an ETL system with two network interface cards (NICs), then you could run two gpfdist instances on that machine to maximize your load performance. You would then divide the external table data files evenly between the two gpfdist programs.

Figure 8: External Tables Using Multiple gpfdist Instances with Multiple NICs

Greenplum Performance Monitoring

Greenplum Database includes a dedicated system monitoring and management database, named gpperfmon, that administrators can install and enable. When this database is enabled, data collection agents on each segment host collect query status and system metrics. At regular intervals (typically every 15 seconds), an agent on the Greenplum master requests the data from the segment agents and updates the gpperfmon database. Users can query the gpperfmon database to see the stored query and system metrics. For more information see the “gpperfmon Database Reference” in the Greenplum Database Reference Guide.

Greenplum Command Center is an optional web-based performance monitoring and management tool for Greenplum Database, based on the gpperfmon database. Administrators can install Command Center separately from Greenplum Database.

Figure 9: Greenplum Performance Monitoring Architecture
Estimating Storage Capacity

To estimate how much data your Greenplum Database system can accommodate, use these measurements as guidelines. Also keep in mind that you may want to have extra space for landing backup files and data load files on each segment host.

Calculating Usable Disk Capacity

To calculate how much data a Greenplum Database system can hold, you have to calculate the usable disk capacity per segment host and then multiply that by the number of segment hosts in your Greenplum Database array. Start with the raw capacity of the physical disks on a segment host that are available for data storage (raw_capacity), which is:

\[
\text{disk_size} \times \text{number_of_disks}
\]

Account for file system formatting overhead (roughly 10 percent) and the RAID level you are using. For example, if using RAID-10, the calculation would be:

\[
\left(\text{raw_capacity} \times 0.9\right) / 2 = \text{formatted_disk_space}
\]

For optimal performance, do not completely fill your disks to capacity, but run at 70% or lower. So with this in mind, calculate the usable disk space as follows:

\[
\text{formatted_disk_space} \times 0.7 = \text{usable_disk_space}
\]

Once you have formatted RAID disk arrays and accounted for the maximum recommended capacity (usable_disk_space), you will need to calculate how much storage is actually available for user data (U). If using Greenplum Database mirrors for data redundancy, this would then double the size of your user data (2 * U). Greenplum Database also requires some space be reserved as a working area for active queries. The work space should be approximately one third the size of your user data (work space = U / 3):

- **With mirrors:** (2 * U) + U / 3 = usable_disk_space
- **Without mirrors:** U + U / 3 = usable_disk_space

Guidelines for temporary file space and user data space assume a typical analytic workload. Highly concurrent workloads or workloads with queries that require very large amounts of temporary space can benefit from reserving a larger working area. Typically, overall system throughput can be increased while decreasing work area usage through proper workload management. Additionally, temporary space and user space can be isolated from each other by specifying that they reside on different tablespaces.

In the Greenplum Database Administrator Guide, see these topics:
- "Managing Workload and Resources" for information about workload management
- "Creating and Managing Tablespaces" for information about moving the location of temporary files
- "Monitoring System State" for information about monitoring Greenplum Database disk space usage

Calculating User Data Size

As with all databases, the size of your raw data will be slightly larger once it is loaded into the database. On average, raw data will be about 1.4 times larger on disk after it is loaded into the database, but could be smaller or larger depending on the data types you are using, table storage type, in-database compression, and so on.

- Page Overhead - When your data is loaded into Greenplum Database, it is divided into pages of 32KB each. Each page has 20 bytes of page overhead.
• Row Overhead - In a regular 'heap' storage table, each row of data has 24 bytes of row overhead. An 'append-optimized' storage table has only 4 bytes of row overhead.

• Attribute Overhead - For the data values itself, the size associated with each attribute value is dependent upon the data type chosen. As a general rule, you want to use the smallest data type possible to store your data (assuming you know the possible values a column will have).

• Indexes - In Greenplum Database, indexes are distributed across the segment hosts as is table data. The default index type in Greenplum Database is B-tree. Because index size depends on the number of unique values in the index and the data to be inserted, precalculating the exact size of an index is impossible. However, you can roughly estimate the size of an index using these formulas.

```
B-tree: unique_values * (data_type_size + 24 bytes)

Bitmap: (unique_values * number_of_rows * 1 bit * compression_ratio / 8) + (unique_values * 32)
```

Calculating Space Requirements for Metadata and Logs

On each segment host, you will also want to account for space for Greenplum Database log files and metadata:

• **System Metadata** — For each Greenplum Database segment instance (primary or mirror) or master instance running on a host, estimate approximately 20 MB for the system catalogs and metadata.

• **Write Ahead Log** — For each Greenplum Database segment (primary or mirror) or master instance running on a host, allocate space for the write ahead log (WAL). The WAL is divided into segment files of 64 MB each. At most, the number of WAL files will be:

```
2 * checkpoint_segments + 1
```

You can use this to estimate space requirements for WAL. The default `checkpoint_segments` setting for a Greenplum Database instance is 8, meaning 1088 MB WAL space allocated for each segment or master instance on a host.

• **Greenplum Database Log Files** — Each segment instance and the master instance generates database log files, which will grow over time. Sufficient space should be allocated for these log files, and some type of log rotation facility should be used to ensure that log files do not grow too large.

• **Command Center Data** — The data collection agents utilized by Command Center run on the same set of hosts as your Greenplum Database instance and utilize the system resources of those hosts. The resource consumption of the data collection agent processes on these hosts is minimal and should not significantly impact database performance. Historical data collected by the collection agents is stored in its own Command Center database (named `gpperfmon`) within your Greenplum Database system. Collected data is distributed just like regular database data, so you will need to account for disk space in the data directory locations of your Greenplum segment instances. The amount of space required depends on the amount of historical data you would like to keep. Historical data is not automatically truncated. Database administrators must set up a truncation policy to maintain the size of the Command Center database.
Configuring Your Systems and Installing Greenplum

Describes how to prepare your operating system environment for Greenplum, and install the Greenplum Database software binaries on all of the hosts that will comprise your Greenplum Database system.

Perform the following tasks in order:

1. Make sure your systems meet the System Requirements
2. Disabling SELinux and Firewall Software
3. Setting the Greenplum Recommended OS Parameters
4. Creating the Greenplum Database Administrative User Account
5. Installing the Greenplum Database Software
6. Installing and Configuring Greenplum on all Hosts
7. Creating the Data Storage Areas
8. Synchronizing System Clocks
9. Next Steps

Unless noted, these tasks should be performed for all hosts in your Greenplum Database array (master, standby master and segments).

For information about running Greenplum Database in the cloud see Cloud Services in the Pivotal Greenplum Partner Marketplace.

Important: When data loss is not acceptable for a Pivotal Greenplum Database cluster, master and segment mirroring must be enabled in order for the cluster to be supported by Pivotal. Without mirroring, system and data availability is not guaranteed, Pivotal will make best efforts to restore a cluster in this case. For information about master and segment mirroring, see About Redundancy and Failover in the Greenplum Database Administrator Guide.

Note: For information about upgrading Pivotal Greenplum Database from a previous version, see the Greenplum Database Release Notes for the release that you are installing.

System Requirements

The following table lists minimum recommended specifications for servers intended to support Greenplum Database on Linux systems in a production environment. All servers in your Greenplum Database system must have the same hardware and software configuration. Greenplum also provides hardware build guides for its certified hardware platforms. It is recommended that you work with a Greenplum Systems Engineer to review your anticipated environment to ensure an appropriate hardware configuration for Greenplum Database.

Warning: Running Pivotal Greenplum on hyper-converged infrastructure (HCI) has known issues with performance, scalability, and stability and is not recommended as a scalable solution for Pivotal Greenplum and may not be supported by Pivotal if stability problems appear related to the infrastructure. HCI virtualizes all of the elements of conventional hardware systems and includes, at a minimum, virtualized computing, a virtualised SAN, and virtualized networking.

Table 26: System Prerequisites for Greenplum Database 5.x

<table>

<tr>
<th>Operating System</th>
<th>Note: See the Greenplum Database Release Notes for current supported platform information.</th>
</tr>
</thead>
<tbody>
<tr>
<td>File Systems</td>
<td>• xfs required for data storage on SUSE Linux and Red Hat (ext3 supported for root file system)</td>
</tr>
</tbody>
</table>
## Minimum CPU

| Minimum CPU | Any x86_64 compatible CPU |

## Minimum Memory

| Minimum Memory | 16 GB RAM per server |

## Disk Requirements

| Disk Requirements | • 150MB per host for Greenplum installation  
|                  | • Approximately 300MB per segment instance for meta data  
|                  | • Appropriate free space for data with disks at no more than 70% capacity |

## Network Requirements

| Network Requirements | 10 Gigabit Ethernet within the array  
|                      | NIC bonding is recommended when multiple interfaces are present  
|                      | Pivotal Greenplum is supported using either IPV4 or IPV6 protocols. |

## Software and Utilities

| Software and Utilities | zlib compression libraries  
|                       | bash shell  
|                       | GNU tar  
|                       | GNU zip  
|                       | GNU sed (used by Greenplum Database gpinitdatabase)  
|                       | perl  
|                       | secure shell |

### Important:
SSL is supported only on the Greenplum Database master host system. It is not supported on the segment host systems.

### Important:
For all Greenplum Database host systems, SELinux must be disabled. You should also disable firewall software, although firewall software can be enabled if it is required for security purposes. See [Disabling SELinux and Firewall Software](#).

## Disabling SELinux and Firewall Software

For all Greenplum Database host systems, SELinux must be disabled. Follow these steps:

1. As the root user, check the status of SELinux:

   ```bash
   # sestatus
   SELinuxstatus: disabled
   ```

2. If SELinux is not disabled, disable it by editing the `/etc/selinux/config` file. As root, change the value of the `SELINUX` parameter in the `config` file as follows:

   ```bash
   SELINUX=disabled
   ```

3. Reboot the system to apply any changes that you made to `/etc/selinux/config` and verify that SELinux is disabled.

For information about disabling SELinux, see the SELinux documentation.

You should also disable firewall software such as `iptables` (on systems such as RHEL 6.x and CentOS 6.x) or `firewalld` (on systems such as RHEL 7.x and CentOS 7.x). Follow these steps:
1. As the root user, check the status of `iptables`:

   ```bash
   # /sbin/chkconfig --list iptables
   ``

   If `iptables` is disabled, the command output is:

   ```
   iptables 0:off 1:off 2:off 3:off 4:off 5:off 6:off
   ```

2. If necessary, execute this command as root to disable `iptables`:

   ```bash
   /sbin/chkconfig iptables off
   ```

   You will need to reboot your system after applying the change.

3. For systems with `firewalld`, check the status of `firewalld` with the command:

   ```bash
   # systemctl status firewalld
   ``

   If `firewalld` is disabled, the command output is:

   ```
   * firewalld.service - firewalld - dynamic firewall daemon
     Loaded: loaded (/usr/lib/systemd/system/firewalld.service; disabled; vendor preset: enabled)
     Active: inactive (dead)
   ```

4. If necessary, execute these commands as root to disable `firewalld`:

   ```bash
   # systemctl stop firewalld.service
   # systemctl disable firewalld.service
   ``

   For more information about configuring your firewall software, see the documentation for the firewall or your operating system.

### Setting the Greenplum Recommended OS Parameters

Greenplum requires the certain Linux operating system (OS) parameters be set on all hosts in your Greenplum Database system (masters and segments).

In general, the following categories of system parameters need to be altered:

- **Shared Memory** - A Greenplum Database instance will not work unless the shared memory segment for your kernel is properly sized. Most default OS installations have the shared memory values set too low for Greenplum Database. On Linux systems, you must also disable the OOM (out of memory) killer. For information about Greenplum Database shared memory requirements, see the Greenplum Database server configuration parameter `shared_buffers` in the Greenplum Database Reference Guide.

- **Network** - On high-volume Greenplum Database systems, certain network-related tuning parameters must be set to optimize network connections made by the Greenplum interconnect.

- **User Limits** - User limits control the resources available to processes started by a user’s shell. Greenplum Database requires a higher limit on the allowed number of file descriptors that a single process can have open. The default settings may cause some Greenplum Database queries to fail because they will run out of file descriptors needed to process the query.

### Linux System Settings

- Edit the `/etc/hosts` file and make sure that it includes the host names and all interface address names for every machine participating in your Greenplum Database system.

- Set the following parameters in the `/etc/sysctl.conf` file and reload with `sysctl -p`:
# kernel.shmall = _PHYS_PAGES / 2 # See Note 1
kernel.shmall = 4000000000
# kernel.shmmax = kernel.shmall * PAGE_SIZE # See Note 1
kernel.shmmax = 5000000000
kernel.shmmni = 4096
vm.overcommit_memory = 2
vm.overcommit_ratio = 95 # See Note 2
net.ipv4.ip_local_port_range = 10000 65535 # See Note 3
kernel.sem = 500 2048000 200 40960
kernel.sysrq = 1
kernel.core_uses_pid = 1
kernel.msgmnb = 65536
kernel.msgmax = 65536
kernel.msgmni = 2048
net.ipv4.tcp_syncookies = 1
net.ipv4.conf.default.accept_source_route = 0
net.ipv4.tcp_max_syn_backlog = 4096
net.ipv4.conf.all.arp_filter = 1
net.core.netdev_max_backlog = 10000
net.core.rmem_max = 2097152
net.core.wmem_max = 2097152
vm.swappiness = 10
vm.zone_reclaim_mode = 0
vm.dirty_expire_centisecs = 500
vm.dirty_writeback_centisecs = 100
vm.dirty_background_ratio = 0 # See Note 5
vm.dirty_ratio = 0
vm.dirty_background_bytes = 1610612736
vm.dirty_bytes = 4294967296

Note: The listed `sysctl.conf` parameters are for performance in a wide variety of environments. However, the settings might require changes in specific situations. These are additional notes about some of the `sysctl.conf` parameters.

1. `kernel.shmall` sets the total amount of shared memory pages that can be used system wide in pages. `kernel.shmmax` sets maximum size of a single shared memory segment in bytes. Set `kernel.shmall` and `kernel.shmmax` values based on your system's physical memory and page size. In general, the value for both parameters should be one half of the system physical memory. You can calculate the parameter values with the operating system variables `_PHYS_PAGES` and `PAGE_SIZE`.

   kernel.shmall = ( _PHYS_PAGES / 2)
   kernel.shmmax = ( _PHYS_PAGES / 2) * PAGE_SIZE

   You can run these two commands in a terminal window on your system to calculate the values for `kernel.shmall` and `kernel.shmmax`. The `getconf` command returns the value of an operating system variable.

   $ echo $(expr $(getconf _PHYS_PAGES) / 2)
   $ echo $(expr $(getconf _PHYS_PAGES) / 2 \* $(getconf PAGE_SIZE))

2. When `vm.overcommit_memory` is 2, you specify a value for `vm.overcommit_ratio`. For information about calculating the value for `vm.overcommit_ratio` when using resource queue-based resource management, see the Greenplum Database server configuration parameter `gp_vmem_protect_limit` in the Greenplum Database Reference Guide. If you are using resource group-based resource management, tune the operating system `vm.overcommit_ratio` as necessary. If your memory utilization is too low, increase the `vm.overcommit_ratio` value; if your memory or swap usage is too high, decrease the value.

3. To avoid port conflicts between Greenplum Database and other applications when initializing Greenplum Database, do not specify Greenplum Database ports in the range specified...
by the operating system parameter `net.ipv4.ip_local_port_range`. For example, if `net.ipv4.ip_local_port_range = 10000 65535`, you could set the Greenplum Database base port numbers to these values.

```
PORT_BASE = 6000
MIRROR_PORT_BASE = 7000
REPLICATION_PORT_BASE = 8000
MIRROR_REPLICATION_PORT_BASE = 9000
```

For information about the port ranges that are used by Greenplum Database, see `gpinitsystem`.

4. Azure deployments require Greenplum Database to not use port 65330. Add the following line to `sysctl.conf`:

```
net.ipv4.ip_local_reserved_ports=65330
```

For additional requirements and recommendations for cloud deployments, see Greenplum Database Cloud Technical Recommendations.

5. For host systems with more than 64GB of memory, these settings are recommended:

```
vm.dirty_background_ratio = 0
vm.dirty_ratio = 0
vm.dirty_background_bytes = 1610612736 # 1.5GB
vm.dirty_bytes = 4294967296 # 4GB
```

For host systems with 64GB of memory or less, remove `vm.dirty_background_bytes` and `vm.dirty_bytes` and set the two `ratio` parameters to these values:

```
vm.dirty_background_ratio = 3
vm.dirty_ratio = 10
```

6. Increase `vm.min_free_kbytes` to ensure `PF_MEMALLOC` requests from network and storage drivers are easily satisfied. This is especially critical on systems with large amounts of system memory. The default value is often far too low on these systems. Use this awk command to set `vm.min_free_kbytes` to a recommended 3% of system physical memory:

```
awk 'BEGIN {OFMT = "%0.f";} /MemTotal/ {print "vm.min_free_kbytes =", $2 * .03;}'
```

```
>/proc/meminfo >> /etc/sysctl.conf
```

Do not set `vm.min_free_kbytes` to higher than 5% of system memory as doing so might cause out of memory conditions.

- Set the following parameters in the `/etc/security/limits.conf` file:

```
* soft nofile 524288
* hard nofile 524288
* soft nproc 131072
* hard nproc 131072
```

For Red Hat Enterprise Linux (RHEL) and CentOS systems, parameter values in the `/etc/security/limits.d/90-nproc.conf` file (RHEL/CentOS 6) or `/etc/security/limits.d/20-nproc.conf` file (RHEL/CentOS 7) override the values in the `limits.conf` file. Ensure that any parameters in the override file are set to the required value. The Linux module `pam_limits` sets user limits by reading the values from the `limits.conf` file and then from the override file. For information about PAM and user limits, see the documentation on PAM and `pam_limits`.

Execute the `ulimit -u` command on each segment host to display the maximum number of processes that are available to each user. Validate that the return value is 131072.
• XFS is the preferred file system on Linux platforms for data storage. The following XFS mount options are recommended:

```bash
rw,nodev,noatime,nobarrier,inode64
```

See the manual page (man) for the `mount` command for more information about using that command (man mount opens the man page).

The XFS options can also be set in the `/etc/fstab` file. This example entry from an `fstab` file specifies the XFS options.

```bash
/dev/data /data xfs nodev,noatime,nobarrier,inode64 0 0
```

• Each disk device file should have a read-ahead (`blockdev`) value of 16384.

To verify the read-ahead value of a disk device:

```bash
# /sbin/blockdev --getra devname
```

For example:

```bash
# /sbin/blockdev --getra /dev/sdb
```

To set blockdev (read-ahead) on a device:

```bash
# /sbin/blockdev --setra bytes devname
```

For example:

```bash
# /sbin/blockdev --setra 16384 /dev/sdb
```

See the manual page (man) for the `blockdev` command for more information about using that command (man blockdev opens the man page).

**Note:** The `blockdev --setra` command is not persistent, it needs to be run every time the system reboots. How to run the command will vary based on your system, but you must to ensure that the read ahead setting is set every time the system reboots.

• The Linux disk I/O scheduler for disk access supports different policies, such as CFQ, AS, and deadline.

The `deadline` scheduler option is recommended. To specify a scheduler until the next system reboot, run the following:

```bash
# echo schedulername > /sys/block/devname/queue/scheduler
```

For example:

```bash
# echo deadline > /sys/block/sdb/queue/scheduler
```

**Note:** Setting the disk I/O scheduler policy with the `echo` command is not persistent, and must be run when the system is rebooted. If you use the `echo` command to set the policy, you must ensure the command is run when the system reboots. How to run the command will vary based on your system.

One method to set the I/O scheduler policy at boot time is with the `elevator` kernel parameter. Add the parameter `elevator=deadline` to the kernel command in the file `/boot/grub/grub.conf`, the GRUB boot loader configuration file. This is an example `kernel command` from a `grub.conf` file on RHEL 6.x or CentOS 6.x. The command is on multiple lines for readability.

```bash
kernel /vmlinuz-2.6.18-274.3.1.el5 ro root=LABEL=/
```
To specify the I/O scheduler at boot time on systems that use grub2 such as RHEL 7.x or CentOS 7.x, use the system utility grubby. This command adds the parameter when run as root.

```
# grubby --update-kernel=ALL --args="elevator=deadline"
```

After adding the parameter, reboot the system.

This grubby command displays kernel parameter settings.

```
# grubby --info=ALL
```

For more information about the grubby utility, see your operating system documentation. If the grubby command does not update the kernels, see the Note at the end of the section.

- Disable Transparent Huge Pages (THP). RHEL 6.0 or higher enables THP by default. THP degrades Greenplum Database performance. One way to disable THP on RHEL 6.x is by adding the parameter `transparent_hugepage=never` to the kernel command in the file `/boot/grub/grub.conf`, the GRUB boot loader configuration file. This is an example kernel command from a grub.conf file. The command is on multiple lines for readability:

```
kernel /vmlinuz-2.6.18-274.3.1.el5 ro root=LABEL=/
    elevator=deadline crashkernel=128M@16M quiet console=tty1
    console=ttyS1,115200 panic=30 transparent_hugepage=never
    initrd /initrd-2.6.18-274.3.1.el5.img
```

On systems that use grub2 such as RHEL 7.x or CentOS 7.x, use the system utility grubby. This command adds the parameter when run as root.

```
# grubby --update-kernel=ALL --args="transparent_hugepage=never"
```

After adding the parameter, reboot the system.

This cat command checks the state of THP. The output indicates that THP is disabled.

```
$ cat /sys/kernel/mm/*transparent_hugepage/enabled
always [never]
```

For more information about Transparent Huge Pages or the grubby utility, see your operating system documentation. If the grubby command does not update the kernels, see the Note at the end of the section.

- Disable IPC object removal for RHEL 7.2 or CentOS 7.2. The default systemd setting `RemoveIPC=yes` removes IPC connections when non-system user accounts log out. This causes the Greenplum Database utility gpinit system to fail with semaphore errors. Perform one of the following to avoid this issue.

  - When you add the gpadmin operating system user account to the master node in Creating the Greenplum Database Administrative User Account, create the user as a system account. You must also add the gpadmin user as a system account on the segment hosts manually or using the gpseginstall command (described in later installation step Installing and Configuring Greenplum on all Hosts).

  **Note:** When you run the gpseginstall utility as the root user to install Greenplum Database on host systems, the utility creates the gpadmin operating system user as a system account on the hosts.
• Disable `RemoveIPC`. Set this parameter in `/etc/systemd/logind.conf` on the Greenplum Database host systems.

```
RemoveIPC=no
```

The setting takes effect after restarting the `systemd-login` service or rebooting the system. To restart the service, run this command as the root user:

```
service systemd-logind restart
```

• Certain Greenplum Database management utilities including `gpexpand`, `gpinitsystem`, and `gpaddmirrors`, utilize secure shell (SSH) connections between systems to perform their tasks. In large Greenplum Database deployments, cloud deployments, or deployments with a large number of segments per host, these utilities may exceed the host's maximum threshold for unauthenticated connections. When this occurs, you receive errors such as: `ssh_exchange_identification: Connection closed by remote host`.

To increase this connection threshold for your Greenplum Database deployment, update the `SSH MaxStartups` configuration parameter in one of the `/etc/ssh/sshd_config` or `/etc/sshd_config` SSH daemon configuration files.

If you specify `MaxStartups` using a single integer value, you identify the maximum number of concurrent unauthenticated connections. For example:

```
MaxStartups 200
```

If you specify `MaxStartups` using the "start:rate:full" syntax, you enable random early connection drop by the SSH daemon. `start` identifies the maximum number of unauthenticated SSH connection attempts allowed. Once `start` number of unauthenticated connection attempts is reached, the SSH daemon refuses `rate` percent of subsequent connection attempts. `full` identifies the maximum number of unauthenticated connection attempts after which all attempts are refused. For example:

```
Max Startups 10:30:200
```

Restart the SSH daemon after you update `MaxStartups`. For example, on a CentOS 6 system, run the following command as the root user:

```
# service sshd restart
```

For detailed information about SSH configuration options, refer to the SSH documentation for your Linux distribution.

• On some SUSE Linux Enterprise Server platforms, the Greenplum Database utility `gpssh` fails with the error message `out of pty devices`. A workaround is to add Greenplum Database operating system users, for example `gpadmin`, to the `tty` group. On SUSE systems, `tty` is required to run `gpssh`.

  Note: If the `grubby` command does not update the kernels of a RHEL 7.x or CentOS 7.x system, you can manually update all kernels on the system. For example, to add the parameter `transparent_hugepage=never` to all kernels on a system.

  1. Add the parameter to the `GRUB_CMDLINE_LINUX` line in the file parameter in `/etc/default/grub`

```
GRUB_TIMEOUT=5
GRUB_DISTRIBUTOR="$(sed 's, release .*$,,g' /etc/system-release)"
GRUB_DEFAULT=saved
GRUB_DISABLE_SUBMENU=true
GRUB_TERMINAL_OUTPUT="console"
GRUB_CMDLINE_LINUX="crashkernel=auto rd.lvm.lv=cl/root rd.lvm.lv=cl/swap rhgb quiet transparent_hugepage=never"
```
GRUB_DISABLE_RECOVERY="true"

2. As root, run the `grub2-mkconfig` command to update the kernels.

```
# grub2-mkconfig -o /boot/grub2/grub.cfg
```

3. Reboot the system.

**Creating the Greenplum Database Administrative User Account**

You must create a dedicated operating system user account on the master node to run Greenplum Database. You administer Greenplum Database as this operating system user. This user account is named, by convention, `gpadmin`.

**Note:** If you are installing the Greenplum Database RPM distribution, create the `gpadmin` user on every host in the Greenplum Database cluster because the installer does not create the `gpadmin` user for you. See the note under *Installing the Greenplum Database Software* for more information.

You cannot run the Greenplum Database server as `root`.

The `gpadmin` user account must have permission to access the services and directories required to install and run Greenplum Database.

To create the `gpadmin` operating system user account, run the `groupadd`, `useradd`, and `passwd` commands as the `root` user.

**Note:** If you are installing Greenplum Database on RHEL 7.2 or CentOS 7.2 and chose to disable IPC object removal by creating the `gpadmin` user as a system account, provide the options `-r` (create the user as a system account) and `-m` (create the user home directory if it does not exist) to the `useradd` command.

**Note:** Make sure the `gpadmin` user has the same user id (uid) and group id (gid) numbers on each host to prevent problems with scripts or services that use them for identity or permissions. For example, backing up Greenplum databases to some networked filesystems or storage appliances could fail if the `gpadmin` user has different uid or gid numbers on different segment hosts. When you create the `gpadmin` group and user, you can use the `groupadd -g` option to specify a gid number and the `useradd -u` option to specify the uid number. Use the command `id gpadmin` to see the uid and gid for the `gpadmin` user on the current host.

This example creates the `gpadmin` operating system group and creates the user account as a system account:

```
# groupadd gpadmin
# useradd gpadmin -r -m -g gpadmin
# passwd gpadmin
New password: <changeme>
Retype new password: <changeme>
```

**Installing the Greenplum Database Software**

Pivotal distributes the Greenplum Database software both as a downloadable RPM file and as a binary installer. You can use either distribution to install the software, but there are important differences between the two installation methods:

- If you use the RPM distribution, install the RPM file on the master, standby master, and every segment host. You will need to create the `gpadmin` user on every host. (See *Creating the Greenplum Database Administrative User Account.*) After the RPM file is installed on every host, you must enable passwordless SSH access for the `gpadmin` user from each host to every other host.
- If you use the binary installer, you can install the distribution on the master host only, and then use the Greenplum Database `gpseginstall` utility to copy the installation from the master host to all other
hosts in the cluster. The `gpseginstall` utility creates the `gpadmin` user on each host, if it does not already exist, and enables passwordless SSH for the `gpadmin` user.

**Warning:** It is possible to install the RPM distribution on the master host, and then use the `gpseginstall` utility to copy the Greenplum Database installation directory to all other hosts. However, this is not recommended because `gpseginstall` does not install the RPM package on the other hosts, so you will be unable to use the OS package management utilities to remove or upgrade the Greenplum software on the standby master host or segment hosts.

If you do not have root access on the master host machine, run the binary installer as the `gpadmin` user and install the software into a directory in which you have write permission.

**Installing the RPM Distribution**

Perform these steps on the master host, standby master host, and every segment host in the Greenplum Database cluster.

1. Log in as root.
2. Download or copy the RPM distribution file to the host machine. The RPM distribution filename has the format `greenplum-db-<version>-<platform>.rpm` where `<platform>` is similar to `rhel7-x86_64` (Red Hat 64-bit) or `sles11-x86_64` (SUSE Linux 64-bit).
3. Install the local RPM file:

   ```
   # rpm -ivh ./greenplum-db-<version>-<platform>.rpm
   Preparing...                ###########################################
   [100%]
   1:greenplum-db           ###########################################
   [100%]
   ```

   The RPM installation copies the Greenplum Database software into a version-specific directory, `/usr/local/greenplum-db-<version>`.
4. Change the ownership and group of the installed files to `gpadmin`:

   ```
   # chown -R gpadmin /usr/local/greenplum-
   # chgrp -R gpadmin /usr/local/greenplum-
   ```

**Enabling Passwordless SSH**

After the RPM has been installed on all hosts in the cluster, use the `gpssh-exkeys` utility to set up passwordless SSH for the `gpadmin` user.

1. Log in to the master host as the `gpadmin` user.
2. Source the path file in the Greenplum Database installation directory.

   ```
   $ source /usr/local/greenplum-db-<version>/greenplum_path.sh
   ```
3. In the `gpadmin` home directory, create a file named `hostfile_exkeys` that has the machine configured host names and host addresses (interface names) for each host in your Greenplum system (master, standby master, and segment hosts). Make sure there are no blank lines or extra spaces. Check the `/etc/hosts` file on your systems for the correct host names to use for your environment. For example, if you have a master, standby master, and three segment hosts with two unbonded network interfaces per host, your file would look something like this:

   ```
   mdw
   mdw-1
   mdw-2
   smdw
   smdw-1
   smdw-2
   sdw1
   ```
4. Run the `gpssh-exkeys` utility with your `hostfile_exkeys` file to enable passwordless SSH for the `gpadmin` user.

   ```
   $ gpssh-exkeys -f hostfile_exkeys
   ```

   Note: You can run the `gpssh-exkeys` utility again as the `root` user if you want to enable passwordless SSH for `root`.

Follow the steps in Confirming Your Installation to verify that the Greenplum Database software is installed correctly.

### Installing the Binary Distribution

1. Log in as `root` on the machine that will become the Greenplum Database master host.
   
   If you do not have root access on the master host machine, run the binary installer as the `gpadmin` user and install the software into a directory in which you have write permission.

2. Download or copy the Binary Installation distribution file to the master host machine. The Binary Installer distribution filename has the format `greenplum-db-<version>-<platform>.zip` where `<platform>` is similar to `rhel7-x86_64` (Red Hat 64-bit) or `sles11-x86_64` (SuSe Linux 64 bit).

3. Unzip the installer file:

   ```
   # unzip greenplum-db-<version>-<platform>.zip
   ```

4. Launch the installer using `bash`:

   ```
   # /bin/bash greenplum-db-<version>-<platform>.bin
   ```

5. The installer prompts you to accept the Greenplum Database license agreement. Type `yes` to accept the license agreement.

6. The installer prompts you to provide an installation path. Press `ENTER` to accept the default install path (`/usr/local/greenplum-db-<version>`), or enter an absolute path to a custom install location. You must have write permission to the location you specify.

7. The installer installs the Greenplum Database software and creates a `greenplum-db` symbolic link one directory level above the version-specific installation directory. The symbolic link is used to facilitate patch maintenance and upgrades between versions. The installed location is referred to as `$GPHOME`.

8. If you installed as `root`, change the ownership and group of the installed files to `gpadmin`:

   ```
   # chown -R gpadmin /usr/local/greenplum*
   # chgrp -R gpadmin /usr/local/greenplum*
   ```

9. To perform additional required system configuration tasks and to install Greenplum Database on other hosts, go to the next task Installing and Configuring Greenplum on all Hosts.

### About Your Greenplum Database Installation

- **greenplum_path.sh** — This file contains the environment variables for Greenplum Database. See Setting Greenplum Environment Variables.

- **bin** — This directory contains the Greenplum Database management utilities. This directory also contains the PostgreSQL client and server programs, most of which are also used in Greenplum Database.
Installing and Configuring Greenplum on all Hosts

When run as root, gpseginstall copies the Greenplum Database installation from the current host and installs it on a list of specified hosts, creates the Greenplum operating system user account (typically named gpadmin), sets the account password (default is changeme), sets the ownership of the Greenplum Database installation directory, and exchanges ssh keys between all specified host address names (both as root and as the specified user account).

Note: If you are setting up a single node system, you can still use gpseginstall to perform the required system configuration tasks on the current host. In this case, the hostfile_exkeys should have only the current host name.

Note: The gpseginstall utility copies the installed files from the current host to the remote hosts. It does not use rpm to install Greenplum Database on the remote hosts, even if you used rpm to install Greenplum Database on the current host.

To install and configure Greenplum Database on all specified hosts

1. Log in to the master host as root:

   $ su -

2. Source the path file from your master host's Greenplum Database installation directory:

   # source /usr/local/greenplum-db/greenplum_path.sh

3. In the gpadmin user's home directory, create a file called hostfile_exkeys that has the machine configured host names and host addresses (interface names) for each host in your Greenplum system (master, standby master and segments). Make sure there are no blank lines or extra spaces. For example, if you have a master, standby master and three segments with two unbonded network interfaces per host, your file would look something like this:

```plaintext
mdw
mdw-1
mdw-2
smdw
smdw-1
smdw-2
sdw1
sdw1-1
sdw1-2
sdw2
sdw2-1
sdw2-2
sdw3
sdw3-1
```
Check the /etc/hosts file on your systems for the correct host names to use for your environment.

The Greenplum Database segment host naming convention is *sdwN* where *sdw* is a prefix and *N* is an integer. For example, segment host names would be *sdw1*, *sdw2* and so on. NIC bonding is recommended for hosts with multiple interfaces, but when the interfaces are not bonded, the convention is to append a dash (--) and number to the host name. For example, *sdw1-1* and *sdw1-2* are the two interface names for host *sdw1*.

4. Run the `gpseinstall` utility referencing the *hostfile_exkeys* file you just created. This example runs the utility as *root*. The utility creates the Greenplum operating system user account *gpadmin* as a system account on all hosts and sets the account password to *changeme* for that user on all segment hosts.

```bash
# gpseinstall -f hostfile_exkeys
```

Use the `-u` and `-p` options to specify a different operating system account name and password. See `gpseinstall` for option information and information about running the utility as a non-root user.

Recommended security best practices:

- Do not use the default password option for production environments.
- Change the password immediately after installation.

**Confirming Your Installation**

To make sure the Greenplum software was installed and configured correctly, run the following confirmation steps from your Greenplum master host. If necessary, correct any problems before continuing on to the next task.

1. Log in to the master host as *gpadmin*:

   ```bash
   $ su - gpadmin
   ```

2. Source the path file from Greenplum Database installation directory:

   ```bash
   # source /usr/local/greenplum-db/greenplum_path.sh
   ```

3. Use the `gpssh` utility to see if you can login to all hosts without a password prompt, and to confirm that the Greenplum software was installed on all hosts. Use the *hostfile_exkeys* file you used for installation. For example:

   ```bash
   $ gpssh -f hostfile_exkeys -e ls -l $GPHOME
   ```

   If the installation was successful, you can log in to all hosts without a password prompt. All hosts should show that they have the same contents in their installation directories, and that the directories are owned by the *gpadmin* user.

   If you are prompted for a password, run the following command to redo the ssh key exchange:

   ```bash
   $ gpssh-exkeys -f hostfile_exkeys
   ```

**Creating the Data Storage Areas**

Every Greenplum Database master and segment instance has a designated storage area on disk that is called the *data directory* location. This is the file system location where the directories that store segment instance data will be created. The master host needs a data storage location for the master data directory. Each segment host needs a data directory storage location for its primary segments, and another for its mirror segments.
**Creating a Data Storage Area on the Master Host**

A data storage area is required on the Greenplum Database master host to store Greenplum Database system data such as catalog data and other system metadata.

**To create the data directory location on the master**

The data directory location on the master is different than those on the segments. The master does not store any user data, only the system catalog tables and system metadata are stored on the master instance, therefore you do not need to designate as much storage space as on the segments.

1. Create or choose a directory that will serve as your master data storage area. This directory should have sufficient disk space for your data and be owned by the gpadmin user and group. For example, run the following commands as root:

   ```
   # mkdir -p /data/master
   ```

2. Change ownership of this directory to the gpadmin user. For example:

   ```
   # chown gpadmin /data/master
   ```

3. Using `gpssh`, create the master data directory location on your standby master as well. For example:

   ```
   # source /usr/local/greenplum-db/greenplum_path.sh
   # gpssh -h smdw -e 'mkdir -p /data/master'
   # gpssh -h smdw -e 'chown gpadmin /data/master'
   ```

**Creating Data Storage Areas on Segment Hosts**

Data storage areas are required on the Greenplum Database segment hosts for primary segments. Separate storage areas are required for mirror segments.

**To create the data directory locations on all segment hosts**

1. On the master host, log in as root:

   ```
   # su
   ```

2. Create a file called `hostfile_gpssh_segonly`. This file should have only one machine configured host name for each segment host. For example, if you have three segment hosts:

   ```
   sdw1
   sdw2
   sdw3
   ```

3. Using `gpssh`, create the primary and mirror data directory locations on all segment hosts at once using the `hostfile_gpssh_segonly` file you just created. For example:

   ```
   # source /usr/local/greenplum-db/greenplum_path.sh
   # gpssh -f hostfile_gpssh_segonly -e 'mkdir -p /data/primary'
   # gpssh -f hostfile_gpssh_segonly -e 'mkdir -p /data/mirror'
   # gpssh -f hostfile_gpssh_segonly -e 'chown -R gpadmin /data/*'
   ```

**Synchronizing System Clocks**

You should use NTP (Network Time Protocol) to synchronize the system clocks on all hosts that comprise your Greenplum Database system. See www.ntp.org for more information about NTP.
NTP on the segment hosts should be configured to use the master host as the primary time source, and the standby master as the secondary time source. On the master and standby master hosts, configure NTP to point to your preferred time server.

**To configure NTP**

1. On the master host, log in as root and edit the `/etc/ntp.conf` file. Set the `server` parameter to point to your data center’s NTP time server. For example (if `10.6.220.20` was the IP address of your data center’s NTP server):

   ```
   server 10.6.220.20
   ```

2. On each segment host, log in as root and edit the `/etc/ntp.conf` file. Set the first `server` parameter to point to the master host, and the second `server` parameter to point to the standby master host. For example:

   ```
   server mdw prefer
   server smdw
   ```

3. On the standby master host, log in as root and edit the `/etc/ntp.conf` file. Set the first `server` parameter to point to the primary master host, and the second `server` parameter to your data center’s NTP time server. For example:

   ```
   server mdw prefer
   server 10.6.220.20
   ```

4. On the master host, use the NTP daemon synchronize the system clocks on all Greenplum hosts. For example, using `gpssh`:

   ```
   # gpssh -f hostfile_gpssh_allhosts -v -e 'ntpd'
   ```

**Enabling iptables**

On Linux systems, you can configure and enable the `iptables` firewall to work with Greenplum Database.

*Note:* Greenplum Database performance might be impacted when `iptables` is enabled. You should test the performance of your application with `iptables` enabled to ensure that performance is acceptable.

For more information about `iptables` see the `iptables` and firewall documentation for your operating system.

**How to Enable iptables**

1. As `gpadmin`, the Greenplum Database administrator, run this command on the Greenplum Database master host to stop Greenplum Database:

   ```
   $ gpstop -a
   ```

2. On the Greenplum Database hosts:
   
   a. Update the file `/etc/sysconfig/iptables` based on the *Example iptables Rules*.
   b. As root user, run these commands to enable `iptables`:

   ```
   # chkconfig iptables on
   # service iptables start
   ```
3. As gpadmin, run this command on the Greenplum Database master host to start Greenplum Database:

```bash
$ gpstart -a
```

**Warning:** After enabling `iptables`, this error in the `/var/log/messages` file indicates that the setting for the `iptables` table is too low and needs to be increased.

```plaintext
ip_conntrack: table full, dropping packet.
```

As root user, run this command to view the `iptables` table value:

```
# sysctl net.ipv4.netfilter.ip_conntrack_max
```

The following is the recommended setting to ensure that the Greenplum Database workload does not overflow the `iptables` table. The value might need to be adjusted for your hosts:

```
net.ipv4.netfilter.ip_conntrack_max=6553600
```

You can update `/etc/sysctl.conf` file with the value. For setting values in the file, see [Setting the Greenplum Recommended OS Parameters](#).

To set the value until the next reboots run this command as root.

```
# sysctl net.ipv4.netfilter.ip_conntrack_max=6553600
```

### Example `iptables` Rules

When `iptables` is enabled, `iptables` manages the IP communication on the host system based on configuration settings (rules). The example rules are used to configure `iptables` for Greenplum Database master host, standby master host, and segment hosts.

- **Example Master and Standby Master `iptables` Rules**
- **Example Segment Host `iptables` Rules**

The two sets of rules account for the different types of communication Greenplum Database expects on the master (primary and standby) and segment hosts. The rules should be added to the `/etc/sysconfig/iptables` file of the Greenplum Database hosts. For Greenplum Database, `iptables` rules should allow the following communication:

- For customer facing communication with the Greenplum Database master, allow at least `postgres` and `28080` (eth1 interface in the example).
- For Greenplum Database system interconnect, allow communication using `tcp`, `udp`, and `icmp` protocols (eth4 and eth5 interfaces in the example).

The network interfaces that you specify in the `iptables` settings are the interfaces for the Greenplum Database hosts that you list in the `hostfile_gpinitsystem` file. You specify the file when you run the `gpinitsystem` command to initialize a Greenplum Database system. See [Initializing a Greenplum Database System](#) for information about the `hostfile_gpinitsystem` file and the `gpinitsystem` command.

- For the administration network on a Greenplum DCA, allow communication using `ssh`, `snmp`, `ntp`, and `icmp` protocols. (eth0 interface in the example).

In the `iptables` file, each append rule command (lines starting with `-A`) is a single line.

The example rules should be adjusted for your configuration. For example:

- The append command, the `-A` lines and connection parameter `-i` should match the connectors for your hosts.
- The CIDR network mask information for the source parameter `-s` should match the IP addresses for your network.
**Example Master and Standby Master iptables Rules**

Example iptables rules with comments for the /etc/sysconfig/iptables file on the Greenplum Database master host and standby master host.

```bash
*filter
# Following 3 are default rules. If the packet passes through
# the rule set it gets these rule.
# Drop all inbound packets by default.
# Drop all forwarded (routed) packets.
# Let anything outbound go through.
:INPUT DROP [0:0]
:FORWARD DROP [0:0]
:OUTPUT ACCEPT [0:0]
# Accept anything on the loopback interface.
-A INPUT -i lo -j ACCEPT
# If a connection has already been established allow the
# remote host packets for the connection to pass through.
-A INPUT -m state --state ESTABLISHED,RELATED -j ACCEPT
# These rules let all tcp and udp through on the standard
# interconnect IP addresses and on the interconnect interfaces.
# NOTE: gpsyncmaster uses random tcp ports in the range 1025 to 65535
# and Greenplum Database uses random udp ports in the range 1025 to 65535.
-A INPUT -i eth4 -p udp -s 192.0.2.0/22 -j ACCEPT
-A INPUT -i eth5 -p udp -s 198.51.100.0/22 -j ACCEPT
-A INPUT -i eth4 -p tcp -s 192.0.2.0/22 -j ACCEPT --syn --state NEW
-A INPUT -i eth5 -p tcp -s 198.51.100.0/22 -j ACCEPT --syn --state NEW
# Allow snmp connections on the admin network on Greenplum DCA.
-A INPUT -i eth0 -p udp --dport snmp -s 203.0.113.0/21 -j ACCEPT
-A INPUT -i eth0 -p tcp --dport snmp -s 203.0.113.0/21 -j ACCEPT --syn --state NEW
-A INPUT -i eth0 -p udp --dport ntp -s 203.0.113.0/21 -j ACCEPT
-A INPUT -i eth0 -p tcp --dport ntp -s 203.0.113.0/21 -j ACCEPT --syn --state NEW
-A INPUT -p tcp --dport ssh -j ACCEPT --syn --state NEW
-A INPUT -p tcp --dport postgres -j ACCEPT --syn --state NEW
-A INPUT -i eth1 -p tcp --dport 28080 -j ACCEPT --syn --state NEW
-A INPUT -i eth4 -p icmp -s 192.0.2.0/22 -j ACCEPT
-A INPUT -i eth5 -p icmp -s 198.51.100.0/22 -j ACCEPT
-A INPUT -i eth0 -p icmp --icmp-type echo-request -s 203.0.113.0/21 -j ACCEPT
# Log an error if a packet passes through the rules to the default
# INPUT rule (a DROP).
-A INPUT -m limit --limit 5/min -j LOG --log-prefix "iptables denied: " --log-level 7
COMMIT
```

**Example Segment Host iptables Rules**

Example iptables rules for the /etc/sysconfig/iptables file on the Greenplum Database segment hosts. The rules for segment hosts are similar to the master rules with fewer interfaces and fewer udp and tcp services.

```bash
*filter
```
Next Steps

After you have configured the operating system environment and installed the Greenplum Database software on all of the hosts in the system, the next steps are:

- **Validating Your Systems**
- **Initializing a Greenplum Database System**
Validating Your Systems

Validate your operating system settings, hardware, and network.

Greenplum provides the following utilities to validate the configuration and performance of your systems:

- `gpcheck`
- `gpcheckperf`

These utilities can be found in `$GPHOME/bin` of your Greenplum installation.

The following tests should be run prior to initializing your Greenplum Database system.

### Validating OS Settings

Greenplum provides a utility called `gpcheck` that can be used to verify that all hosts in your array have the recommended OS settings for running a production Greenplum Database system. To run `gpcheck`:

1. Log in on the master host as the `gpadmin` user.
2. Source the `greenplum_path.sh` path file from your Greenplum installation. For example:
   
   ```bash
   $ source /usr/local/greenplum-db/greenplum_path.sh
   ```

3. Create a file called `hostfile_gpcheck` that has the machine-configured host names of each Greenplum host (master, standby master and segments), one host name per line. Make sure there are no blank lines or extra spaces. This file should just have a single host name per host. For example:

   ```
   mdw
   smdw
   sdw1
   sdw2
   sdw3
   ```

4. Run the `gpcheck` utility using the host file you just created. For example:

   ```bash
   $ gpcheck -f hostfile_gpcheck -m mdw -s smdw
   ```

5. After `gpcheck` finishes verifying OS parameters on all hosts (masters and segments), you might be prompted to modify certain OS parameters before initializing your Greenplum Database system.

### Validating Hardware Performance

Greenplum provides a management utility called `gpcheckperf`, which can be used to identify hardware and system-level issues on the machines in your Greenplum Database array. `gpcheckperf` starts a session on the specified hosts and runs the following performance tests:

- Network Performance (`gpnetbench*`)
- Disk I/O Performance (`dd` test)
- Memory Bandwidth (`stream` test)

Before using `gpcheckperf`, you must have a trusted host setup between the hosts involved in the performance test. You can use the utility `gpssh-exkeys` to update the known host files and exchange public keys between hosts if you have not done so already. Note that `gpcheckperf` calls to `gpssh` and `gpscp`, so these Greenplum utilities must be in your $PATH.

### Validating Network Performance

To test network performance, run `gpcheckperf` with one of the network test run options: parallel pair test (`-r N`), serial pair test (`-r n`), or full matrix test (`-r M`). The utility runs a network benchmark program
that transfers a 5 second stream of data from the current host to each remote host included in the test. By default, the data is transferred in parallel to each remote host and the minimum, maximum, average and median network transfer rates are reported in megabytes (MB) per second. If the summary transfer rate is slower than expected (less than 100 MB/s), you can run the network test serially using the \(-r n\) option to obtain per-host results. To run a full-matrix bandwidth test, you can specify \(-r M\) which will cause every host to send and receive data from every other host specified. This test is best used to validate if the switch fabric can tolerate a full-matrix workload.

Most systems in a Greenplum Database array are configured with multiple network interface cards (NICs), each NIC on its own subnet. When testing network performance, it is important to test each subnet individually. For example, considering the following network configuration of two NICs per host:

<table>
<thead>
<tr>
<th>Greenplum Host</th>
<th>Subnet1 NICs</th>
<th>Subnet2 NICs</th>
</tr>
</thead>
<tbody>
<tr>
<td>Segment 1</td>
<td>sdw1-1</td>
<td>sdw1-2</td>
</tr>
<tr>
<td>Segment 2</td>
<td>sdw2-1</td>
<td>sdw2-2</td>
</tr>
<tr>
<td>Segment 3</td>
<td>sdw3-1</td>
<td>sdw3-2</td>
</tr>
</tbody>
</table>

You would create four distinct host files for use with the `gpcheckperf` network test:

<table>
<thead>
<tr>
<th>hostfile_gpchecknet_ic1</th>
<th>hostfile_gpchecknet_ic2</th>
</tr>
</thead>
<tbody>
<tr>
<td>sdw1-1</td>
<td>sdw1-2</td>
</tr>
<tr>
<td>sdw2-1</td>
<td>sdw2-2</td>
</tr>
<tr>
<td>sdw3-1</td>
<td>sdw3-2</td>
</tr>
</tbody>
</table>

You would then run `gpcheckperf` once per subnet. For example (if testing an even number of hosts, run in parallel pairs test mode):

```
$ gpcheckperf -f hostfile_gpchecknet_ic1 -r N -d /tmp > subnet1.out  
$ gpcheckperf -f hostfile_gpchecknet_ic2 -r N -d /tmp > subnet2.out
```

If you have an odd number of hosts to test, you can run in serial test mode (\(-r n\)).

### Validating Disk I/O and Memory Bandwidth

To test disk and memory bandwidth performance, run `gpcheckperf` with the disk and stream test run options (\(-r ds\)). The disk test uses the `dd` command (a standard UNIX utility) to test the sequential throughput performance of a logical disk or file system. The memory test uses the STREAM benchmark program to measure sustainable memory bandwidth. Results are reported in MB per second (MB/s).

#### To run the disk and stream tests
1. Log in on the master host as the `gpadmin` user.
2. Source the `greenplum_path.sh` path file from your Greenplum installation. For example:

   ```bash
   $ source /usr/local/greenplum-db/greenplum_path.sh
   ```

3. Create a host file named `hostfile_gpcheckperf` that has one host name per segment host. Do not include the master host. For example:

   ```bash
   sdw1
   ```
4. Run the `gpcheckperf` utility using the `hostfile_gpcheckperf` file you just created. Use the `-d` option to specify the file systems you want to test on each host (you must have write access to these directories). You will want to test all primary and mirror segment data directory locations. For example:

```bash
$ gpcheckperf -f hostfile_gpcheckperf -r ds -D -d /data1/primary -d /data2/primary -d /data1/mirror -d /data2/mirror
```

5. The utility may take a while to perform the tests as it is copying very large files between the hosts. When it is finished you will see the summary results for the Disk Write, Disk Read, and Stream tests.
Initializing a Greenplum Database System

Describes how to initialize a Greenplum Database database system.

The instructions in this chapter assume you have already installed the Greenplum Database software on all of the hosts in the system according to the instructions in Configuring Your Systems and Installing Greenplum.

This chapter contains the following topics:

• Overview
• Initializing Greenplum Database
• Next Steps

Overview

Because Greenplum Database is distributed, the process for initializing a Greenplum Database management system (DBMS) involves initializing several individual PostgreSQL database instances (called segment instances in Greenplum).

Each database instance (the master and all segments) must be initialized across all of the hosts in the system in such a way that they can all work together as a unified DBMS. Greenplum provides its own version of initdb called gpinitsystem, which takes care of initializing the database on the master and on each segment instance, and starting each instance in the correct order.

After the Greenplum Database database system has been initialized and started, you can then create and manage databases as you would in a regular PostgreSQL DBMS by connecting to the Greenplum master.

Initializing Greenplum Database

These are the high-level tasks for initializing Greenplum Database:

1. Make sure you have completed all of the installation tasks described in Configuring Your Systems and Installing Greenplum.
2. Create a host file that contains the host addresses of your segments. See Creating the Initialization Host File.
4. By default, Greenplum Database will be initialized using the locale of the master host system. Make sure this is the correct locale you want to use, as some locale options cannot be changed after initialization. See Configuring Timezone and Localization Settings for more information.
5. Run the Greenplum Database initialization utility on the master host. See Running the Initialization Utility.
6. Set the Greenplum Database timezone. See Setting the Greenplum Database Timezone.

Creating the Initialization Host File

The gpinitsystem utility requires a host file that contains the list of addresses for each segment host. The initialization utility determines the number of segment instances per host by the number host addresses listed per host times the number of data directory locations specified in the gpinitsystem_config file.

This file should only contain segment host addresses (not the master or standby master). For segment machines with multiple, unbonded network interfaces, this file should list the host address names for each interface — one per line.
Note: The Greenplum Database segment host naming convention is sdwN where sdw is a prefix and N is an integer. For example, sdw2 and so on. If hosts have multiple unbonded NICs, the convention is to append a dash (-) and number to the host name. For example, sdw1-1 and sdw1-2 are the two interface names for host sdw1. However, NIC bonding is recommended to create a load-balanced, fault-tolerant network.

To create the initialization host file
1. Log in as gpadmin.
   
   ```bash
   $ su - gpadmin
   ```

2. Create a file named `hostfile_gpinitsystem`. In this file add the host address name(s) of your `segment` host interfaces, one name per line, no extra lines or spaces. For example, if you have four `segment` hosts with two unbonded network interfaces each:

   ```
   sdw1-1
   sdw1-2
   sdw2-1
   sdw2-2
   sdw3-1
   sdw3-2
   sdw4-1
   sdw4-2
   ```

3. Save and close the file.
   
   Note: If you are not sure of the host names and/or interface address names used by your machines, look in the `/etc/hosts` file.

Creating the Greenplum Database Configuration File

Your Greenplum Database configuration file tells the `gpinitsystem` utility how you want to configure your Greenplum Database system. An example configuration file can be found in `$GPHOME/docs/cli_help/gpconfigs/gpinitsystem_config`.

To create a `gpinitsystem_config` file
1. Log in as gpadmin.
   
   ```bash
   $ su - gpadmin
   ```

2. Make a copy of the `gpinitsystem_config` file to use as a starting point. For example:

   ```bash
   $ cp $GPHOME/docs/cli_help/gpconfigs/gpinitsystem_config \
   /home/gpadmin/gpconfigs/gpinitsystem_config
   ```

3. Open the file you just copied in a text editor.
   
   Set all of the required parameters according to your environment. See `gpinitsystem` for more information. A Greenplum Database system must contain a master instance and at least two segment instances (even if setting up a single node system).

   The `DATA_DIRECTORY` parameter is what determines how many segments per host will be created. If your segment hosts have multiple network interfaces, and you used their interface address names in your host file, the number of segments will be evenly spread over the number of available interfaces.

   Here is an example of the `required` parameters in the `gpinitsystem_config` file:

   ```
   ARRAY_NAME="Greenplum Data Platform"
   SEG_PREFIX=gpseg
   PORT_BASE=40000
   ```
4. (Optional) If you want to deploy mirror segments, uncomment and set the mirroring parameters according to your environment. Here is an example of the optional mirror parameters in the `gpinitsystem_config` file:

```bash
MIRROR_PORT_BASE=7000
REPLICATION_PORT_BASE=8000
MIRROR_REPLICATION_PORT_BASE=9000
declare -a MIRROR_DATA_DIRECTORY=(/data1/mirror /data1/mirror /data1/mirror /data2/mirror /data2/mirror /data2/mirror)
```

**Note:** You can initialize your Greenplum system with primary segments only and deploy mirrors later using the `gpaddmirrors` utility.

5. Save and close the file.

## Running the Initialization Utility

The `gpinitsystem` utility will create a Greenplum Database system using the values defined in the configuration file.

### To run the initialization utility

1. Run the following command referencing the path and file name of your initialization configuration file (`gpinitsystem_config`) and host file (`hostfile_gpinitsystem`). For example:

   ```bash
   $ cd ~
   $ gpinitsystem -c gpconfigs/gpinitsystem_config -h gpconfigs/hostfile_gpinitsystem
   ```

   For a fully redundant system (with a standby master and a `spread` mirror configuration) include the `-s` and `-S` options. For example:

   ```bash
   $ gpinitsystem -c gpconfigs/gpinitsystem_config -h gpconfigs/hostfile_gpinitsystem
   -s standby_master_hostname -S
   ```

2. The utility will verify your setup information and make sure it can connect to each host and access the data directories specified in your configuration. If all of the pre-checks are successful, the utility will prompt you to confirm your configuration. For example:

   ```
   => Continue with Greenplum creation? Yy/Nn
   ```

3. Press `y` to start the initialization.

4. The utility will then begin setup and initialization of the master instance and each segment instance in the system. Each segment instance is set up in parallel. Depending on the number of segments, this process can take a while.

5. At the end of a successful setup, the utility will start your Greenplum Database system. You should see:

   ```
   => Greenplum Database instance successfully created.
   ```
Troubleshooting Initialization Problems

If the utility encounters any errors while setting up an instance, the entire process will fail, and could possibly leave you with a partially created system. Refer to the error messages and logs to determine the cause of the failure and where in the process the failure occurred. Log files are created in ~\gpAdminLogs.

Depending on when the error occurred in the process, you may need to clean up and then try the gpinitsystem utility again. For example, if some segment instances were created and some failed, you may need to stop postgres processes and remove any utility-created data directories from your data storage area(s). A backout script is created to help with this cleanup if necessary.

Using the Backout Script

If the gpinitsystem utility fails, it will create the following backout script if it has left your system in a partially installed state:

~/gpAdminLogs/backout_gpinitsystem_<user>_<timestamp>

You can use this script to clean up a partially created Greenplum Database system. This backout script will remove any utility-created data directories, postgres processes, and log files. After correcting the error that caused gpinitsystem to fail and running the backout script, you should be ready to retry initializing your Greenplum Database array.

The following example shows how to run the backout script:

$ sh backout_gpinitsystem_gpadmin_20071031_121053

Setting the Greenplum Database Timezone

As a best practice, configure Greenplum Database and the host systems to use a known, supported timezone. Greenplum Database uses a timezone from a set of internally stored PostgreSQL timezones. Setting the Greenplum Database timezone prevents Greenplum Database from selecting a timezone each time the cluster is restarted and sets the timezone for the Greenplum Database master and segment instances.

Use the gpconfig utility to show and set the Greenplum Database timezone. For example, these commands show the Greenplum Database timezone and set the timezone to US/Pacific.

# gpconfig -s TimeZone
# gpconfig -c TimeZone -v 'US/Pacific'

You must restart Greenplum Database after changing the timezone. The command gpstop -ra restarts Greenplum Database. The catalog view pg_timezone_names provides Greenplum Database timezone information.

For more information about the Greenplum Database timezone, see Configuring Timezone and Localization Settings.

Setting Greenplum Environment Variables

You must configure your environment on the Greenplum Database master (and standby master). A greenplum_path.sh file is provided in your $GPHOME directory with environment variable settings for Greenplum Database. You can source this file in the gpadmin user’s startup shell profile (such as .bashrc).

The Greenplum Database management utilities also require that the MASTER_DATA_DIRECTORY environment variable be set. This should point to the directory created by the gpinitsystem utility in the master data directory location.
To set up your user environment for Greenplum

1. Make sure you are logged in as gpadmin:

   ```
   $ su - gpadmin
   ```

2. Open your profile file (such as .bashrc) in a text editor. For example:

   ```
   $ vi ~/.bashrc
   ```

3. Add lines to this file to source the `greenplum_path.sh` file and set the `MASTER_DATA_DIRECTORY` environment variable. For example:

   ```
   source /usr/local/greenplum-db/greenplum_path.sh
   export MASTER_DATA_DIRECTORY=/data/master/gpseg-1
   ```

4. (Optional) You may also want to set some client session environment variables such as `PGPORT`, `PGUSER` and `PGDATABASE` for convenience. For example:

   ```
   export PGPORT=5432
   export PGUSER=gpadmin
   export PGDATABASE=default_login_database_name
   ```

5. (Optional) If you use RHEL 7 or CentOS 7, add the following line to the end of the `.bashrc` file to enable using the `ps` command in the `greenplum_path.sh` environment:

   ```
   export LD_PRELOAD=/lib64/libz.so.1 ps
   ```

6. Save and close the file.

7. After editing the profile file, source it to make the changes active. For example:

   ```
   $ source ~/.bashrc
   ```

8. If you have a standby master host, copy your environment file to the standby master as well. For example:

   ```
   $ cd ~
   $ scp .bashrc standby_hostname:`pwd`
   ```

   **Note:** The `.bashrc` file should not produce any output. If you wish to have a message display to users upon logging in, use the `.profile` file instead.

**Next Steps**

After your system is up and running, the next steps are:

- **Allowing Client Connections**
- **Creating Databases and Loading Data**

**Allowing Client Connections**

After a Greenplum Database is first initialized it will only allow local connections to the database from the `gpadmin` role (or whatever system user ran `gpinitsystem`). If you would like other users or client machines to be able to connect to Greenplum Database, you must give them access. See the `Greenplum Database Administrator Guide` for more information.
Creating Databases and Loading Data

After verifying your installation, you may want to begin creating databases and loading data. See *Defining Database Objects* and *Loading and Unloading Data* in the *Greenplum Database Administrator Guide* for more information about creating databases, schemas, tables, and other database objects in Greenplum Database and loading your data.
Installing Optional Extensions

Information about installing optional Greenplum Database extensions and packages, such as the Procedural Language extensions and the Python and R Data Science Packages.

Procedural Language, Machine Learning, and Geospatial Extensions

Optional. Use the Greenplum package manager (gppkg) to install Greenplum Database extensions such as PL/Java, PL/R, PostGIS, and MADlib, along with their dependencies, across an entire cluster. The package manager also integrates with existing scripts so that any packages are automatically installed on any new hosts introduced into the system following cluster expansion or segment host recovery.

See gppkg for more information, including usage.

Extension packages can be downloaded from the Greenplum Database page on Pivotal Network. The extension documentation in the Greenplum Database Reference Guide contains information about installing extension packages and using extensions.

- Greenplum PL/R Language Extension
- Greenplum PL/Java Language Extension
- Greenplum MADlib Extension for Analytics
- Greenplum PostGIS Extension

Important: If you intend to use an extension package with Greenplum Database 5.x you must install and use a Greenplum Database extension package (gppkg files and contrib modules) that is built for Greenplum Database 5.x. Any custom modules that were used with earlier versions must be rebuilt for use with Greenplum Database 5.x.

Python Data Science Module Package

Greenplum Database provides a collection of data science-related Python modules that can be used with the Greenplum Database PL/Python language. You can download these modules in .gppkg format from Pivotal Network.

This section contains the following information:

- Python Data Science Modules
- Installing the Python Data Science Module Package
- Uninstalling the Python Data Science Module Package

For information about the Greenplum Database PL/Python Language, see Greenplum PL/Python Language Extension.

Python Data Science Modules

Modules provided in the Python Data Science package include:

Table 29: Data Science Modules

<table>
<thead>
<tr>
<th>Module Name</th>
<th>Description/Used For</th>
</tr>
</thead>
<tbody>
<tr>
<td>Beautiful Soup</td>
<td>Navigating HTML and XML</td>
</tr>
<tr>
<td>Gensim</td>

Installating the Python Data Science Module Package

Before you install the Python Data Science Module package, make sure that your Greenplum Database is running, you have sourced `greenplum_path.sh`, and that the `$MASTER_DATA_DIRECTORY` and `$GPHOME` environment variables are set.

**Note:** The PyMC3 module depends on Tk. If you want to use PyMC3, you must install the tk OS package on every node in your cluster. For example:

```bash
$ yum install tk
```

1. Locate the Python Data Science module package that you built or downloaded.

   The file name format of the package is `DataSciencePython-<version>-relhel<N>-x86_64.gppkg`.

2. Copy the package to the Greenplum Database master host.

3. Use the `gppkg` command to install the package. For example:

   ```bash
   $ gppkg -i DataSciencePython-<version>-relhel<N>-x86_64.gppkg
   ```

   `gppkg` installs the Python Data Science modules on all nodes in your Greenplum Database cluster. The command also updates the PYTHONPATH, PATH, and LD_LIBRARY_PATH environment variables in your `greenplum_path.sh` file.

4. Restart Greenplum Database. You must re-source `greenplum_path.sh` before restarting your Greenplum cluster:

   ```bash
   $ source /usr/local/greenplum-db/greenplum_path.sh
   $ gpstop -r
   ```
The Greenplum Database Python Data Science Modules are installed in the following directory:

\$GPHOME/ext/DataSciencePython/lib/python2.7/site-packages/

**Uninstalling the Python Data Science Module Package**

Use the `gppkg` utility to uninstall the Python Data Science Module package. You must include the version number in the package name you provide to `gppkg`.

To determine your Python Data Science Module package version number and remove this package:

```
$ gppkg -q --all | grep DataSciencePython
DataSciencePython-<version>
$ gppkg -r DataSciencePython-<version>
```

The command removes the Python Data Science modules from your Greenplum Database cluster. It also updates the `PYTHONPATH`, `PATH`, and `LD_LIBRARY_PATH` environment variables in your `greenplum_path.sh` file to their pre-installation values.

Re-source `greenplum_path.sh` and restart Greenplum Database after you remove the Python Data Science Module package:

```
$ . /usr/local/greenplum-db/greenplum_path.sh
$ gpstop -r
```

**Note:** When you uninstall the Python Data Science Module package from your Greenplum Database cluster, any UDFs that you have created that import Python modules installed with this package will return an error.

### R Data Science Library Package

R packages are modules that contain R functions and data sets. Greenplum Database provides a collection of data science-related R libraries that can be used with the Greenplum Database PL/R language. You can download these libraries in .gppkg format from Pivotal Network.

This chapter contains the following information:

- R Data Science Libraries
- Installing the R Data Science Library Package
- Uninstalling the R Data Science Library Package

For information about the Greenplum Database PL/R Language, see Greenplum PL/R Language Extension.

### R Data Science Libraries

Libraries provided in the R Data Science package include:

<table>
<thead>
<tr>
<th>abind</th>
<th>glmnet</th>
<th>quantreg</th>
</tr>
</thead>
<tbody>
<tr>
<td>adabag</td>
<td>gplots</td>
<td>R2jags</td>
</tr>
<tr>
<td>arm</td>
<td>gttable</td>
<td>R6</td>
</tr>
<tr>
<td>assertthat</td>
<td>gtools</td>
<td>randomForest</td>
</tr>
<tr>
<td>BH</td>
<td>hms</td>
<td>RColorBrewer</td>
</tr>
<tr>
<td>bitops</td>
<td>hybridHclust</td>
<td>Rcpp</td>
</tr>
<tr>
<td>car</td>
<td>igraph</td>
<td>RcppEigen</td>
</tr>
</tbody>
</table>
Installing the R Data Science Library Package

Before you install the R Data Science Library package, make sure that your Greenplum Database is running, you have sourced `greenplum_path.sh`, and that the `$MASTER_DATA_DIRECTORY` and `$GPHOME` environment variables are set.

1. Locate the R Data Science library package that you built or downloaded.
   
   The file name format of the package is `DataScienceR-<version>-relhel<N>-x86_64.gppkg`.

2. Copy the package to the Greenplum Database master host.

3. Use the `gppkg` command to install the package. For example:

   ```bash
   $ gppkg -i DataScienceR-<version>-relhel<N>-x86_64.gppkg
   ```

   `gppkg` installs the R Data Science libraries on all nodes in your Greenplum Database cluster. The command also sets the `R_LIBS_USER` environment variable and updates the `PATH` and `LD_LIBRARY_PATH` environment variables in your `greenplum_path.sh` file.

4. Restart Greenplum Database. You must re-source `greenplum_path.sh` before restarting your Greenplum cluster:

   ```bash
   $ source /usr/local/greenplum-db/greenplum_path.sh
   $ gpstop -r
   ```

The Greenplum Database R Data Science Modules are installed in the following directory:

```
$GPHOME/ext/DataScienceR/library
```

**Note:** `rjags` libraries are installed in the `$GPHOME/ext/DataScienceR/extlib/lib` directory. If you want to use `rjags` and your `$GPHOME` is not `/usr/local/greenplum-db`, you must...
perform additional configuration steps to create a symbolic link from `$GPHOME` to `/usr/local/greenplum-db` on each node in your Greenplum Database cluster. For example:

```
$ gpssh -f all_hosts -e 'ln -s $GPHOME /usr/local/greenplum-db'
$ gpssh -f all_hosts -e 'chown -h gpadmin /usr/local/greenplum-db'
```

**Uninstalling the R Data Science Library Package**

Use the `gppkg` utility to uninstall the R Data Science Library package. You must include the version number in the package name you provide to `gppkg`.

To determine your R Data Science Library package version number and remove this package:

```
$ gppkg -q --all | grep DataScienceR
DataScienceR-<version>
$ gppkg -r DataScienceR-<version>
```

The command removes the R Data Science libraries from your Greenplum Database cluster. It also removes the `R_LIBS_USER` environment variable and updates the `PATH` and `LD_LIBRARY_PATH` environment variables in your `greenplum_path.sh` file to their pre-installation values.

Re-source `greenplum_path.sh` and restart Greenplum Database after you remove the R Data Science Library package:

```
$ . /usr/local/greenplum-db/greenplum_path.sh
$ gpstop -r
```

**Note:** When you uninstall the R Data Science Library package from your Greenplum Database cluster, any UDFs that you have created that use R libraries installed with this package will return an error.

**Greenplum Platform Extension Framework (PXF)**

*Optional.* If you do not plan to use PXF, no action is necessary.

If you plan to use PXF, refer to *Configuring PXF* for instructions.

**Oracle Compatibility Functions**

*Optional.* Many Oracle Compatibility SQL functions are available in Greenplum Database. These functions target PostgreSQL.

Before using any Oracle Compatibility Functions, you need to run the installation script `$GPHOME/share/postgresql/contrib/orafunc.sql` once for each database. For example, to install the functions in database `testdb`, use the command

```
$ psql -d testdb -f $GPHOME/share/postgresql/contrib/orafunc.sql
```

To uninstall Oracle Compatibility Functions, use the script:

```
$GPHOME/share/postgresql/contrib/uninstall_orafunc.sql
```

**Note:** The following functions are available by default and can be accessed without running the Oracle Compatibility installer: `sinh`, `tanh`, `cosh` and `decode`.

For more information about Greenplum's Oracle compatibility functions, see "Oracle Compatibility Functions" in the *Greenplum Database Utility Guide.*
**dblink Connectivity Functions**

The PostgreSQL `dblink` module provides simple connections to other Greenplum Database databases from installations with the same major version number residing either on the same database host, or on a remote host. Greenplum Database provides `dblink` support for database users to perform short ad hoc queries in other databases. It is not intended as a replacement for external tables or administrative tools such as `gpcopy`.

Before you can use `dblink` functions, run the installation script `$GPHOME/share/postgresql/ contrib/dblink.sql` in each database where you want the ability to query other databases:

```
$ psql -d testdb -f $GPHOME/share/postgresql/contrib/dblink.sql
```

See [dblink Functions](#) for basic information about using `dblink` to query other databases. See `dblink` in the PostgreSQL documentation for more information about individual functions.

**pgcrypto Cryptographic Functions**

Greenplum Database is installed with an optional module of encryption/decryption functions called `pgcrypto`. The `pgcrypto` functions allow database administrators to store certain columns of data in encrypted form. This adds an extra layer of protection for sensitive data, as data stored in Greenplum Database in encrypted form cannot be read by anyone who does not have the encryption key, nor can it be read directly from the disks.

*Note:* The `pgcrypto` functions run inside the database server, which means that all the data and passwords move between `pgcrypto` and the client application in clear-text. For optimal security, consider also using SSL connections between the client and the Greenplum master server.

Before you can use `pgcrypto` functions, run the installation script `$GPHOME/share/ postgresql/contrib/pgcrypto.sql` in each database where you want the ability to query other databases:

```
$ psql -d testdb -f $GPHOME/share/postgresql/contrib/pgcrypto.sql
```

See `pgcrypto` in the PostgreSQL documentation for more information about individual functions.
Configuring Timezone and Localization Settings

Describes the available timezone and localization features of Greenplum Database.

Configuring the Timezone

Greenplum Database selects a timezone to use from a set of internally stored PostgreSQL timezones. The available PostgreSQL timezones are taken from the Internet Assigned Numbers Authority (IANA) Time Zone Database, and Greenplum Database updates its list of available timezones as necessary when the IANA database changes for PostgreSQL.

Greenplum Database selects the timezone by matching a PostgreSQL timezone with the value of the TimeZone server configuration parameter, or the host system time zone if TimeZone is not set. For example, when selecting a default timezone from the host system time zone, Greenplum Database uses an algorithm to select a PostgreSQL timezone based on the host system timezone files. If the system timezone includes leap second information, Greenplum Database cannot match the system timezone with a PostgreSQL timezone. In this case, Greenplum Database calculates a “best match” with a PostgreSQL timezone based on information from the host system.

As a best practice, configure Greenplum Database and the host systems to use a known, supported timezone. This sets the timezone for the Greenplum Database master and segment instances, and prevents Greenplum Database from selecting a best match timezone each time the cluster is restarted, using the current system timezone and Greenplum Database timezone files (which may have been updated from the IANA database since the last restart). Use the gpconfig utility to show and set the Greenplum Database timezone. For example, these commands show the Greenplum Database timezone and set the timezone to US/Pacific.

```bash
# gpconfig -s TimeZone
# gpconfig -c TimeZone -v 'US/Pacific'
```

You must restart Greenplum Database after changing the timezone. The command gpstop -ra restarts Greenplum Database. The catalog view pg_timezone_names provides Greenplum Database timezone information.

About Locale Support in Greenplum Database

Greenplum Database supports localization with two approaches:

- Using the locale features of the operating system to provide locale-specific collation order, number formatting, and so on.
- Providing a number of different character sets defined in the Greenplum Database server, including multiple-byte character sets, to support storing text in all kinds of languages, and providing character set translation between client and server.

Locale support refers to an application respecting cultural preferences regarding alphabets, sorting, number formatting, etc. Greenplum Database uses the standard ISO C and POSIX locale facilities provided by the server operating system. For additional information refer to the documentation of your operating system.

Locale support is automatically initialized when a Greenplum Database system is initialized. The initialization utility, gpinitsystem, will initialize the Greenplum array with the locale setting of its execution environment by default, so if your system is already set to use the locale that you want in your Greenplum Database system then there is nothing else you need to do.
When you are ready to initiate Greenplum Database and you want to use a different locale (or you are not sure which locale your system is set to), you can instruct `gpinitsystem` exactly which locale to use by specifying the `-n locale` option. For example:

```
$ gpinitsystem -c gp_init_config -n sv_SE
```

See *Initializing a Greenplum Database System* for information about the database initialization process.

The example above sets the locale to Swedish (sv) as spoken in Sweden (SE). Other possibilities might be `en_US` (U.S. English) and `fr_CA` (French Canadian). If more than one character set can be useful for a locale then the specifications look like this: `cs_CZ.ISO8859-2`. What locales are available under what names on your system depends on what was provided by the operating system vendor and what was installed. On most systems, the command `locale -a` will provide a list of available locales.

Occasionally it is useful to mix rules from several locales, for example use English collation rules but Spanish messages. To support that, a set of locale subcategories exist that control only a certain aspect of the localization rules:

- LC_COLLATE — String sort order
- LC_CTYPE — Character classification (What is a letter? Its upper-case equivalent?)
- LC_MESSAGES — Language of messages
- LC_MONETARY — Formatting of currency amounts
- LC_NUMERIC — Formatting of numbers
- LC_TIME — Formatting of dates and times

If you want the system to behave as if it had no locale support, use the special locale `C` or `POSIX`.

The nature of some locale categories is that their value has to be fixed for the lifetime of a Greenplum Database system. That is, once `gpinitsystem` has run, you cannot change them anymore. `LC_COLLATE` and `LC_CTYPE` are those categories. They affect the sort order of indexes, so they must be kept fixed, or indexes on text columns will become corrupt. Greenplum Database enforces this by recording the values of `LC_COLLATE` and `LC_CTYPE` that are seen by `gpinitsystem`. The server automatically adopts those two values based on the locale that was chosen at initialization time.

The other locale categories can be changed as desired whenever the server is running by setting the server configuration parameters that have the same name as the locale categories (see the *Greenplum Database Reference Guide* for more information on setting server configuration parameters). The defaults that are chosen by `gpinitsystem` are written into the master and segment `postgresql.conf` configuration files to serve as defaults when the Greenplum Database system is started. If you delete these assignments from the master and each segment `postgresql.conf` files then the server will inherit the settings from its execution environment.

Note that the locale behavior of the server is determined by the environment variables seen by the server, not by the environment of any client. Therefore, be careful to configure the correct locale settings on each Greenplum Database host (master and segments) before starting the system. A consequence of this is that if client and server are set up in different locales, messages may appear in different languages depending on where they originated.

Inheriting the locale from the execution environment means the following on most operating systems: For a given locale category, say the collation, the following environment variables are consulted in this order until one is found to be set: `LC_ALL`, `LC_COLLATE` (the variable corresponding to the respective category), `LANG`. If none of these environment variables are set then the locale defaults to `C`.

Some message localization libraries also look at the environment variable `LANGUAGE` which overrides all other locale settings for the purpose of setting the language of messages. If in doubt, please refer to the documentation for your operating system, in particular the documentation about `gettext`, for more information.

Native language support (NLS), which enables messages to be translated to the user’s preferred language, is not enabled in Greenplum Database for languages other than English. This is independent of the other locale support.
Locale Behavior

The locale settings influence the following SQL features:

- Sort order in queries using `ORDER BY` on textual data
- The ability to use indexes with `LIKE` clauses
- The `upper`, `lower`, and `initcap` functions
- The `to_char` family of functions

The drawback of using locales other than `C` or `POSIX` in Greenplum Database is its performance impact. It slows character handling and prevents ordinary indexes from being used by `LIKE`. For this reason use locales only if you actually need them.

Troubleshooting Locales

If locale support does not work as expected, check that the locale support in your operating system is correctly configured. To check what locales are installed on your system, you may use the command `locale -a` if your operating system provides it.

Check that Greenplum Database is actually using the locale that you think it is. `LC_COLLATE` and `LC_CTYPE` settings are determined at initialization time and cannot be changed without redoing `gpinitsystem`. Other locale settings including `LC_MESSAGES` and `LC_MONETARY` are initially determined by the operating system environment of the master and/or segment host, but can be changed after initialization by editing the `postgresql.conf` file of each Greenplum master and segment instance. You can check the active locale settings of the master host using the `SHOW` command. Note that every host in your Greenplum Database array should be using identical locale settings.

Character Set Support

The character set support in Greenplum Database allows you to store text in a variety of character sets, including single-byte character sets such as the ISO 8859 series and multiple-byte character sets such as EUC (Extended Unix Code), UTF-8, and Mule internal code. All supported character sets can be used transparently by clients, but a few are not supported for use within the server (that is, as a server-side encoding). The default character set is selected while initializing your Greenplum Database array using `gpinitsystem`. It can be overridden when you create a database, so you can have multiple databases each with a different character set.

Table 30: Greenplum Database Character Sets

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Language</th>
<th>Server?</th>
<th>Bytes/Char</th>
<th>Aliases</th>
</tr>
</thead>
<tbody>
<tr>
<td>BIG5</td>
<td>Big Five</td>

</tbody>
</table>

**Setting the Character Set**

gpinitsystem defines the default character set for a Greenplum Database system by reading the setting of the ENCODING parameter in the gp_init_config file at initialization time. The default character set is **UNICODE** or **UTF8**.

---

2 The SQL_ASCII setting behaves considerably differently from the other settings. Byte values 0-127 are interpreted according to the ASCII standard, while byte values 128-255 are taken as uninterpreted characters. If you are working with any non-ASCII data, it is unwise to use the SQL_ASCII setting as a client encoding. SQL_ASCII is not supported as a server encoding.
You can create a database with a different character set besides what is used as the system-wide default. For example:

```
=> CREATE DATABASE korean WITH ENCODING 'EUC_KR';
```

**Important**: Although you can specify any encoding you want for a database, it is unwise to choose an encoding that is not what is expected by the locale you have selected. The `LC_COLLATE` and `LC_CTYPE` settings imply a particular encoding, and locale-dependent operations (such as sorting) are likely to misinterpret data that is in an incompatible encoding.

Since these locale settings are frozen by `gpinitsystem`, the apparent flexibility to use different encodings in different databases is more theoretical than real.

One way to use multiple encodings safely is to set the locale to `C` or `POSIX` during initialization time, thus disabling any real locale awareness.

## Character Set Conversion Between Server and Client

Greenplum Database supports automatic character set conversion between server and client for certain character set combinations. The conversion information is stored in the master `pg_conversion` system catalog table. Greenplum Database comes with some predefined conversions or you can create a new conversion using the SQL command `CREATE CONVERSION`.

### Table 31: Client/Server Character Set Conversions

</tbody>
</table>

To enable automatic character set conversion, you have to tell Greenplum Database the character set (encoding) you would like to use in the client. There are several ways to accomplish this:

- Using the `\encoding` command in `psql`, which allows you to change client encoding on the fly.
- Using `SET client_encoding TO`. Setting the client encoding can be done with this SQL command:

```sql
=> SET CLIENT_ENCODING TO 'value';
```

To query the current client encoding:

```sql
=> SHOW client_encoding;
```

To return to the default encoding:

```sql
=> RESET client_encoding;
```
• Using the PGCLIENTENCODING environment variable. When PGCLIENTENCODING is defined in the client’s environment, that client encoding is automatically selected when a connection to the server is made. (This can subsequently be overridden using any of the other methods mentioned above.)

• Setting the configuration parameter client_encoding. If client_encoding is set in the master postgresql.conf file, that client encoding is automatically selected when a connection to Greenplum Database is made. (This can subsequently be overridden using any of the other methods mentioned above.)

If the conversion of a particular character is not possible — suppose you chose EUC_JP for the server and LATIN1 for the client, then some Japanese characters do not have a representation in LATIN1 — then an error is reported.

If the client character set is defined as SQL_ASCII, encoding conversion is disabled, regardless of the server’s character set. The use of SQL_ASCII is unwise unless you are working with all-ASCII data. SQL_ASCII is not supported as a server encoding.
About Implicit Text Casting in Greenplum Database

Greenplum Database version 4.3.x is based on PostgreSQL version 8.2. Greenplum Database version 5.x is based on PostgreSQL version 8.3. PostgreSQL 8.3 removed automatic implicit casts between the text type and other data types. When you migrate from Greenplum Database version 4.3.x to version 5.x, this change in behavior might impact existing applications and queries.

For information about how Greenplum Database 5.x performs type casts, see Type Casts in the Greenplum Database Administrator Guide.

What is different in Greenplum Database 5.x?

Greenplum Database 5.x does not automatically implicitly cast between text and other data types. Greenplum Database 5.x also treats certain automatic implicit casts differently than version 4.3.x, and in some cases does not handle them at all. Applications or queries that you wrote for Greenplum Database 4.3.x that rely on automatic implicit casting may fail on Greenplum Database version 5.x.

(The term implicit cast, when used in the remainder of this section, refers to implicit casts automatically applied by Greenplum Database.)

- Greenplum Database 5.x has downgraded implicit casts in the to-text type direction; these casts are now treated as assignment casts. A cast from a data type to the text type will continue to work in Greenplum Database 5.x if used in assignment contexts.
- Greenplum Database 5.x no longer automatically provides an implicit cast in the to-text type direction that can be used in expression contexts. Additionally, Greenplum Database 5.x no longer provides implicit casts in the from-text type direction. When such expressions or assignments are encountered, Greenplum Database 5.x returns an error and the following message:

```
HINT: No operator matches the given name and argument type(s). You might need to add explicit type casts.
```

To illustrate, suppose you create two tables:

```
CREATE TABLE foo (a int) DISTRIBUTED RANDOMLY;
CREATE TABLE bar (b text) DISTRIBUTED RANDOMLY;
```

The following examples demonstrate certain types of text comparison queries that will fail on Greenplum Database 5.x.

**Note:** This is not an exhaustive list of failure scenarios.

- Queries that reference text type and non-text type columns in an expression. In this example query, the comparison expression returns a cast error.

```
SELECT * FROM foo, bar WHERE foo.a = bar.b;
```

```
ERROR: operator does not exist: integer = text
```

```
LINE 1: SELECT * FROM foo, bar WHERE foo.a = bar.b;
```

```
^ HINT: No operator matches the given name and argument type(s). You might need to add explicit type casts.
```

The updated example casts the text type to an integer type.

```
SELECT * FROM foo, bar WHERE foo.a = bar.b::int;
```

- Queries that mix the text type and non-text type columns in function and aggregate arguments. In this example, the query that executes the example function `concat` returns a cast error.

```
CREATE FUNCTION concat(TEXT, TEXT)
```
RETURNS TEXT AS $$
    SELECT $1 || $2
$$ STRICT LANGUAGE SQL;

SELECT concat('a':TEXT, 2);

Adding an explicit cast from integer to text fixes the issue.

SELECT concat('a', 2::text);

• Queries that perform comparisons between a text type column and a non-quoted literal such as an integer, number, float, or oid. This example query that compares text and non-quoted integer returns an error.

SELECT * FROM bar WHERE b = 123;

Adding an explicit cast to text fixes the issue.

SELECT * FROM bar WHERE b = 123::text;

• Queries that perform comparisons between a date type column or literal and an integer-like column (Greenplum Database internally converts date types to the text type). This example query that compares an integer column with a literal of type date returns an error.

SELECT * FROM foo WHERE a = '20130101':DATE;

There is no built-in cast from integer type to date type. However, you can explicitly cast an integer to text and then to date. The updated examples use the cast and :: syntax.

SELECT * FROM foo WHERE cast(cast(a AS text) AS date)  = '20130101':date;
SELECT * FROM foo WHERE (a::text)::date  = '20130101':date;

The only supported workaround for the implicit casting differences between Greenplum Database versions 4.3.x and 5.x is to analyze failing applications and queries and update the application or query to use explicit casts to fix the failures.

If rewriting the application or query is not feasible, you may choose to temporarily work around the change in behaviour introduced by the removal of automatic implicit casts in Greenplum Database 5.x. There are two well-known workarounds to this PostgreSQL issue:

• Re-create the implicit casts (described in Readding implicit casts in PostgreSQL 8.3).
• Create missing operators (described in Problems and workaround recreating implicit casts using 8.3+).

The workaround to re-create the implicit casts is not recommended as it breaks concatenation functionality. With the create missing operators workaround, you create the operators and functions that implement the comparison expressions that are failing in your applications and queries.

**Workaround: Manually Creating Missing Operators**

**Warning:** Use this workaround only to aid migration to Greenplum Database 5.x for evaluation purposes. Do not use this workaround in a production environment.

When you create an operator, you identify the data types of the left operand and the right operand. You also identify the name of a function that Greenplum Database invokes to evaluate the operator expression between the specified data types. The operator function evaluates the expression by performing either to-text or from-text conversion using the INPUT/OUTPUT methods of the data types involved. By creating operators for each (text type, other data type) and (other data type, text type) combination, you effectively implement the casts that are missing in Greenplum Database 5.x.
To implement this workaround, complete the following tasks after you install Greenplum Database 5.x:

1. Identify and note the names of the Greenplum 5.x databases in which you want to create the missing operators. Consider applying this workaround to all databases in your Greenplum Database deployment.

2. Identify a schema in which to create the operators and functions. Use a schema other than pg_catalog to ensure that these objects are included in a pg_dump or gpbackup of the database. This procedure will use a schema named cast_fix for illustrative purposes.

3. Review the blog entry Problems and workaround recreating implicit casts using 8.3+. The blog discusses this temporary workaround to the casting issue, i.e. creating missing operators. It also references a SQL script that you can run to create a set of equality (=) operators and functions for several text and other data type comparisons.

4. Download the 8.3 operator workaround.sql script referenced on the blog page, noting the location to which the file was downloaded on your local system.

5. The 8.3 operator workaround.sql script creates the equality operators and functions. Open the script in the editor of your choice, and examine the contents. For example, using the vi editor:

   ```
   vi 8.3 operator workaround.sql
   ```

   Notice that the script creates the operators and functions in the pg_catalog schema.

6. Replace occurrences of pg_catalog in the script with the name of the schema that you identified in Step 2, and then save the file and exit the editor. (You will create this schema in an upcoming step if the schema does not already exist.) For example:

   ```
   :s/pg_catalog/cast_fix/g
   :wq
   ```

7. Analyze your failing queries, identifying the operators and from-type and to-type data type comparisons that are the source of the failures. Compare this list to the contents of the 8.3 operator workaround.sql script, and identify the minimum set of additional operators and left_type/right_type expression combinations that you must support.

8. For each operator and left_type/right_type combination that you identify in the previous step, add CREATE statements for the following objects to the 8.3 operator workaround.sql script:

   a. Create the function that implements the left_type operator right_type comparison. For example, to create a function that implements the greater than (>) operator for text (left_type) to integer (right_type) comparison:

   ```
   CREATE FUNCTION cast_fix.textgtint(text, integer)
   RETURNS boolean
   STRICT IMMUTABLE LANGUAGE SQL AS $$
   SELECT textin(int4out($2)) > $1;
   $$;
   ```

   Be sure to schema-qualify the function name.

   b. Create the operator. For example, to create a greater than (>) operator for text (left_type) to integer (right_type) type comparison that specifies the function you created above:

   ```
   CREATE OPERATOR cast_fix.> (PROCEDURE=cast_fix.textgtint, LEFTARG=text, RIGHTARG=integer, COMMUTATOR=OPERATOR(cast_fix.>))
   ```

   Be sure to schema-qualify the operator and function names.

   c. You must create another operator and function if you want the operator to work in reverse (i.e. using the example above, if you want a greater than operator for integer (left_type) to text (right_type) comparison.)

9. For each database that you identified in Step 1, add the missing operators. For example:
a. Connect to the database as an administrative user. For example:

```sql
$ psql -d database1 -U gpadmin
```

b. Create the schema if it does not already exist. For example:

```sql
CREATE SCHEMA cast_fix;
```

c. Run the script. For example, if you downloaded the file to the `/tmp` directory:

```sql
\i /tmp/8.3 operator workaround.sql
```

You must create the schema and run the script for every new database that you create in your Greenplum Database cluster.

10. Identify and note the names of the users/roles to which you want to provide this capability. Consider exposing this to all roles in your Greenplum Database deployment.

11. For each role that you identified in Step 10, add the schema to the role's `search_path`. For example:

```sql
SHOW search_path;
ALTER ROLE bill SET search_path TO existing_search_path, cast_fix;
```

If required, also grant schema-level permissions to the role.
## Installation Management Utilities

References for the command-line management utilities used to install and initialize a Greenplum Database system.

For a full reference of all Greenplum Database utilities, see the *Greenplum Database Utility Guide*.

The following Greenplum Database management utilities are located in `$GPHOME/bin`.

<table>
<thead>
<tr>
<th>Utilities</th>
<th>Utilities</th>
</tr>
</thead>
<tbody>

Greenplum Environment Variables

Reference of the environment variables to set for Greenplum Database.
Set these in your user’s startup shell profile (such as ~/.bashrc or ~/.bash_profile), or in /etc/profile if you want to set them for all users.

Required Environment Variables

Note: GPHOME, PATH and LD_LIBRARY_PATH can be set by sourcing the greenplum_path.sh file from your Greenplum Database installation directory

GPHOME
This is the installed location of your Greenplum Database software. For example:

```
GPHOME=/usr/local/greenplum-db-4.3.x.x
export GPHOME
```

PATH
Your PATH environment variable should point to the location of the Greenplum Database bin directory. For example:

```
PATH=$GPHOME/bin:$PATH
export PATH
```

LD_LIBRARY_PATH
The LD_LIBRARY_PATH environment variable should point to the location of the Greenplum Database/ PostgreSQL library files. For example:

```
LD_LIBRARY_PATH=$GPHOME/lib
export LD_LIBRARY_PATH
```

MASTER_DATA_DIRECTORY
This should point to the directory created by the gpinitsystem utility in the master data directory location. For example:

```
MASTER_DATA_DIRECTORY=/data/master/gpseg-1
export MASTER_DATA_DIRECTORY
```

Optional Environment Variables

The following are standard PostgreSQL environment variables, which are also recognized in Greenplum Database. You may want to add the connection-related environment variables to your profile for convenience, so you do not have to type so many options on the command line for client connections. Note that these environment variables should be set on the Greenplum Database master host only.
PGAPPNAME
The name of the application that is usually set by an application when it connects to the server. This name is displayed in the activity view and in log entries. The PGAPPNAME environmental variable behaves the same as the application_name connection parameter. The default value for application_name is psql. The name cannot be longer than 63 characters.

PGDATABASE
The name of the default database to use when connecting.

PGHOST
The Greenplum Database master host name.

PGHOSTADDR
The numeric IP address of the master host. This can be set instead of or in addition to PGHOST to avoid DNS lookup overhead.

PGPASSWORD
The password used if the server demands password authentication. Use of this environment variable is not recommended for security reasons (some operating systems allow non-root users to see process environment variables via ps). Instead consider using the ~/.pgpass file.

PGPASSFILE
The name of the password file to use for lookups. If not set, it defaults to ~/.pgpass. See the topic about The Password File in the PostgreSQL documentation for more information.

PGOPTIONS
Sets additional configuration parameters for the Greenplum Database master server.

PGPORT
The port number of the Greenplum Database server on the master host. The default port is 5432.

PGUSER
The Greenplum Database user name used to connect.

PGDATESTYLE
Sets the default style of date/time representation for a session. (Equivalent to SET datestyle TO...)

PGTZ
Sets the default time zone for a session. (Equivalent to SET timezone TO...)

PGCLIENTENCODING
Sets the default client character set encoding for a session. (Equivalent to SET client_encoding TO...
Chapter 7

Greenplum Database Administrator Guide

Information about configuring, managing and monitoring Greenplum Database installations, and administering, monitoring, and working with databases. The guide also contains information about Greenplum Database architecture and concepts such as parallel processing.
Greenplum Database Concepts

This section provides an overview of Greenplum Database components and features such as high availability, parallel data loading features, and management utilities.

This section contains the following topics:

- About the Greenplum Architecture
- About Management and Monitoring Utilities
- About Parallel Data Loading
- About Redundancy and Failover in Greenplum Database
- About Database Statistics in Greenplum Database

About the Greenplum Architecture

Greenplum Database is a massively parallel processing (MPP) database server with an architecture specially designed to manage large-scale analytic data warehouses and business intelligence workloads.

MPP (also known as a *shared nothing* architecture) refers to systems with two or more processors that cooperate to carry out an operation, each processor with its own memory, operating system and disks. Greenplum uses this high-performance system architecture to distribute the load of multi-terabyte data warehouses, and can use all of a system’s resources in parallel to process a query.

Greenplum Database is based on PostgreSQL open-source technology. It is essentially several PostgreSQL disk-oriented database instances acting together as one cohesive database management system (DBMS). It is based on PostgreSQL 8.3.23, and in most cases is very similar to PostgreSQL with regard to SQL support, features, configuration options, and end-user functionality. Database users interact with Greenplum Database as they would with a regular PostgreSQL DBMS.

Greenplum Database can use the append-optimized (AO) storage format for bulk loading and reading of data, and provides performance advantages over HEAP tables. Append-optimized storage provides checksums for data protection, compression and row/column orientation. Both row-oriented or column-oriented append-optimized tables can be compressed.

The main differences between Greenplum Database and PostgreSQL are as follows:

- GPORCA is leveraged for query planning, in addition to the legacy query planner, which is based on the Postgres query planner.
- Greenplum Database can use append-optimized storage.
- Greenplum Database has the option to use column storage, data that is logically organized as a table, using rows and columns that are physically stored in a column-oriented format, rather than as rows. Column storage can only be used with append-optimized tables. Column storage is compressible. It also can provide performance improvements as you only need to return the columns of interest to you. All compression algorithms can be used with either row or column-oriented tables, but Run-LengthEncoded (RLE) compression can only be used with column-oriented tables. Greenplum Database provides compression on all Append-Optimized tables that use column storage.

The internals of PostgreSQL have been modified or supplemented to support the parallel structure of Greenplum Database. For example, the system catalog, optimizer, query executor, and transaction manager components have been modified and enhanced to be able to execute queries simultaneously across all of the parallel PostgreSQL database instances. The Greenplum *interconnect* (the networking layer) enables communication between the distinct PostgreSQL instances and allows the system to behave as one logical database.

Greenplum Database also can use declarative partitions and sub-partitions to implicitly generate partition constraints.
Greenplum Database also includes features designed to optimize PostgreSQL for business intelligence (BI) workloads. For example, Greenplum has added parallel data loading (external tables), resource management, query optimizations, and storage enhancements, which are not found in standard PostgreSQL. Many features and optimizations developed by Greenplum make their way into the PostgreSQL community. For example, table partitioning is a feature first developed by Greenplum, and it is now in standard PostgreSQL.

Greenplum Database queries use a Volcano-style query engine model, where the execution engine takes an execution plan and uses it to generate a tree of physical operators, evaluates tables through physical operators, and delivers results in a query response.

Greenplum Database stores and processes large amounts of data by distributing the data and processing workload across several servers or hosts. Greenplum Database is an array of individual databases based upon PostgreSQL 8.3 working together to present a single database image. The master is the entry point to the Greenplum Database system. It is the database instance to which clients connect and submit SQL statements. The master coordinates its work with the other database instances in the system, called segments, which store and process the data.

**Figure 10: High-Level Greenplum Database Architecture**

The following topics describe the components that make up a Greenplum Database system and how they work together.

**About the Greenplum Master**

The Greenplum Database master is the entry to the Greenplum Database system, accepting client connections and SQL queries, and distributing work to the segment instances.

Greenplum Database end-users interact with Greenplum Database (through the master) as they would with a typical PostgreSQL database. They connect to the database using client programs such as `psql` or application programming interfaces (APIs) such as JDBC, ODBC or `libpq` (the PostgreSQL C API).
The master is where the *global system catalog* resides. The global system catalog is the set of system tables that contain metadata about the Greenplum Database system itself. The master does not contain any user data; data resides only on the *segments*. The master authenticates client connections, processes incoming SQL commands, distributes workloads among segments, coordinates the results returned by each segment, and presents the final results to the client program.

Greenplum Database uses Write-Ahead Logging (WAL) for master/standby master mirroring. In WAL-based logging, all modifications are written to the log before being applied, to ensure data integrity for any in-process operations.  

**Note:** WAL logging is not yet available for segment mirroring.

**About the Greenplum Segments**

Greenplum Database segment instances are independent PostgreSQL databases that each store a portion of the data and perform the majority of query processing.

When a user connects to the database via the Greenplum master and issues a query, processes are created in each segment database to handle the work of that query. For more information about query processes, see *About Greenplum Query Processing*.

User-defined tables and their indexes are distributed across the available segments in a Greenplum Database system; each segment contains a distinct portion of data. The database server processes that serve segment data run under the corresponding segment instances. Users interact with segments in a Greenplum Database system through the master.

Segments run on a servers called *segment hosts*. A segment host typically executes from two to eight Greenplum segments, depending on the CPU cores, RAM, storage, network interfaces, and workloads. Segment hosts are expected to be identically configured. The key to obtaining the best performance from Greenplum Database is to distribute data and workloads *evenly* across a large number of equally capable segments so that all segments begin working on a task simultaneously and complete their work at the same time.

**About the Greenplum Interconnect**

The interconnect is the networking layer of the Greenplum Database architecture.

The *interconnect* refers to the inter-process communication between segments and the network infrastructure on which this communication relies. The Greenplum interconnect uses a standard Ethernet switching fabric. For performance reasons, a 10-Gigabit system, or faster, is recommended.

By default, the interconnect uses User Datagram Protocol with flow control (UDPIFC) for interconnect traffic to send messages over the network. The Greenplum software performs packet verification beyond what is provided by UDP. This means the reliability is equivalent to Transmission Control Protocol (TCP), and the performance and scalability exceeds TCP. If the interconnect is changed to TCP, Greenplum Database has a scalability limit of 1000 segment instances. With UDPIFC as the default protocol for the interconnect, this limit is not applicable.

**About Management and Monitoring Utilities**

Greenplum Database provides standard command-line utilities for performing common monitoring and administration tasks.

Greenplum command-line utilities are located in the `$GPHOME/bin` directory and are executed on the master host. Greenplum provides utilities for the following administration tasks:

- Installing Greenplum Database on an array
- Initializing a Greenplum Database System
- Starting and stopping Greenplum Database
- Adding or removing a host
- Expanding the array and redistributing tables among new segments
- Managing recovery for failed segment instances
- Managing failover and recovery for a failed master instance
- Backing up and restoring a database (in parallel)
- Loading data in parallel
- Transferring data between Greenplum databases
- System state reporting

Greenplum Database includes an optional performance management database that contains query status information and system metrics. The `gpperfmon_install` management utility creates the database, named `gpperfmon`, and enables data collection agents that execute on the Greenplum Database master and segment hosts. Data collection agents on the segment hosts collect query status from the segments, as well as system metrics such as CPU and memory utilization. An agent on the master host periodically (typically every 15 seconds) retrieves the data from the segment host agents and updates the `gpperfmon` database. Users can query the `gpperfmon` database to see the query and system metrics.

Pivotal provides an optional system monitoring and management tool, Greenplum Command Center, which administrators can install and enable with Greenplum Database. Greenplum Command Center, which depends upon the `gpperfmon` database, provides a web-based user interface for viewing the system metrics and allows administrators to perform additional system management tasks. For more information about Greenplum Command Center, see the Greenplum Command Center documentation.

![Figure 11: Greenplum Command Center Architecture](image)

**About Concurrency Control in Greenplum Database**

Greenplum Database uses the PostgreSQL Multiversion Concurrency Control (MVCC) model to manage concurrent transactions for heap tables.

Concurrency control in a database management system allows concurrent queries to complete with correct results while ensuring the integrity of the database. Traditional databases use a two-phase locking protocol that prevents a transaction from modifying data that has been read by another concurrent transaction and prevents any concurrent transaction from reading or writing data that another transaction has updated.
The locks required to coordinate transactions add contention to the database, reducing overall transaction throughput.

Greenplum Database uses the PostgreSQL Multiversion Concurrency Control (MVCC) model to manage concurrency for heap tables. With MVCC, each query operates on a snapshot of the database when the query starts. While it executes, a query cannot see changes made by other concurrent transactions. This ensures that a query sees a consistent view of the database. Queries that read rows can never block waiting for transactions that write rows. Conversely, queries that write rows cannot be blocked by transactions that read rows. This allows much greater concurrency than traditional database systems that employ locks to coordinate access between transactions that read and write data.

Note: Append-optimized tables are managed with a different concurrency control model than the MVCC model discussed in this topic. They are intended for "write-once, read-many" applications that never, or only very rarely, perform row-level updates.

Snapshots

The MVCC model depends on the system's ability to manage multiple versions of data rows. A query operates on a snapshot of the database at the start of the query. A snapshot is the set of rows that are visible at the beginning of a statement or transaction. The snapshot ensures the query has a consistent and valid view of the database for the duration of its execution.

Each transaction is assigned a unique transaction ID (XID), an incrementing 32-bit value. When a new transaction starts, it is assigned the next XID. An SQL statement that is not enclosed in a transaction is treated as a single-statement transaction—the BEGIN and COMMIT are added implicitly. This is similar to autocommit in some database systems.

Note: Greenplum Database assigns XID values only to transactions that involve DDL or DML operations, which are typically the only transactions that require an XID.

When a transaction inserts a row, the XID is saved with the row in the xmin system column. When a transaction deletes a row, the XID is saved in the xmax system column. Updating a row is treated as a delete and an insert, so the XID is saved to the xmax of the current row and the xmin of the newly inserted row. The xmin and xmax columns, together with the transaction completion status, specify a range of transactions for which the version of the row is visible. A transaction can see the effects of all transactions less than xmin, which are guaranteed to be committed, but it cannot see the effects of any transaction greater than or equal to xmax.

Multi-statement transactions must also record which command within a transaction inserted a row (cmin) or deleted a row (cmax) so that the transaction can see changes made by previous commands in the transaction. The command sequence is only relevant during the transaction, so the sequence is reset to 0 at the beginning of a transaction.

XID is a property of the database. Each segment database has its own XID sequence that cannot be compared to the XIDs of other segment databases. The master coordinates distributed transactions with the segments using a cluster-wide session ID number, called gp_session_id. The segments maintain a mapping of distributed transaction IDs with their local XIDs. The master coordinates distributed transactions across all of the segment with the two-phase commit protocol. If a transaction fails on any one segment, it is rolled back on all segments.

You can see the xmin, xmax, cmin, and cmax columns for any row with a SELECT statement:

```
SELECT xmin, xmax, cmin, cmax, * FROM tablename;
```

Because you run the SELECT command on the master, the XIDs are the distributed transactions IDs. If you could execute the command in an individual segment database, the xmin and xmax values would be the segment's local XIDs.
Transaction ID Wraparound

The MVCC model uses transaction IDs (XIDs) to determine which rows are visible at the beginning of a query or transaction. The XID is a 32-bit value, so a database could theoretically execute over four billion transactions before the value overflows and wraps to zero. However, Greenplum Database uses modulo $2^{32}$ arithmetic with XIDs, which allows the transaction IDs to wrap around, much as a clock wraps at twelve o'clock. For any given XID, there could be about two billion past XIDs and two billion future XIDs. This works until a version of a row persists through about two billion transactions, when it suddenly appears to be a new row. To prevent this, Greenplum has a special XID, called FrozenXID, which is always considered older than any regular XID it is compared with. The xmin of a row must be replaced with FrozenXID within two billion transactions, and this is one of the functions the VACUUM command performs.

Vacuuming the database at least every two billion transactions prevents XID wraparound. Greenplum Database monitors the transaction ID and warns if a VACUUM operation is required.

A warning is issued when a significant portion of the transaction IDs are no longer available and before transaction ID wraparound occurs:

```
WARNING: database "database_name" must be vacuumed within number_of_transactions transactions
```

When the warning is issued, a VACUUM operation is required. If a VACUUM operation is not performed, Greenplum Database stops creating transactions to avoid possible data loss when it reaches a limit prior to when transaction ID wraparound occurs and issues this error:

```
FATAL: database is not accepting commands to avoid wraparound data loss in database "database_name"
```

See Recovering from a Transaction ID Limit Error for the procedure to recover from this error.

The server configuration parameters xid_warn_limit and xid_stop_limit control when the warning and error are displayed. The xid_warn_limit parameter specifies the number of transaction IDs before the xid_stop_limit when the warning is issued. The xid_stop_limit parameter specifies the number of transaction IDs before wraparound would occur when the error is issued and new transactions cannot be created.

Transaction Isolation Modes

The SQL standard describes three phenomena that can occur when database transactions run concurrently:

- **Dirty read** – a transaction can read uncommitted data from another concurrent transaction.
- **Non-repeatable read** – a row read twice in a transaction can change because another concurrent transaction committed changes after the transaction began.
- **Phantom read** – a query executed twice in the same transaction can return two different sets of rows because another concurrent transaction added rows.

The SQL standard defines four transaction isolation modes that database systems must support:

Table 32: Transaction Isolation Modes

<table>
<thead>
<tr>
<th>Level</th>
<th>Dirty Read</th>
<th>Non-Repeatable</th>
<th>Phantom Read</th>
</tr>
</thead>
<tbody>
<tr>
<td>Read Uncommitted</td>
<td>Possible</td>
<td>Possible</td>
<td>Possible</td>
</tr>
<tr>
<td>Read Committed</td>
<td>Impossible</td>
<td>Possible</td>
<td>Possible</td>
</tr>
<tr>
<td>Repeatable Read</td>
<td>Impossible</td>
<td>Impossible</td>
<td>Possible</td>
</tr>
<tr>
<td>Serializable</td>
<td>Impossible</td>
<td>Impossible</td>
<td>Impossible</td>
</tr>
</tbody>
</table>
The Greenplum Database SQL commands allow you to request READ UNCOMMITTED, READ COMMITTED, or SERIALizable. Greenplum Database treats READ UNCOMMITTED the same as READ COMMITTED. Requesting REPEATABLE READ produces an error; use SERIALizable instead. The default isolation mode is READ COMMITTED.

The difference between READ COMMITTED and SERIALizable is that in READ COMMITTED mode, each statement in a transaction sees only rows committed before the statement started, while in SERIALizable mode, all statements in a transaction see only rows committed before the transaction started.

The READ COMMITTED isolation mode permits greater concurrency and better performance than the SERIALizable mode. It allows non-repeatable reads, where the values in a row retrieved twice in a transaction can differ because another concurrent transaction has committed changes since the transaction began. READ COMMITTED mode also permits phantom reads, where a query executed twice in the same transaction can return two different sets of rows.

The SERIALizable isolation mode prevents both non-repeatable reads and phantom reads, but at the cost of concurrency and performance. Each concurrent transaction has a consistent view of the database taken at the beginning of execution. A concurrent transaction that attempts to modify data modified by another transaction is rolled back. Applications that execute transactions in SERIALizable mode must be prepared to handle transactions that fail due to serialization errors. If SERIALizable isolation mode is not required by the application, it is better to use READ COMMITTED mode.

The SQL standard specifies that concurrent serializable transactions produce the same database state they would produce if executed sequentially. The MVCC snapshot isolation model prevents dirty reads, non-repeatable reads, and phantom reads without expensive locking, but there are other interactions that can occur between some SERIALizable transactions in Greenplum Database that prevent them from being truly serializable. These anomalies can often be attributed to the fact that Greenplum Database does not perform predicate locking, which means that a write in one transaction can affect the result of a previous read in another concurrent transaction.

Transactions that run concurrently should be examined to identify interactions that are not prevented by disallowing concurrent updates of the same data. Problems identified can be prevented by using explicit table locks or by requiring the conflicting transactions to update a dummy row introduced to represent the conflict.

The SQL SET TRANSACTION ISOLATION LEVEL statement sets the isolation mode for the current transaction. The mode must be set before any SELECT, INSERT, DELETE, UPDATE, or COPY statements:

```
BEGIN;
SET TRANSACTION ISOLATION LEVEL SERIALizable;
...
COMMIT;
```

The isolation mode can also be specified as part of the BEGIN statement:

```
BEGIN TRANSACTION ISOLATION LEVEL SERIALizable;
```

The default transaction isolation mode can be changed for a session by setting the `default_transaction_isolation` configuration property.

### Removing Dead Rows from Tables

Updating or deleting a row leaves an expired version of the row in the table. When an expired row is no longer referenced by any active transactions, it can be removed and the space it occupied can be reused. The VACUUM command marks the space used by expired rows for reuse.

When expired rows accumulate in a table, the disk files must be extended to accommodate new rows. Performance suffers due to the increased disk I/O required to execute queries. This condition is called bloat and it should be managed by regularly vacuuming tables.
The `VACUUM` command (without `FULL`) can run concurrently with other queries. It marks the space previously used by the expired rows as free. If the amount of remaining free space is significant, it adds the page to the table’s free space map. When Greenplum Database later needs space for new rows, it first consults the table’s free space map to find pages with available space. If none are found, new pages will be appended to the file.

`VACUUM` (without `FULL`) does not consolidate pages or reduce the size of the table on disk. The space it recovers is only available through the free space map. To prevent disk files from growing, it is important to run `VACUUM` often enough. The frequency of required `VACUUM` runs depends on the frequency of updates and deletes in the table (inserts only ever add new rows). Heavily updated tables might require several `VACUUM` runs per day, to ensure that the available free space can be found through the free space map. It is also important to run `VACUUM` after running a transaction that updates or deletes a large number of rows.

The `VACUUM FULL` command rewrites the table without expired rows, reducing the table to its minimum size. Every page in the table is checked, and visible rows are moved up into pages which are not yet fully packed. Empty pages are discarded. The table is locked until `VACUUM FULL` completes. This is very expensive compared to the regular `VACUUM` command, and can be avoided or postponed by vacuuming regularly. It is best to run `VACUUM FULL` during a maintenance period. An alternative to `VACUUM FULL` is to recreate the table with a `CREATE TABLE AS` statement and then drop the old table.

The free space map resides in shared memory and keeps track of free space for all tables and indexes. Each table or index uses about 60 bytes of memory and each page with free space consumes six bytes. Two system configuration parameters configure the size of the free space map:

```
max_fsm_pages
Sets the maximum number of disk pages that can be added to the shared free space map.
Six bytes of shared memory are consumed for each page slot. The default is 200000. This
parameter must be set to at least 16 times the value of `max_fsm_relations`.

max_fsm_relations
Sets the maximum number of relations that will be tracked in the shared memory free
space map. This parameter should be set to a value larger than the total number of
`tables` + `indexes` + `system tables`. The default is 1000. About 60 bytes of memory are consumed
for each relation per segment instance. It is better to set the parameter too high than too
low.
```

If the free space map is undersized, some disk pages with available space will not be added to the map, and that space cannot be reused until at least the next `VACUUM` command runs. This causes files to grow.

You can run `VACUUM VERBOSE tablename` to get a report, by segment, of the number of dead rows removed, the number of pages affected, and the number of pages with usable free space.

Query the `pg_class` system table to find out how many pages a table is using across all segments. Be sure to `ANALYZE` the table first to get accurate data.

```
SELECT relname, relpages, reltuples FROM pg_class WHERE relname='tablename';
```

Another useful tool is the `gp_bloat_diag` view in the `gp_toolkit` schema, which identifies bloat in tables by comparing the actual number of pages used by a table to the expected number. See "The `gp_toolkit` Administrative Schema" in the Greenplum Database Reference Guide for more about `gp_bloat_diag`.

**Example of Managing Transaction IDs**

For Greenplum Database, the transaction ID (XID) value an incrementing 32-bit ($2^{32}$) value. The maximum unsigned 32-bit value is 4,294,967,295, or about four billion. The XID values restart at 3 after the maximum is reached. Greenplum Database handles the limit of XID values with two features:
• Calculations on XID values using modulo-\(2^{32}\) arithmetic that allow Greenplum Database to reuse XID values. The modulo calculations determine the order of transactions, whether one transaction has occurred before or after another, based on the XID.

Every XID value can have up to two billion (\(2^{31}\)) XID values that are considered previous transactions and two billion (\(2^{31} - 1\)) XID values that are considered newer transactions. The XID values can be considered a circular set of values with no endpoint similar to a 24 hour clock.

Using the Greenplum Database modulo calculations, as long as two XIDs are within \(2^{31}\) transactions of each other, comparing them yields the correct result.

• A frozen XID value that Greenplum Database uses as the XID for current (visible) data rows. Setting a row's XID to the frozen XID performs two functions.

  • When Greenplum Database compares XIDs using the modulo calculations, the frozen XID is always smaller, earlier, when compared to any other XID. If a row's XID is not set to the frozen XID and \(2^{31}\) new transactions are executed, the row appears to be executed in the future based on the modulo calculation.

  • When the row’s XID is set to the frozen XID, the original XID can be used, without duplicating the XID. This keeps the number of data rows on disk with assigned XIDs below (\(2^{32}\)).

  Note: Greenplum Database assigns XID values only to transactions that involve DDL or DML operations, which are typically the only transactions that require an XID.

**Simple MVCC Example**

This is a simple example of the concepts of a MVCC database and how it manages data and transactions with transaction IDs. This simple MVCC database example consists of a single table:

• The table is a simple table with 2 columns and 4 rows of data.
• The valid transaction ID (XID) values are from 0 up to 9, after 9 the XID restarts at 0.
• The frozen XID is -2. This is different than the Greenplum Database frozen XID.
• Transactions are performed on a single row.
• Only insert and update operations are performed.
• All updated rows remain on disk, no operations are performed to remove obsolete rows.

The example only updates the amount values. No other changes to the table.

The example shows these concepts.

  • How transaction IDs are used to manage multiple, simultaneous transactions on a table.
  • How transaction IDs are managed with the frozen XID
  • How the modulo calculation determines the order of transactions based on transaction IDs

**Managing Simultaneous Transactions**

This table is the initial table data on disk with no updates. The table contains two database columns for transaction IDs, \(x_{\text{min}}\) (transaction that created the row) and \(x_{\text{max}}\) (transaction that updated the row). In the table, changes are added, in order, to the bottom of the table.

**Table 33: Example Table**

<table>
<thead>
<tr>
<th>item</th>
<th>amount</th>
<th>(x_{\text{min}})</th>
<th>(x_{\text{max}})</th>
</tr>
</thead>
<tbody>
<tr>
<td>widget</td>
<td>100</td>
<td>0</td>
<td>null</td>
</tr>
<tr>
<td>giblet</td>
<td>200</td>
<td>1</td>
<td>null</td>
</tr>
<tr>
<td>sprocket</td>
<td>300</td>
<td>2</td>
<td>null</td>
</tr>
<tr>
<td>gizmo</td>
<td>400</td>
<td>3</td>
<td>null</td>
</tr>
</tbody>
</table>
The next table shows the table data on disk after some updates on the amount values have been performed.

\[
\begin{align*}
\text{xid} &= 4: \text{update tbl set amount}=208 \text{ where item = 'widget'} \\
\text{xid} &= 5: \text{update tbl set amount}=133 \text{ where item = 'sprocket'} \\
\text{xid} &= 6: \text{update tbl set amount}=16 \text{ where item = 'widget'}
\end{align*}
\]

In the next table, the bold items are the current rows for the table. The other rows are obsolete rows, table data that on disk but is no longer current. Using the xmax value, you can determine the current rows of the table by selecting the rows with null value. Greenplum Database uses a slightly different method to determine current table rows.

<table>
<thead>
<tr>
<th>item</th>
<th>amount</th>
<th>xmin</th>
<th>xmax</th>
</tr>
</thead>
<tbody>
<tr>
<td>widget</td>
<td>100</td>
<td>0</td>
<td>4</td>
</tr>
<tr>
<td>giblet</td>
<td>200</td>
<td>1</td>
<td>null</td>
</tr>
<tr>
<td>sprocket</td>
<td>300</td>
<td>2</td>
<td>5</td>
</tr>
<tr>
<td>gizmo</td>
<td>400</td>
<td>3</td>
<td>null</td>
</tr>
<tr>
<td>widget</td>
<td>208</td>
<td>4</td>
<td>6</td>
</tr>
<tr>
<td>sproket</td>
<td>133</td>
<td>5</td>
<td>null</td>
</tr>
<tr>
<td>widget</td>
<td>16</td>
<td>6</td>
<td>null</td>
</tr>
</tbody>
</table>

The simple MVCC database works with XID values to determine the state of the table. For example, both these independent transactions execute concurrently.

- **UPDATE** command changes the sprocket amount value to 133 (xmin value 5)
- **SELECT** command returns the value of sprocket.

During the **UPDATE** transaction, the database returns the value of sprocket 300, until the **UPDATE** transaction completes.

**Managing XIDs and the Frozen XID**

For this simple example, the database is close to running out of available XID values. When Greenplum Database is close to running out of available XID values, Greenplum Database takes these actions.

- Greenplum Database issues a warning stating that the database is running out of XID values.

```text
WARNING: database "database_name" must be vacuumed within number_of_transactions transactions
```

- Before the last XID is assigned, Greenplum Database stops accepting transactions to prevent assigning an XID value twice and issues this message.

```text
FATAL: database is not accepting commands to avoid wraparound data loss in database "database_name"
```

To manage transaction IDs and table data that is stored on disk, Greenplum Database provides the **VACUUM** command.

- A **VACUUM** operation frees up XID values so that a table can have more than 10 rows by changing the xmin values to the frozen XID.
- A **VACUUM** operation manages obsolete or deleted table rows on disk. This database's **VACUUM** command changes the XID values obsolete to indicate obsolete rows. A Greenplum Database
VACUUM operation, without the FULL option, deletes the data opportunistically to remove rows on disk with minimal impact to performance and data availability.

For the example table, a VACUUM operation has been performed on the table. The command updated table data on disk. This version of the VACUUM command performs slightly differently than the Greenplum Database command, but the concepts are the same.

- For the widget and sprocket rows on disk that are no longer current, the rows have been marked as obsolete.
- For the giblet and gizmo rows that are current, the xmin has been changed to the frozen XID.

The values are still current table values (the row's xmax value is null). However, the table row is visible to all transactions because the xmin value is frozen XID value that is older than all other XID values when modulo calculations are performed.

After the VACUUM operation, the XID values 0, 1, 2, and 3 available for use.

Table 35: Example Table after VACUUM

<table>
<thead>
<tr>
<th>item</th>
<th>amount</th>
<th>xmin</th>
<th>xmax</th>
</tr>
</thead>
<tbody>
<tr>
<td>widget</td>
<td>100</td>
<td>obsolete</td>
<td>obsolete</td>
</tr>
<tr>
<td>giblet</td>
<td>200</td>
<td>-2</td>
<td>null</td>
</tr>
<tr>
<td>sprocket</td>
<td>300</td>
<td>obsolete</td>
<td>obsolete</td>
</tr>
<tr>
<td>gizmo</td>
<td>400</td>
<td>-2</td>
<td>null</td>
</tr>
<tr>
<td>widget</td>
<td>208</td>
<td>4</td>
<td>6</td>
</tr>
<tr>
<td>sprocket</td>
<td>133</td>
<td>5</td>
<td>null</td>
</tr>
<tr>
<td>widget</td>
<td>16</td>
<td>6</td>
<td>null</td>
</tr>
</tbody>
</table>

When a row disk with the xmin value of -2 is updated, the xmax value is replaced with the transaction XID as usual, and the row on disk is considered obsolete after any concurrent transactions that access the row have completed.

Obsolete rows can be deleted from disk. For Greenplum Database, the VACUUM command, with FULL option, does more extensive processing to reclaim disk space.

Example of XID Modulo Calculations

The next table shows the table data on disk after more UPDATE transactions. The XID values have rolled over and start over at 0. No additional VACUUM operations have been performed.

Table 36: Example Table with Wrapping XID

<table>
<thead>
<tr>
<th>item</th>
<th>amount</th>
<th>xmin</th>
<th>xmax</th>
</tr>
</thead>
<tbody>
<tr>
<td>widget</td>
<td>100</td>
<td>obsolete</td>
<td>obsolete</td>
</tr>
<tr>
<td>giblet</td>
<td>200</td>
<td>-2</td>
<td>1</td>
</tr>
<tr>
<td>sprocket</td>
<td>300</td>
<td>obsolete</td>
<td>obsolete</td>
</tr>
<tr>
<td>gizmo</td>
<td>400</td>
<td>-2</td>
<td>9</td>
</tr>
<tr>
<td>widget</td>
<td>208</td>
<td>4</td>
<td>6</td>
</tr>
<tr>
<td>sprocket</td>
<td>133</td>
<td>5</td>
<td>null</td>
</tr>
<tr>
<td>widget</td>
<td>16</td>
<td>6</td>
<td>7</td>
</tr>
</tbody>
</table>
When performing the modulo calculations that compare XIDs, Greenplum Database, considers the XIDs of the rows and the current range of available XIDs to determine if XID wrapping has occurred between row XIDs.

For the example table XID wrapping has occurred. The XID 1 for giblet row is a later transaction than the XID 7 for widget row based on the modulo calculations for XID values even though the XID value 7 is larger than 1.

For the widget and sprocket rows, XID wrapping has not occurred and XID 7 is a later transaction than XID 5.

**About Parallel Data Loading**

This topic provides a short introduction to Greenplum Database data loading features.

In a large scale, multi-terabyte data warehouse, large amounts of data must be loaded within a relatively small maintenance window. Greenplum supports fast, parallel data loading with its external tables feature. Administrators can also load external tables in single row error isolation mode to filter bad rows into a separate error table while continuing to load properly formatted rows. Administrators can specify an error threshold for a load operation to control how many improperly formatted rows cause Greenplum to abort the load operation.

By using external tables in conjunction with Greenplum Database's parallel file server (gpfdist), administrators can achieve maximum parallelism and load bandwidth from their Greenplum Database system.
Another Greenplum utility, gpload, runs a load task that you specify in a YAML-formatted control file. You describe the source data locations, format, transformations required, participating hosts, database destinations, and other particulars in the control file and gpload executes the load. This allows you to describe a complex task and execute it in a controlled, repeatable fashion.

**About Redundancy and Failover in Greenplum Database**

This topic provides a high-level overview of Greenplum Database high availability features.

You can deploy Greenplum Database without a single point of failure by mirroring components. The following sections describe the strategies for mirroring the main components of a Greenplum system. For a more detailed overview of Greenplum high availability features, see [Overview of Greenplum Database High Availability](#).

**Important:** When data loss is not acceptable for a Pivotal Greenplum Database cluster, master and segment mirroring must be enabled in order for the cluster to be supported by Pivotal. Without mirroring, system and data availability is not guaranteed, Pivotal will make best efforts to restore a cluster in this case.

**About Segment Mirroring**

When you deploy your Greenplum Database system, you can configure mirror segments. Mirror segments allow database queries to fail over to a backup segment if the primary segment becomes unavailable. Mirroring is strongly recommended for production systems and required for Pivotal support.

The secondary (mirror) segment must always reside on a different host than its primary segment to protect against a single host failure. In virtualized environments, the secondary (mirror) must always reside on a different storage system than the master. Mirror segments can be arranged over the remaining hosts in the cluster in configurations designed to maximize availability, or minimize the performance degradation when hosts or multiple primary segments fail.

Two standard mirroring configurations are available when you initialize or expand a Greenplum system. The default configuration, called group mirroring, places all the mirrors for a host’s primary segments on
one other host in the cluster. The other standard configuration, spread mirroring, can be selected with a command-line option. Spread mirroring spreads each host's mirrors over the remaining hosts and requires that there are more hosts in the cluster than primary segments per host.

Figure 13: Spread Mirroring in Greenplum Database shows how table data is distributed across segments when spread mirroring is configured.

**Segment Failover and Recovery**

When mirroring is enabled in a Greenplum Database system, the system will automatically fail over to the mirror segment if a primary copy becomes unavailable. A Greenplum Database system can remain operational if a segment instance or host goes down as long as all the data is available on the remaining active segments.

If the master cannot connect to a segment instance, it marks that segment instance as down in the Greenplum Database system catalog and brings up the mirror segment in its place. A failed segment instance will remain out of operation until an administrator takes steps to bring that segment back online. The `gpstate` utility can be used to identify failed segments. An administrator can recover a failed segment while the system is up and running. The recovery process copies over only the changes that were missed while the segment was out of operation.

If you do not have mirroring enabled, the system will automatically shut down if a segment instance becomes invalid. You must recover all failed segments before operations can continue.

**About Master Mirroring**

You can also optionally deploy a backup or mirror of the master instance on a separate host from the master node. A backup master host serves as a warm standby in the event that the primary master host becomes unoperational. The standby master is kept up to date by a transaction log replication process,
which runs on the standby master host and synchronizes the data between the primary and standby master hosts.

If the primary master fails, the log replication process stops, and the standby master can be activated in its place. The switchover does not happen automatically, but must be triggered externally. Upon activation of the standby master, the replicated logs are used to reconstruct the state of the master host at the time of the last successfully committed transaction. The activated standby master effectively becomes the Greenplum Database master, accepting client connections on the master port (which must be set to the same port number on the master host and the backup master host).

Since the master does not contain any user data, only the system catalog tables need to be synchronized between the primary and backup copies. When these tables are updated, changes are automatically copied over to the standby master to ensure synchronization with the primary master.

Figure 14: Master Mirroring in Greenplum Database

About Interconnect Redundancy

The interconnect refers to the inter-process communication between the segments and the network infrastructure on which this communication relies. You can achieve a highly available interconnect using by deploying dual Gigabit Ethernet switches on your network and redundant Gigabit connections to the Greenplum Database host (master and segment) servers. For performance reasons, 10-Gb Ethernet, or faster, is recommended.

About Database Statistics in Greenplum Database

An overview of statistics gathered by the `ANALYZE` command in Greenplum Database.

Statistics are metadata that describe the data stored in the database. The query optimizer needs up-to-date statistics to choose the best execution plan for a query. For example, if a query joins two tables and one of them must be broadcast to all segments, the optimizer can choose the smaller of the two tables to minimize network traffic.

The statistics used by the optimizer are calculated and saved in the system catalog by the `ANALYZE` command. There are three ways to initiate an analyze operation:

- You can run the `ANALYZE` command directly.
- You can run the `analyzedb` management utility outside of the database, at the command line.
- An automatic analyze operation can be triggered when DML operations are performed on tables that have no statistics or when a DML operation modifies a number of rows greater than a specified threshold.

These methods are described in the following sections. The `VACUUM` `ANALYZE` command is another way to initiate an analyze operation, but its use is discouraged because vacuum and analyze are different operations with different purposes.
Calculating statistics consumes time and resources, so Greenplum Database produces estimates by calculating statistics on samples of large tables. In most cases, the default settings provide the information needed to generate correct execution plans for queries. If the statistics produced are not producing optimal query execution plans, the administrator can tune configuration parameters to produce more accurate statistics by increasing the sample size or the granularity of statistics saved in the system catalog. Producing more accurate statistics has CPU and storage costs and may not produce better plans, so it is important to view explain plans and test query performance to ensure that the additional statistics-related costs result in better query performance.

System Statistics

Table Size

The query planner seeks to minimize the disk I/O and network traffic required to execute a query, using estimates of the number of rows that must be processed and the number of disk pages the query must access. The data from which these estimates are derived are the pg_class system table columns reltuples and repages, which contain the number of rows and pages at the time a VACUUM or ANALYZE command was last run. As rows are added or deleted, the numbers become less accurate. However, an accurate count of disk pages is always available from the operating system, so as long as the ratio of reltuples to repages does not change significantly, the optimizer can produce an estimate of the number of rows that is sufficiently accurate to choose the correct query execution plan.

When the reltuples column differs significantly from the row count returned by SELECT COUNT(*), an analyze should be performed to update the statistics.

When a REINDEX command finishes recreating an index, the repages and reltuples columns are set to zero. The ANALYZE command should be run on the base table to update these columns.

The pg_statistic System Table and pg_stats View

The pg_statistic system table holds the results of the last ANALYZE operation on each database table. There is a row for each column of every table. It has the following columns:

- **starelid**: The object ID of the table or index the column belongs to.
- **staaattnum**: The number of the described column, beginning with 1.
- **stanullfrac**: The fraction of the column's entries that are null.
- **stawidth**: The average stored width, in bytes, of non-null entries.
- **stadistinct**: A positive number is an estimate of the number of distinct values in the column; the number is not expected to vary with the number of rows. A negative value is the number of distinct values divided by the number of rows, that is, the ratio of rows with distinct values for the column, negated. This form is used when the number of distinct values increases with the number of rows. A unique column, for example, has an n_distinct value of -1.0. Columns with an average width greater than 1024 are considered unique.
- **stakindN**: A code number indicating the kind of statistics stored in the Nth slot of the pg_statistic row.
- **staopN**: An operator used to derive the statistics stored in the Nth slot. For example, a histogram slot would show the < operator that defines the sort order of the data.
stanumbers\(N\)
float4 array containing numerical statistics of the appropriate kind for the \(N\)th slot, or NULL if the slot kind does not involve numerical values.

stavalues\(N\)
Column data values of the appropriate kind for the \(N\)th slot, or NULL if the slot kind does not store any data values. Each array's element values are actually of the specific column's data type, so there is no way to define these columns' types more specifically than anyarray.

The statistics collected for a column vary for different data types, so the pg_statistic table stores statistics that are appropriate for the data type in four slots, consisting of four columns per slot. For example, the first slot, which normally contains the most common values for a column, consists of the columns stakind1, staop1, stanumbers1, and stavalues1.

The stakind\(N\) columns each contain a numeric code to describe the type of statistics stored in their slot. The stakind code numbers from 1 to 99 are reserved for core PostgreSQL data types. Greenplum Database uses code numbers 1, 2, 3, and 99. A value of 0 means the slot is unused. The following table describes the kinds of statistics stored for the three codes.

<table>
<thead>
<tr>
<th>stakind Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Most CommonValues (MCV) Slot</td>
</tr>
<tr>
<td></td>
<td>• staop contains the object ID of the &quot;=&quot; operator, used to decide whether values are the same or not.</td>
</tr>
<tr>
<td></td>
<td>• stavalues contains an array of the (K) most common non-null values appearing in the column.</td>
</tr>
<tr>
<td></td>
<td>• stanumbers contains the frequencies (fractions of total row count) of the values in the stavalues array.</td>
</tr>
</tbody>
</table>

The values are ordered in decreasing frequency. Since the arrays are variable-size, \(K\) can be chosen by the statistics collector. Values must occur more than once to be added to the stavalues array; a unique column has no MCV slot.

| 2            | Histogram Slot – describes the distribution of scalar data. |
|              | • staop is the object ID of the "<" operator, which describes the sort ordering. |
|              | • stavalues contains \(M\) (where \(M\geq2\)) non-null values that divide the non-null column data values into \(M-1\) bins of approximately equal population. The first stavalues item is the minimum value and the last is the maximum value. |
|              | • stanumbers is not used and should be NULL. |

If a Most Common Values slot is also provided, then the histogram describes the data distribution after removing the values listed in the MCV array. (It is a compressed histogram in the technical parlance). This allows a more accurate representation of the distribution of a column with some very common values. In a column with only a few distinct values, it is possible that the MCV list describes the entire data population; in this case the histogram reduces to empty and should be omitted.
<table>
<thead>
<tr>
<th>stakind Code</th>
<th>Description</th>
</tr>
</thead>
</table>
| 3            | **Correlation Slot** – describes the correlation between the physical order of table tuples and the ordering of data values of this column.  
• staop is the object ID of the "<" operator. As with the histogram, more than one entry could theoretically appear.  
• stavalues is not used and should be NULL.  
• stanumbers contains a single entry, the correlation coefficient between the sequence of data values and the sequence of their actual tuple positions. The coefficient ranges from +1 to -1. |
| 99           | **Hyperloglog Slot** - for child leaf partitions of a partitioned table, stores the hyperloglog_counter created for the sampled data. The hyperloglog_counter data structure is converted into a bytea and stored in a stavalues4 slot of the pg_statistic catalog table. |

The `pg_stats` view presents the contents of `pg_statistic` in a friendlier format. The `pg_stats` view has the following columns:

- **schemaname**: The name of the schema containing the table.
- **tablename**: The name of the table.
- **attname**: The name of the column this row describes.
- **null_frac**: The fraction of column entries that are null.
- **avg_width**: The average storage width in bytes of the column's entries, calculated as `avg(pg_column_size(column_name))`.
- **n_distinct**: A positive number is an estimate of the number of distinct values in the column; the number is not expected to vary with the number of rows. A negative value is the number of distinct values divided by the number of rows, that is, the ratio of rows with distinct values for the column, negated. This form is used when the number of distinct values increases with the number of rows. A unique column, for example, has an `n_distinct` value of -1.0. Columns with an average width greater than 1024 are considered unique.
- **most_common_vals**: An array containing the most common values in the column, or null if no values seem to be more common. If the `n_distinct` column is -1, `most_common_vals` is null. The length of the array is the lesser of the number of actual distinct column values or the value of the `default_statistics_target` configuration parameter. The number of values can be overridden for a column using `ALTER TABLE table SET COLUMN column SET STATISTICS N`.
- **most_common_freqs**: An array containing the frequencies of the values in the `most_common_vals` array. This is the number of occurrences of the value divided by the total number of rows. The array is the same.
**length** as the **most_common_vals** array. It is null if **most_common_vals** is null.

### histogram_bounds

An array of values that divide the column values into groups of approximately the same size. A histogram can be defined only if there is a **max()** aggregate function for the column. The number of groups in the histogram is the same as the **most_common_vals** array size.

### correlation

Greenplum Database does not calculate the correlation statistic.

Newly created tables and indexes have no statistics. You can check for tables with missing statistics using the **gp_stats_missing** view, which is in the **gp_toolkit** schema:

```sql
SELECT * from gp_toolkit.gp_stats_missing;
```

## Sampling

When calculating statistics for large tables, Greenplum Database creates a smaller table by sampling the base table. If the table is partitioned, samples are taken from all partitions.

If the number of rows in the base table is estimated to be less than the value of the **gp_statistics_sampling_threshold** configuration parameter, the entire base table is used to calculate the statistics.

If a sample table is created, the number of rows in the sample is calculated to provide a maximum acceptable relative error. The amount of acceptable error is specified with the **gp_analyze_relative_error** system configuration parameter, which is set to .25 (25%) by default. This is usually sufficiently accurate to generate correct query plans. If **ANALYZE** is not producing good estimates for a table column, you can increase the sample size by setting the **gp_analyze_relative_error** configuration parameter to a lower value. Beware that setting this parameter to a low value can lead to a very large sample size and dramatically increase analyze time.

## Updating Statistics

Running **ANALYZE** with no arguments updates statistics for all tables in the database. This could take a very long time, so it is better to analyze tables selectively after data has changed. You can also analyze a subset of the columns in a table, for example columns used in joins, **WHERE** clauses, **SORT** clauses, **GROUP BY** clauses, or **HAVING** clauses.

Analyzing a severely bloated table can generate poor statistics if the sample contains empty pages, so it is good practice to vacuum a bloated table before analyzing it.

See the **SQL Command Reference** in the **Greenplum Database Reference Guide** for details of running the **ANALYZE** command.

Refer to the **Greenplum Database Management Utility Reference** for details of running the **analyzedb** command.

## Analyzing Partitioned Tables

When the **ANALYZE** command is run on a partitioned table, it analyzes each child leaf partition table, one at a time. You can run **ANALYZE** on just new or changed partition files to avoid analyzing partitions that have not changed.

The **analyzedb** command-line utility skips unchanged partitions automatically. It also runs concurrent sessions so it can analyze several partitions concurrently. It runs five sessions by default, but the number of sessions can be set from 1 to 10 with the **-p** command-line option. Each time **analyzedb** runs, it saves state information for append-optimized tables and partitions in the **db_analyze** directory in the master...
data directory. The next time it runs, `analyzedb` compares the current state of each table with the saved state and skips analyzing a table or partition if it is unchanged. Heap tables are always analyzed.

If GPORCA is enabled (the default), you also need to run `ANALYZE` or `ANALYZE ROOTPARTITION` to refresh the root partition statistics. GPORCA requires statistics at the root level for partitioned tables. The legacy optimizer does not use these statistics.

The time to analyze a partitioned table is similar to the time to analyze a non-partitioned table with the same data since `ANALYZE` or `ANALYZE ROOTPARTITION` does not collect statistics on the leaf partitions (the data is only sampled). The `analyzedb` utility updates root partition statistics by default but you can add the `--skip_root_stats` option to leave root partition statistics empty if you do not use GPORCA.

The Greenplum Database server configuration parameter `optimizer_analyze_root_partition` affects when statistics are collected on the root partition of a partitioned table. If the parameter is on (the default), the `ROOTPARTITION` keyword is not required to collect statistics on the root partition when you run `ANALYZE`. Root partition statistics are collected when you run `ANALYZE` on the root partition, or when you run `ANALYZE` on a child leaf partition of the partitioned table and the other child leaf partitions have statistics. If the parameter is off, you must run `ANALYZE` or `ANALYZE ROOTPARTITION` to collect root partition statistics.

If you do not intend to execute queries on partitioned tables with GPORCA (setting the server configuration parameter `optimizer` to off), you can also set the server configuration parameter `optimizer_analyze_root_partition` to off to limit when `ANALYZE` updates the root partition statistics.

### Configuring Statistics

There are several options for configuring Greenplum Database statistics collection.

#### Statistics Target

The statistics target is the size of the `most_common_vals`, `most_common_freqs`, and `histogram_bounds` arrays for an individual column. By default, the target is 25. The default target can be changed by setting a server configuration parameter and the target can be set for any column using the `ALTER TABLE` command. Larger values increase the time needed to do `ANALYZE`, but may improve the quality of the legacy query optimizer (planner) estimates.

Set the system default statistics target to a different value by setting the `default_statistics_target` server configuration parameter. The default value is usually sufficient, and you should only raise or lower it if your tests demonstrate that query plans improve with the new target. For example, to raise the default statistics target from 100 to 150 you can use the `gpconfig` utility:

```
gpconfig -c default_statistics_target -v 150
```

The statistics target for individual columns can be set with the `ALTER TABLE` command. For example, some queries can be improved by increasing the target for certain columns, especially columns that have irregular distributions. You can set the target to zero for columns that never contribute to query optimization. When the target is 0, `ANALYZE` ignores the column. For example, the following `ALTER TABLE` command sets the statistics target for the `notes` column in the `emp` table to zero:

```
ALTER TABLE emp ALTER COLUMN notes SET STATISTICS 0;
```

The statistics target can be set in the range 0 to 1000, or set it to -1 to revert to using the system default statistics target.

Setting the statistics target on a parent partition table affects the child partitions. If you set statistics to 0 on some columns on the parent table, the statistics for the same columns are set to 0 for all children partitions. However, if you later add or exchange another child partition, the new child partition will use either the
default statistics target or, in the case of an exchange, the previous statistics target. Therefore, if you add
or exchange child partitions, you should set the statistics targets on the new child table.

**Automatic Statistics Collection**

Greenplum Database can be set to automatically run `ANALYZE` on a table that either has no statistics
or has changed significantly when certain operations are performed on the table. For partitioned tables,
automatic statistics collection is only triggered when the operation is run directly on a leaf table, and then
only the leaf table is analyzed.

Automatic statistics collection has three modes:

- **none** disables automatic statistics collection.
- **on_no_stats** triggers an `ANALYZE` operation for a table with no existing statistics when any of the
  commands `CREATE TABLE AS SELECT`, `INSERT`, or `COPY` are executed on the table.
- **on_change** triggers an `ANALYZE` operation when any of the commands `CREATE TABLE AS SELECT`,
  `UPDATE`, `DELETE`, `INSERT`, or `COPY` are executed on the table and the number of rows affected
  exceeds the threshold defined by the `gp_autostats_on_change_threshold` configuration
  parameter.

The automatic statistics collection mode is set separately for commands that occur within a procedural
language function and commands that execute outside of a function:

- The `gp_autostats_mode` configuration parameter controls automatic statistics collection behavior
  outside of functions and is set to **on_no_stats** by default.
- The `gp_autostats_mode_in_functions` parameter controls the behavior when table operations
  are performed within a procedural language function and is set to **none** by default.

With the **on_change** mode, `ANALYZE` is triggered only if the number of rows affected exceeds the
threshold defined by the `gp_autostats_on_change_threshold` configuration parameter. The default
value for this parameter is a very high value, 2147483647, which effectively disables automatic statistics
collection; you must set the threshold to a lower number to enable it. The **on_change** mode could trigger
large, unexpected `ANALYZE` operations that could disrupt the system, so it is not recommended to set it
globally. It could be useful in a session, for example to automatically analyze a table following a load.

To disable automatic statistics collection outside of functions, set the `gp_autostats_mode` parameter to
**none**:

```
gpconfigure -c gp_autostats_mode -v none
```

To enable automatic statistics collection in functions for tables that have no statistics, change
`gp_autostats_mode_in_functions` to **on_no_stats**:

```
gpconfigure -c gp_autostats_mode_in_functions -v on_no_stats
```

Set the `log_autostats` system configuration parameter to **on** if you want to log automatic statistics
collection operations.
Managing a Greenplum System

This section describes basic system administration tasks performed by a Greenplum Database system administrator.

This section contains the following topics:

- About the Greenplum Database Release Version Number
- Starting and Stopping Greenplum Database
- Accessing the Database
- Configuring the Greenplum Database System
- Enabling High Availability and Data Consistency Features
- Backing Up and Restoring Databases
- Expanding a Greenplum System
- Migrating Data with gptransfer
- Migrating Data with gpcopy
- Defining Database Objects
- Routine System Maintenance Tasks

About the Greenplum Database Release Version Number

Greenplum Database version numbers and they way they change identify what has been modified from one Greenplum Database release to the next.

A Greenplum Database release version number takes the format x.y.z, where:

- x identifies the Major version number
- y identifies the Minor version number
- z identifies the Patch version number

Greenplum Database releases that have the same Major release number are guaranteed to be backwards compatible. Greenplum Database increments the Major release number when the catalog changes or when incompatible feature changes or new features are introduced. Previously deprecated functionality may be removed in a major release.

The Minor release number for a given Major release increments when backwards compatible new features are introduced or when a Greenplum Database feature is deprecated. (Previously deprecated functionality will never be removed in a minor release.)

Greenplum Database increments the Patch release number for a given Minor release for backwards-compatible bug fixes.

Starting and Stopping Greenplum Database

In a Greenplum Database DBMS, the database server instances (the master and all segments) are started or stopped across all of the hosts in the system in such a way that they can work together as a unified DBMS.

Because a Greenplum Database system is distributed across many machines, the process for starting and stopping a Greenplum Database system is different than the process for starting and stopping a regular PostgreSQL DBMS.

Use the gpstart and gpstop utilities to start and stop Greenplum Database, respectively. These utilities are located in the $GPHOME/bin directory on your Greenplum Database master host.

Important: Do not issue a kill command to end any Postgres process. Instead, use the database command pg_cancel_backend().
Issuing a `kill -9` or `kill -11` can introduce database corruption and prevent root cause analysis from being performed.

For information about `gpstart` and `gpstop`, see the *Greenplum Database Utility Guide*.

### Starting Greenplum Database

Start an initialized Greenplum Database system by running the `gpstart` utility on the master instance.

Use the `gpstart` utility to start a Greenplum Database system that has already been initialized by the `gpinitsystem` utility, but has been stopped by the `gpstop` utility. The `gpstart` utility starts Greenplum Database by starting all the Postgres database instances on the Greenplum Database cluster. `gpstart` orchestrates this process and performs the process in parallel.

- Run `gpstart` on the master host to start Greenplum Database:

  ```
  $ gpstart
  ```

### Restarting Greenplum Database

Stop the Greenplum Database system and then restart it.

The `gpstop` utility with the `-r` option can stop and then restart Greenplum Database after the shutdown completes.

- To restart Greenplum Database, enter the following command on the master host:

  ```
  $ gpstop -r
  ```

### Reloading Configuration File Changes Only

Reload changes to Greenplum Database configuration files without interrupting the system.

The `gpstop` utility can reload changes to the `pg_hba.conf` configuration file and to runtime parameters in the master `postgresql.conf` file and `pg_hba.conf` file without service interruption. Active sessions pick up changes when they reconnect to the database. Many server configuration parameters require a full system restart (`gpstop -r`) to activate. For information about server configuration parameters, see the *Greenplum Database Reference Guide*.

- Reload configuration file changes without shutting down the system using the `gpstop` utility:

  ```
  $ gpstop -u
  ```

### Starting the Master in Maintenance Mode

Start only the master to perform maintenance or administrative tasks without affecting data on the segments.

Maintenance mode should only be used with direction from Pivotal Technical Support. For example, you could connect to a database only on the master instance in maintenance mode and edit system catalog settings. For more information about system catalog tables, see the *Greenplum Database Reference Guide*.

1. Run `gpstart` using the `-m` option:

   ```
   $ gpstart -m
   ```

2. Connect to the master in maintenance mode to do catalog maintenance. For example:

   ```
   $ PGOPTIONS='"-c gp_session_role=utility"' psql postgres
   ```
3. After completing your administrative tasks, stop the master in utility mode. Then, restart it in production mode.

   $ gpstop -mr

   **Warning:**
   Incorrect use of maintenance mode connections can result in an inconsistent system state. Only Technical Support should perform this operation.

### Stopping Greenplum Database

The *gpstop* utility stops or restarts your Greenplum Database system and always runs on the master host. When activated, *gpstop* stops all *postgres* processes in the system, including the master and all segment instances. The *gpstop* utility uses a default of up to 64 parallel worker threads to bring down the Postgres instances that make up the Greenplum Database cluster. The system waits for any active transactions to finish before shutting down. To stop Greenplum Database immediately, use fast mode.

- To stop Greenplum Database:

  $ gpstop

- To stop Greenplum Database in fast mode:

  $ gpstop -M fast

By default, you are not allowed to shut down Greenplum Database if there are any client connections to the database. Use the `-M fast` option to roll back all in progress transactions and terminate any connections before shutting down.

### Stopping Client Processes

Greenplum Database launches a new backend process for each client connection. A Greenplum Database user with `SUPERUSER` privileges can cancel and terminate these client backend processes.

Canceling a backend process with the `pg_cancel_backend()` function ends a specific queued or active client query. Terminating a backend process with the `pg_terminate_backend()` function terminates a client connection to a database.

The `pg_cancel_backend()` function has two signatures:

- `pg_cancel_backend( pid int4 )`
- `pg_cancel_backend( pid int4, msg text )`

The `pg_terminate_backend()` function has two similar signatures:

- `pg_terminate_backend( pid int4 )`
- `pg_terminate_backend( pid int4, msg text )`

If you provide a `msg`, Greenplum Database includes the text in the cancel message returned to the client. The `msg` is limited to 128 bytes; Greenplum Database truncates anything longer.

The `pg_cancel_backend()` and `pg_terminate_backend()` functions return `true` if successful, and `false` otherwise.

To cancel or terminate a backend process, you must first identify the process ID of the backend. You can obtain the process ID from the `procpid` column of the `pg_stat_activity` view. For example, to view the process information associated with all running and queued queries:

```sql
=# SELECT usename, procpid, waiting, current_query, datname
    FROM pg_stat_activity;
```
Sample partial query output:

<table>
<thead>
<tr>
<th>username</th>
<th>procpid</th>
<th>waiting</th>
<th>current_query</th>
<th>datname</th>
</tr>
</thead>
<tbody>
<tr>
<td>sammy</td>
<td>31861</td>
<td>f</td>
<td>&lt;IDLE&gt; in transaction</td>
<td>testdb</td>
</tr>
<tr>
<td>billy</td>
<td>31905</td>
<td>t</td>
<td>SELECT * FROM topten;</td>
<td>testdb</td>
</tr>
</tbody>
</table>

Use the output to identify the process id (procpid) of the query or client connection.

For example, to cancel the pending query identified in the sample output above and include "Admin canceled long-running query." in the message returned to the client:

```
=# SELECT pg_cancel_backend(31905 ,'Admin canceled long-running query. ');
ERROR:  canceling statement due to user request: "Admin canceled long-running query."
```

## Accessing the Database

This topic describes the various client tools you can use to connect to Greenplum Database, and how to establish a database session.

### Establishing a Database Session

Users can connect to Greenplum Database using a PostgreSQL-compatible client program, such as `psql`. Users and administrators **always** connect to Greenplum Database through the `master`; the segments cannot accept client connections.

In order to establish a connection to the Greenplum Database master, you will need to know the following connection information and configure your client program accordingly.

### Table 38: Connection Parameters

<table>
<thead>
<tr>
<th>Connection Parameter</th>
<th>Description</th>
<th>Environment Variable</th>
</tr>
</thead>
<tbody>
<tr>
<td>Application name</td>
<td>The application name that is connecting to the database. The default value, held in the <code>application_name</code> connection parameter is <code>psql</code>.</td>
<td>$PGAPPNAME</td>
</tr>
<tr>
<td>Database name</td>
<td>The name of the database to which you want to connect. For a newly initialized system, use the <code>postgres</code> database to connect for the first time.</td>
<td>$PGDATABASE</td>
</tr>
<tr>
<td>Host name</td>
<td>The host name of the Greenplum Database master. The default host is the local host.</td>
<td>$PGHOST</td>
</tr>
<tr>
<td>Port</td>
<td>The port number that the Greenplum Database master instance is running on. The default is 5432.</td>
<td>$PGPORT</td>
</tr>
<tr>
<td>User name</td>
<td>The database user (role) name to connect as. This is not necessarily the same as your OS user name. Check with your Greenplum administrator if you are not sure what your database user name is. Note that every Greenplum Database system has one superuser account that is created automatically at initialization time. This account has the same name as the OS name of the user who initialized the Greenplum system (typically <code>gpadmin</code>).</td>
<td>$PGUSER</td>
</tr>
</tbody>
</table>

`Connecting with psql` provides example commands for connecting to Greenplum Database.
Supported Client Applications

Users can connect to Greenplum Database using various client applications:

- A number of Greenplum Database Client Applications are provided with your Greenplum installation. The `psql` client application provides an interactive command-line interface to Greenplum Database.
- Using standard Database Application Interfaces, such as ODBC and JDBC, users can create their own client applications that interface to Greenplum Database.
- Most client tools that use standard database interfaces, such as ODBC and JDBC, can be configured to connect to Greenplum Database.

Greenplum Database Client Applications

Greenplum Database comes installed with a number of client utility applications located in the `$GPHOME/bin` directory of your Greenplum Database master host installation. The following are the most commonly used client utility applications:

Table 39: Commonly used client applications

<table>
<thead>
<tr>
<th>Name</th>
<th>Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>createdb</code></td>
<td>create a new database</td>
</tr>
<tr>
<td><code>creatolang</code></td>
<td>define a new procedural language</td>
</tr>
<tr>
<td><code>createuser</code></td>
<td>define a new database role</td>
</tr>
<tr>
<td><code>dropdb</code></td>
<td>remove a database</td>
</tr>
<tr>
<td><code>droplang</code></td>
<td>remove a procedural language</td>
</tr>
<tr>
<td><code>dropuser</code></td>
<td>remove a role</td>
</tr>
<tr>
<td><code>psql</code></td>
<td>PostgreSQL interactive terminal</td>
</tr>
<tr>
<td><code>reindexdb</code></td>
<td>reindex a database</td>
</tr>
<tr>
<td><code>vacuumdb</code></td>
<td>garbage-collect and analyze a database</td>
</tr>
</tbody>
</table>

When using these client applications, you must connect to a database through the Greenplum master instance. You will need to know the name of your target database, the host name and port number of the master, and what database user name to connect as. This information can be provided on the command-line using the options `-d`, `-h`, `-p`, and `-U` respectively. If an argument is found that does not belong to any option, it will be interpreted as the database name first.

All of these options have default values which will be used if the option is not specified. The default host is the local host. The default port number is 5432. The default user name is your OS system user name, as is the default database name. Note that OS user names and Greenplum Database user names are not necessarily the same.

If the default values are not correct, you can set the environment variables `PGDATABASE`, `PGHOST`, `PGPORT`, and `PGUSER` to the appropriate values, or use a `psql ~/.pgpass` file to contain frequently-used passwords.

For information about Greenplum Database environment variables, see the Greenplum Database Reference Guide. For information about `psql`, see the Greenplum Database Utility Guide.
Connecting with psql

Depending on the default values used or the environment variables you have set, the following examples show how to access a database via psql:

```
$ psql -d gpdatabase -h master_host -p 5432 -U gpadmin
```

```
$ psql gpdatabase
```

```
$ psql
```

If a user-defined database has not yet been created, you can access the system by connecting to the postgres database. For example:

```
$ psql postgres
```

After connecting to a database, psql provides a prompt with the name of the database to which psql is currently connected, followed by the string => (or # if you are the database superuser). For example:

```
gpdatabase=>
```

At the prompt, you may type in SQL commands. A SQL command must end with a ; (semicolon) in order to be sent to the server and executed. For example:

```
=> SELECT * FROM mytable;
```

See the Greenplum Reference Guide for information about using the psql client application and SQL commands and syntax.

Using the PgBouncer Connection Pooler

The PgBouncer utility manages connection pools for PostgreSQL and Greenplum Database connections. The following topics describe how to set up and use PgBouncer with Greenplum Database. Refer to the PgBouncer web site for information about using PgBouncer with PostgreSQL.

- Overview
- Migrating PgBouncer
- Configuring PgBouncer
- Starting PgBouncer
- Managing PgBouncer

Overview

A database connection pool is a cache of database connections. Once a pool of connections is established, connection pooling eliminates the overhead of creating new database connections, so clients connect much faster and the server load is reduced.

The PgBouncer connection pooler, from the PostgreSQL community, is included in your Greenplum Database installation. PgBouncer is a light-weight connection pool manager for Greenplum and PostgreSQL. PgBouncer maintains a pool for connections for each database and user combination. PgBouncer either creates a new database connection for a client or reuses an existing connection for the same user and database. When the client disconnects, PgBouncer returns the connection to the pool for re-use.

PgBouncer shares connections in one of three pool modes:
• **Session pooling** – When a client connects, a connection is assigned to it as long as it remains connected. When the client disconnects, the connection is placed back into the pool.

• **Transaction pooling** – A connection is assigned to a client for the duration of a transaction. When PgBouncer notices the transaction is done, the connection is placed back into the pool. This mode can be used only with applications that do not use features that depend upon a session.

• **Statement pooling** – Statement pooling is like transaction pooling, but multi-statement transactions are not allowed. This mode is intended to enforce autocommit mode on the client and is targeted for PL/Proxy on PostgreSQL.

You can set a default pool mode for the PgBouncer instance. You can override this mode for individual databases and users.

PgBouncer supports the standard connection interface shared by PostgreSQL and Greenplum Database. The Greenplum Database client application (for example, psql) connects to the host and port on which PgBouncer is running rather than the Greenplum Database master host and port.

PgBouncer includes a psql-like administration console. Authorized users can connect to a virtual database to monitor and manage PgBouncer. You can manage a PgBouncer daemon process via the admin console. You can also use the console to update and reload PgBouncer configuration at runtime without stopping and restarting the process.

PgBouncer natively supports TLS.

**Migrating PgBouncer**

When you migrate to a new Greenplum Database version, you must migrate your PgBouncer instance to that in the new Greenplum Database installation.

• **If you are migrating to a Greenplum Database version 5.8.x or earlier**, you can migrate PgBouncer without dropping connections. Launch the new PgBouncer process with the `-R` option and the configuration file that you started the process with:

```bash
$ pgbouncer -R -d pgbouncer.ini
```

The `-R` (reboot) option causes the new process to connect to the console of the old process through a Unix socket and issue the following commands:

```bash
SUSPEND;
SHOW FDS;
SHUTDOWN;
```

When the new process detects that the old process is gone, it resumes the work with the old connections. This is possible because the `SHOW FDS` command sends actual file descriptors to the new process. If the transition fails for any reason, kill the new process and the old process will resume.

• **If you are migrating to a Greenplum Database version 5.9.0 or later**, you must shut down the PgBouncer instance in your old installation and reconfigure and restart PgBouncer in your new installation.

• If you used stunnel to secure PgBouncer connections in your old installation, you must configure SSL/TLS in your new installation using the built-in TLS capabilities of PgBouncer 1.8.1 and later.

• If you used LDAP authentication in your old installation, you must configure LDAP in your new installation using the built-in PAM integration capabilities of PgBouncer 1.8.1 and later. You must also remove or replace any ldap://-/prefixed password strings in the `auth_file`.

**Configuring PgBouncer**

You configure PgBouncer and its access to Greenplum Database via a configuration file. This configuration file, commonly named `pgbouncer.ini`, provides location information for Greenplum databases. The
pgbouncer.ini file also specifies process, connection pool, authorized users, and authentication configuration for PgBouncer.

Sample pgbouncer.ini file contents:

```
[databases]
postgres = host=127.0.0.1 port=5432 dbname=postgres
pgb_mydb = host=127.0.0.1 port=5432 dbname=mydb

[pgbouncer]
pool_mode = session
listen_port = 6543
listen_addr = 127.0.0.1
auth_type = md5
auth_file = users.txt
logfile = pgbouncer.log
pidfile = pgbouncer.pid
admin_users = gpadmin
```

Refer to the pgbouncer.ini reference page for the PgBouncer configuration file format and the list of configuration properties it supports.

When a client connects to PgBouncer, the connection pooler looks up the the configuration for the requested database (which may be an alias for the actual database) that was specified in the pgbouncer.ini configuration file to find the host name, port, and database name for the database connection. The configuration file also identifies the authentication mode in effect for the database.

PgBouncer requires an authentication file, a text file that contains a list of Greenplum Database users and passwords. The contents of the file are dependent on the auth_type you configure in the pgbouncer.ini file. Passwords may be either clear text or MD5-encoded strings. You can also configure PgBouncer to query the destination database to obtain password information for users that are not in the authentication file.

### PgBouncer Authentication File Format

PgBouncer requires its own user authentication file. You specify the name of this file in the auth_file property of the pgbouncer.ini configuration file. auth_file is a text file in the following format:

```
"username1" "password" ...
"username2" "md5abcdef012342345" ...
```

auth_file contains one line per user. Each line must have at least two fields, both of which are enclosed in double quotes (" "). The first field identifies the Greenplum Database user name. The second field is either a plain-text or an MD5-encoded password. PgBouncer ignores the remainder of the line.

(The format of auth_file is similar to that of the pg_auth text file that Greenplum Database uses for authentication information. PgBouncer can work directly with this Greenplum Database authentication file.)

Use an MD5 encoded password. The format of an MD5 encoded password is:

```
"md5" + MD5_encoded(<password><username>)
```

You can also obtain the MD5-encoded passwords of all Greenplum Database users from the pg_shadow view.

### Configuring HBA-based Authentication for PgBouncer

PgBouncer supports HBA-based authentication. To configure HBA-based authentication for PgBouncer, you set auth_type=hba in the pgbouncer.ini configuration file. You also provide the filename of the HBA-format file in the auth_hba_file parameter of the pgbouncer.ini file.
Contents of an example PgBouncer HBA file named `hba_bouncer.conf`:

<table>
<thead>
<tr>
<th>Local</th>
<th>All</th>
<th>Bouncer</th>
<th>Trust</th>
</tr>
</thead>
<tbody>
<tr>
<td>Host</td>
<td>All</td>
<td>Bouncer</td>
<td>127.0.0.1/32</td>
</tr>
</tbody>
</table>

Example excerpt from the related `pgbouncer.ini` configuration file:

```ini
[databases]
p0 = port=15432 host=127.0.0.1 dbname=p0 user=bouncer pool_size=2
p1 = port=15432 host=127.0.0.1 dbname=p1 user=bouncer
...

[pgbouncer]
auth_type = hba
auth_file = userlist.txt
auth_hba_file = hba_bouncer.conf
...
```

Refer to the [HBA file format](#) discussion in the PgBouncer documentation for information about PgBouncer support of the HBA authentication file format.

### Starting PgBouncer

You can run PgBouncer on the Greenplum Database master or on another server. If you install PgBouncer on a separate server, you can easily switch clients to the standby master by updating the PgBouncer configuration file and reloading the configuration using the PgBouncer Administration Console.

Follow these steps to set up PgBouncer.

1. Create a PgBouncer configuration file. For example, add the following text to a file named `pgbouncer.ini`:

```ini
[databases]
postgres = host=127.0.0.1 port=5432 dbname=postgres
pgb_mydb = host=127.0.0.1 port=5432 dbname=mydb

[pgbouncer]
pool_mode = session
listen_port = 6543
listen_addr = 127.0.0.1
auth_type = md5
auth_file = users.txt
logfile = pgbouncer.log
pidfile = pgbouncer.pid
admin_users = gpadmin
```

The file lists databases and their connection details. The file also configures the PgBouncer instance. Refer to the [pgbouncer.ini](#) reference page for information about the format and content of a PgBouncer configuration file.

2. Create an authentication file. The filename should be the name you specified for the `auth_file` parameter of the `pgbouncer.ini` file, `users.txt`. Each line contains a user name and password. The format of the password string matches the `auth_type` you configured in the PgBouncer configuration file. If the `auth_type` parameter is `plain`, the password string is a clear text password, for example:

```
"gpadmin" "gpadmin1234"
```
If the `auth_type` in the following example is `md5`, the authentication field must be MD5-encoded. The format for an MD5-encoded password is:

```plaintext
"md5" + MD5_encoded(<password><username>)
```

3. Launch `pgbouncer`:

```plaintext
$ $GPHOME/bin/pgbouncer -d pgbouncer.ini
```

The `-d` option runs PgBouncer as a background (daemon) process. Refer to the `pgbouncer` reference page for the `pgbouncer` command syntax and options.

4. Update your client applications to connect to `pgbouncer` instead of directly to Greenplum Database server. For example, to connect to the Greenplum database named `mydb` configured above, run `psql` as follows:

```plaintext
$ psql -p 6543 -U someuser pgb_mydb
```

The `-p` option value is the `listen_port` that you configured for the PgBouncer instance.

### Managing PgBouncer

PgBouncer provides a `psql`-like administration console. You log in to the PgBouncer Administration Console by specifying the PgBouncer port number and a virtual database named `pgbouncer`. The console accepts SQL-like commands that you can use to monitor, reconfigure, and manage PgBouncer.

For complete documentation of PgBouncer Administration Console commands, refer to the `PgBouncer Administration Console` command reference.

Follow these steps to get started with the PgBouncer Administration Console.

1. Use `psql` to log in to the `pgbouncer` virtual database:

```plaintext
$ psql -p 6543 -U username pgbouncer
```

The `username` that you specify must be listed in the `admin_users` parameter in the `pgbouncer.ini` configuration file. You can also log in to the PgBouncer Administration Console with the current Unix `username` if the `pgbouncer` process is running under that user's UID.

2. To view the available PgBouncer Administration Console commands, run the `SHOW help` command:

```plaintext
pgbouncer=# SHOW help;
NOTICE: Console usage
DETAIL:
  SHOW HELP|CONFIG|DATABASES|POOLS|CLIENTS|SERVERS|VERSION
  SHOW FDS|SOCKETS|ACTIVE_SOCKETS|LISTS|MEM
  SHOW DNS_HOSTS|DNS_ZONES
  SHOW STATS|STATS_TOTALS|STATS_AVERAGES
  SET key = arg
  RELOAD
  PAUSE [<db>]
  RESUME [<db>]
  DISABLE <db>
  ENABLE <db>
  KILL <db>
  SUSPEND
  SHUTDOWN
```

3. If you update PgBouncer configuration by editing the `pgbouncer.ini` configuration file, you use the `RELOAD` command to reload the file:

```plaintext
pgbouncer=# RELOAD;
```
Mapping PgBouncer Clients to Greenplum Database Server Connections

To map a PgBouncer client to a Greenplum Database server connection, use the PgBouncer Administration Console `SHOW CLIENTS` and `SHOW SERVERS` commands:

1. Use `ptr` and `link` to map the local client connection to the server connection.
2. Use the `addr` and the `port` of the client connection to identify the TCP connection from the client.
3. Use `local_addr` and `local_port` to identify the TCP connection to the server.

Database Application Interfaces

You may want to develop your own client applications that interface to Greenplum Database. PostgreSQL provides a number of database drivers for the most commonly used database application programming interfaces (APIs), which can also be used with Greenplum Database. These drivers are available as a separate download. Each driver (except libpq, which comes with PostgreSQL) is an independent PostgreSQL development project and must be downloaded, installed and configured to connect to Greenplum Database. The following drivers are available:

<table>
<thead>
<tr>
<th>API</th>
<th>PostgreSQL Driver</th>
<th>Download Link</th>
</tr>
</thead>
<tbody>
<tr>
<td>JDBC</td>
<td>Greenplum DataDirect JDBC Driver</td>
<td><a href="https://network.pivotal.io/products/pivotal-gpdb">https://network.pivotal.io/products/pivotal-gpdb</a></td>
</tr>
<tr>
<td>Perl DBI</td>
<td>pgperl</td>
<td><a href="http://search.cpan.org/dist/DBD-Pg/">http://search.cpan.org/dist/DBD-Pg/</a></td>
</tr>
<tr>
<td>Python DBI</td>
<td>pygresql</td>
<td><a href="http://www.pygresql.org/">http://www.pygresql.org/</a></td>
</tr>
<tr>
<td>libpq C Library</td>
<td>libpq</td>
<td><a href="https://www.postgresql.org/docs/8.3/static/libpq.html">https://www.postgresql.org/docs/8.3/static/libpq.html</a></td>
</tr>
</tbody>
</table>

General instructions for accessing a Greenplum Database with an API are:

1. Download your programming language platform and respective API from the appropriate source. For example, you can get the Java Development Kit (JDK) and JDBC API from Oracle.
2. Write your client application according to the API specifications. When programming your application, be aware of the SQL support in Greenplum Database so you do not include any unsupported SQL syntax.

See the Greenplum Database Reference Guide for more information.

Download the appropriate driver and configure connectivity to your Greenplum Database master instance.

Troubleshooting Connection Problems

A number of things can prevent a client application from successfully connecting to Greenplum Database. This topic explains some of the common causes of connection problems and how to correct them.
Table 41: Common connection problems

<table>
<thead>
<tr>
<th>Problem</th>
<th>Solution</th>
</tr>
</thead>
<tbody>
<tr>
<td>No <code>pg_hba.conf</code> entry for host or user</td>
<td>To enable Greenplum Database to accept remote client connections, you must configure your Greenplum Database master instance so that connections are allowed from the client hosts and database users that will be connecting to Greenplum Database. This is done by adding the appropriate entries to the <code>pg_hba.conf</code> configuration file (located in the master instance's data directory). For more detailed information, see <a href="#">Allowing Connections to Greenplum Database</a>.</td>
</tr>
<tr>
<td>Greenplum Database is not running</td>
<td>If the Greenplum Database master instance is down, users will not be able to connect. You can verify that the Greenplum Database system is up by running the <code>gpstate</code> utility on the Greenplum master host.</td>
</tr>
<tr>
<td>Network problems</td>
<td>If users connect to the Greenplum master host from a remote client, network problems can prevent a connection (for example, DNS host name resolution problems, the host system is down, and so on.). To ensure that network problems are not the cause, connect to the Greenplum master host from the remote client host. For example: <code>ping hostname</code> .</td>
</tr>
<tr>
<td>Interconnect timeouts</td>
<td>If the system cannot resolve the host names and IP addresses of the hosts involved in Greenplum Database, queries and connections will fail. For some operations, connections to the Greenplum Database master use <code>localhost</code> and others use the actual host name, so you must be able to resolve both. If you encounter this error, first make sure you can connect to each host in your Greenplum Database array from the master host over the network. In the <code>/etc/hosts</code> file of the master and all segments, make sure you have the correct host names and IP addresses for all hosts involved in the Greenplum Database array. The <code>127.0.0.1</code> IP must resolve to <code>localhost</code>.</td>
</tr>
<tr>
<td>Too many clients already</td>
<td>By default, Greenplum Database is configured to allow a maximum of 250 concurrent user connections on the master and 750 on a segment. A connection attempt that causes that limit to be exceeded will be refused. This limit is controlled by the <code>max_connections</code> parameter in the <code>postgresql.conf</code> configuration file of the Greenplum Database master. If you change this setting for the master, you must also make appropriate changes at the segments.</td>
</tr>
</tbody>
</table>

**Configuring the Greenplum Database System**

Server configuration parameters affect the behavior of Greenplum Database. They are part of the PostgreSQL "Grand Unified Configuration" system, so they are sometimes called "GUCs." Most of the Greenplum Database server configuration parameters are the same as the PostgreSQL configuration parameters, but some are Greenplum-specific.

**About Greenplum Database Master and Local Parameters**

Server configuration files contain parameters that configure server behavior. The Greenplum Database configuration file, `postgresql.conf`, resides in the data directory of the database instance.

The master and each segment instance have their own `postgresql.conf` file. Some parameters are `local`: each segment instance examines its `postgresql.conf` file to get the value of that parameter. Set local parameters on the master and on each segment instance.

Other parameters are `master` parameters that you set on the master instance. The value is passed down to (or in some cases ignored by) the segment instances at query run time.

See the [Greenplum Database Reference Guide](#) for information about `local` and `master` server configuration parameters.
Setting Configuration Parameters

Many configuration parameters limit who can change them and where or when they can be set. For example, to change certain parameters, you must be a Greenplum Database superuser. Other parameters can be set only at the system level in the `postgresql.conf` file or require a system restart to take effect.

Many configuration parameters are session parameters. You can set session parameters at the system level, the database level, the role level or the session level. Database users can change most session parameters within their session, but some require superuser permissions.

See the Greenplum Database Reference Guide for information about setting server configuration parameters.

Setting a Local Configuration Parameter

To change a local configuration parameter across multiple segments, update the parameter in the `postgresql.conf` file of each targeted segment, both primary and mirror. Use the `gpconfig` utility to set a parameter in all Greenplum `postgresql.conf` files. For example:

```
$ gpconfig -c gp_vmem_protect_limit -v 4096
```

Restart Greenplum Database to make the configuration changes effective:

```
$ gpstop -r
```

Setting a Master Configuration Parameter

To set a master configuration parameter, set it at the Greenplum Database master instance. If it is also a session parameter, you can set the parameter for a particular database, role or session. If a parameter is set at multiple levels, the most granular level takes precedence. For example, session overrides role, role overrides database, and database overrides system.

Setting Parameters at the System Level

Master parameter settings in the master `postgresql.conf` file are the system-wide default. To set a master parameter:

1. Edit the `$MASTER_DATA_DIRECTORY/postgresql.conf` file.
2. Find the parameter to set, uncomment it (remove the preceding `#` character), and type the desired value.
3. Save and close the file.
4. For session parameters that do not require a server restart, upload the `postgresql.conf` changes as follows:

   ```
   $ gpstop -u
   ```

5. For parameter changes that require a server restart, restart Greenplum Database as follows:

   ```
   $ gpstop -r
   ```

For details about the server configuration parameters, see the Greenplum Database Reference Guide.

Setting Parameters at the Database Level

Use `ALTER DATABASE` to set parameters at the database level. For example:

```
=# ALTER DATABASE mydatabase SET search_path TO myschema;
```
When you set a session parameter at the database level, every session that connects to that database uses that parameter setting. Settings at the database level override settings at the system level.

**Setting Parameters at the Role Level**

Use `ALTER ROLE` to set a parameter at the role level. For example:

```sql
=# ALTER ROLE bob SET search_path TO bobschema;
```

When you set a session parameter at the role level, every session initiated by that role uses that parameter setting. Settings at the role level override settings at the database level.

**Setting Parameters in a Session**

Any session parameter can be set in an active database session using the `SET` command. For example:

```sql
=# SET statement_mem TO '200MB';
```

The parameter setting is valid for the rest of that session or until you issue a `RESET` command. For example:

```sql
=# RESET statement_mem;
```

Settings at the session level override those at the role level.

**Viewing Server Configuration Parameter Settings**

The SQL command `SHOW` allows you to see the current server configuration parameter settings. For example, to see the settings for all parameters:

```bash
$ psql -c 'SHOW ALL;'
```

`SHOW` lists the settings for the master instance only. To see the value of a particular parameter across the entire system (master and all segments), use the `gpconfig` utility. For example:

```bash
$ gpconfig --show max_connections
```

**Configuration Parameter Categories**

Configuration parameters affect categories of server behaviors, such as resource consumption, query tuning, and authentication. The following topics describe Greenplum Database configuration parameter categories.

For details about configuration parameter categories, see the [Greenplum Database Reference Guide](#).

**Connection and Authentication Parameters**

These parameters control how clients connect and authenticate to Greenplum Database.

See [Managing Greenplum Database Access](#) for information about configuring client authentication.

**Connection Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>gp_connection_send_timeout</td>
<td></td>
</tr>
<tr>
<td>gp_vmem_idle_resource_timeout</td>
<td></td>
</tr>
<tr>
<td>listen_addresses</td>
<td></td>
</tr>
<tr>
<td>max_connections</td>
<td></td>
</tr>
<tr>
<td>tcp_keepalives_count</td>
<td></td>
</tr>
<tr>
<td>tcp_keepalives_idle</td>
<td></td>
</tr>
<tr>
<td>tcp_keepalives_interval</td>
<td></td>
</tr>
<tr>
<td>unix_socket_directory</td>
<td></td>
</tr>
<tr>
<td>max_prepared_transactions</td>
<td>unix_socket_group</td>
</tr>
<tr>
<td>----------------------------</td>
<td>-------------------</td>
</tr>
<tr>
<td>superuser_reserved_connections</td>
<td>unix_socket_permissions</td>
</tr>
</tbody>
</table>

**Security and Authentication Parameters**

<table>
<thead>
<tr>
<th>authentication_timeout</th>
<th>krb_srvname</th>
</tr>
</thead>
<tbody>
<tr>
<td>db_user_namespace</td>
<td>password_encryption</td>
</tr>
<tr>
<td>krb_caseins_users</td>
<td>password_hash_algorithm</td>
</tr>
<tr>
<td>krb_server_keyfile</td>
<td>ssl</td>
</tr>
<tr>
<td></td>
<td>ssl_ciphers</td>
</tr>
</tbody>
</table>

**System Resource Consumption Parameters**

**Memory Consumption Parameters**

These parameters control system memory usage. You can adjust `gp_vmem_protect_limit` to avoid running out of memory at the segment hosts during query processing.

<table>
<thead>
<tr>
<th>gp_vmem_idle_resource_timeout</th>
<th>max_stack_depth</th>
</tr>
</thead>
<tbody>
<tr>
<td>gp_vmem_protect_limit</td>
<td>shared_buffers</td>
</tr>
<tr>
<td>gp_vmem_protect_segworker_cache_limit</td>
<td>temp_buffers</td>
</tr>
<tr>
<td>gp_workfile_limit_files_per_query</td>
<td></td>
</tr>
<tr>
<td>gp_workfile_limit_per_query</td>
<td></td>
</tr>
<tr>
<td>gp_workfile_limit_per_segment</td>
<td></td>
</tr>
<tr>
<td>max_appendonly_tables</td>
<td></td>
</tr>
<tr>
<td>max_prepared_transactions</td>
<td></td>
</tr>
</tbody>
</table>

**Free Space Map Parameters**

These parameters control the sizing of the free space map, which contains expired rows. Use `VACUUM` to reclaim the free space map disk space.

See [Vacuum and Analyze for Query Optimization](#) for information about vacuuming a database.

- max fsm pages
- max fsm relations

**OS Resource Parameters**

- max files per process
- shared preload libraries

**Cost-Based Vacuum Delay Parameters**

**Warning:** Using cost-based vacuum delay is discouraged because it runs asynchronously among the segment instances. The vacuum cost limit and delay is invoked at the segment level without taking into account the state of the entire Greenplum array.

You can configure the execution cost of `VACUUM` and `ANALYZE` commands to reduce the I/O impact on concurrent database activity. When the accumulated cost of I/O operations reaches the limit, the process performing the operation sleeps for a while, then resets the counter and continues execution.
**Transaction ID Management Parameters**

- xid_stop_limit
- xid_warn_limit

**Query Tuning Parameters**

**GPORCA Configuration Parameters**

<table>
<thead>
<tr>
<th>optimizer</th>
<th>optimizer_analyze_root_partition</th>
<th>optimizer_array_expansion_threshold</th>
<th>optimizer_cteInlining_bound</th>
<th>optimizer_enable_associativity</th>
<th>optimizer_control</th>
<th>optimizer_enable_master_only_queries</th>
<th>optimizer_force_multistage_agg</th>
<th>optimizer_force_three_stage_scalar_dqa</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Query Plan Operator Control Parameters**

The following parameters control the types of plan operations the legacy query optimizer can use. Enable or disable plan operations to force the legacy query optimizer to choose a different plan. This is useful for testing and comparing query performance using different plan types.

| enable_bitmapscan | enable_groupagg | enable_hashagg | enable_hashjoin | enable_indexscan | enable_mergejoin | enable_nestloop | enable_seqscan | enable_sort | enable_tidscan | gp_enable_agg_distinct | gp_enable_agg_distinct_pruning | gp_enable_direct_dispatch | gp_enableFallback_plan | gp_enableFast_sri | gp_enable_grouppext_distinct__gather | gp_enable_grouppext_distinct__pruning | gp_enable_multiphase_agg | gp_enable_predicate__propagation | gp_enable_preunique | gp_enable_recursive iteration | gp_enable_recursive_plan | gp_enable_sort_distinct | gp_enable_sort_limit |
Legacy Query Optimizer Costing Parameters

**Warning:** Do not adjust these query costing parameters. They are tuned to reflect Greenplum Database hardware configurations and typical workloads. All of these parameters are related. Changing one without changing the others can have adverse effects on performance.

<table>
<thead>
<tr>
<th>cpu_index_tuple_cost</th>
<th>gp_motion_cost_per_row</th>
</tr>
</thead>
<tbody>
<tr>
<td>cpu_operator_cost</td>
<td>gp_segments_for_planner</td>
</tr>
<tr>
<td>cpu_tuple_cost</td>
<td>random_page_cost</td>
</tr>
<tr>
<td>cursor_tuple_fraction</td>
<td>seq_page_cost</td>
</tr>
<tr>
<td>effective_cache_size</td>
<td></td>
</tr>
</tbody>
</table>

Database Statistics Sampling Parameters

These parameters adjust the amount of data sampled by an ANALYZE operation. Adjusting these parameters affects statistics collection system-wide. You can configure statistics collection on particular tables and columns by using the ALTER TABLE SET STATISTICS clause.

- default_statistics_target
- gp_analyze_relative_error

Sort Operator Configuration Parameters

- gp_enable_sort_distinct
- gp_enable_sort_limit

Aggregate Operator Configuration Parameters

- gp_enable_agg_distinct
- gp_enable_agg_distinct_pruning
- gp_enable_multiphase_agg
- gp_enable_preunique
- gp_enable_groupext_distinct_gather
- gp_enable_groupext_distinct_pruning
- gp_workfile_compress_algorithm

Join Operator Configuration Parameters

- joinCollapse_limit
- gp_adjust_selectivity_for_outerjoins
- gp_hashjoin_tuples_per_bucket
- gp_statistics_use_fkeys
- gp_workfile_compress_algorithm

Other Legacy Query Optimizer Configuration Parameters

- fromCollapse_limit
- gp_enable_predicate_propagation
- gp_max_plan_size
- gp_statistics_pullup_from_child_partition
Error Reporting and Logging Parameters

Log Rotation

| log_rotation_age          | log_truncate_on_rotation                  |
| log_rotation_size         |                                           |

When to Log

| client_min_messages       | log_min_error_statement                   |
| gp_interconnect_debug_retry_interval | log_min_messages                        |
| log_error_verbosity       | optimizer_minidump                       |
| log_min_duration_statement|                                           |

What to Log

| debug_pretty_print       | log_executor_stats                       |
| debug_print_parse        | log_hostname                             |
| debug_print_plan         | gp_log_interconnect                      |
| debug_print_prelim_plan  | log_parser_stats                         |
| debug_print_rewritten    | log_planner_stats                        |
| debug_print_slice_table  | log_statement                            |
| log_autostats            | log_statement_stats                      |
| log_connections          | log_statement_stats                      |
| log_disconnections       | gp_debug_linger                          |
| log_dispatch_stats       | gp_log_format                            |
| log_duration             | gp_log_gang                              |
|                           | gp_max_csv_line_length                   |
|                           | gp_reraise_signal                        |

System Monitoring Parameters

SNMP Alerts

The following parameters send SNMP notifications when events occur.

| gp_snmp_community         | gp_snmp_use_inform_or_trap               |
| gp_snmp_monitor_address   |                                           |

Email Alerts

The following parameters configure the system to send email alerts for fatal error events, such as a segment going down or a server crash and reset.
Greenplum Command Center Agent

The following parameters configure the data collection agents that populate the `gpperfmon` database used by Greenplum Command Center.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>gp_enable_gpperfmon</td>
<td>Enables or disables gpperfmon</td>
</tr>
<tr>
<td>gp_gpperfmon_send_interval</td>
<td>Set the interval for sending data</td>
</tr>
<tr>
<td>gpperfmon_log_alert_level</td>
<td>Set the log alert level</td>
</tr>
<tr>
<td>gpperfmon_port</td>
<td>Set the port for gpperfmon</td>
</tr>
</tbody>
</table>

Runtime Statistics Collection Parameters

These parameters control the server statistics collection feature. When statistics collection is enabled, you can access the statistics data using the `pg_stat` and `pg_statio` family of system catalog views.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>stats_queue_level</td>
<td>Set the queue level for statistics</td>
</tr>
<tr>
<td>track_activities</td>
<td>Track activities</td>
</tr>
<tr>
<td>track_counts</td>
<td>Track counts</td>
</tr>
<tr>
<td>update_process_title</td>
<td>Update process title</td>
</tr>
</tbody>
</table>

Automatic Statistics Collection Parameters

When automatic statistics collection is enabled, you can run `ANALYZE` automatically in the same transaction as an `INSERT`, `UPDATE`, `DELETE`, `COPY` or `CREATE TABLE ... AS SELECT` statement when a certain threshold of rows is affected (`on_change`), or when a newly generated table has no statistics (`on_no_stats`). To enable this feature, set the following server configuration parameters in your Greenplum master `postgresql.conf` file and restart Greenplum Database:

- `gp_autostats_mode`
- `gp_autostats_mode_in_functions`
- `log_autostats`
- `gp_autostats_on_change_threshold`

Warning: Depending on the specific nature of your database operations, automatic statistics collection can have a negative performance impact. Carefully evaluate whether the default setting of `on_no_stats` is appropriate for your system.

Client Connection Default Parameters

Statement Behavior Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>check_function_bodies</td>
<td>Check function bodies</td>
</tr>
<tr>
<td>default_tablespace</td>
<td>Default tablespace</td>
</tr>
<tr>
<td>default_transaction_isolation</td>
<td>Default transaction isolation</td>
</tr>
<tr>
<td>default_transaction_read_only</td>
<td>Default transaction read only</td>
</tr>
<tr>
<td>search_path</td>
<td>Search path</td>
</tr>
<tr>
<td>statement_timeout</td>
<td>Statement timeout</td>
</tr>
<tr>
<td>vacuum_freeze_min_age</td>
<td>Vacuum freeze min age</td>
</tr>
</tbody>
</table>

Locale and Formatting Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>client_encoding</td>
<td>Client encoding</td>
</tr>

</table>

**Database Table Parameters**

The following parameter configures default option settings for Greenplum Database tables.

See *Creating and Managing Tables* for more information about Greenplum Database tables.

- `gp_create_table_random_default_distribution`
- `gp_default_storage_options`
• \texttt{gp\_enable\_exchange\_default\_partition}
• \texttt{gp\_enable\_segment\_copy\_checking}

\textbf{Append-Optimized Table Parameters}

The following parameters configure the append-optimized tables feature of Greenplum Database.

See \textit{Append-Optimized Storage} for more information about append-optimized tables.

• \texttt{gp\_default\_storage\_options}
• \texttt{max\_appendonly\_tables}
• \texttt{gp\_appendonly\_compaction}
• \texttt{gp\_appendonly\_compaction\_threshold}
• \texttt{validate\_previous\_free\_tid}

\textbf{Database and Tablespace/Filespace Parameters}

The following parameters configure the maximum number of databases, tablespaces, and filespaces allowed in a system.

• \texttt{gp\_max\_tablespaces}
• \texttt{gp\_max\_filesystems}
• \texttt{gp\_max\_databases}

\textbf{Past Version Compatibility Parameters}

The following parameters provide compatibility with older PostgreSQL and Greenplum Database versions. You do not need to change these parameters in Greenplum Database.

\textbf{PostgreSQL}

\begin{tabular}{l|l}
\texttt{add\_missing\_from} & \texttt{regex\_flavor} \\
\texttt{array\_nulls} & \texttt{standard\_conforming\_strings} \\
\texttt{backslash\_quote} & \texttt{transform\_null\_equals} \\
\texttt{escape\_string\_warning} & \\
\end{tabular}

\textbf{Greenplum Database}

\texttt{gp\_ignore\_error\_table}

\textbf{Greenplum Array Configuration Parameters}

The parameters in this topic control the configuration of the Greenplum Database array and its components: segments, master, distributed transaction manager, master mirror, and interconnect.

\textbf{Interconnect Configuration Parameters}

\begin{tabular}{l|l}
\texttt{gp\_interconnect\_fc\_method} & \texttt{gp\_interconnect\_setup\_timeout} \\
\texttt{gp\_interconnect\_hash\_multiplier} & \texttt{gp\_interconnect\_snd\_queue\_depth} \\
\texttt{gp\_interconnect\_queue\_depth} & \texttt{gp\_interconnect\_type} \\
\texttt{gp\_max\_packet\_size} & \\
\end{tabular}

\textbf{Note}: Greenplum Database supports only the UDPIFC and TCP interconnect types.
Dispatch Configuration Parameters

<table>

Distributed Transaction Management Parameters

- gp_max_local_distributed_cache

Read-Only Parameters

- gp_command_count
- gp_content
- gp_dbid
- gp_num_contents_in_cluster
- gp_role
- gp_session_id

Greenplum Master and Segment Mirroring Parameters

These parameters control the configuration of the replication between Greenplum Database primary master and standby master.

- keep_wal_segments
- repl_catchup_within_range
- replication_timeout
- wal_receiver_status_interval

This parameter controls validation between Greenplum Database primary segment and standby segment during incremental resynchronization.

- filerep_mirrorvalidation_during_resync

Greenplum Database Extension Parameters

The parameters in this topic control the configuration of Greenplum Database extensions.

- pljava_classpath
- pljava_classpath_insecure
- pljava_statement_cache_size
- pljava_release_lingering_savepoints
- pljava_vmoptions

XML Data Parameters

- xmlbinary
- xmloption
Enabling High Availability and Data Consistency Features

The fault tolerance and the high-availability features of Greenplum Database can be configured.

Important: When data loss is not acceptable for a Pivotal Greenplum Database cluster, master and segment mirroring must be enabled in order for the cluster to be supported by Pivotal. Without mirroring, system and data availability is not guaranteed, Pivotal will make best efforts to restore a cluster in this case. For information about master and segment mirroring, see About Redundancy and Failover.

For information about the utilities that are used to enable high availability, see the Greenplum Database Utility Guide.

Overview of Greenplum Database High Availability

A Greenplum Database cluster can be made highly available by providing a fault-tolerant hardware platform, by enabling Greenplum Database high-availability features, and by performing regular monitoring and maintenance procedures to ensure the health of all system components.

Hardware components will eventually fail, whether due to normal wear or an unexpected circumstance. Loss of power can lead to temporarily unavailable components. A system can be made highly available by providing redundant standbys for components that can fail so that services can continue uninterrupted when a failure does occur. In some cases, the cost of redundancy is higher than users’ tolerance for interruption in service. When this is the case, the goal is to ensure that full service is able to be restored, and can be restored within an expected timeframe.

With Greenplum Database, fault tolerance and data availability is achieved with:

- Hardware level RAID storage protection
- Data storage checksums
- Greenplum segment mirroring
- Master mirroring
- Dual clusters
- Database backup and restore

Hardware level RAID

A best practice Greenplum Database deployment uses hardware level RAID to provide high performance redundancy for single disk failure without having to go into the database level fault tolerance. This provides a lower level of redundancy at the disk level.

Data storage checksums

Greenplum Database uses checksums to verify that data loaded from disk to memory has not been corrupted on the file system.

Greenplum Database has two kinds of storage for user data: heap and append-optimized. Both storage models use checksums to verify data read from the file system and, with the default settings, they handle checksum verification errors in a similar way.

Greenplum Database primary and segment database processes update data on pages in the memory they manage. When a memory page is updated and flushed to disk, checksums are computed and saved with the page. When a page is later retrieved from disk, the checksums are verified and the page is only permitted to enter managed memory if the verification succeeds. A failed checksum verification is an indication of corruption in the file system and causes Greenplum Database to generate an error, aborting the transaction.

The default checksum settings provide the best level of protection from undetected disk corruption propagating into the database and to mirror segments.
Heap checksum support is enabled by default when the Greenplum Database cluster is initialized with the `gpinitsystem` management utility. Although it is strongly discouraged, a cluster can be initialized without heap checksum support by setting the `HEAP_CHECKSUM` parameter to off in the `gpinitsystem` cluster configuration file. See `gpinitsystem`.

Once initialized, it is not possible to change heap checksum support for a cluster without reinitializing the system and reloading databases.

You can check the read-only server configuration parameter `data_checksums` to see if heap checksums are enabled in a cluster:

```
$ gpconfig -s data_checksums
```

When a Greenplum Database cluster starts up, the `gpstart` utility checks that heap checksums are consistently enabled or disabled on the master and all segments. If there are any differences, the cluster fails to start. See `gpstart`.

In cases where it is necessary to ignore heap checksum verification errors so that data can be recovered, setting the `ignore_checksum_failure` system configuration parameter to on causes Greenplum Database to issue a warning when a heap checksum verification fails, but the page is then permitted to load into managed memory. If the page is updated and saved to disk, the corrupted data could be replicated to the mirror segment. Because this can lead to data loss, setting `ignore_checksum_failure` to on should only be done to enable data recovery.

For append-optimized storage, checksum support is one of several storage options set at the time an append-optimized table is created with the `CREATE TABLE` statement. The default storage options are specified in the `gp_default_storage_options` server configuration parameter. The checksum storage option is enabled by default and disabling it is strongly discouraged.

If you choose to disable checksums for an append-optimized table, you can either

- change the `gp_default_storage_options` configuration parameter to include `checksum=false` before creating the table, or
- add the `checksum=false` option to the `WITH storage_options` clause of the `CREATE TABLE` statement.

Note that the `CREATE TABLE` statement allows you to set storage options, including checksums, for individual partition files.

See the `CREATE TABLE` command reference and the `gp_default_storage_options` configuration parameter reference for syntax and examples.

**Segment Mirroring**

Greenplum Database stores data in multiple segments, each of which is a Greenplum Database Postgres instance. The data for each table is spread between the segments based on the distribution policy that is defined for the table in the DDL at the time the table is created. When segment mirroring is enabled, for each segment there is a primary and mirror pair. The primary and mirror perform the same IO operations and store copies of the same data.

The mirror instance for each segment is usually initialized with the `gpinitsystem` utility or the `gpexpand` utility. The mirror runs on a different host than the primary instance to protect from a single machine failure. There are different strategies for assigning mirrors to hosts. When choosing the layout of the primaries and mirrors, it is important to consider the failure scenarios to ensure that processing skew is minimized in the case of a single machine failure.

**Master Mirroring**

There are two masters in a highly available cluster, a primary and a standby. As with segments, the master and standby should be deployed on different hosts so that the cluster can tolerate a single host failure. Clients connect to the primary master and queries can be executed only on the primary master.
The secondary master is kept up-to-date by replicating the write-ahead log (WAL) from the primary to the secondary.

If the master fails, the administrator runs the `gpactivatestandby` utility to have the standby master take over as the new primary master. You can configure a virtual IP address for the master and standby so that client programs do not have to switch to a different network address when the current master changes. If the master host fails, the virtual IP address can be swapped to the actual acting master.

**Dual Clusters**

An additional level of redundancy can be provided by maintaining two Greenplum Database clusters, both storing the same data.

Two methods for keeping data synchronized on dual clusters are “dual ETL” and “backup/restore.”

Dual ETL provides a complete standby cluster with the same data as the primary cluster. ETL (extract, transform, and load) refers to the process of cleansing, transforming, validating, and loading incoming data into a data warehouse. With dual ETL, this process is executed twice in parallel, once on each cluster, and is validated each time. It also allows data to be queried on both clusters, doubling the query throughput. Applications can take advantage of both clusters and also ensure that the ETL is successful and validated on both clusters.

To maintain a dual cluster with the backup/restore method, create backups of the primary cluster and restore them on the secondary cluster. This method takes longer to synchronize data on the secondary cluster than the dual ETL strategy, but requires less application logic to be developed. Populating a second cluster with backups is ideal in use cases where data modifications and ETL are performed daily or less frequently.

**Backup and Restore**

Making regular backups of the databases is recommended except in cases where the database can be easily regenerated from the source data. Backups should be taken to protect from operational, software, and hardware errors.

Use the `gpcrondump` utility to backup Greenplum databases. `gpcrondump` performs the backup in parallel across segments, so backup performance scales up as hardware is added to the cluster.

When designing a backup strategy, a primary concern is where to store the backup data. The data each segment manages can be backed up on the segment's local storage, but should not be stored there permanently—the backup reduces disk space available to the segment and, more importantly, a hardware failure could simultaneously destroy the segment's live data and the backup. After performing a backup, the backup files should be moved from the primary cluster to separate, safe storage. Alternatively, the backup can be made directly to separate storage.

Additional options are available to backup databases, including the following:

**Data Domain**

Through native API integration backups can be streamed to a Dell EMC Data Domain appliance.

**NetBackup**

Through native API integration, backups can be streamed to a Veritas NetBackup cluster.

**NFS**

If an NFS mount is created on each Greenplum Database host in the cluster, backups can be written directly to the NFS mount. A scale out NFS solution is recommended to ensure that backups do not bottleneck on IO throughput of the NFS device. Dell EMC Isilon is an example that can scale out along side the Greenplum cluster.
Incremental Backups

Greenplum Database allows *incremental backup* at the partition level for append-optimized and column-oriented tables. When you perform an incremental backup, only the partitions for append-optimized and column-oriented tables that have changed since the previous backup are backed up. (Heap tables are *always* backed up.) Restoring an incremental backup requires restoring the previous full backup and subsequent incremental backups.

Incremental backup is beneficial only when the database contains large, partitioned tables where all but one or a few partitions remain unchanged between backups. An incremental backup saves just the changed partitions and the heap tables. By not backing up the unchanged partitions, the backup size and time can be significantly reduced.

If a large fact table is not partitioned, and a single row is added or changed, the entire table is backed up, and there is no savings in backup size or time. Therefore, incremental backup is only recommended for databases with large, partitioned tables and relatively small dimension tables.

If you maintain dual clusters and use incremental backup, you can populate the second cluster with the incremental backups. Use the `--noplan` option to achieve this, allowing backups from the primary site to be applied faster.

Overview of Segment Mirroring

When Greenplum Database High Availability is enabled, there are two types of segments: *primary* and *mirror*. Each primary segment has one corresponding mirror segment. A primary segment receives requests from the master to make changes to the segment's database and then replicates those changes to the corresponding mirror. If Greenplum Database detects that a primary segment has failed or become unavailable, it changes the role of its mirror segment to primary segment and the role of the unavailable primary segment to mirror segment. Transactions in progress when the failure occurred roll back and must be restarted. The administrator must then recover the mirror segment, allow the mirror to synchronize with the current primary segment, and then exchange the primary and mirror segments so they are in their preferred roles.

Segment mirroring employs a physical file replication scheme—data file I/O at the primary is replicated to the secondary so that the mirror's files are identical to the primary's files. Data in Greenplum Database are represented with *tuples*, which are packed into *blocks*. Database tables are stored in disk files consisting of one or more blocks. A change to a tuple changes the block it is saved in, which is then written to disk on the primary and copied over the network to the mirror. The mirror updates the corresponding block in its copy of the file.

For heap tables, blocks are saved in an in-memory cache until they are evicted to make room for newly changed blocks. This allows the system to read or update a block in memory multiple times without performing expensive disk I/O. When the block is evicted from the cache, it is written to disk and replicated to the secondary. While the block is held in cache, the primary and mirror have different images of the block. However, the databases are still consistent because the transaction log has been replicated. If a mirror takes over for a failed primary, the transactions in its log are applied to the database tables.

Other database objects — for example filespaces, which are tablespaces internally represented with directories—also use file replication to perform various file operations in a synchronous way.

Append-optimized tables do not use the in-memory caching mechanism. Changes made to append-optimized table blocks are replicated to the mirror immediately. Typically, file write operations are asynchronous, while opening, creating, and synchronizing files are "sync-replicated," which means the primary blocks until it receives the acknowledgment from the secondary.

If a primary segment fails, the file replication process stops and the mirror segment automatically starts as the active segment instance. The new active mirror's system state becomes *Change Tracking*, which means the mirror maintains a system table and change-log of all blocks updated while the primary segment is unavailable. When the failed primary segment is repaired and ready to be brought back online, an administrator initiates a recovery process and the system goes into *Resynchronization* state. The recovery
process applies the logged changes to the repaired primary segment. The system state changes to \textit{Synchronized} when the recovery process completes.

If the mirror segment fails or becomes inaccessible while the primary is active, the primary's system state changes to \textit{Change Tracking}, and it tracks changes to be applied to the mirror when it is recovered.

Mirror segments can be placed on hosts in the cluster in different configurations, as long as the primary and mirror instance for a segment are on different hosts. Each host must have the same number of primary and mirror segments. The default mirroring configuration is \textit{group mirroring}, where the mirror segments for each host's primary segments are placed on one other host. If a single host fails, the number of active primary segments doubles on the host that backs the failed host. \textit{Figure 15: Group Segment Mirroring in Greenplum Database} illustrates a group mirroring configuration.

\textit{Spread mirroring} spreads each host's mirrors over multiple hosts so that if any single host fails, no other host will have more than one mirror promoted to the active primary segment. Spread mirroring is possible only if there are more hosts than segments per host. \textit{Figure 16: Spread Segment Mirroring in Greenplum Database} illustrates the placement of mirrors in a spread segment mirroring configuration.

\begin{figure}
\centering
\includegraphics[width=\textwidth]{segment-mirroring.png}
\caption{Group Segment Mirroring in Greenplum Database}
\end{figure}

\begin{figure}
\centering
\includegraphics[width=\textwidth]{spread-mirroring.png}
\caption{Spread Segment Mirroring in Greenplum Database}
\end{figure}
Figure 16: Spread Segment Mirroring in Greenplum Database

The Greenplum Database utilities that create mirror segments support group and spread segment configurations. Custom mirroring configurations can be described in a configuration file and passed on the command line.

**Overview of Master Mirroring**

You can deploy a backup or mirror of the master instance on a separate host machine or on the same host machine. A backup master or standby master serves as a warm standby if the primary master becomes nonoperational. You create a standby master from the primary master while the primary is online.

The primary master continues to provide service to users while a transactional snapshot of the primary master instance is taken. While the transactional snapshot is taken and deployed on the standby master, changes to the primary master are also recorded. After the snapshot is deployed on the standby master, the updates are deployed to synchronize the standby master with the primary master.

Once the primary master and standby master are synchronized, the standby master is kept up to date by the **wal sender** and **wal receiver** replication processes. The **wal receiver** is a standby master process. The **wal sender** process is a primary master process. The two processes use Write-Ahead Logging (WAL)-based streaming replication to keep the primary and standby masters synchronized. In WAL logging, all modifications are written to the log before being applied, to ensure data integrity for any in-process operations.

**Note:** WAL logging is not yet available for segment mirroring.

Since the master does not house user data, only system catalog tables are synchronized between the primary and standby masters. When these tables are updated, changes are automatically copied to the standby master to keep it current with the primary.
If the primary master fails, the replication process stops, and an administrator can activate the standby master. Upon activation of the standby master, the replicated logs reconstruct the state of the primary master at the time of the last successfully committed transaction. The activated standby then functions as the Greenplum Database master, accepting connections on the port specified when standby master was initialized.

**Overview of Fault Detection and Recovery**

The Greenplum Database server (`postgres`) subprocess named `ftsprobe` handles fault detection. `ftsprobe` monitors the Greenplum Database array; it connects to and scans all segments and database processes at intervals that you can configure.

If `ftsprobe` cannot connect to a segment, it marks the segment as "down" in the Greenplum Database system catalog. The segment remains nonoperational until an administrator initiates the recovery process.

With mirroring enabled, Greenplum Database automatically fails over to a mirror copy if a primary copy becomes unavailable. The system is operational if a segment instance or host fails provided all data is available on the remaining active segments.

To recover failed segments, an administrator runs the `gprecoverseg` recovery utility. This utility locates the failed segments, verifies they are valid, and compares the transactional state with the currently active segment to determine changes made while the segment was offline. `gprecoverseg` synchronizes the changed database files with the active segment and brings the segment back online. Administrators perform the recovery while Greenplum Database is up and running.

With mirroring disabled, the system automatically shuts down if a segment instance fails. Administrators manually recover all failed segments before operations resume.

See [Detecting a Failed Segment](#) for a more detailed description of the fault detection and recovery process and configuration options.

**Enabling Mirroring in Greenplum Database**

You can configure your Greenplum Database system with mirroring at setup time using `gpinitsystem` or enable mirroring later using `gpaddmirrors` and `gpinitstandby`. This topic assumes you are adding mirrors to an existing system that was initialized without mirrors.

You can enable the following types of mirroring:

- **Enabling Segment Mirroring**
- **Enabling Master Mirroring**
**Enabling Segment Mirroring**

Mirror segments allow database queries to fail over to a backup segment if the primary segment is unavailable. By default, mirrors are configured on the same array of hosts as the primary segments. You may choose a completely different set of hosts for your mirror segments so they do not share machines with any of your primary segments.

**Important:** During the online data replication process, Greenplum Database should be in a quiescent state, workloads and other queries should not be running.

To add segment mirrors to an existing system (same hosts as primaries)

1. Allocate the data storage area for mirror data on all segment hosts. The data storage area must be different from your primary segments' file system location.
2. Use `gpssh-exkeys` to ensure that the segment hosts can SSH and SCP to each other without a password prompt.
3. Run the `gpaddmirrors` utility to enable mirroring in your Greenplum Database system. For example, to add 10000 to your primary segment port numbers to calculate the mirror segment port numbers:

   ```
   $ gpaddmirrors -p 10000
   ```

   Where `-p` specifies the number to add to your primary segment port numbers. Mirrors are added with the default group mirroring configuration.

To add segment mirrors to an existing system (different hosts from primaries)

1. Ensure the Greenplum Database software is installed on all hosts. See the *Greenplum Database Installation Guide* for detailed installation instructions.
2. Allocate the data storage area for mirror data on all segment hosts.
3. Use `gpssh-exkeys` to ensure the segment hosts can SSH and SCP to each other without a password prompt.
4. Create a configuration file that lists the host names, ports, and data directories on which to create mirrors. To create a sample configuration file to use as a starting point, run:

   ```
   $ gpaddmirrors -o filename
   ```

   The format of the mirror configuration file is:

   ```
   filespaceOrder=[filespace1_fsname[:filespace2_fsname:...]]
   mirror[content]=content:address:port:mir_replication_port:
   pri_replication_port:fseolocation[:fseolocation:...]
   ```

   For example, a configuration for two segment hosts and two segments per host, with no additional filesystems configured besides the default `pg_system` filesystem:

   ```
   filespaceOrder=
   mirror0=0:sdw1-1:52001:53001:54001:/gpdata/mir1/gp0
   mirror1=1:sdw1-2:52002:53002:54002:/gpdata/mir1/gp1
   mirror2=2:sdw2-1:52001:53001:54001:/gpdata/mir1/gp2
   mirror3=3:sdw2-2:52002:53002:54002:/gpdata/mir1/gp3
   ```

5. Run the `gpaddmirrors` utility to enable mirroring in your Greenplum Database system:

   ```
   $ gpaddmirrors -i mirror_config_file
   ```
Where \(-i\) names the mirror configuration file you created.

**Enabling Master Mirroring**

You can configure a new Greenplum Database system with a standby master using `gpinitsystem` or enable it later using `gpinitstandby`. This topic assumes you are adding a standby master to an existing system that was initialized without one.

For information about the utilities `gpinitsystem` and `gpinitstandby`, see the *Greenplum Database Utility Guide*.

**To add a standby master to an existing system**

1. Ensure the standby master host is installed and configured: `gpadmin` system user created, Greenplum Database binaries installed, environment variables set, SSH keys exchanged, and data directory created.
2. Run the `gpinitstandby` utility on the currently active primary master host to add a standby master host to your Greenplum Database system. For example:

   ```
   $ gpinitstandby -s smdw
   ```

   Where \(-s\) specifies the standby master host name.

3. To switch operations to a standby master, see *Recovering a Failed Master*.

**To check the status of the master mirroring process (optional)**

You can display the information in the Greenplum Database system view `pg_stat_replication`. The view lists information about the `walsender` process that is used for Greenplum Database master mirroring. For example, this command displays the process ID and state of the `walsender` process:

```
$ psql dbname -c 'SELECT procpid, state FROM pg_stat_replication;'
```

For information about the `pg_stat_replication` system view, see the *Greenplum Database Reference Guide*.

**Detecting a Failed Segment**

With mirroring enabled, Greenplum Database automatically fails over to a mirror segment when a primary segment goes down. Provided one segment instance is online per portion of data, users may not realize a segment is down. If a transaction is in progress when a fault occurs, the in-progress transaction rolls back and restarts automatically on the reconfigured set of segments.

If the entire Greenplum Database system becomes nonoperational due to a segment failure (for example, if mirroring is not enabled or not enough segments are online to access all user data), users will see errors when trying to connect to a database. The errors returned to the client program may indicate the failure.

For example:

```
ERROR: All segment databases are unavailable
```

**How Segment Failure is Detected and Managed**

On the Greenplum Database master host, the Postgres `postmaster` process forks a fault probe process, `ftsprobe`. This is sometimes called the FTS (Fault Tolerance Server) process. The `postmaster` process restarts the FTS if it fails.

The FTS runs in a loop with a sleep interval between each cycle. On each loop, the FTS probes each primary segment database by making a TCP socket connection to the segment database using the hostname and port registered in the `gp_segment_configuration` table. If the connection succeeds, the
segment performs a few simple checks and reports back to the FTS. The checks include executing a `stat` system call on critical segment directories and checking for internal faults in the segment instance. If no issues are detected, a positive reply is sent to the FTS and no action is taken for that segment database.

If the connection cannot be made, or if a reply is not received in the timeout period, then a retry is attempted for the segment database. If the configured maximum number of probe attempts fail, the FTS probes the segment’s mirror to ensure that it is up, and then updates the `gp_segment_configuration` table, marking the primary segment “down” and setting the mirror to act as the primary. The FTS updates the `gp_configuration_history` table with the operations performed.

When there is only an active primary segment and the corresponding mirror is down, the primary goes into “Change Tracking Mode.” In this mode, changes to the segment are recorded, so the mirror can be synchronized without performing a full copy of data from the primary to the mirror.

The `gprecoverseg` utility is used to bring up a mirror that is down. By default, `gprecoverseg` performs an incremental recovery, placing the mirror into resync mode, which starts to replay the recorded changes from the primary onto the mirror. If the incremental recovery cannot be completed, the recovery fails and `gprecoverseg` should be run again with the `-F` option, to perform full recovery. This causes the primary to copy all of the data to the mirror.

You can see the mode—“change tracking”, “resync”, or “in-sync”—for each segment, as well as the status “up” or “down”, in the `gp_segment_configuration` table.

The `gp_segment_configuration` table also has columns `role` and `preferred_role`. These can have values of either `p` for primary or `m` for mirror. The `role` column shows the segment database’s current role and the `preferred_role` shows the original role of the segment. In a balanced system the `role` and `preferred_role` matches for all segments. When they do not match, there may be skew resulting from the number of active primary segments on each hardware host. To rebalance the cluster and bring all the segments into their preferred role, the `gprecoverseg` command can be run with the `-r` option.

There is a set of server configuration parameters that affect FTS behavior:

**`gp_fts_probe_threadcount`**

The number of threads used for probing segments. Default: 16

**`gp_fts_probe_interval`**

How often, in seconds, to begin a new FTS loop. For example if the setting is 60 and the probe loop takes 10 seconds, the FTS process sleeps 50 seconds. If the setting is 60 and probe loop takes 75 seconds, the process sleeps 0 seconds. The default is 60, and the maximum is 3600.

**`gp_fts_probe_timeout`**

Probe timeout between master and segment, in seconds. The default is 20, and the maximum is 3600.

**`gp_fts_probe_retries`**

The number of attempts to probe a segment. For example if the setting is 5 there will be 4 retries after the first attempt fails. Default: 5

**`gp_log_fts`**

Logging level for FTS. The value may be “off”, “terse”, “verbose”, or “debug”. The “verbose” setting can be used in production to provide useful data for troubleshooting. The “debug” setting should not be used in production. Default: “terse”

**`gp_segment_connect_timeout`**

The maximum time (in seconds) allowed for a mirror to respond. Default: 180

In addition to the fault checking performed by the FTS, a primary segment that is unable to send data to its mirror can change the status of the mirror to down. The primary queues up the data and after `gp_segment_connect_timeout` seconds passes, indicates a mirror failure, causing the mirror to be marked down and the primary to go into change tracking mode.
**Enabling Alerts and Notifications**

To receive notifications of system events such as segment failures, enable email or SNMP alerts. See *Enabling System Alerts and Notifications*.

**Checking for Failed Segments**

With mirroring enabled, you may have failed segments in the system without interruption of service or any indication that a failure has occurred. You can verify the status of your system using the `gpstate` utility. `gpstate` provides the status of each individual component of a Greenplum Database system, including primary segments, mirror segments, master, and standby master.

**To check for failed segments**

1. On the master, run the `gpstate` utility with the `-e` option to show segments with error conditions:

   ```
   $ gpstate -e
   ```

   Segments in *Change Tracking* mode indicate the corresponding mirror segment is down. When a segment is not in its *preferred role*, the segment does not operate in the role to which it was assigned at system initialization. This means the system is in a potentially unbalanced state, as some segment hosts may have more active segments than is optimal for top system performance.

   See *Recovering From Segment Failures* for instructions to fix this situation.

2. To get detailed information about a failed segment, check the `gp_segment_configuration` catalog table. For example:

   ```
   $ psql -c "SELECT * FROM gp_segment_configuration WHERE status='d';"
   ```

3. For failed segment instances, note the host, port, preferred role, and data directory. This information will help determine the host and segment instances to troubleshoot.

4. To show information about mirror segment instances, run:

   ```
   $ gpstate -m
   ```

**Checking the Log Files for Failed Segments**

Log files can provide information to help determine an error's cause. The master and segment instances each have their own log file in `pg_log` of the data directory. The master log file contains the most information and you should always check it first.

Use the `gplogfilter` utility to check the Greenplum Database log files for additional information. To check the segment log files, run `gplogfilter` on the segment hosts using `gpssh`.

**To check the log files**

1. Use `gplogfilter` to check the master log file for WARNING, ERROR, FATAL or PANIC log level messages:

   ```
   $ gplogfilter -t
   ```

2. Use `gpssh` to check for WARNING, ERROR, FATAL, or PANIC log level messages on each segment instance. For example:

   ```
   $ gpssh -f seg_hosts_file -e 'source /usr/local/greenplum-db/greenplum_path.sh ; gplogfilter -t /data1/primary/*/pg_log/gpdb*.log' > seglog.out
   ```
Recovering a Failed Segment

If the master cannot connect to a segment instance, it marks that segment as down in the Greenplum Database system catalog. The segment instance remains offline until an administrator takes steps to bring the segment back online. The process for recovering a failed segment instance or host depends on the failure cause and whether or not mirroring is enabled. A segment instance can be unavailable for many reasons:

- A segment host is unavailable; for example, due to network or hardware failures.
- A segment instance is not running; for example, there is no `postgres` database listener process.
- The data directory of the segment instance is corrupt or missing; for example, data is not accessible, the file system is corrupt, or there is a disk failure.

*Figure 18: Segment Failure Troubleshooting Matrix* shows the high-level steps for each of the preceding failure scenarios.

![Segment Failure Troubleshooting Matrix](image-url)
Recovering From Segment Failures

Segment host failures usually cause multiple segment failures: all primary or mirror segments on the host are marked as down and nonoperational. If mirroring is not enabled and a segment goes down, the system automatically becomes nonoperational.

To recover with mirroring enabled

1. Ensure you can connect to the segment host from the master host. For example:

   `$ ping failed_seg_host_address`

2. Troubleshoot the problem that prevents the master host from connecting to the segment host. For example, the host machine may need to be restarted or replaced.

3. After the host is online and you can connect to it, run the `gprecoverseg` utility from the master host to reactivate the failed segment instances. For example:

   `$ gprecoverseg`

4. The recovery process brings up the failed segments and identifies the changed files that need to be synchronized. The process can take some time; wait for the process to complete. During this process, database write activity is suspended.

5. After `gprecoverseg` completes, the system goes into `Resynchronizing` mode and begins copying the changed files. This process runs in the background while the system is online and accepting database requests.

6. When the resynchronization process completes, the system state is `Synchronized`. Run the `gpstate` utility to verify the status of the resynchronization process:

   `$ gpstate -m`

To return all segments to their preferred role

When a primary segment goes down, the mirror activates and becomes the primary segment. After running `gprecoverseg`, the currently active segment remains the primary and the failed segment becomes the mirror. The segment instances are not returned to the preferred role that they were given at system initialization time. This means that the system could be in a potentially unbalanced state if segment hosts have more active segments than is optimal for top system performance. To check for unbalanced segments and rebalance the system, run:

   `$ gpstate -e`

All segments must be online and fully synchronized to rebalance the system. Database sessions remain connected during rebalancing, but queries in progress are canceled and rolled back.

1. Run `gpstate -m` to ensure all mirrors are `Synchronized`.

   `$ gpstate -m`

2. If any mirrors are in `Resynchronizing` mode, wait for them to complete.

3. Run `gprecoverseg` with the `-r` option to return the segments to their preferred roles.

   `$ gprecoverseg -r`

4. After rebalancing, run `gpstate -e` to confirm all segments are in their preferred roles.

   `$ gpstate -e`
To recover from a double fault

In a double fault, both a primary segment and its mirror are down. This can occur if hardware failures on different segment hosts happen simultaneously. Greenplum Database is unavailable if a double fault occurs. To recover from a double fault:

1. Restart Greenplum Database:

   $ gpstop -r

2. After the system restarts, run gprecoverseg:

   $ gprecoverseg

3. After gprecoverseg completes, use gpstate to check the status of your mirrors:

   $ gpstate -m

4. If you still have segments in Change Tracking mode, run a full copy recovery:

   $ gprecoverseg -F

If a segment host is not recoverable and you have lost one or more segments, recreate your Greenplum Database system from backup files. See Backing Up and Restoring Databases.

To recover without mirroring enabled

1. Ensure you can connect to the segment host from the master host. For example:

   $ ping failed_seg_host_address

2. Troubleshoot the problem that is preventing the master host from connecting to the segment host. For example, the host machine may need to be restarted.

3. After the host is online, verify that you can connect to it and restart Greenplum Database. For example:

   $ gpstop -r

4. Run the gpstate utility to verify that all segment instances are online:

   $ gpstate

When a segment host is not recoverable

If a host is nonoperational, for example, due to hardware failure, recover the segments onto a spare set of hardware resources. If mirroring is enabled, you can recover a segment from its mirror onto an alternate host using gprecoverseg. For example:

$ gprecoverseg -i recover_config_file

Where the format of recover_config_file is:

filespaceOrder=[filespace1_name:].*:filespace2_name:...:failed_host_address:port:fselocation [recovery_host_address:port:replication_port:fselocation [::fselocation:...]]

For example, to recover to a different host than the failed host without additional filespaces configured (besides the default pg_system filesystem):

filespaceOrder=sdw5-2:50002:/gpdata/gpseg2 sdw9-2:50002:53002:/gpdata/gpseg2
The `gp_segment_configuration` and `pg_filespace_entry` system catalog tables can help determine your current segment configuration so you can plan your mirror recovery configuration. For example, run the following query:

```
=# SELECT dbid, content, hostname, address, port,
    replication_port, fselocation as datadir
FROM gp_segment_configuration, pg_filespace_entry
WHERE dbid=fsedbid
ORDER BY dbid;
```

The new recovery segment host must be pre-installed with the Greenplum Database software and configured exactly as the existing segment hosts.

**About the Segment Recovery Process**

This topic describes the process for recovering segments, initiated by the `gprecoverseg` management utility. It describes actions `gprecoverseg` performs and how the Greenplum File Replication and FTS (fault tolerance service) processes complete the recovery initiated with `gprecoverseg`.

Although `gprecoverseg` is an online operation, there are two brief periods during which all IO is paused. First, when recovery is initiated, IO is suspended while empty data files are created on the mirror. Second, after data files are synchronized, IO is suspended while system files such as transaction logs are copied from the primary to the mirror. The duration of these pauses is affected primarily by the number of file system files that must be created on the mirror and the sizes of the system flat files that must be copied. The system is online and available while database tables are replicated from the primary to the mirror, and any changes made to the database during recovery are replicated directly to the mirror.

To initiate recovery, the administrator runs the `gprecoverseg` utility. `gprecoverseg` prepares segments for recovery and initiates synchronization. When synchronization is complete and the segment status is updated in the system catalog, the segments are recovered. If the recovered segments are not running in their preferred roles, `gprecoverseg -r` can be used to bring the system back into balance.

Without the `-F` option, `gprecoverseg` recovers segments incrementally, copying only the changes since the mirror entered down status. The `-F` option fully recovers mirrors by deleting their data directories and then synchronizing all persistent data files from the primary to the mirror.

You can run `gpstate -e` to view the mirroring status of the segments before and during the recovery process. The primary and mirror segment statuses are updated as the recovery process proceeds.

Consider a single primary-mirror segment pair where the primary is active and the mirror is down. The following table shows the segment status before beginning recovery of the mirror.

<table>
<thead>
<tr>
<th></th>
<th>preferred_role</th>
<th>role</th>
<th>mode</th>
<th>status</th>
</tr>
</thead>
<tbody>
<tr>
<td>Primary</td>
<td>p (primary)</td>
<td>p (primary)</td>
<td>c (change tracking)</td>
<td>u (up)</td>
</tr>
<tr>
<td>Mirror</td>
<td>m (mirror)</td>
<td>m (mirror)</td>
<td>s (synchronizing)</td>
<td>d (down)</td>
</tr>
</tbody>
</table>

The segments are in their preferred roles, but the mirror is down. The primary is up and is in change tracking mode because it is unable to send changes to its mirror.

**Segment Recovery Preparation**

The `gprecoverseg` utility prepares the segments for recovery and then exits, allowing the Greenplum file replication processes to copy data from the primary to the mirror.

During the `gprecoverseg` execution the following recovery process steps are completed.
1. The down segments are identified.
2. The mirror segment processes are initialized.
3. For full recovery (-af):
   - The data directories of the down segments are deleted.
   - A new data directory structure is created.
4. The segment mode in the gp_segment_configuration system table is updated to 'r' (resynchronization mode).
5. The backend performs the following:
   - Suspends IO—connections to the master are allowed, but reads and writes from the segment being recovered are not allowed.
   - Scans persistent tables on the primary segment.
   - For each persistent file object (relfilenode in the pg_class system table), creates a data file on the mirror.

   The greater the number of data files, the longer IO is suspended.

   For incremental recovery, the IO is suspended for a shorter period because only file system objects added (or dropped) on the primary after the mirror was marked down need to be created (or deleted) on the mirror.
6. The gprecoverseg script completes.

Once gprecoverseg has completed, the segments are in the states shown in the following table.

<table>
<thead>
<tr>
<th>preferred_role</th>
<th>role</th>
<th>mode</th>
<th>status</th>
</tr>
</thead>
<tbody>
<tr>
<td>Primary</td>
<td>p (primary)</td>
<td>p (primary)</td>
<td>r (resynchronizing)</td>
</tr>
<tr>
<td>Mirror</td>
<td>m (mirror)</td>
<td>m (mirror)</td>
<td>r (resynchronizing)</td>
</tr>
</tbody>
</table>

### Data File Replication

Data file resynchronization is performed in the background by file replication processes. Run gpstate -e to check the process of resynchronization. The Greenplum system is fully available for workloads while this process completes.

Following are steps in the resynchronization process:

1. Data copy (full and incremental recovery):
   
   After the file system objects are created, data copy is initiated for the affected segments. The ResyncManager process scans the persistent table system catalogs to find the file objects to be synchronized. ResyncWorker processes sync the file objects from the primary to the mirror.

2. Any changes or new data created with database transactions during the data copy are mirrored directly to the mirror.

3. Once data copy has finished synchronizing persistent data files, file replication updates the shared memory state on the current primary segment to 'insync'.

### Flat File Replication

During this phase, system files in the primary segment's data directory are copied to the segment data directory. IO is suspended while the following flat files are copied from the primary data directory to the segment data directory:

- pg_xlog/*
- pg_clog/*
IOSUSPEND ends after these files are copied.

The next time the fault tolerance server (ftsprobe) process on the master wakes, it will set the primary and mirror states to synchronized (mode=s, state=u). A distributed query will also trigger the ftsprobe process to update the state.

When all segment recovery and file replication processes are complete, the segment status in the `gp_segment_configuration` system table and `gp_state -e` output is as shown in the following table.

<table>
<thead>
<tr>
<th>preferred_role</th>
<th>role</th>
<th>mode</th>
<th>status</th>
</tr>
</thead>
<tbody>
<tr>
<td>Primary</td>
<td>p (primary)</td>
<td>p (primary)</td>
<td>s (synchronized)</td>
</tr>
<tr>
<td>Mirror</td>
<td>m (mirror)</td>
<td>m (mirror)</td>
<td>s (synchronized)</td>
</tr>
</tbody>
</table>

**Factors Affecting Duration of Segment Recovery**

Following are some factors that can affect the duration of the segment recovery process.

- The number of database objects, mainly tables and indexes.
- The number of data files in segment data directories.
- The types of workloads updating data during resynchronization — both DDL and DML (insert, update, delete, and truncate).
- The size of the data.
- The size of system files, such as transaction log files, `pg_database`, `pg_auth`, and `pg_auth_time_constraint`.

**Recovering a Failed Master**

If the primary master fails, log replication stops. Use the `gpstate -f` command to check the state of standby replication. Use `gpactivatestandby` to activate the standby master. Upon activation of the standby master, Greenplum Database reconstructs the master host state at the time of the last successfully committed transaction.

**To activate the standby master**

1. Ensure a standby master host is configured for the system. See *Enabling Master Mirroring*.
2. Run the `gpactivatestandby` utility from the standby master host you are activating. For example:

   ```bash
   $ gpactivatestandby -d /data/master/gpseg-1
   ```

   Where `-d` specifies the data directory of the master host you are activating.

   After you activate the standby, it becomes the *active or primary* master for your Greenplum Database array.
3. After the utility finishes, run `gpstate` to check the status:

```
$ gpstate -f
```

The newly activated master's status should be `Active`. If you configured a new standby host, its status is `Passive`. When a standby master is not configured, the command displays `-No entries found` and the message indicates that a standby master instance is not configured.

4. After switching to the newly active master host, run `ANALYZE` on it. For example:

```
$ psql dbname -c 'ANALYZE;'
```

5. Optional: If you did not specify a new standby host when running the `gpactivatestandby` utility, use `gpinitstandby` to configure a new standby master at a later time. Run `gpinitstandby` on your active master host. For example:

```
$ gpinitstandby -s new_standby_master_hostname
```

**Restoring Master Mirroring After a Recovery**

After you activate a standby master for recovery, the standby master becomes the primary master. You can continue running that instance as the primary master if it has the same capabilities and dependability as the original master host.

You must initialize a new standby master to continue providing master mirroring unless you have already done so while activating the prior standby master. Run `gpinitstandby` on the active master host to configure a new standby master.

You may restore the primary and standby master instances on the original hosts. This process swaps the roles of the primary and standby master hosts, and it should be performed only if you strongly prefer to run the master instances on the same hosts they occupied prior to the recovery scenario.

For information about the Greenplum Database utilities, see the *Greenplum Database Utility Guide*.

**To restore the master and standby instances on original hosts (optional)**

1. Ensure the original master host is in dependable running condition; ensure the cause of the original failure is fixed.

2. On the original master host, move or remove the data directory, `gpseg-1`. This example moves the directory to `backup_gpseg-1`:

```
$ mv /data/master/gpseg-1 /data/master/backup_gpseg-1
```

You can remove the backup directory once the standby is successfully configured.

3. Initialize a standby master on the original master host. For example, run this command from the current master host, `smdw`:

```
$ gpinitstandby -s mdw
```

4. After the initialization completes, check the status of standby master, `mdw`, run `gpstate` with the `-f` option to check the status:

```
$ gpstate -f
```

The status should be `In Synch`. 

5. Stop Greenplum Database master instance on the standby master. For example:

   $ gpstop -m

6. Run the `gpactivatestandby` utility from the original master host, mdw, that is currently a standby master. For example:

   $ gpactivatestandby -d $MASTER_DATA_DIRECTORY

   Where the `-d` option specifies the data directory of the host you are activating.

7. After the utility completes, run `gpstate` to check the status:

   $ gpstate -f

   Verify the original primary master status is *Active*. When a standby master is not configured, the command displays *-No entries found* and the message indicates that a standby master instance is not configured.

8. On the standby master host, move or remove the data directory, gpseg-1. This example moves the directory:

   $ mv /data/master/gpseg-1 /data/master/backup_gpseg-1

   You can remove the backup directory once the standby is successfully configured.

9. After the original master host runs the primary Greenplum Database master, you can initialize a standby master on the original standby master host. For example:

   $ gpinitstandby -s smdw

To check the status of the master mirroring process (optional)

You can display the information in the Greenplum Database system view `pg_stat_replication`. The view lists information about the `walSender` process that is used for Greenplum Database master mirroring. For example, this command displays the process ID and state of the `walSender` process:

   $ psql dbname -c 'SELECT procpid, state FROM pg_stat_replication;'

**Backing Up and Restoring Databases**

This topic describes how to use Greenplum backup and restore features.

Performing backups regularly ensures that you can restore your data or rebuild your Greenplum Database system if data corruption or system failure occur. You can also use backups to migrate data from one Greenplum Database system to another.

**Backup and Restore Overview**

Greenplum Database supports parallel and non-parallel methods for backing up and restoring databases. Parallel operations scale regardless of the number of segments in your system, because segment hosts each write their data to local disk storage simultaneously. With non-parallel backup and restore operations, the data must be sent over the network from the segments to the master, which writes all of the data to its storage. In addition to restricting I/O to one host, non-parallel backup requires that the master have sufficient local disk storage to store the entire database.

**Parallel Backup with gpcrondump and gpdbrestore**

The Greenplum Database parallel dump utility `gpcrondump` backs up the Greenplum master instance and each active segment instance at the same time.
By default, `gpcrondump` creates dump files in the `db_dumps` subdirectory of each segment instance. On the master, `gpcrondump` creates several dump files, containing database information such as DDL statements, the system catalog tables, and metadata files. On each segment, `gpcrondump` creates one dump file, which contains commands to recreate the data on that segment. Each file created for a backup begins with a 14-digit timestamp key that identifies the backup set the file belongs to.

![Parallel Backups in Greenplum Database](image1)

**Figure 19: Parallel Backups in Greenplum Database**

The `gpdbrestore` parallel restore utility takes the timestamp key generated by `gpcrondump`, validates the backup set, and restores the database objects and data into a distributed database. Parallel restore operations require a complete backup set created by `gpcrondump`, a full backup, and any required incremental backups. As the following figure illustrates, all segments restore data from local backup files simultaneously.

![Parallel Restores in Greenplum Database](image2)

**Figure 20: Parallel Restores in Greenplum Database**
The `gpdbrestore` utility provides flexibility and verification options for use with the automated backup files produced by `gpcrondump` or with backup files moved from the Greenplum cluster to an alternate location. See *Restoring Greenplum Databases*. `gpdbrestore` can also be used to copy files to the alternate location.

### Parallel Backup with `gpbackup` and `gprestore`

`gpbackup` and `gprestore` are new utilities that are designed to improve the performance, functionality, and reliability of backups as compared to `gpcrondump` and `gpdbrestore`. `gpbackup` utilizes `ACCESS SHARE` locks at the individual table level, instead of `EXCLUSIVE` locks on the `pg_class` catalog table. This enables you to execute DML statements during the backup, such as `CREATE`, `ALTER`, `DROP`, and `TRUNCATE` operations, as long as those operations do not target the current backup set.

Backup files created with `gpbackup` are designed to provide future capabilities for restoring individual database objects along with their dependencies, such as functions and required user-defined datatypes. See *Parallel Backup with `gpbackup` and `gprestore`* for more information.

### Non-Parallel Backup with pg_dump

The PostgreSQL `pg_dump` and `pg_dumpall` non-parallel backup utilities can be used to create a single dump file on the master host that contains all data from all active segments.

The PostgreSQL non-parallel utilities should be used only for special cases. They are much slower than using the Greenplum backup utilities since all of the data must pass through the master. Additionally, it is often the case that the master host has insufficient disk space to save a backup of an entire distributed Greenplum database.

The `pg_restore` utility requires compressed dump files created by `pg_dump` or `pg_dumpall`. Before starting the restore, you should modify the `CREATE TABLE` statements in the dump files to include the Greenplum `DISTRIBUTED` clause. If you do not include the `DISTRIBUTED` clause, Greenplum Database assigns default values, which may not be optimal. For details, see `CREATE TABLE` in the *Greenplum Database Reference Guide*.

To perform a non-parallel restore using parallel backup files, you can copy the backup files from each segment host to the master host, and then load them through the master. See *Restoring to a Different Greenplum System Configuration*.

---

**Figure 21: Non-parallel Restore Using Parallel Backup Files**
Another non-parallel method for backing up Greenplum Database data is to use the `COPY TO SQL` command to copy all or a portion of a table out of the database to a delimited text file on the master host.

**Parallel Backup with gpcrondump and gpdbrestore**

`gpcrondump` backs up the Greenplum master instance and each active segment instance at the same time. `gpdbrestore` takes the timestamp key generated by `gpcrondump`, validates the backup set, and restores database objects and data into a distributed database.

**Backup and Restore Options**

The Greenplum Database backup and restore utilities support various locations for backup files:

- With the `gpcrondump` utility, backup files may be saved in the default location, the `db_dumps` subdirectory of the master and each segment, or saved to a different directory specified with the `gpcrondump -u` option.
- Both the `gpcrondump` and `gpdbrestore` utilities have integrated support for Dell EMC Data Domain Boost and Veritas NetBackup systems.
- Backup files can be saved through named pipes to any network accessible location.
- Backup files saved to the default location may be moved to an archive server on the network. This allows performing the backup at the highest transfer rates (when segments write the backup data to fast local disk arrays) and then freeing up disk space by moving the files to remote storage.

You can create dumps containing selected database objects:

- You can backup tables belonging to one or more schema you specify on the command line or in a text file.
- You can specify schema to exclude from the backup, as command-line options or in a list provided in a text file.
- You can backup a specified set of tables listed on the command line or in a text file. The table and schema options cannot be used together in a single backup.
- In addition to database objects, `gpcrondump` can backup the configuration files `pg_hba.conf`, `pg_ident.conf`, and `postgresql.conf`, and global database objects, such as roles and tablespaces.

You can create incremental backups:

- An incremental backup contains only append-optimized and column-oriented tables that have changed since the most recent incremental or full backup.
- For partitioned append-optimized tables, only changed append-optimized/column-oriented table partitions are backed up.
- Incremental backups include all heap tables.
- Use the `gpcrondump --incremental` flag to specify an incremental backup.
- Restoring an incremental backup requires a full backup and all subsequent incremental backups, up to the backup you are restoring.

The `gpdbrestore` utility offers many options:

- By default, `gpdbrestore` restores data to the database it was backed up from.
- The `--redirect` flag allows you to restore a backup to a different database.
- The restored database can be dropped and recreated, but the default is to restore into an existing database.
- Selected tables can be restored from a backup by listing the tables on the command line or by listing them in a text file and specifying the text file on the command line.
- You can restore a database from backup files moved to an archive server. The backup files are copied back into place on the master host and each segment host and then restored to the database.
### Backing Up with gpcrondump

Use `gpcrondump` to backup databases, data, and objects such as database roles and server configuration files.

The `gpcrondump` utility dumps the contents of a Greenplum database to SQL script files on the master and each segment. The script files can then be used to restore the database.

The master backup files contain SQL commands to create the database schema. The segment data dump files contain SQL statements to load the data into the tables. The segment dump files are compressed using `gzip`. Optionally, the server configuration files `postgresql.conf`, `pg_ident.conf`, and `pg_hba.conf` and global data such as roles and tablespaces can be included in a backup.

The `gpcrondump` utility has one required flag, `-x`, which specifies the database to dump:

```
gpcrondump -x mydb
```

This performs a full backup of the specified database to the default locations.

**Note:** By default, the utility creates the `public.gpcrondump_history` table that contains details of the database dump. If the `public` schema has been deleted from the database, you must specify the `-H` option to prevent `gpcrondump` from returning an error when it attempts to create the table.

By default, `gpcrondump` creates the backup files in the data directory on the master and each segment instance in the `data_directory/db_dumps` directory. You can specify a different backup location using the `-u` flag. For example, the following command will save backup files to the `/backups` directory:

```
gpcrondump mydb -u /backups
```

The `gpcrondump` utility creates the `db_dumps` subdirectory in the specified directory. If there is more than one primary segment per host, all of the segments on the host write their backup files to the same directory. This differs from the default, where each segment writes backups to its own data directory. This can be used to consolidate backups to a single directory or mounted storage device.

In the `db_dumps` directory, backups are saved to a directory in the format `YYYYMMDD`, for example `data_directory/db_dumps/20151012` for a backup created on October 12, 2015. The backup file names in the directory contain a full timestamp for the backup in the format `YYYYMMDDHHMMSS`, for example `gp_dump_0_2_20151012195916.gz`. The `gpdbrestore` command uses the most recent backup by default but you can specify an earlier backup to restore.

The utility creates backup files with this file name format.

```
prefix_gp_dump_content_dbid_timestamp
```

The `content` and `dbid` are identifiers for the Greenplum Database segment instances that are assigned by Greenplum Database. For information about the identifiers, see the Greenplum Database system catalog table `gp_id` in the *Greenplum Database Reference Guide*.

If you include the `-g` option, `gpcrondump` saves the configuration files with the backup. These configuration files are dumped in the master or segment data directory to `db_dumps/YYYYMMDD/config_files_timestamp.tar`. If `--ddboost` is specified, the backup is located on the default storage unit in the directory specified by `--ddboost-backupdir` when the Data Domain Boost credentials were set. The `--G` option backs up global objects such as roles and tablespaces to a file in the master backup directory named `gp_global_1_1_timestamp`.

If `--ddboost` is specified, the backup is located on the default storage unit in the directory specified by `--ddboost-backupdir` when the Data Domain Boost credentials were set.
There are many more `gpcrondump` options available to configure backups. Refer to the *Greenplum Utility Reference Guide* for information about all of the available options. See *Backing Up Databases with Data Domain Boost* for details of backing up with Data Domain Boost.

**Warning:** Backing up a database with `gpcrondump` while simultaneously running `ALTER TABLE` might cause `gpcrondump` to fail.

Back up a database with `gpcrondump` while simultaneously running DDL commands might cause issues with locks. You might see either the DDL command or `gpcrondump` waiting to acquire locks.

**Backing Up a Set of Tables**

You can create a backup that includes a subset of the schema or tables in a database by using the following `gpcrondump` options:

- `-t schema.tablename` – specify a table to include in the backup. You can use the `-t` option multiple times.
- `--table-file=filename` – specify a file containing a list of tables to include in the backup.
- `-T schema.tablename` – specify a table to exclude from the backup. You can use the `-T` option multiple times.
- `--exclude-table-file=filename` – specify a file containing a list of tables to exclude from the backup.
- `-s schema_name` – include all tables qualified by a specified schema name in the backup. You can use the `-s` option multiple times.
- `--schema-file=filename` – specify a file containing a list of schemas to include in the backup.
- `-S schema_name` – exclude tables qualified by a specified schema name from the backup. You can use the `-S` option multiple times.
- `--exclude-schema-file=filename` – specify a file containing schema names to exclude from the backup.

Only a set of tables or set of schemas can be specified. For example, the `-s` option cannot be specified with the `-t` option.

Refer to *Incremental Backup with Sets* for additional information about using these `gpcrondump` options with incremental backups.

**Creating Incremental Backups**

The `gpcrondump` and `gpdbrestore` utilities support incremental backups and restores of append-optimized tables, including column-oriented tables. Use the `gpcrondump` option `--incremental` to create an incremental backup.

An incremental backup only backs up an append-optimized or column-oriented table if one of the following operations was performed on the table after the last full or incremental backup:

- `ALTER TABLE`
- `DELETE`
- `INSERT`
- `TRUNCATE`
- `UPDATE`
- `DROP` and then re-create the table

For partitioned append-optimized tables, only the changed partitions are backed up.

Heap tables are backed up with every full and incremental backup.

Incremental backups are efficient when the total amount of data in append-optimized table partitions or column-oriented tables that changed is small compared to the data that has not changed.
Each time `gpcrondump` runs, it creates state files that contain row counts for each append optimized and column-oriented table and partition in the database. The state files also store metadata operations such as truncate and alter. When `gpcrondump` runs with the `--incremental` option, it compares the current state with the stored state to determine if the table or partition should be included in the incremental backup.

A unique 14-digit timestamp key identifies files that comprise an incremental backup set.

To create an incremental backup or to restore data from an incremental backup, you need the complete backup set. A complete backup set consists of a full backup and any incremental backups that were created since the last full backup. When you archive incremental backups, all incremental backups between the last full backup and the target incremental backup must be archived. You must archive all the files created on the master and all segments.

**Important:** For incremental backup sets, a full backup and associated incremental backups, the backup set must be on a single device. For example, a backup set must all be on a Data Domain system. The backup set cannot have some backups on a Data Domain system and others on the local file system or a NetBackup system.

**Note:** You can use a Data Domain server as an NFS file system (without Data Domain Boost) to perform incremental backups.

Changes to the Greenplum Database segment configuration invalidate incremental backups. After you change the segment configuration you must create a full backup before you can create an incremental backup.

### Incremental Backup Example

Each backup set has a key, which is a timestamp taken when the backup is created. For example, if you create a backup on May 14, 2016, the backup set file names contain `20160514hhmmss`. The `hhmmss` represents the time: hour, minute, and second.

For this example, assume you have created both full and incremental backups of the database `mytest`. To create the full backup, you used the following command:

```
gpcrondump -x mytest -u /backupdir
```

Later, after some changes have been made to append optimized tables, you created an incremental backup with the following command:

```
gpcrondump -x mytest -u /backupdir --incremental
```

When you specify the `--u` option, the backups are created in the `/backupdir` directory on each Greenplum Database host. The file names include the following timestamp keys. The full backups have the timestamp key `20160514054532` and `20161114064330`. The other backups are incremental backups.

- `20160514054532` (full backup)
- `20160714095512`
- `20160914081205`
- `20161114064330` (full backup)
- `20170114051246`

To create a new incremental backup, you need both the most recent incremental backup `20170114051246` and the preceding full backup `20161114064330`. Also, you must specify the same `--u` option for any incremental backups that are part of the backup set.

To restore a database with the incremental backup `20160914081205`, you need the incremental backups `20160914081205` and `20160714095512`, and the full backup `20160514054532`.
To restore the `mytest` database with the incremental backup `20170114051246`, you need only the incremental backup and the full backup `20161114064330`. The restore command would be similar to this command.

```bash
gpdbrestore -t 20170114051246 -u /backupdir
```

### Incremental Backup with Sets

To back up a set of database tables with incremental backup, identify the backup set with the `--prefix` option when you create the full backup with `gpcrondump`. For example, to create incremental backups for tables in the `myschema` schema, first create a full backup with a prefix, such as `myschema`:

```bash
gpcrondump -x mydb -s myschema --prefix myschema
```

The `-s` option specifies that tables qualified by the `myschema` schema are to be included in the backup. See [Backing Up a Set of Tables](#) for more options to specify a set of tables to back up.

Once you have a full backup you can create an incremental backup for the same set of tables by specifying the `gpcrondump --incremental` and `--prefix` options, specifying the prefix you set for the full backup. The incremental backup is automatically limited to only the tables in the full backup. For example:

```bash
gpcrondump -x mydb --incremental --prefix myschema
```

The following command lists the tables that were included or excluded for the full backup.

```bash
gpcrondump -x mydb --incremental --prefix myschema --list-filter-tables
```

### Restoring From an Incremental Backup

When restoring a backup with `gpdbrestore`, the command-line output displays whether the restore type is incremental or a full database restore. You do not have to specify that the backup is incremental. For example, the following `gpdbrestore` command restores the most recent backup of the `mydb` database. `gpdbrestore` searches the `db_dumps` directory to locate the most recent dump and displays information about the backup it found.

```bash
$ gpdbrestore -s mydb
...
20151015:20:10:34:002664 gpdbrestore:mdw:gpadmin-[INFO]:-------------------------------------------
20151015:20:10:34:002664 gpdbrestore:mdw:gpadmin-[INFO]:-Greenplum database restore parameters
20151015:20:10:34:002664 gpdbrestore:mdw:gpadmin-[INFO]:-------------------------------------------
20151015:20:10:34:002664 gpdbrestore:mdw:gpadmin-[INFO]:-Restore type = Incremental Restore
20151015:20:10:34:002664 gpdbrestore:mdw:gpadmin-[INFO]:-Database to be restored = mydb
20151015:20:10:34:002664 gpdbrestore:mdw:gpadmin-[INFO]:-Drop and re-create db = Off
20151015:20:10:34:002664 gpdbrestore:mdw:gpadmin-[INFO]:-Restore method = Search for latest
20151015:20:10:34:002664 gpdbrestore:mdw:gpadmin-[INFO]:-Restore timestamp = 20151014194445
20151015:20:10:34:002664 gpdbrestore:mdw:gpadmin-[INFO]:-Restore compressed dump = On
20151015:20:10:34:002664 gpdbrestore:mdw:gpadmin-[INFO]:-Restore global objects = Off
20151015:20:10:34:002664 gpdbrestore:mdw:gpadmin-[INFO]:-Array fault tolerance = f
```
gpdbrestore ensures that the full backup and other required incremental backups are available before restoring the backup. With the --list-backup option you can display the full and incremental backup sets required to perform a restore.

If the gpdbrestore option -q is specified, the backup type information is written to the log file. With the gpdbrestore option --noplan, you can restore only the data contained in an incremental backup.

**Backup Process and Locks**

During backups, the gpcrondump utility locks the `pg_class` system table and the tables that are backed up. Locking the `pg_class` table with an EXCLUSIVE lock ensures that no tables are added, deleted, or altered until gpcrondump locks tables that are to be backed up with ACCESS SHARE locks.

The steps below describe the process gpcrondump follows to dump databases, including what happens before locks are placed, while locks are held, and after locks are removed.

If more than one database is specified, this process is executed for each database in sequence.

- **gpcrondump** parses the command-line arguments and verifies that options and arguments are properly specified.
- If any of the following filter options are specified, gpcrondump prepares filters to determine the set of tables to back up. Otherwise, all tables are included in the backup.
  - `-s schema_name` - Includes all the tables qualified by the specified schema.
  - `-S schema_name` - Excludes all tables qualified by the specified schema.
  - `--schema-file=filename` - Includes all the tables qualified by the schema listed in `filename`.
  - `--exclude-schema-file=filename` - Excludes all tables qualified by the schema listed in `filename`.
  - `-t schema.table_name` - Dumps the specified table.
  - `-T schema.table_name` - Excludes the specified table.
  - `--table-file=filename` - Dumps the tables specified in `filename`.
  - `--exclude-table-file=filename` - Dumps all tables except tables specified in `filename`.
- gpcrondump verifies the backup targets:
  - Verifies that the database exists.
  - Verifies that specified tables or schemas to be dumped exist.
  - Verifies that the current primary for each segment is up.
  - Verifies that the backup directory exists and is writable for the master and each segment.
  - Verifies that sufficient disk space is available to back up each segment. Note that if more than one segment is backed up to the same disk volume, this disk space check cannot ensure there is space available for all segments.
- Places an EXCLUSIVE lock on the catalog table `pg_class`. The lock permits only concurrent read operations on a table. While the lock is on the catalog table, relations such as tables, indexes, and views cannot be created, altered, or dropped in the database.

  gpcrondump starts a thread to watch for a lock file (`dump_dir/gp_lockfile_timestamp`) to appear, signaling the parallel backup on the segments has completed.
- gpcrondump locks tables that are to be backed up with an ACCESS SHARE lock.

  An ACCESS SHARE lock only conflicts with an ACCESS EXCLUSIVE lock. The following SQL statements acquire an ACCESS EXCLUSIVE lock:
  - ALTERTABLE
  - CLUSTER
• DROP TABLE
• REINDEX
• TRUNCATE
• VACUUM FULL

• Threads are created and dispatched for the master and segments to perform the database dump.
• When the threads have acquired ACCESS SHARED locks on all the required tables, the dump_dir/gp_lockfile_timestamp lock file is created, signaling gpcrondump to release the EXCLUSIVE lock on the pg_class catalog table, while tables are being backed up.
• gpcrondump checks the status files for each primary segment for any errors to report. If a dump fails and the -r flag was specified, the backup is rolled back.
• The ACCESS SHARE locks on the target tables are released.
• If the backup succeeded and a post-dump script was specified with the -R option, gpcrondump runs the script now.
• gpcrondump reports the backup status, sends email if configured, and saves the backup status in the public.gpcrondump_history table in the database.

Using Direct I/O

The operating system normally caches file I/O operations in memory because memory access is much faster than disk access. The application writes to a block of memory that is later flushed to the storage device, which is usually a RAID controller in a Greenplum Database system. Whenever the application accesses a block that is still resident in memory, a device access is avoided. Direct I/O allows you to bypass the cache so that the application writes directly to the storage device. This reduces CPU consumption and eliminates a data copy operation. Direct I/O is efficient for operations like backups where file blocks are only handled once.

Note: Direct I/O is supported only on Red Hat, CentOS, and SUSE.

Turning on Direct I/O

Set the gp_backup_directIO system configuration parameter on to enable direct I/O for backups:

$ gpconfig -c gp_backup_directIO -v on

To see if direct I/O is enabled, use this command:

$ gpconfig -s gp_backup_directIO

Decrease network data chunks sent to dump when the database is busy

The gp_backup_directIO_read_chunk_mb configuration parameter sets the size, in MB, of the I/O chunk when direct I/O is enabled. The default chunk size, 20MB, has been tested and found to be optimal. Decreasing it increases the backup time and increasing it results in little change to backup time.

To find the current direct I/O chunk size, enter this command:

$ gpconfig -s gp_backup_directIO_read_chunk_mb

The following example changes the default chunk size to 10MB.

$ gpconfig -c gp_backup_directIO_read_chunk_mb -v 10
Using Named Pipes

Greenplum Database allows the use of named pipes with gpcrondump and gpdbrestore to back up and restore Greenplum databases. When backing up a database with regular files, the files that contain the backup information are placed in directories on the Greenplum Database segments. If segment hosts do not have enough local disk space available to backup to files, you can use named pipes to back up to non-local storage, such as storage on another host on the network or to a backup appliance.

Backing up with named pipes is not supported if the --ddboost option is specified.

To back up a Greenplum database using named pipes

1. Run the gpcrondump command with options -K timestamp and --list-backup-files.
   
   This creates two text files that contain the names of backup files, one per line. The file names include the timestamp you specified with the -K timestamp option and have the suffixes _pipes and _regular_files. For example:

   | gp_dump_20150519160000_pipes |
   | gp_dump_20150519160000_regular_files |

   The file names listed in the _pipes file are to be created as named pipes. The file names in the _regular_files file should not be created as named pipes. gpcrondump and gpdbrestore use the information in these files during backup and restore operations.

2. Create named pipes on all Greenplum Database segments using the file names in the generated _pipes file.

3. Redirect the output of each named pipe to the destination process or file object.

4. Run gpcrondump to back up the database using the named pipes.
   
   To create a complete set of Greenplum Database backup files, the files listed in the _regular_files file must also be backed up.

To restore a database that used named pipes during backup

1. Direct the contents of each backup file to the input of its named pipe, for example cat filename > pipename, if the backup file is accessible as a local file object.

2. Run the gpdbrestore command to restore the database using the named pipes.

Example

This example shows how to back up a database over the network using named pipes and the netcat (nc) Linux command. The segments write backup files to the inputs of the named pipes. The outputs of the named pipes are piped through nc commands, which make the files available on TCP ports. Processes on other hosts can then connect to the segment hosts at the designated ports to receive the backup files. This example requires that the nc package is installed on all Greenplum hosts.

1. Enter the following gpcrondump command to generate the lists of backup files for the testdb database in the /backups directory.

   $ gpcrondump -x testdb -K 20150519160000 --list-backup-files -u /backups

2. View the files that gpcrondump created in the /backup directory:

   $ ls -LR /backups
   /backups:
   drwxrwxr-x 3 gpadmin gpadmin 4096 May 19 21:49 db_dumps
   /backups/db_dumps:
   total 4
   drwxrwxr-x 2 gpadmin gpadmin 4096 May 19 21:49 20150519

   $ ls -LR /backups/db_dumps:
   drwxrwxr-x 2 gpadmin gpadmin 4096 May 19 21:49 20150519

   $ ls -LR /backups/20150519:
   total 8
   drwxrwxr-x 2 gpadmin gpadmin 4096 May 19 21:49 20150519_000_150519_000000_pipes
   drwxrwxr-x 2 gpadmin gpadmin 4096 May 19 21:49 20150519_000_150519_000000_regular_files
3. View the contents of the _pipes file.

```bash
$ cat /backups/db_dumps/20150519/gp_dump_20150519160000_pipes
sdw1:/backups/db_dumps/20150519/gp_dump_0_2_20150519160000.gz
sdw2:/backups/db_dumps/20150519/gp_dump_0_2_20150519160000.gz
mdw:/backups/db_dumps/20150519/gp_dump_-1_1_20150519160000.gz
mdw:/backups/db_dumps/20150519/gp_dump_-1_1_20150519160000_post_data.gz
```

4. Create the specified named pipes on the Greenplum Database segments. Also set up a reader for the named pipe.

```bash
gpssh -h sdw1
[sdw1] mkdir -p /backups/db_dumps/20150519/
[sdw1] mkfifo /backups/db_dumps/20150519/gp_dump_0_2_20150519160000.gz
[sdw1] cat /backups/db_dumps/20150519/gp_dump_0_2_20150519160000.gz | nc -l 21000
[sdw1] exit
```

Complete these steps for each of the named pipes listed in the _pipes file. Be sure to choose an available TCP port for each file.

5. On the destination hosts, receive the backup files with commands like the following:

```bash
nc sdw1 21000 > gp_dump_0_2_20150519160000.gz
```

6. Run gpcrondump to begin the backup:

```bash
gpcrondump -x testdb -K 20150519160000 -u /backups
```

To restore a database with named pipes, reverse the direction of the backup files by sending the contents of the backup files to the inputs of the named pipes and run the gpdbrestore command:

```bash
gpdbrestore -x testdb -t 20150519160000 -u /backups
```

gpdbrestore reads from the named pipes' outputs.

**Backing Up Databases with Data Domain Boost**

Dell EMC Data Domain Boost (DD Boost) is Dell EMC software that can be used with the gpcrondump and gpdbrestore utilities to perform faster backups to the Dell EMC Data Domain storage appliance. Data Domain performs deduplication on the data it stores, so after the initial backup operation, the appliance stores only pointers to data that is unchanged. This reduces the size of backups on disk. When DD Boost is used with gpcrondump, Greenplum Database participates in the deduplication process, reducing the volume of data sent over the network. When you restore files from the Data Domain system with Data Domain Boost, some files are copied to the master local disk and are restored from there, and others are restored directly.

With Data Domain Boost managed file replication, you can replicate Greenplum Database backup images that are stored on a Data Domain system for disaster recover purposes. The gpmfr utility manages the Greenplum Database backup sets that are on the primary and a remote Data Domain system. For information about gpmfr, see the Greenplum Database Utility Guide.

Managed file replication requires network configuration when a replication network is being used between two Data Domain systems:
• The Greenplum Database system requires the Data Domain login credentials to be configured using gpcrondump. Credentials must be created for both the local and remote Data Domain systems.

• When the non-management network interface is used for replication on the Data Domain systems, static routes must be configured on the systems to pass the replication data traffic to the correct interfaces.

Do not use Data Domain Boost with `pg_dump` or `pg_dumpall`.

Refer to Data Domain Boost documentation for detailed information.

**Important:** For incremental back up sets, a full backup and the associated incremental backups must be on a single device. For example, a backup set must all be on a file system. The backup set cannot have some backups on the local file system and others on single storage unit of a Data Domain system. For backups on a Data Domain system, the backup set must be in a single storage unit.

**Note:** You can use a Data Domain server as an NFS file system (without Data Domain Boost) to perform incremental backups.

### Data Domain Boost Requirements

Using Data Domain Boost requires the following.

• Data Domain Boost is included only with the commercial release of Pivotal Greenplum Database.

• Purchase and install Dell EMC Data Domain Boost and Replicator licenses on the Data Domain systems.

• Obtain sizing recommendations for Data Domain Boost. Make sure the Data Domain system supports sufficient write and read streams for the number of segment hosts in your Greenplum cluster.

Contact your Dell EMC Data Domain account representative for assistance.

### One-Time Data Domain Boost Credential Setup

There is a one-time process to set up credentials to use Data Domain Boost. Credential setup connects one Greenplum Database instance to one Data Domain instance. If you are using the `gpcrondump --replicate` option or DD Boost managed file replication capabilities for disaster recovery purposes, you must set up credentials for both the local and remote Data Domain systems.

To set up credentials, run `gpcrondump` with the following options:

```
--ddboost-host ddboost_hostname --ddboost-user ddboost_user
--ddboost-backupdir backup_directory --ddboost-storage-unit storage_unit_ID
```

The `--ddboost-storage-unit` is optional. If not specified, the storage unit ID is GPDB.

To remove credentials, run `gpcrondump` with the `--ddboost-config-remove` option.

To manage credentials for the remote Data Domain system that is used for backup replication, include the `--ddboost-remote` option with the other `gpcrondump` options. For example, the following options set up credentials for a Data Domain system that is used for backup replication. The system IP address is 192.0.2.230, the user ID is `ddboostmyuser`, and the location for the backups on the system is `GPDB/gp_production`:

```
--ddboost-host 192.0.2.230 --ddboost-user ddboostmyuser
--ddboost-backupdir gp_production --ddboost-remote
```

For details, see `gpcrondump` in the *Greenplum Database Utility Guide.*
If you use two or more network connections to connect to the Data Domain system, use `gpcrondump` to set up the login credentials for the Data Domain hostnames associated with the network interfaces. To perform this setup for two network connections, run `gpcrondump` with the following options:

```
--ddboost-host ddboost_hostname1
--ddboost-host ddboost_hostname2 --ddboost-user ddboost_user
--ddboost-backupdir backup_directory
```

### About DD Boost Credential Files

The `gpcrondump` utility is used to schedule DD Boost backup operations. The utility is also used to set, change, or remove one-time credentials and a storage unit ID for DD Boost. The `gpcrondump`, `gpdbrestore`, and `gpmfr` utilities use the DD Boost credentials to access Data Domain systems. DD Boost information is stored in these files.

- **DDBOOST_CONFIG** is used by `gpdbrestore` and `gpcrondump` for backup and restore operations with the Data Domain system. The `gpdbrestore` utility creates or updates the file when you specify Data Domain information with the `--ddboost-host` option.
- **DDBOOST_MFR_CONFIG** is used by `gpmfr` for remote replication operations with the remote Data Domain system. The `gpdbrestore` utility creates or updates the file when you specify Data Domain information with the `--ddboost-host` option and `--ddboost-remote` option.

The configuration files are created in the current user (`gpadmin`) home directory on the Greenplum Database master and segment hosts. The path and file name cannot be changed. Information in the configuration files includes:

- Data Domain host name or IP address
- DD Boost user name
- DD Boost password
- Default Data Domain backup directory (**DDBOOST_CONFIG** only)
- Data Domain storage unit ID: default is GPDB (**DDBOOST_CONFIG** only)
- Data Domain default log level: default is WARNING
- Data Domain default log size: default is 50

Use the `gpcrondump` option `--ddboost-show-config` to display the current DD Boost configuration information from the Greenplum Database master configuration file. Specify the `--remote` option to display the configuration information for the remote Data Domain system.

### About Data Domain Storage Units

When you use a Data Domain system to perform a backup, restore, or remote replication operation with the `gpcrondump`, `gpdbrestore`, or `gpmfr` utility, the operation uses a storage unit on a Data Domain system. You can specify the storage unit ID when you perform these operations:

- **When you set the DD Boost credentials with the `gpcrondump` utility `--ddboost-host` option.**

  If you specify the `--ddboost-storage-unit` option, the storage unit ID is written to the Greenplum Database DD Boost configuration file `DDBOOST_CONFIG`. If the storage unit ID is not specified, the default value is GPDB.

  If you specify the `--ddboost-storage-unit` option and the `--ddboost-remote` option to set DD Boost credentials for the remote Data Domain server, the storage ID information is ignored. The storage unit ID in the `DDBOOST_CONFIG` file is the default ID that is used for remote replication operations.

- **When you perform a backup, restore, or remote replication operation with `gpcrondump`, `gpdbrestore`, or `gpmfr`.**

  When you specify the `--ddboost-storage-unit` option, the utility uses the specified Data Domain storage unit for the operation. The value in the configuration file is not changed.
A Greenplum Database utility uses the storage unit ID based on this order of precedence from highest to lowest:

- Storage unit ID specified with `--ddboost-storage-unit`
- Storage unit ID specified in the configuration file
- Default storage unit ID `GPDB`

Greenplum Database master and segment instances use a single storage unit ID when performing a backup, restore, or remote replication operation.

**Important:** The storage unit ID in the Greenplum Database master and segment host configuration files must be the same. The Data Domain storage unit is created by the `gpcrondump` utility from the Greenplum Database master host.

The following occurs if storage unit IDs are different in the master and segment host configuration files:

- If all the storage units have not been created, the operation fails.
- If all the storage units have been created, a backup operation completes. However, the backup files are in different storage units and a restore operation fails because a full set of backup files is not in a single storage unit.

When performing a full backup operation (not an incremental backup), the storage unit is created on the Data Domain system if it does not exist.

A storage unit is not created if these `gpcrondump` options are specified: `--incremental`, `--list-backup-file`, `--list-filter-tables`, `-o`, or `--ddboost-config-remove`.

Greenplum Database replication operations use the same storage unit ID on both systems. For example, if you specify the `--ddboost-storage-unit` option for `--replicate` or `--recover` through `gpmfr` or `--replicate` from `gpcrondump`, the storage unit ID applies to both local and remote Data Domain systems.

When performing a replicate or recover operation with `gpmfr`, the storage unit on the destination Data Domain system (where the backup is being copied) is created if it does not exist.

### Configuring Data Domain Boost for Greenplum Database

After you set up credentials for Data Domain Boost on the Greenplum Database, perform the following tasks in Data Domain to allow Data Domain Boost to work with Greenplum Database:

- Configuring Distributed Segment Processing in Data Domain
- Configuring Advanced Load Balancing and Link Failover in Data Domain
- Export the Data Domain Path to Greenplum Database Hosts

#### Configuring Distributed Segment Processing in Data Domain

Configure the distributed segment processing option on the Data Domain system. The configuration applies to all the Greenplum Database servers with the Data Domain Boost plug-in installed on them. This option is enabled by default, but verify that it is enabled before using Data Domain Boost backups:

```
# ddboost option show
```

To enable or disable distributed segment processing:

```
# ddboost option set distributed-segment-processing {enabled | disabled}
```

#### Configuring Advanced Load Balancing and Link Failover in Data Domain

If you have multiple network connections on a network subnet, you can create an interface group to provide load balancing and higher network throughput on your Data Domain system. When a Data
Domain system on an interface group receives data from the media server clients, the data transfer is load balanced and distributed as separate jobs on the private network. You can achieve optimal throughput with multiple 10 GbE connections.

**Note:** To ensure that interface groups function properly, use interface groups only when using multiple network connections on the same networking subnet.

To create an interface group on the Data Domain system, create interfaces with the `net` command. If interfaces do not already exist, add the interfaces to the group, and register the Data Domain system with the backup application.

1. Add the interfaces to the group:

```bash
# ddboost ifgroup add interface 192.0.2.1
# ddboost ifgroup add interface 192.0.2.2
# ddboost ifgroup add interface 192.0.2.3
# ddboost ifgroup add interface 192.0.2.4
```

**Note:** You can create only one interface group and this group cannot be named.

2. Select one interface on the Data Domain system to register with the backup application. Create a failover aggregated interface and register that interface with the backup application.

**Note:** You do not have to register one of the `ifgroup` interfaces with the backup application.

   You can use an interface that is not part of the `ifgroup` to register with the backup application.

3. Enable `ddboost` on the Data Domain system:

```bash
# ddboost ifgroup enable
```

4. Verify the Data Domain system configuration as follows:

```bash
# ddboost ifgroup show config
```

Results similar to the following are displayed.

```
Interface
---------
192.0.2.1
192.0.2.2
192.0.2.3
192.0.2.4
```

You can add or delete interfaces from the group at any time.

**Note:** Manage Advanced Load Balancing and Link Failover (an interface group) using the `ddboost ifgroup` command or from the Enterprise Manager Data Management > DD Boost view.

**Export the Data Domain Path to Greenplum Database Hosts**

The commands and options in this topic apply to DDOS 5.0.x and 5.1.x. See the Data Domain documentation for details.

Use the following Data Domain commands to export the `/backup/ost` directory to a Greenplum Database host for Data Domain Boost backups.

```bash
# nfs add /backup/ost 192.0.2.0/24, 198.51.100.0/24 (insecure)
```

**Note:** The IP addresses refer to the Greenplum Database system working with the Data Domain Boost system.
Create the Data Domain Login Credentials for the Greenplum Database Host

Create a username and password for the host to access the DD Boost Storage Unit (SU) at the time of backup and restore:

```
# user add user [password password] [priv {admin | security | user}]
```

Backup Options for Data Domain Boost

Specify the `gpcrondump` options to match the setup.

Data Domain Boost backs up files to a storage unit in the Data Domain system. Status and report files remain on the local disk. If needed, specify the Data Domain system storage unit with the `--ddboost-storage-unit` option. This DD Boost command displays the names of all storage units on a Data Domain system:

```
ddboost storage-unit show
```

To configure Data Domain Boost to remove old backup directories before starting a backup operation, specify a `gpcrondump` backup expiration option:

- The `-c` option clears all backup directories.
- The `-o` option clears the oldest backup directory.

To remove the oldest dump directory, specify `gpcrondump --ddboost` with the `-o` option. For example, if your retention period is 30 days, use `gpcrondump --ddboost` with the `-o` option on day 31.

Use `gpcrondump --ddboost` with the `-c` option to clear out all the old dump directories in `db_dumps`. The `-c` option deletes all dump directories that are at least one day old.

Using CRON to Schedule a Data Domain Boost Backup

1. Ensure the One-Time Data Domain Boost Credential Setup is complete.
2. Add the option `--ddboost` to the `gpcrondump` option:

```
gpcrondump -x mydatabase -z -v --ddboost
```

If needed, specify the Data Domain system storage unit with the `--ddboost-storage-unit` option.

**Important:** Do not use compression with Data Domain Boost backups. The `-z` option turns backup compression off.

Some of the options available in `gpcrondump` have different implications when using Data Domain Boost. For details, see `gpcrondump` in the Greenplum Database Utility Reference.

Restoring From a Data Domain System with Data Domain Boost

1. Ensure the One-Time Data Domain Boost Credential Setup is complete.
2. Add the option `--ddboost` to the `gpdbrestore` command:

```
$ gpdbrestore -t backup_timestamp -v -ddboost
```

If needed, specify the Data Domain system storage unit with the `--ddboost-storage-unit` option.

**Note:** Some of the `gpdbrestore` options available have different implications when using Data Domain. For details, see `gpdbrestore` in the Greenplum Database Utility Reference.
**Backing Up Databases with Veritas NetBackup**

For Greenplum Database on Red Hat Enterprise Linux, you can configure Greenplum Database to perform backup and restore operations with Veritas NetBackup. You configure Greenplum Database and NetBackup and then run a Greenplum Database `gpcrondump` or `gpdbrestore` command. The following topics describe how to set up NetBackup and back up or restore Greenplum Databases.

- **About NetBackup Software**
- **Limitations**
- **Configuring Greenplum Database Hosts for NetBackup**
- **Configuring NetBackup for Greenplum Database**
- **Performing a Back Up or Restore with NetBackup**
- **Example NetBackup Back Up and Restore Commands**

**About NetBackup Software**

NetBackup includes the following server and client software:

- The NetBackup master server manages NetBackup backups, archives, and restores. The master server is responsible for media and device selection for NetBackup.
- NetBackup Media servers are the NetBackup device hosts that provide additional storage by allowing NetBackup to use the storage devices that are attached to them.
- NetBackup client software that resides on the Greenplum Database hosts that contain data to be backed up.

See the [Veritas NetBackup Getting Started Guide](#) for information about NetBackup.

See the Release Notes for information about compatible NetBackup versions for this release of Pivotal Greenplum Database.

**Limitations**

- NetBackup is not compatible with DDBoost. Both NetBackup and DDBoost cannot be used in a single back up or restore operation.
- For incremental back up sets, a full backup and associated incremental backups, the backup set must be on a single device. For example, a backup set must all be on a NetBackup system. The backup set cannot have some backups on a NetBackup system and others on the local file system or a Data Domain system.

**Configuring Greenplum Database Hosts for NetBackup**

You install and configure NetBackup client software on the Greenplum Database master host and all segment hosts. The NetBackup client software must be able to communicate with the NetBackup server software.

1. Install the NetBackup client software on Greenplum Database hosts. See the NetBackup installation documentation for information on installing NetBackup clients on UNIX systems.
2. Set parameters in the NetBackup configuration file `/usr/openv/netbackup/bp.conf` on the Greenplum Database master and segment hosts. Set the following parameters on each Greenplum Database host.

### Table 42: NetBackup bp.conf parameters for Greenplum Database

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SERVER</td>
<td>Host name of the NetBackup Master Server</td>
</tr>
<tr>
<td>MEDIA_SERVER</td>
<td>Host name of the NetBackup Media Server</td>
</tr>
</tbody>
</table>
### Parameter | Description
--- | ---
CLIENT_NAME | Host name of the Greenplum Database Host

See the *Veritas NetBackup Administrator’s Guide* for information about the bp.conf file.

3. Set the `LD_LIBRARY_PATH` environment variable for Greenplum Database hosts to use NetBackup client. Greenplum Database installs NetBackup SDK library files that are used with the NetBackup client. To configure Greenplum Database to use the library files that correspond to the version of the NetBackup client that is installed on the hosts, add the following line to the file `$GPHOME/greenplum_path.sh`:

```
LD_LIBRARY_PATH=$GPHOME/lib/nbuNN/lib:$LD_LIBRARY_PATH
```

Replace the `NN` with the NetBackup client version that is installed on the host (for example, use 77 for NetBackup 7.7.x).

The `LD_LIBRARY_PATH` line should be added before this line in `$GPHOME/greenplum_path.sh`:

```
export LD_LIBRARY_PATH
```

4. Execute this command to remove the current `LD_LIBRARY_PATH` value:

```
unset LD_LIBRARY_PATH
```

5. Execute this command to update the environment variables for Greenplum Database:

```
source $GPHOME/greenplum_path.sh
```

See the *Veritas NetBackup Administrator’s Guide* for information about configuring NetBackup servers.

1. Ensure that the Greenplum Database hosts are listed as NetBackup clients for the NetBackup server.

   In the NetBackup Administration Console, the information for the NetBackup clients, Media Server, and Master Server is in the NetBackup Management node within the Host Properties node.

2. Configure a NetBackup storage unit. The storage unit must be configured to point to a writable disk location.

   In the NetBackup Administration Console, the information for NetBackup storage units is in NetBackup Management node within the Storage node.

3. Configure a NetBackup backup policy and schedule within the policy.

   In the NetBackup Administration Console, the Policy node below the Master Server node is where you create a policy and a schedule for the policy.
   
   - In the Policy Attributes tab, these values are required for Greenplum Database:
     
     The value in the Policy type field must be DataStore
     
     The value in the Policy storage field is the storage unit created in the previous step.
     
     The value in Limit jobs per policy field must be at least 3.
   
   - In the Policy Schedules tab, create a NetBackup schedule for the policy.

---

**Configuring NetBackup for Greenplum Database**

See the *Veritas NetBackup Administrator’s Guide* for information about configuring NetBackup servers.

1. Ensure that the Greenplum Database hosts are listed as NetBackup clients for the NetBackup server.

   In the NetBackup Administration Console, the information for the NetBackup clients, Media Server, and Master Server is in NetBackup Management node within the Host Properties node.

2. Configure a NetBackup storage unit. The storage unit must be configured to point to a writable disk location.
In the NetBackup Administration Console, the information for NetBackup storage units is in **NetBackup Management** node within the **Storage** node.

3. Configure a NetBackup backup policy and schedule within the policy.

   In the NetBackup Administration Console, the **Policy** node below the **Master Server** node is where you create a policy and a schedule for the policy.

   - In the **Policy Attributes** tab, these values are required for Greenplum Database:
     
     The value in the **Policy type** field must be DataStore

     The value in the **Policy storage** field is the storage unit created in the previous step.

     The value in **Limit jobs per policy** field must be at least 3.

   - In the **Policy Schedules** tab, create a NetBackup schedule for the policy.

---

**Performing a Back Up or Restore with NetBackup**

The Greenplum Database `gpcrondump` and `gpdbrestore` utilities support options to back up or restore data to a NetBackup storage unit. When performing a back up, Greenplum Database transfers data files directly to the NetBackup storage unit. No backup data files are created on the Greenplum Database hosts. The backup metadata files are both stored on the hosts and backed up to the NetBackup storage unit.

When performing a restore, the files are retrieved from the NetBackup server, and then restored.

Following are the `gpcrondump` utility options for NetBackup:

```bash
--netbackup-service-host netbackup_master_server
--netbackup-policy policy_name
--netbackup-schedule schedule_name
--netbackup-block-size size (optional)
--netbackup-keyword keyword (optional)
```

The `gpdbrestore` utility provides the following options for NetBackup:

```bash
--netbackup-service-host netbackup_master_server
--netbackup-block-size size (optional)
```

**Note:** When performing a restore operation from NetBackup, you must specify the backup timestamp with the `gpdbrestore` utility `-t` option.

The policy name and schedule name are defined on the NetBackup master server. See **Configuring NetBackup for Greenplum Database** for information about policy name and schedule name. See the **Greenplum Database Utility Guide** for information about the Greenplum Database utilities.

**Note:** You must run the `gpcrondump` or `gpdbrestore` command during a time window defined for the NetBackup schedule.

During a back up or restore operation, a separate NetBackup job is created for the following types of Greenplum Database data:

- Segment data for each segment instance
- C database data
- Metadata
- Post data for the master
- State files Global objects (`gpcrondump -G` option)
- Configuration files for master and segments (`gpcrondump -g` option)
- Report files (`gpcrondump -h` option)

In the NetBackup Administration Console, the Activity Monitor lists NetBackup jobs. For each job, the job detail displays Greenplum Database backup information.
**Note:** When backing up or restoring a large amount of data, set the NetBackup `CLIENT_READ_TIMEOUT` option to a value that is at least twice the expected duration of the operation (in seconds). The `CLIENT_READ_TIMEOUT` default value is 300 seconds (5 minutes).

For example, if a backup takes 3 hours, set the `CLIENT_READ_TIMEOUT` to 21600 (2 x 3 x 60 x 60). You can use the NetBackup `nbgetconfig` and `nbsetconfig` commands on the NetBackup server to view and change the option value.

For information about `CLIENT_READ_TIMEOUT` and the `nbgetconfig`, and `nbsetconfig` commands, see the NetBackup documentation.

**Example NetBackup Back Up and Restore Commands**

This `gpcrondump` command backs up the database `customer` and specifies a NetBackup policy and schedule that are defined on the NetBackup master server `nbu_server1`. A block size of 1024 bytes is used to transfer data to the NetBackup server.

```bash
gpcrondump -x customer --netbackup-service-host=nbu_server1 \
   --netbackup-policy=gpdb_cust --netbackup-schedule=gpdb_backup \
   --netbackup-block-size=1024
```

This `gpdbrestore` command restores Greenplum Database data from the data managed by NetBackup master server `nbu_server1`. The option `-t 20170530090000` specifies the timestamp generated by `gpcrondump` when the backup was created. The `-e` option specifies that the target database is dropped before it is restored.

```bash
gpdbrestore -t 20170530090000 -e --netbackup-service-host=nbu_server1
```

**Restoring Greenplum Databases**

How you restore a database from parallel backup files depends on how you answer the following questions.

1. **Where are your backup files?** If your backup files are on the segment hosts where `gpcrondump` created them, you can restore the database with `gpdbrestore`. If you moved your backup files away from the Greenplum array, for example to an archive server with `gpcrondump`, use `gpdbrestore`.

2. **Are you recreating the Greenplum Database system, or just restoring your data?** If Greenplum Database is running and you are restoring your data, use `gpdbrestore`. If you lost your entire array and need to rebuild the entire system from backup, use `gpinitsystem`.

3. **Are you restoring to a system with the same number of segment instances as your backup set?** If you are restoring to an array with the same number of segment hosts and segment instances per host, use `gpdbrestore`. If you are migrating to a different array configuration, you must do a non-parallel restore. See *Restoring to a Different Greenplum System Configuration*.

**Restoring a Database Using gpdbrestore**

The `gpdbrestore` utility restores a database from backup files created by `gpcrondump`.

The `gpdbrestore` requires one of the following options to identify the backup set to restore:

- `-t timestamp` — restore the backup with the specified timestamp.
- `-b YYYYMMDD` — restore dump files for the specified date in the `db_dumps` subdirectories on the segment data directories.
- `-s database_name` — restore the latest dump files for the specified database found in the segment data directories.
- `-R hostname:path` — restore the backup set located in the specified directory of a remote host.
To restore an incremental backup, you need a complete set of backup files—a full backup and any required incremental backups. You can use the `--list-backups` option to list the full and incremental backup sets required for an incremental backup specified by timestamp. For example:

```
$ gpdbrestore -t 20151013195916 --list-backup
```

You can restore a backup to a different database using the `--redirect database` option. The database is created if it does not exist. The following example restores the most recent backup of the mydb database to a new database named mydb_snapshot:

```
$ gpdbrestore -s grants --redirect grants_snapshot
```

You can also restore a backup to a different Greenplum Database system. See Restoring to a Different Greenplum System Configuration for information about this option.

### To restore from an archive host using gpdbrestore

You can restore a backup saved on a host outside of the Greenplum cluster using the `-R` option. Although the Greenplum Database software does not have to be installed on the remote host, the remote host must have a `gpadmin` account configured with passwordless ssh access to all hosts in the Greenplum cluster. This is required because each segment host will use scp to copy its segment backup file from the archive host. See `gpssh-exkeys` in the Greenplum Database Utility Guide for help adding the remote host to the cluster.

This procedure assumes that the backup set was moved off the Greenplum array to another host in the network.

1. Ensure that the archive host is reachable from the Greenplum master host:
   
   ```
   $ ping archive_host
   ```

2. Ensure that you can ssh into the remote host with the `gpadmin` account and no password.
   
   ```
   $ ssh gpadmin@archive_host
   ```

3. Ensure that you can ping the master host from the archive host:
   
   ```
   $ ping mdw
   ```

4. Ensure that the restore's target database exists. For example:
   
   ```
   $ createdb database_name
   ```

5. From the master, run the `gpdbrestore` utility. The `-R` option specifies the host name and path to a complete backup set:
   
   ```
   $ gpdbrestore -R archive_host:/gpdb/backups/archive/20120714 -e dbname
   ```

   Omit the `--` `dbname` option if the database has already been created.

### Restoring to a Different Greenplum System Configuration

To perform a parallel restore operation using `gpdbrestore`, the system you are restoring to must have the same configuration as the system that was backed up. To restore your database objects and data into a different system configuration, for example, to expand into a system with more segments, restore your parallel backup files by loading them through the Greenplum master. To perform a non-parallel restore, you must have:

- A full backup set created by a `gpcrondump` operation. The backup file of the master contains the DDL to recreate your database objects. The backup files of the segments contain the data.
- A running Greenplum Database system.
- The database you are restoring to exists in the system.

Segment dump files contain a `COPY` command for each table followed by the data in delimited text format. Collect all of the dump files for all of the segment instances and run them through the master to restore your data and redistribute it across the new system configuration.

**To restore a database to a different system configuration**

1. Ensure that you have a complete backup set, including dump files of the master (`gp_dump_-1_1_timestamp, gp_dump_-1_1_timestamp_post_data`) and one for each segment instance (for example, `gp_dump_0_2_timestamp, gp_dump_1_3_timestamp, gp_dump_2_4_timestamp`, and so on). Each dump file must have the same timestamp key. `gpcrondump` creates the dump files in each segment instance’s data directory. You must collect all the dump files and move them to one location on the master host. You can copy each segment dump file to the master, load it, and then delete it after it loads successfully.

2. Ensure that the database you are restoring to is created in the system. For example:

```
$ createdb database_name
```

3. Load the master dump file to restore the database objects. For example:

```
$ psql database_name -f /gpdb/backups/gp_dump_-1_1_20160714
```

4. Load each segment dump file to restore the data. For example:

```
$ psql database_name -f /gpdb/backups/gp_dump_0_2_20160714
$ psql database_name -f /gpdb/backups/gp_dump_1_3_20160714
$ psql database_name -f /gpdb/backups/gp_dump_2_4_20160714
$ psql database_name -f /gpdb/backups/gp_dump_3_5_20160714
...```

5. Load the post data file to restore database objects such as indexes, triggers, primary key constraints, etc.

```
$ psql database_name -f /gpdb/backups/gp_dump_0_5_20160714_post_data
```

6. Update the database sequences based on the values from the original database.

You can use the system utilities `gunzip` and `egrep` to extract the sequence value information from the original Greenplum Database master dump file `gp_dump_-1_1_timestamp.gz` into a text file. This command extracts the information into the file `schema_path_and_seq_next_val`.

```
gunzip -c path_to_master_dump_directory/gp_dump_-1_1_timestamp.gz | egrep "SET search_path|SELECT pg_catalog.setval" > schema_path_and_seq_next_val
```

This example command assumes the original Greenplum Database master dump file is in `/data/gpdb/master/gpseg-1/db_dumps/20150112`.

```
gunzip -c /data/gpdb/master/gpseg-1/db_dumps/20150112/gp_dump_-1_1_20150112140316.gz | egrep "SET search_path|SELECT pg_catalog.setval" > schema_path_and_seq_next_val
```

After extracting the information, use the Greenplum Database `psql` utility to update the sequences in the database. This example command updates the sequence information in the database `test_restore`:

```
psql test_restore -f schema_path_and_seq_next_val
```
Parallel Backup with gpbackup and gprestore

`gpbackup` and `gprestore` are Greenplum Database utilities that create and restore backup sets for Greenplum Database. By default, `gpbackup` stores only the object metadata files and DDL files for a backup in the Greenplum Database master data directory. Greenplum Database segments use the `COPY ... ON SEGMENT` command to store their data for backed-up tables in compressed CSV data files, located in each segment's `backups` directory.

The backup metadata files contain all of the information that `gprestore` needs to restore a full backup set in parallel. Backup metadata also provides the framework for restoring only individual objects in the data set, along with any dependent objects, in future versions of `gprestore`. (See Understanding Backup Files for more information.) Storing the table data in CSV files also provides opportunities for using other restore utilities, such as `gpload`, to load the data either in the same cluster or another cluster. By default, one file is created for each table on the segment. You can specify the `--leaf-partition-data` option with `gpbackup` to create one data file per leaf partition of a partitioned table, instead of a single file. This option also enables you to filter backup sets by leaf partitions.

Each `gpbackup` task uses a single transaction in Greenplum Database. During this transaction, metadata is backed up on the master host, and data for each table on each segment host is written to CSV backup files using `COPY ... ON SEGMENT` commands in parallel. The backup process acquires an `ACCESS SHARE` lock on each table that is backed up.

For information about the `gpbackup` and `gprestore` utility options, see `gpbackup` and `gprestore`.

Requirements and Limitations

The `gpbackup` and `gprestore` utilities are available with Greenplum Database 5.5.0 and later.

`gpbackup` and `gprestore` have the following limitations:

- If you create an index on a parent partitioned table, `gpbackup` does not back up that same index on child partitioned tables of the parent, as creating the same index on a child would cause an error. However, if you exchange a partition, `gpbackup` does not detect that the index on the exchanged partition is inherited from the new parent table. In this case, `gpbackup` backs up conflicting `CREATE INDEX` statements, which causes an error when you restore the backup set.
- You can execute multiple instances of `gpbackup`, but each execution requires a distinct timestamp.
- Database object filtering is currently limited to schemas and tables.
- If you use the `gpbackup --single-data-file` option to combine table backups into a single file per segment, you cannot perform a parallel restore operation with `gprestore` (cannot set `--jobs` to a value higher than 1).
- You cannot use the `--exclude-table-file` with `--leaf-partition-data`. Although you can specify leaf partition names in a file specified with `--exclude-table-file`, `gpbackup` ignores the partition names.
- Backing up a database with `gpbackup` while simultaneously running DDL commands might cause `gpbackup` to fail, in order to ensure consistency within the backup set. For example, if a table is dropped after the start of the backup operation, `gpbackup` exits and displays the error message `ERROR: relation <schema.table> does not exist.`

`gpbackup` might fail when a table is dropped during a backup operation due to table locking issues. `gpbackup` generates a list of tables to back up and acquires an `ACCESS SHARED` lock on the tables. If an `EXCLUSIVE LOCK` is held on a table, `gpbackup` acquires the `ACCESS SHARED` lock after the existing lock is released. If the table no longer exists when `gpbackup` attempts to acquire a lock on the table, `gpbackup` exits with the error message.

For tables that might be dropped during a backup, you can exclude the tables from a backup with a `gpbackup` table filtering option such as `--exclude-table` or `--exclude-schema`. 
**Objects Included in a Backup or Restore**

The following table lists the objects that are backed up and restored with `gpbackup` and `gprestore`. Database objects are backed up for the database you specify with the `--dbname` option. Global objects (Greenplum Database system objects) are also backed up by default, but they are restored only if you include the `--with-globals` option to `gprestore`.

**Table 43: Objects that are backed up and restored**

<table>
<thead>
<tr>
<th>Database (for database specified with <code>--dbname</code>)</th>
<th>Global (requires the <code>--with-globals</code> option to restore)</th>
</tr>
</thead>
<tbody>
<tr>
<td>• Session-level configuration parameter settings (GUCs)</td>
<td>• Tablespaces</td>
</tr>
<tr>
<td>• Schemas, see Note</td>
<td>• Databases</td>
</tr>
<tr>
<td>• Procedural language extensions</td>
<td>• Database-wide configuration parameter settings (GUCs)</td>
</tr>
<tr>

</tr>
</tbody>
</table>

**Note:** These schemas are not included in a backup.

- `gp_toolkit`
- `information_schema`
- `pg_aoseg`
- `pg_bitmapindex`
- `pg_catalog`
- `pg_toast*`
- `pg_temp*`

When restoring to an existing database, `gprestore` assumes the `public` schema exists when restoring objects to the `public` schema. When restoring to a new database (with the `--create-`
gprestore creates the public schema automatically when creating a database with the CREATE DATABASE command. The command uses the template0 database that contains the public schema.

See also Understanding Backup Files.

Performing Basic Backup and Restore Operations

To perform a complete backup of a database, as well as Greenplum Database system metadata, use the command:

$ gpbackup --dbname <database_name>

For example:

$ gpbackup --dbname demo
  Timestamp = 20180105112754
  Database = demo
  Type = Unfiltered Compressed Full Backup
  Gathering list of tables for backup
  Acquiring ACCESS SHARE locks on tables
  Locks acquired:  6 / 6
  [================================================================] 100.00% 0s
  Gathering additional table metadata
  Writing global database metadata
  Global database metadata backup complete
  Writing pre-data metadata
  Pre-data metadata backup complete
  Writing post-data metadata
  Post-data metadata backup complete
  Writing data to file
  Tables backed up:  3 / 3
  [================================================================] 100.00% 0s
  Data backup complete
  Found neither /usr/local/greenplum-db/bin/gp_email_contacts.yaml nor /home/gpadmin/gp_email_contacts.yaml
  Email containing gpbackup_report /gpmaster/seg-1/backups/20180105/20180105112754/gpbackup_20180105112754_report will not be sent
The above command creates a file that contains global and database-specific metadata on the Greenplum Database master host in the default directory, `$MASTER_DATA_DIRECTORY/backups/<YYYYMMDD>/`. For example:

```bash
$ ls /gpmaster/gpse-1/backups/20180105/20180105112754
gpbackup_20180105112754_config.yaml  gpbackup_20180105112754_report
gpbackup_20180105112754_metadata.sql  gpbackup_20180105112754_toc.yaml
```

By default, each segment stores each table's data for the backup in a separate compressed CSV file in `<seg_dir>/backups/<YYYYMMDD>/`:

```bash
$ ls /gpdata1/gpse0/backups/20180105/20180105112754/
gpbackup_0_20180105112754_17166.gz  gpbackup_0_20180105112754_26303.gz
gpbackup_0_20180105112754_21816.gz
```

To consolidate all backup files into a single directory, include the `--backup-dir` option. Note that you must specify an absolute path with this option:

```bash
$ gpbackup --dbname demo --backup-dir /home/gpadmin/backups
20171103:15:31:56 gpbackup:gpadmin:0ee2f5fb02c9:017586-[INFO]:-Starting backup of database demo ...
20171103:15:31:58 gpbackup:gpadmin:0ee2f5fb02c9:017586-[INFO]:-Backup completed successfully
```

When performing a backup operation, you can use the `--single-data-file` in situations where the additional overhead of multiple files might be prohibitive. For example, if you use a third party storage solution such as Data Domain with back ups.

**Restoring from Backup**

To use `gprestore` to restore from a backup set, you must use the `--timestamp` option to specify the exact timestamp value (`YYYYMMDDHHMMSS`) to restore. Include the `--create-db` option if the database does not exist in the cluster. For example:

```bash
$ dropdb demo
$ gprestore --timestamp 20171103153156 --create-db
20171103:15:45:30 gprestore:gpadmin:0ee2f5fb02c9:017714-[INFO]:-Restore Key = 20171103153156
```
If you specified a custom `--backup-dir` to consolidate the backup files, include the same `--backup-dir` option when using `gprestore` to locate the backup files:

```bash
$ dropdb demo
$ gprestore --backup-dir /home/gpadmin/backups/ --timestamp 20171103153156 --create-db
20171103:15:51:02 gprestore:gpadmin:0ee2f5fb02c9:017819-[INFO]:-Restore Key = 20171103153156
...  
20171103:15:51:17 gprestore:gpadmin:0ee2f5fb02c9:017819-[INFO]:-Post-data metadata restore complete
```

`gprestore` does not attempt to restore global metadata for the Greenplum System by default. If this is required, include the `--with-globals` argument.

By default, `gprestore` uses 1 connection to restore table data and metadata. If you have a large backup set, you can improve performance of the restore by increasing the number of parallel connections with the `--jobs` option. For example:

```bash
$ gprestore --backup-dir /home/gpadmin/backups/ --timestamp 20171103153156 --create-db --jobs 8
```

Test the number of parallel connections with your backup set to determine the ideal number for fast data recovery.

**Note:** You cannot perform a parallel restore operation with `gprestore` if the backup combined table backups into a single file per segment with the `gpbackup` option `--single-data-file`.

### Report Files

When performing a backup or restore operation, `gpbackup` and `gprestore` generate a report file. When email notification is configured, the email sent contains the contents of the report file. For information about email notification, see [Configuring Email Notifications](#).

The report file is placed in the Greenplum Database master backup directory. The report file name contains the timestamp of the operation. These are the formats of the `gpbackup` and `gprestore` report file names.

```
gpbackup_<backup_timestamp>_<report>
gprestore_<backup_timestamp>_<restore_timestamp>_<report>
```
For these example report file names, 20180213114446 is the timestamp of the backup and 20180213115426 is the timestamp of the restore operation.

This backup directory on a Greenplum Database master host contains both a gpbackup and gprestore report file.

```bash
$ ls -l /gpmaster/seg-1/backups/20180213/20180213114446
```

The contents of the report files are similar. This is an example of the contents of a gprestore report file.

```
Greenplum Database Restore Report

Timestamp Key: 20180213114446
GPDB Version: 5.4.1+dev.8.g9f83645 build
  commit:9f836456b00f85595952749d5790ed1c6efc042
gprestore Version: 1.0.0-alpha.3+dev.73.g0406681

Database Name: test
Command Line: gprestore --timestamp 20180213114446 --with-globals --createdb

Start Time: 2018-02-13 11:54:26
End Time: 2018-02-13 11:54:31
Duration: 0:00:05

Restore Status: Success
```

**History File**

When performing a backup operation, gpbackup appends backup information in the gpbackup history file, gpbackup_history.yaml, in the Greenplum Database master data directory. The file contains the backup timestamp, information about the backup options, and backup set information for incremental backups. This file is not backed up by gpbackup.

gpbackup uses the information in the file to find a matching backup for an incremental backup when you run gpbackup with the --incremental option and do not specify the --from-timesamp option to indicate the backup that you want to use as the latest backup in the incremental backup set. For information about incremental backups, see *Creating Incremental Backups with gpbackup and gprestore*.

**Return Codes**

One of these codes is returned after gpbackup or gprestore completes.

- **0** – Backup or restore completed with no problems
- **1** – Backup or restore completed with non-fatal errors. See log file for more information.
- **2** – Backup or restore failed with a fatal error. See log file for more information.
Filtering the Contents of a Backup or Restore

gpbackup backs up all schemas and tables in the specified database, unless you exclude or include individual schema or table objects with schema level or table level filter options.

The schema level options are --include-schema or --exclude-schema command-line options to gpbackup. For example, if the "demo" database includes only two schemas, "wikipedia" and "twitter," both of the following commands back up only the "wikipedia" schema:

\$ gpbackup --dbname demo --include-schema wikipedia
\$ gpbackup --dbname demo --exclude-schema twitter

You can include multiple --include-schema options in a gpbackup or multiple --exclude-schema options. For example:

\$ gpbackup --dbname demo --include-schema wikipedia --include-schema twitter

To filter the individual tables that are included in a backup set, or excluded from a backup set, specify individual tables with the --include-table option or the --exclude-table option. The table must be schema qualified, <schema-name>.<table-name>. The individual table filtering options can be specified multiple times. However, --include-table and --exclude-table cannot both be used in the same command.

You can create a list of qualified table names in a text file. When listing tables in a file, each line in the text file must define a single table using the format <schema-name>.<table-name>. The file must not include trailing lines. For example:

wikipedia.articles
twitter.message

If a table or schema name uses any character other than a lowercase letter, number, or an underscore character, then you must include that name in double quotes. For example:

beer."IPA"
"Wine".riesling
"Wine"."sauvignon blanc"
water.tonic

After creating the file, you can use it either to include or exclude tables with the gpbackup options --include-table-file or --exclude-table-file. For example:

\$ gpbackup --dbname demo --include-table-file /home/gpadmin/table-list.txt

You can combine --include-schema with --exclude-table or --exclude-table-file for a backup. This example uses --include-schema with --exclude-table to back up a schema except for a single table.

\$ gpbackup --dbname demo --include-schema mydata --exclude-table mydata.addresses

You cannot combine --include-schema with --include-table or --include-table-file, and you cannot combine --exclude-schema with any table filtering option such as --exclude-table or --include-table.

When you use --include-table or --include-table-file dependent objects are not automatically backed up or restored, you must explicitly specify the dependent objects that are required. For example, if you back up or restore a view, you must also specify the tables that the view uses. If you backup or restore a table that uses a sequence, you must also specify the sequence.
Filtering by Leaf Partition

By default, `gpbackup` creates one file for each table on a segment. You can specify the `--leaf-partition-data` option to create one data file per leaf partition of a partitioned table, instead of a single file. You can also filter backups to specific leaf partitions by listing the leaf partition names in a text file to include. For example, consider a table that was created using the statement:

```sql
CREATE TABLE sales (id int, date date, amt decimal(10,2))
DISTRIBUTED BY (id)
PARTITION BY RANGE (date)
 ( PARTITION Jan17 START (date '2017-01-01') INCLUSIVE ,
   PARTITION Feb17 START (date '2017-02-01') INCLUSIVE ,
   PARTITION Mar17 START (date '2017-03-01') INCLUSIVE ,
   PARTITION Apr17 START (date '2017-04-01') INCLUSIVE ,
   PARTITION May17 START (date '2017-05-01') INCLUSIVE ,
   PARTITION Jun17 START (date '2017-06-01') INCLUSIVE ,
   PARTITION Jul17 START (date '2017-07-01') INCLUSIVE ,
   PARTITION Aug17 START (date '2017-08-01') INCLUSIVE ,
   PARTITION Sep17 START (date '2017-09-01') INCLUSIVE ,
   PARTITION Oct17 START (date '2017-10-01') INCLUSIVE ,
   PARTITION Nov17 START (date '2017-11-01') INCLUSIVE ,
   PARTITION Dec17 START (date '2017-12-01') INCLUSIVE
END (date '2018-01-01') EXCLUSIVE);
```

To back up only data for the last quarter of the year, first create a text file that lists those leaf partition names instead of the full table name:

```
public.sales_1_prt_oct17
public.sales_1_prt_nov17
public.sales_1_prt_dec17
```

Then specify the file with the `--include-table-file` option to generate one data file per leaf partition:

```
$ gpbackup --dbname demo --include-table-file last-quarter.txt --leaf-partition-data
```
When you specify `--leaf-partition-data`, `gpbackup` generates one data file per leaf partition when backing up a partitioned table. For example, this command generates one data file for each leaf partition:

```
$ gpbackup --dbname demo --include-table public.sales --leaf-partition-data
```

When leaf partitions are backed up, the leaf partition data is backed up along with the metadata for the entire partitioned table.

**Note:** You cannot use the `--exclude-table-file` option with `--leaf-partition-data`. Although you can specify leaf partition names in a file specified with `--exclude-table-file`, `gpbackup` ignores the partition names.

**Filtering with gprestore**

After creating a backup set with `gpbackup`, you can filter the schemas and tables that you want to restore from the backup set using the `gprestore --include-schema` and `--include-table-file` options. These options work in the same way as their `gpbackup` counterparts, but have the following restrictions:

- The tables that you attempt to restore must not already exist in the database.
- If you attempt to restore a schema or table that does not exist in the backup set, the `gprestore` does not execute.
- If you use the `--include-schema` option, `gprestore` cannot restore objects that have dependencies on multiple schemas.
- If you use the `--include-table-file` option, `gprestore` does not create roles or set the owner of the tables. The utility restores table indexes and rules. Triggers are also restored but are not supported in Greenplum Database.
- The file that you specify with `--include-table-file` cannot include a leaf partition name, as it can when you specify this option with `gpbackup`. If you specified leaf partitions in the backup set, specify the partitioned table to restore the leaf partition data.

When restoring a backup set that contains data from some leaf partitions of a partitioned table, the partitioned table is restored along with the data for the leaf partitions. For example, you create a backup with the `gpbackup` option `--include-table-file` and the text file lists some leaf partitions of a partitioned table. Restoring the backup creates the partitioned table and restores the data only for the leaf partitions listed in the file.

**Configuring Email Notifications**

`gpbackup` and `gprestore` can send email notifications after a back up or restore operation completes.

To have `gpbackup` or `gprestore` send out status email notifications, you must place a file named `gp_email_contacts.yaml` in the home directory of the user running `gpbackup` or `gprestore` in the same directory as the utilities (`$GPHOME/bin`). A utility issues a message if it cannot locate a `gp_email_contacts.yaml` file in either location. If both locations contain a `.yaml` file, the utility uses the file in user `$HOME`.

The email subject line includes the utility name, timestamp, status, and the name of the Greenplum Database master. This is an example subject line for a `gpbackup` email.

```
gpbackup 20180202133601 on gp-master completed
```

The email contains summary information about the operation including options, duration, and number of objects backed up or restored. For information about the contents of a notification email, see *Report Files*.

**Note:** The UNIX mail utility must be running on the Greenplum Database host and must be configured to allow the Greenplum superuser (`gpadmin`) to send email. Also ensure that the mail program executable is locatable via the `gpadmin` user's `$PATH`.

gpbackup and gprestore Email File Format

The gpbackup and gprestore email notification YAML file gp_email_contacts.yaml uses indentation (spaces) to determine the document hierarchy and the relationships of the sections to one another. The use of white space is significant. White space should not be used simply for formatting purposes, and tabs should not be used at all.

Note: If the status parameters are not specified correctly, the utility does not issue a warning. For example, if the success parameter is misspelled and is set to true, a warning is not issued and an email is not sent to the email address after a successful operation. To ensure email notification is configured correctly, run tests with email notifications configured.

This is the format of the gp_email_contacts.yaml YAML file for gpbackup email notifications:

```yaml
contacts:
gpbackup:
  - address: user@domain
    status:
      success: [true | false]
      success_with_errors: [true | false]
      failure: [true | false]
gprestore:
  - address: user@domain
    status:
      success: [true | false]
      success_with_errors: [true | false]
      failure: [true | false]
```

Email YAML File Sections

contacts

Required. The section that contains the gpbackup and gprestore sections. The YAML file can contain a gpbackup section, a gprestore section, or one of each.

gpbackup

Optional. Begins the gpbackup email section.

dev

Required. At least one email address must be specified. Multiple email address parameters can be specified. Each address requires a status section.

user@domain is a single, valid email address.

status

Required. Specify when the utility sends an email to the specified email address. The default is to not send email notification.

You specify sending email notifications based on the completion status of a backup or restore operation. At least one of these parameters must be specified and each parameter can appear at most once.

success

Optional. Specify if an email is sent if the operation completes without errors. If the value is true, an email is sent if the operation completes without errors. If the value is false (the default), an email is not sent.

success_with_errors

Optional. Specify if an email is sent if the operation completes with errors. If the value is true, an email is sent if the operation completes with errors. If the value is false (the default), an email is not sent.

failure
Optional. Specify if an email is sent if the operation fails. If the value is `true`, an email is sent if the operation fails. If the value is `false` (the default), an email is not sent.

**gprestore**

Optional. Begins the `gprestore` email section. This section contains the `address` and `status` parameters that are used to send an email notification after a `gprestore` operation. The syntax is the same as the `gpbackup` section.

**Examples**

This example YAML file specifies sending email to email addresses depending on the success or failure of an operation. For a backup operation, an email is sent to a different address depending on the success or failure of the backup operation. For a restore operation, an email is sent to `gpadmin@example.com` only when the operation succeeds or completes with errors.

```yaml
contacts:
gpbackup:
- address: gpadmin@example.com
  status:
    success: true
- address: my_dba@example.com
  status:
    success_with_errors: true
    failure: true
gprestore:
- address: gpadmin@example.com
  status:
    success: true
    success_with_errors: true
```

**Understanding Backup Files**

**Warning:** All `gpbackup` metadata files are created with read-only permissions. Never delete or modify the metadata files for a `gpbackup` backup set. Doing so will render the backup files non-functional.

A complete backup set for `gpbackup` includes multiple metadata files, supporting files, and CSV data files, each designated with the timestamp at which the backup was created.

By default, metadata and supporting files are stored on the Greenplum Database master host in the directory `$$MASTER_DATA_DIRECTORY/backups/YYYYMMDD/YYYYMMDDHHMMSS/`. If you specify a custom backup directory, this same file path is created as a subdirectory of the backup directory. The following table describes the names and contents of the metadata and supporting files.
### Table 44: gpbackup Metadata Files (master)

<table>
<thead>
<tr>
<th>File name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>gpbackup_&lt;YYYYMMDDHHMMSS&gt;_metadata.sql</td>
<td>Contains global and database-specific metadata:</td>
</tr>
<tr>
<td></td>
<td>• DDL for objects that are global to the Greenplum Database cluster, and not owned by a specific database within the cluster.</td>
</tr>
<tr>
<td></td>
<td>• DDL for objects in the backed-up database (specified with --dbname) that must be created before restoring the actual data, and DDL for objects that must be created after restoring the data.</td>
</tr>
<tr>
<td></td>
<td>Global objects include:</td>
</tr>
<tr>
<td></td>
<td>• Tablespaces</td>
</tr>
<tr>
<td></td>
<td>• Databases</td>
</tr>
<tr>

<td>Description</td>
</tr>
<tr>
<td>----------------------------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>gpbackup_&lt;YYYYMMDDHHMMSS&gt;_toc.yaml</td>
<td>Contains metadata for locating object DDL in the _predata.sql and _postdata.sql files. This file also contains the table names and OIDs used for locating the corresponding table data in CSV data files that are created on each segment. See Segment Data Files.</td>
</tr>
</tbody>
</table>
| gpbackup_<YYYYMMDDHHMMSS>_report        | Contains information about the backup operation that is used to populate the email notice (if configured) that is sent after the backup completes. This file contains information such as:  
  - Command-line options that were provided  
  - Database that was backed up  
  - Database version  
  - Backup type  
  See Configuring Email Notifications. |
| gpbackup_<YYYYMMDDHHMMSS>_config.yaml   | Contains metadata about the execution of the particular backup task, including:  
  - gpbackup version  
  - Database name  
  - Greenplum Database version  
  - Additional option settings such as --no-compression, --compression-level, --metadata-only, --data-only, and --with-stats. |
| gpbackup_history.yaml                   | Contains information about options that were used when creating a backup with gpbackup, and information about incremental backups.  
  Stored on the Greenplum Database master host in the Greenplum Database master data directory.  
  This file is not backed up by gpbackup.  
  For information about incremental backups, see Creating Incremental Backups with gpbackup and gprestore. |

### Segment Data Files

By default, each segment creates one compressed CSV file for each table that is backed up on the segment. You can optionally specify the --single-data-file option to create a single data file on each segment. The files are stored in <seg_dir>/backups/YYYYMMDD/YYYYMMDDHHMMSS/.

If you specify a custom backup directory, segment data files are copied to this same file path as a subdirectory of the backup directory. If you include the --leaf-partition-data option, gpbackup creates one data file for each leaf partition of a partitioned table, instead of just one table for file.

Each data file uses the file name format gpbackup_<content_id>_<YYYYMMDDHHMMSS>_<oid>.gz where:
• `<content_id>` is the content ID of the segment.
• `<YYYYMMDDHHMMSS>` is the timestamp of the `gpbackup` operation.
• `<oid>` is the object ID of the table. The metadata file `gpbackup_<YYYYMMDDHHMMSS>_toc.yaml` references this `<oid>` to locate the data for a specific table in a schema.

You can optionally specify the gzip compression level (from 1-9) using the `--compression-level` option, or disable compression entirely with `--no-compression`. If you do not specify a compression level, `gpbackup` uses compression level 1 by default.

**Creating Incremental Backups with gpbackup and gprestore**

The `gpbackup` and `gprestore` utilities support creating incremental backups of append-optimized tables and restoring from incremental backups. An incremental backup backs up all specified heap tables and backs up append-optimized tables (including append-optimized, column-oriented tables) only if the tables have changed. For example, if a row of an append-optimized table has changed, the table is backed up. For partitioned append-optimized tables, only the changed leaf partitions are backed up.

Incremental backups are efficient when the total amount of data in append-optimized tables or table partitions that changed is small compared to the data that has not changed since the last backup.

An incremental backup backs up an append-optimized table only if one of the following operations was performed on the table after the last full or incremental backup:

• `ALTER TABLE`
• `DELETE`
• `INSERT`
• `TRUNCATE`
• `UPDATE`
• `DROP` and then re-create the table

To restore data from incremental backups, you need a complete incremental backup set.

**About Incremental Backup Sets**

An incremental backup set includes the following backups:

• A full backup. This is the full backup that the incremental backups are based on.
• The set of incremental backups that capture the changes to the database from the time of the full backup.

For example, you can create a full backup and then create three daily incremental backups. The full backup and all three incremental backups are the backup set. For information about using an incremental backup set, see [Example Using Incremental Backup Sets](#).

When you create or add to an incremental backup set, `gpbackup` ensures that the backups in the set are created with a consistent set of backup options to ensure that the backup set can be used in a restore operation. For information about backup set consistency, see [Using Incremental Backups](#).

When you create an incremental backup you include these options with the other `gpbackup` options to create a backup:

• `--leaf-partition-data` - Required for all backups in the incremental backup set.
• Required when you create a full backup that will be the base backup for an incremental backup set.
• Required when you create an incremental backup.
• `--incremental` - Required when you create an incremental backup.

You cannot combine `--data-only` or `--metadata-only` with `--incremental`.
• `--from-timestamp` - Optional. This option can be used with `--incremental`. The timestamp you specify is an existing backup. The timestamp can be either a full backup or incremental backup. The
backup being created must be compatible with the backup specified with the --from-timestamp option.

If you do not specify --from-timestamp, gpbackup attempts to find a compatible backup based on information in the gpbackup history file. See Incremental Backup Notes.

Using Incremental Backups

- Example Using Incremental Backup Sets
- Creating an Incremental Backup with gpbackup
- Restoring from an Incremental Backup with gprestore
- Incremental Backup Notes

When you add an incremental backup to a backup set, gpbackup ensures that the full backup and the incremental backups are consistent by checking these gpbackup options:

- --dbname - The database must be the same.
- --backup-dir - The directory must be the same. The backup set, the full backup and the incremental backups, must be in the same location.
- --single-data-file - This option must be either specified or absent for all backups in the set.
- --plugin-config - If this option is specified, it must be specified for all backups in the backup set. The configuration must reference the same plugin binary.
- --include-table-file, --include-schema, or any other options that filter tables and schemas must be the same.

When checking schema filters, only the schema names are checked, not the objects contained in the schemas.
- --no-compression - If this option is specified, it must be specified for all backups in the backup set.

If compression is used on the on the full backup, compression must be used on the incremental backups. Different compression levels are allowed for the backups in the backup set. For a backup, the default is compression level 1.

If you try to add an incremental backup to a backup set, the backup operation fails if the gpbackup options are not consistent.

For information about the gpbackup and gprestore utility options, see gpbackup and gprestore in the Greenplum Database Utility Guide.

Example Using Incremental Backup Sets

Each backup has a timestamp taken when the backup is created. For example, if you create a backup on May 14, 2017, the backup file names contain 20170514hhmmss. The hhmmss represents the time: hour, minute, and second.

This example assumes that you have created two full backups and incremental backups of the database mytest. To create the full backups, you used this command:

```
gpbackup --dbname mytest --backup-dir /mybackup --leaf-partition-data
```

You created incremental backups with this command:

```
gpbackup --dbname mytest --backup-dir /mybackup --leaf-partition-data --incremental
```

When you specify the --backup-dir option, the backups are created in the /mybackup directory on each Greenplum Database host.

In the example, the full backups have the timestamp keys 20170514054532 and 20171114064330. The other backups are incremental backups. The example consists of two backup sets, the first with two
incremental backups, and second with one incremental backup. The backups are listed from earliest to most recent.

- 20170514054532 (full backup)
- 20170714095512
- 20170914081205
- 20171114064330 (full backup)
- 20180114051246

To create a new incremental backup based on the latest incremental backup, you must include the same --backup-dir option as the incremental backup as well as the options --leaf-partition-data and --incremental.

```
gpbackup --dbname mytest --backup-dir /mybackup --leaf-partition-data --incremental
```

You can specify the --from-timestamp option to create an incremental backup based on an existing incremental or full backup. Based on the example, this command adds a fourth incremental backup to the backup set that includes 20170914081205 as an incremental backup and uses 20170514054532 as the full backup.

```
gpbackup --dbname mytest --backup-dir /mybackup --leaf-partition-data --incremental --from-timestamp 20170914081205
```

This command creates an incremental backup set based on the full backup 20171114064330 and is separate from the backup set that includes the incremental backup 20180114051246.

```
gpbackup --dbname mytest --backup-dir /mybackup --leaf-partition-data --incremental --from-timestamp 20171114064330
```

To restore a database with the incremental backup 20170914081205, you need the incremental backups 20120914081205 and 20170714095512, and the full backup 20170514054532. This would be the `gprestore` command.

```
gprestore --backup-dir /backupdir --timestamp 20170914081205
```

### Creating an Incremental Backup with gpbackup

The `gpbackup` output displays the timestamp of the backup on which the incremental backup is based. In this example, the incremental backup is based on the backup with timestamp 20180802171642. The backup 20180802171642 can be an incremental or full backup.

```
$ gpbackup --dbname test --backup-dir /backups --leaf-partition-data --incremental
20180803:15:40:51 gpbackup:gpadmin:mdw:002907-[INFO]:-Starting backup of database test
20180803:15:40:52 gpbackup:gpadmin:mdw:002907-[INFO]:-Backup Timestamp = 20180803154051
20180803:15:40:52 gpbackup:gpadmin:mdw:002907-[INFO]:-Backup Database = test
20180803:15:40:52 gpbackup:gpadmin:mdw:002907-[INFO]:-Gathering list of tables for backup
20180803:15:40:52 gpbackup:gpadmin:mdw:002907-[INFO]:-Acquiring ACCESS SHARE locks on tables
Locks acquired: 5 / 5
[================================================================] 100.00%
0s
20180803:15:40:52 gpbackup:gpadmin:mdw:002907-[INFO]:-Gathering additional table metadata
```
Restoring from an Incremental Backup with gprestore

When restoring an from an incremental backup, you can specify the --verbose option to display the backups that are used in the restore operation on the command line. For example, the following gprestore command restores a backup using the timestamp 20180807092740, an incremental backup. The output includes the backups that were used to restore the database data.

```
$ gprestore --create-db --timestamp 20180807162904 --verbose
...
20180807:16:31:56 gprestore:gpadmin:mdw:008603-[INFO]:-Pre-data metadata restore complete
20180807:16:31:56 gprestore:gpadmin:mdw:008603-[DEBUG]:-Reading data for table public.tbl_ao from file (table 1 of 1)
20180807:16:31:56 gprestore:gpadmin:mdw:008603-[DEBUG]:-Checking whether segment agents had errors during restore
20180807:16:31:56 gprestore:gpadmin:mdw:008603-[DEBUG]:-Reading data for table public.test_ao from file (table 1 of 1)
20180807:16:31:56 gprestore:gpadmin:mdw:008603-[DEBUG]:-Checking whether segment agents had errors during restore
20180807:16:31:56 gprestore:gpadmin:mdw:008603-[DEBUG]:-Reading data for table public.homes2 from file (table 1 of 4)
20180807:16:31:56 gprestore:gpadmin:mdw:008603-[DEBUG]:-Reading data for table public.test2 from file (table 2 of 4)
```
The output shows that the restore operation used three backups.

When restoring an from an incremental backup, `gprestore` also lists the backups that are used in the restore operation in the `gprestore` log file.

During the restore operation, `gprestore` displays an error if the full backup or other required incremental backup is not available.

**Incremental Backup Notes**

To create an incremental backup, or to restore data from an incremental backup set, you need the complete backup set. When you archive incremental backups, the complete backup set must be archived. You must archive all the files created on the master and all segments.

Each time `gpbackup` runs, the utility adds backup information to the history file `gpbackup_history.yaml` in the Greenplum Database master data directory. The file includes backup options and other backup information.

If you do not specify the `--from-timestamp` option when you create an incremental backup, `gpbackup` uses the most recent backup with a consistent set of options. The utility checks the backup history file to find the backup with a consistent set of options. If the utility cannot find a backup with a consistent set of options or the history file does not exist, `gpbackup` displays a message stating that a full backup must be created before an incremental can be created.

If you specify the `--from-timestamp` option when you create an incremental backup, `gpbackup` ensures that the options of the backup that is being created are consistent with the options of the specified backup.

The `gpbackup` option `--with-stats` is not required to be the same for all backups in the backup set. However, to perform a restore operation with the `gprestore` option `--with-stats` to restore statistics, the backup you specify must have must have used the `--with-stats` when creating the backup.

You can perform a restore operation from any backup in the backup set. However, changes captured in incremental backups later than the backup use to restore database data will not be restored.

When restoring from an incremental backup set, `gprestore` checks the backups and restores each append-optimized table from the most recent version of the append-optimized table in the backup set and restores the heap tables from the latest backup.

The incremental back up set, a full backup and associated incremental backups, must be on a single device. For example, the backups in a backup set must all be on a file system or must all be on a Data Domain system.

**Warning:** Changes to the Greenplum Database segment configuration invalidate incremental backups. After you change the segment configuration (add or remove segment instances), you must create a full backup before you can create an incremental backup.
Using gpbackup and gprestore with BoostFS

You can use the Greenplum Database gpbackup and gprestore utilities with the Data Domain DD Boost File System Plug-In (BoostFS) to access a Data Domain system. BoostFS leverages DD Boost technology and helps reduce bandwidth usage, can improve backup-times, offers load-balancing and in-flight encryption, and supports the Data Domain multi-tenancy feature set.

You install the BoostFS plug-in on the Greenplum Database host systems to provide access to a Data Domain system as a standard file system mount point. With direct access to a BoostFS mount point, gpbackup and gprestore can leverage the storage and network efficiencies of the DD Boost protocol for backup and recovery.

For information about configuring BoostFS, you can download the BoostFS for Linux Configuration Guide from the Dell support site https://www.dell.com/support (requires login). After logging into the support site, you can find the guide by searching for "BoostFS for Linux Configuration Guide". You can limit your search results by choosing to list only Manuals & Documentation as resources.

To back up or restore with BoostFS, you include the option --backup-dir with the gpbackup or gprestore command to access the Data Domain system.

Installing BoostFS

Download the latest BoostFS RPM from the Dell support site https://www.dell.com/support (requires login).

After logging into the support site, you can find the RPM by searching for "boostfs". You can limit your search results by choosing to list only Downloads & Drivers as resources. To list the most recent RPM near the top of your search results, sort your results by descending date.

The RPM supports both RHEL and SuSE.

These steps install BoostFS and create a mounted directory that accesses a Data Domain system.

Perform the steps on all Greenplum Database hosts. The mounted directory you create must be the same on all hosts.

1. Copy the BoostFS RPM to the host and install the RPM.

   After installation, the DDBoostFS package files are located under /opt/emc/boostfs.

2. Set up the BoostFS lockbox with the storage unit with the boostfs utility. Enter the Data Domain user password at the prompts.

   ```
   /opt/emc/boostfs/bin/boostfs lockbox set -d <Data_Domain_IP> -s <Storage_Unit> -u <Data_Domain_User>
   ```

   The `<Storage_Unit>` is the Data Domain storage unit ID. The `<Data_Domain_User>` is a Data Domain user with access to the storage unit.

3. Create the directory in the location you want to mount BoostFS.

   ```
   mkdir <path_to_mount_directory>
   ```

4. Mount the Data Domain storage unit with the boostfs utility. Use the mount option -allow-others=true to allow other users to write to the BoostFS mounted file system.

   ```
   /opt/emc/boostfs/bin/boostfs mount <path_to_mount_directory> -d $<Data_Domain_IP> -s <Storage_Unit> -o allow-others=true
   ```

5. Confirm that the mount was successful by running this command.

   ```
   mountpoint <mounted_directory>
   ```
The command lists the directory as a mount point.

```
<mounted_directory> is a mountpoint
```

You can now run `gpbackup` and `gprestore` with the `--backup-dir` option to back up a database to `<mounted_directory>` on the Data Domain system and restore data from the Data Domain system.

**Backing Up and Restoring with BoostFS**

These are required `gpbackup` options when backing up data to a Data Domain system with BoostFS.

- `--backup-dir` - Specify the mounted Data Domain storage unit.
- `--single-data-file` - Create a single data file on each segment host. A single data file avoids a BoostFS stream limitation.

When you use `gprestore` to restore a backup from a Data Domain system with BoostFS, you must specify the mounted Data Domain storage unit with the option `--backup-dir`.

When you use the `gpbackup` option `--single-data-file`, you cannot specify the `--jobs` option to perform a parallel restore operation with `gprestore`.

This example `gpbackup` command backs up the database `test`. The example assumes that the directory `/boostfs-test` is the mounted Data Domain storage unit.

```
$ gpbackup --dbname test --backup-dir /boostfs-test/ --single-data-file --no-compression
```

These commands drop the database `test` and restore the database from the backup.

```
$ dropdb test
$ gprestore --backup-dir /boostfs-test/ --timestamp 20171103153156 --create-db
```

The value `20171103153156` is the timestamp of the `gpbackup` backup set to restore. For information about how `gpbackup` uses timestamps when creating backups, see *Parallel Backup with gpbackup and gprestore*. For information about the `--timestamp` option, see `gprestore`.

**Using gpbackup Storage Plugins**

You can configure the Greenplum Database `gpbackup` and `gprestore` utilities to use a storage plugin to process backup files during a backup or restore operation. For example, during a backup operation, the plugin sends the backup files to a remote location. During a restore operation, the plugin retrieves the files from the remote location.

You can also develop a custom storage plugin with the Greenplum Database Backup/Restore Storage Plugin API (Beta). See *Backup/Restore Storage Plugin API (Beta)*.

*Note:* Only the Backup/Restore Storage Plugin API is a Beta feature. The storage plugins are supported features.

**Using the S3 Storage Plugin with gpbackup and gprestore**

The S3 storage plugin application lets you use an Amazon Simple Storage Service (Amazon S3) location to store and retrieve backups when you run `gpbackup` and `gprestore`. Amazon S3 provides secure, durable, highly-scalable object storage.

The S3 storage plugin can also connect to an Amazon S3 compatible service such as Dell EMC Elastic Cloud Storage (ECS) and Minio.
To use the S3 storage plugin application, you specify the location of the plugin and the S3 login and
backup location in a configuration file. When you run `gpbackup` or `gprestore`, you specify the
configuration file with the option `--plugin-config`. For information about the configuration file, see `S3
Storage Plugin Configuration File Format`.

If you perform a backup operation with the `gpbackup` option `--plugin-config`, you must also specify
the `--plugin-config` option when you restore the backup with `gprestore`.

**S3 Storage Plugin Configuration File Format**

The configuration file specifies the absolute path to the Greenplum Database S3 storage plugin
executable, connection credentials, and S3 location.

The S3 storage plugin configuration file uses the `YAML 1.1` document format and implements its own
schema for specifying the location of the Greenplum Database S3 storage plugin, connection credentials,
and S3 location and login information.

The configuration file must be a valid YAML document. The `gpbackup` and `gprestore` utilities process
the control file document in order and use indentation (spaces) to determine the document hierarchy and
the relationships of the sections to one another. The use of white space is significant. White space should
not be used simply for formatting purposes, and tabs should not be used at all.

This is the structure of a S3 storage plugin configuration file.

```yaml
executablepath: <absolute-path-to-gpbackup_s3_plugin>
options:
  region: <aws-region>
  endpoint: <S3-endpoint>
  aws_access_key_id: <aws-user-id>
  aws_secret_access_key: <aws-user-id-key>
  bucket: <s3-bucket>
  folder: <s3-location>
  encryption: [on|off]
```

**executablepath**

Required. Absolute path to the plugin executable. For example, the Pivotal Greenplum
Database installation location is `$GPHOME/bin/gpbackup_s3_plugin`. The plugin must
be in the same location on every Greenplum Database host.

**options**

Required. Begins the S3 storage plugin options section.

**region**

Required for AWS S3. If connecting to an S3 compatible service, this option is not
required.

**endpoint**

Required for an S3 compatible service. Specify this option to connect to an S3 compatible
service such as ECS. The plugin connects to the specified S3 endpoint (hostname or IP
address) to access the S3 compatible data store.

If this option is specified, the plugin ignores the `region` option and does not use AWS
to resolve the endpoint. When this option is not specified, the plugin uses the `region` to
determine AWS S3 endpoint.

**aws_access_key_id**

Optional. The S3 ID to access the S3 bucket location that stores backup files.

If this parameter is not specified, S3 authentication information from the session
environment is used. See `Notes`.

**aws_secret_access_key**
Required only if you specify `aws_access_key_id`. The S3 passcode for the S3 ID to access the S3 bucket location.

**bucket**

Required. The name of the S3 bucket in the AWS region or S3 compatible data store. The bucket must exist.

**folder**

Required. The S3 location for backups. During a backup operation, the plugin creates the S3 location if it does not exist in the S3 bucket.

**encryption**

Optional. Enable or disable use of Secure Sockets Layer (SSL) when connecting to an S3 location. Default value is `on`, use connections that are secured with SSL. Set this option to `off` to connect to an S3 compatible service that is not configured to use SSL. Any value other than `off` is treated as `on`.

**Example**

This is an example S3 storage plugin configuration file that is used in the next `gpbackup` example command. The name of the file is `s3-test-config.yaml`.

```
executablepath: $GPHOME/bin/gpbackup_s3_plugin
options:
  region: us-west-2
  aws_access_key_id: test-s3-user
  aws_secret_access_key: asdf1234asdf
  bucket: gpdb-backup
  folder: test/backup3
```

This `gpbackup` example backs up the database demo using the S3 storage plugin. The absolute path to the S3 storage plugin configuration file is `/home/gpadmin/s3-test`.

```
gpbackup --dbname demo --plugin-config /home/gpadmin/s3-test-config.yaml
```

The S3 storage plugin writes the backup files to this S3 location in the AWS region `us-west-2`.

```
gpdb-backup/test/backup3/backups/YYYYMMDD/YYYYMMDDHHMMSS/
```

**Notes**

The S3 storage plugin application must be in the same location on every Greenplum Database host. The configuration file is required only on the master host.

When you perform a backup with the S3 storage plugin, the plugin stores the backup files in this location in the S3 bucket.

```
<folder>/backups/<datestamp>/<timestamp>
```

Where `folder` is the location you specified in the S3 configuration file, and `datestamp` and `timestamp` are the backup date and time stamps.

Using Amazon S3 to back up and restore data requires an Amazon AWS account with access to the Amazon S3 bucket. These are the Amazon S3 bucket permissions required for backing up and restoring data.

- **Upload/Delete** for the S3 user ID that uploads the files
- **Open/Download and View** for the S3 user ID that accesses the files
If `aws_access_key_id` and `aws_secret_access_key` are not specified in the configuration file, the S3 plug-in uses S3 authentication information from the system environment of the session running the backup operation. The S3 plug-in searches for the information in these sources, using the first available source.

1. The environment variables `AWS_ACCESS_KEY_ID` and `AWS_SECRET_ACCESS_KEY`.

2. The authentication information set with the AWS CLI command `aws configure`.

3. The credentials of the Amazon EC2 IAM role if the backup is run from an EC2 instance.

For information about Amazon S3, see Amazon S3.

- For information about Amazon S3 regions and endpoints, see [http://docs.aws.amazon.com/general/latest/gr/rande.html#s3_region](http://docs.aws.amazon.com/general/latest/gr/rande.html#s3_region).
- For information about S3 buckets and folders, see the Amazon S3 documentation [https://aws.amazon.com/documentation/s3/](https://aws.amazon.com/documentation/s3/).

### Using the DD Boost Storage Plugin with gpbackup and gprestore

**Note:** The DD Boost storage plugin is available only in the commercial release of Pivotal Greenplum Database.

Dell EMC Data Domain Boost (DD Boost) is Dell EMC software that can be used with the `gpbackup` and `gprestore` utilities to perform faster backups to the Dell EMC Data Domain storage appliance. You can also replicate a backup on a separate, remote Data Domain system for disaster recovery.

To use the DD Boost storage plugin application, you first create a configuration file to specify the location of the plugin, the DD Boost login, and the backup location. When you run `gpbackup` or `gprestore`, you specify the configuration file with the option `--plugin-config`. For information about the configuration file, see [DD Boost Storage Plugin Configuration File Format](#).

If you perform a backup operation with the `gpbackup` option `--plugin-config`, you must also specify the `--plugin-config` option when you restore the backup with `gprestore`.

To replicate a backup set on a separate Data Domain system for disaster recovery, add the backup replication options to the configuration file. Set the `replication` option to `on` and add the options that the plugin uses to access the remote Data Domain system that stores the replicated backup. During the backup operation, the DD Boost storage plugin replicates the backup set on the remote Data Domain system with DD Boost managed file replication.

To restore data from a replicated backup, you can use `gprestore` with the DD Boost storage plugin and specify the location of the backup in the DD Boost configuration file.

### DD Boost Storage Plugin Configuration File Format

The configuration file specifies the absolute path to the Greenplum Database DD Boost storage plugin executable, DD Boost connection credentials, and Data Domain location.

The DD Boost storage plugin configuration file uses the YAML 1.1 document format and implements its own schema for specifying the DD Boost information.

The configuration file must be a valid YAML document. The `gpbackup` and `gprestore` utilities process the configuration file document in order and use indentation (spaces) to determine the document hierarchy and the relationships of the sections to one another. The use of white space is significant. White space should not be used simply for formatting purposes, and tabs should not be used at all.

This is the structure of a DD Boost storage plugin configuration file.

```yaml
executablepath: <absolute-path-to-gpbackup_ddboost_plugin>
options:
  hostname: "<data-domain-host>"
  username: "<ddboost-ID>"
  password: "<ddboost-pwd>"
  storage_unit: "<data-domain-id>"
  directory: "<data-domain-dir>"
```
**executablepath**

Required. Absolute path to the plugin executable. For example, the Pivotal Greenplum Database installation location is $GPHOME/bin/gpbackup_ddboost_plugin. The plugin must be in the same location on every Greenplum Database host.

**options**

Required. Begins the DD Boost storage plugin options section.

**hostname**

Required. The IP address or hostname of the host. There is a 30-character limit.

**username**

Required. The Data Domain Boost user name. There is a 30-character limit.

**password**

Required. The passcode for the DD Boost user to access the Data Domain storage unit.

**storage-unit**

Required. A valid storage unit name for the Data Domain system that is used for backup and restore operations.

**directory**

Required. The location for the backup files, configuration files, and global objects on the Data Domain system. The location on the system is /<data-domain-dir> in the storage unit of the system.

During a backup operation, the plugin creates the directory location if it does not exist in the storage unit and stores the backup in this directory /<data-domain-dir>/YYYYMMDD/YYYYMMDDHHMMSS/.

**replication**

Optional. Enables or disables backup replication with DD Boost managed file replication when gpbackup performs a backup operation. Value is either on or off. Default value is off, backup replication is disabled. When the value is on, the DD Boost plugin replicates the backup on the Data Domain system that you specify with the remote_* options.

The replication option and remote_* options are ignored when performing a restore operation with gprestore. The remote_* options are ignored if replication is off.

**remote_hostname**

Required if replication is on. The IP address or hostname of the Data Domain system that is used for remote backup storage. There is a 30-character limit.

**remote_username**

Required if replication is on. The Data Domain Boost user name that accesses the remote Data Domain system. There is a 30-character limit.

**remote_password**

Required if replication is on. The passcode for the DD Boost user to access the Data Domain storage unit on the remote system.

**remote_storage-unit**

Required if replication is on. A valid storage unit name for the remote Data Domain system that is used for backup replication.
remote_directory

Required if replication is on. The location for the replicated backup files, configuration files, and global objects on the remote Data Domain system. The location on the system is `/<remote-dd-dir>` in the storage unit of the remote system.

During a backup operation, the plugin creates the directory location if it does not exist in the storage unit of the remote Data Domain system and stores the replicated backup in this directory `/<remote-dd-dir>/YYYYMMDD/YYYYMMDDHHMMSS/`.

Example

This is an example DD Boost storage plugin configuration file that is used in the next gpbackup example command. The name of the file is `ddboost-test-config.yaml`.

```yaml
executablepath: $GPHOME/bin/gpbackup_ddboost_plugin
options:
  hostname: "192.0.2.230"
  username: "test-ddb-user"
  password: "asdf1234asdf"
  storage_unit: "gpdb-backup"
  directory: "test/backup"
```

This `gpbackup` example backs up the database demo using the DD Boost storage plugin. The absolute path to the DD Boost storage plugin configuration file is `/home/gpadmin/ddboost-test-config.yml`.

```bash
gpbackup --dbname demo --single-data-file --plugin-config /home/gpadmin/ddboost-test-config.yaml
```

The DD Boost storage plugin writes the backup files to this directory of the Data Domain storage unit `gpdb-backup`.

`/test/backup/YYYYMMDD/YYYYMMDDHHMMSS/`

This is an example DD Boost storage plugin configuration file that enables replication.

```yaml
executablepath: $GPHOME/bin/gpbackup_ddboost_plugin
options:
  hostname: "192.0.2.230"
  username: "test-ddb-user"
  password: "asdf1234asdf"
  storage_unit: "gpdb-backup"
  directory: "test/backup"
  replication: "on"
  remote_hostname: "192.0.3.20"
  remote_username: "test-dd-remote"
  remote_password: "qwer2345erty"
  remote_storage_unit: "gpdb-remote"
  remote_directory: "test/replication"
```

To restore from the replicated backup in the previous example, you can run `gprestore` with the DD Boost storage plugin and specify a configuration file with this information.

```bash
executablepath: $GPHOME/bin/gpbackup_ddboost_plugin
options:
  hostname: "192.0.3.20"
  remote_username: "test-dd-remote"
  remote_password: "qwer2345erty"
  storage_unit: "gpdb-remote"
  directory: "test/replication"
```
Notes

Dell EMC DD Boost is integrated with Pivotal Greenplum Database and requires a DD Boost license. Open source Greenplum Database cannot use the DD Boost software, but can back up to a Dell EMC Data Domain system mounted as an NFS share on the Greenplum master and segment hosts.

The DD Boost storage plugin application must be in the same location on every Greenplum Database host. The configuration file is required only on the master host.

When you perform a backup with the DD Boost storage plugin, the plugin stores the backup files in this location in the Data Domain storage unit.

\[<\text{directory}>/\text{backups}/<\text{datestamp}>/<\text{timestamp}>\]

Where \(<\text{directory}>\) is the location you specified in the DD Boost configuration file, and \(<\text{datestamp}>\) and \(<\text{timestamp}>\) are the backup date and time stamps.

When performing a backup operation with replication, the Data Domain system where the backup is stored must have access to the remote Data Domain system where the replicated backup is stored.

Performing a backup operation with replication increases the time required to perform a backup. The backup set is copied to the local Data Domain system, and then replicated on the remote Data Domain system using DD Boost managed file replication. The backup operation completes after the backup set is replicated on the remote system.

Backup/Restore Storage Plugin API (Beta)

This topic describes how to develop a custom storage plugin with the Greenplum Database Backup/Restore Storage Plugin API.

Note: Only the Backup/Restore Storage Plugin API is a Beta feature. The storage plugins are supported features.

The Backup/Restore Storage Plugin API provides a framework that you can use to develop and integrate a custom backup storage system with the Greenplum Database \(\text{gpbackup}\) and \(\text{gprestore}\) utilities.

The Backup/Restore Storage Plugin API defines a set of interfaces that a plugin must support. The API also specifies the format and content of a configuration file for a plugin.

When you use the Backup/Restore Storage Plugin API, you create a plugin that the Greenplum Database administrator deploys to the Greenplum Database cluster. Once deployed, the plugin is available for use in certain backup and restore operations.

This topic includes the following subtopics:

- Plugin Configuration File
- Plugin API
- Plugin Commands
- Implementing a Backup/Restore Storage Plugin
- Verifying a Backup/Restore Storage Plugin
- Packaging and Deploying a Backup/Restore Storage Plugin

Plugin Configuration File

Specifying the \(--\text{plugin-config}\) option to the \(\text{gpbackup}\) and \(\text{gprestore}\) commands instructs the utilities to use the plugin specified in the configuration file for the operation.

The plugin configuration file provides information for both Greenplum Database and the plugin. The Backup/Restore Storage Plugin API defines the format of, and certain keywords used in, the plugin configuration file.
A plugin configuration file is a YAML file in the following format:

```yaml
executablepath: path_to_plugin_executable
options:
  keyword1: value1
  keyword2: value2
  ...
  keywordN: valueN
```

`gpbackup` and `gprestore` use the `executablepath` value to determine the file system location of the plugin executable program.

The plugin configuration file may also include keywords and values specific to a plugin instance. A backup/restore storage plugin can use the `options` block specified in the file to obtain information from the user that may be required to perform its tasks. This information may include location, connection, or authentication information, for example. The plugin should both specify and consume the content of this information in `keyword: value` syntax.

A sample plugin configuration file for the Greenplum Database S3 backup/restore storage plugin follows:

```yaml
executablepath: $GPHOME/bin/gpbackup_s3_plugin
options:
  region: us-west-2
  aws_access_key_id: notarealID
  aws_secret_access_key: notarealkey
  bucket: gp_backup_bucket
  folder: greenplum_backups
```

**Plugin API**

The plugin that you implement when you use the Backup/Restore Storage Plugin API is an executable program that supports specific `commands` invoked by `gpbackup` and `gprestore` at defined points in their respective life cycle operations:

- The Greenplum Database Backup/Restore Storage Plugin API provides hooks into the `gpbackup` lifecycle at initialization, during backup, and at cleanup/exit time.
- The API provides hooks into the `gprestore` lifecycle at initialization, during restore, and at cleanup/exit time.
- The API provides arguments that specify the execution scope (master host, segment host, or segment instance) for a plugin setup or cleanup command. The scope can be one of these values.
  - `master` - Execute the plugin once on the master host.
  - `segment_host` - Execute the plugin once on each of the segment hosts.
  - `segment` - Execute the plugin once for each active segment instance on the host running the segment instance.

The Greenplum Database hosts and segment instances are based on the Greenplum Database configuration when the backup started. The values `segment_host` and `segment` are provided as a segment host can host multiple segment instances. There might be some setup or cleanup required at the segment host level as compared to each segment instance.

The Backup/Restore Storage Plugin API defines the following call syntax for a backup/restore storage plugin executable program:

```
plugin_executable command config_file args
```

where:

- `plugin_executable` - The absolute path of the backup/restore storage plugin executable program. This path is determined by the `executablepath` property value configured in the plugin's configuration YAML file.
• **command** - The name of a Backup/Restore Storage Plugin API command that identifies a specific entry point to a `gpbackup` or `gprestore` lifecycle operation.

• **config_file** - The absolute path of the plugin’s configuration YAML file.

• **args** - The command arguments; the actual arguments differ depending upon the *command* specified.

### Plugin Commands

The Greenplum Database Backup/Restore Storage Plugin API defines the following commands:

#### Table 45: Backup/Restore Storage Plugin API Commands

<table>
<thead>
<tr>
<th>Command Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>plugin_api_version</code></td>
<td>Return the version of the Backup/Restore Storage Plugin API supported by the plugin. The only supported version is 0.3.0.</td>
</tr>
<tr>
<td><code>setup_plugin_for_backup</code></td>
<td>Initialize the plugin for a backup operation.</td>
</tr>
<tr>
<td><code>backup_file</code></td>
<td>Move a backup file to the remote storage system.</td>
</tr>
<tr>
<td><code>backup_data</code></td>
<td>Move streaming data from <code>stdin</code> to a file on the remote storage system.</td>
</tr>
<tr>
<td><code>cleanup_plugin_for_backup</code></td>
<td>Clean up after a backup operation.</td>
</tr>
<tr>
<td><code>setup_plugin_for_restore</code></td>
<td>Initialize the plugin for a restore operation.</td>
</tr>
<tr>
<td><code>restore_file</code></td>
<td>Move a backup file from the remote storage system to a designated location on the local host.</td>
</tr>
<tr>
<td><code>restore_data</code></td>
<td>Move a backup file from the remote storage system, streaming the data to <code>stdout</code>.</td>
</tr>
<tr>
<td><code>cleanup_plugin_for_restore</code></td>
<td>Clean up after a restore operation.</td>
</tr>
</tbody>
</table>

A backup/restore storage plugin must support every command identified above, even if it is a no-op.

### Implementing a Backup/Restore Storage Plugin

You can implement a backup/restore storage plugin executable in any programming or scripting language. The tasks performed by a backup/restore storage plugin will be very specific to the remote storage system. As you design the plugin implementation, you will want to:

• Examine the connection and data transfer interface to the remote storage system.

• Identify the storage path specifics of the remote system.

• Identify configuration information required from the user.

• Define the keywords and value syntax for information required in the plugin configuration file.

• Determine if, and how, the plugin will modify (compress, etc.) the data en route to/from the remote storage system.

• Define a mapping between a `gpbackup` file path and the remote storage system.

• Identify how `gpbackup` options affect the plugin, as well as which are required and/or not applicable. For example, if the plugin performs its own compression, `gpbackup` must be invoked with the `--no-compression` option to prevent the utility from compressing the data.

A backup/restore storage plugin that you implement must:

• Support all plugin commands identified in *Plugin Commands*. Each command must exit with the values identified on the command reference page.

Refer to the `gpbackup-s3-plugin` github repository for an example plugin implementation.
Verifying a Backup/Restore Storage Plugin

The Backup/Restore Storage Plugin API includes a test bench that you can run to ensure that a plugin is well integrated with gpbackup and gprestore.

The test bench is a bash script that you run in a Greenplum Database installation. The script generates a small (<1MB) data set in a Greenplum Database table, explicitly tests each command, and runs a backup and restore of the data (file and streaming). The test bench invokes gpbackup and gprestore, which in turn individually call/test each Backup/Restore Storage Plugin API command implemented in the plugin.

The test bench program calling syntax is:

```
plugin_test_bench.sh plugin_executable plugin_config
```

Procedure

To run the Backup/Restore Storage Plugin API test bench against a plugin:

1. Log in to the Greenplum Database master host and set up your environment. For example:

   ```
   $ ssh gpadmin@gpmaster
   gpadmin@gpmaster$ . /usr/local/greenplum-db/greenplum_path.sh
   ```

2. Obtain a copy of the test bench from the gpbackup github repository. For example:

   ```
   $ git clone git@github.com:greenplum-db/gpbackup.git
   ```

   The clone operation creates a directory named gpbackup/ in the current working directory.

3. Locate the test bench program in the gpbackup/master/plugins directory. For example:

   ```
   $ ls gpbackup/master/plugins/plugin_test_bench.sh
   ```

4. Copy the plugin executable program and the plugin configuration YAML file from your development system to the Greenplum Database master host. Note the file system location to which you copied the files.

5. Copy the plugin executable program from the Greenplum Database master host to the same file system location on each segment host.

6. If required, edit the plugin configuration YAML file to specify the absolute path of the plugin executable program that you just copied to the Greenplum segments.

7. Run the test bench program against the plugin. For example:

   ```
   $ gpbackup/master/plugins/plugin_test_bench.sh /path/to/pluginexec /path/to/plugincfg.yaml
   ```

8. Examine the test bench output. Your plugin passed the test bench if all output messages specify RUNNING and PASSED. For example:

   ```
   # ---------------------------------------------------------
   # Starting gpbackup plugin tests
   # ---------------------------------------------------------
   [RUNNING] plugin_api_version
   [PASSED] plugin_api_version
   [RUNNING] setup_plugin_for_backup
   [RUNNING] backup_file
   [RUNNING] setup_plugin_for_restore
   [RUNNING] restore_file
   [PASSED] setup_plugin_for_backup
   [PASSED] backup_file
   [PASSED] setup_plugin_for_restore
   [PASSED] restore_file
   ```
Packaging and Deploying a Backup/Restore Storage Plugin

Your backup/restore storage plugin is ready to be deployed to a Greenplum Database installation after the plugin passes your testing and the test bench verification. When you package the backup/restore storage plugin, consider the following:

- The backup/restore storage plugin must be installed in the same file system location on every host in the Greenplum Database cluster. Provide installation instructions for the plugin indentifying the same.
- The `gpadmin` user must have permission to traverse the file system path to the backup/restore plugin executable program.
- Include a template configuration file with the plugin.
- Document the valid plugin configuration keywords, making sure to include the syntax of expected values.
- Document required `gpbackup` options and how they affect plugin processing.

**backup_data**

Plugin command to move streaming data from `stdin` to the remote storage system.

**Synopsis**

```
plugin_executable backup_data plugin_config_file data_filenamekey
```

**Description**

`gpbackup` invokes the `backup_data` plugin command on each segment host during a streaming backup. The `backup_data` implementation should read a potentially large stream of data from `stdin` and write the data to a single file on the remote storage system. The data is sent to the command as a single continuous stream per Greenplum Database segment. If `backup_data` modifies the data in any manner (i.e. compresses), `restore_data` must perform the reverse operation.

Name or maintain a mapping from the destination file to `data_filenamekey`. This will be the file key used for the restore operation.

**Arguments**

- `plugin_config_file`
  - The absolute path to the plugin configuration YAML file.

- `data_filenamekey`
  - The mapping key for a specially-named backup file for streamed data.
Exit Code

The `backup_data` command must exit with a value of 0 on success, non-zero if an error occurs. In the case of a non-zero exit code, `gpbackup` displays the contents of `stderr` to the user.

`backup_file`

Plugin command to move a backup file to the remote storage system.

Synopsis

```
plugin_executable backup_file plugin_config_file file_to_backup
```

Description

`gpbackup` invokes the `backup_file` plugin command on the master and each segment host for the file that `gpbackup` writes to a backup directory on local disk.

The `backup_file` implementation should process and copy the file to the remote storage system. Do not remove the local copy of the file that you specify with `file_to_backup`.

Arguments

`plugin_config_file`

- The absolute path to the plugin configuration YAML file.

`file_to_backup`

- The absolute path to a local backup file generated by `gpbackup`. Do not remove the local copy of the file that you specify with `file_to_backup`.

Exit Code

The `backup_file` command must exit with a value of 0 on success, non-zero if an error occurs. In the case of a non-zero exit code, `gpbackup` displays the contents of `stderr` to the user.

`cleanup_plugin_for_backup`

Plugin command to clean up a storage plugin after backup.

Synopsis

```
plugin_executable cleanup_plugin_for_backup plugin_config_file local_backup_dir scope
```

```
plugin_executable cleanup_plugin_for_backup plugin_config_file local_backup_dir scope contentID
```

Description

`gpbackup` invokes the `cleanup_plugin_for_backup` plugin command when a `gpbackup` operation completes, both in success and failure cases. The `scope` argument specifies the execution scope. `gpbackup` will invoke the command with each of the `scope` values.

The `cleanup_plugin_for_backup` command should perform the actions necessary to clean up the remote storage system after a backup. Clean up activities may include removing remote directories or temporary files created during the backup, disconnecting from the backup service, etc.

Arguments

`plugin_config_file`

- The absolute path to the plugin configuration YAML file.
**local_backup_dir**

The local directory on the Greenplum Database host (master and segments) to which `gpbackup` wrote backup files.

- When `scope` is `master`, the `local_backup_dir` is the backup directory of the Greenplum Database master.
- When `scope` is `segment`, the `local_backup_dir` is the backup directory of a segment instance. The `contentID` identifies the segment instance.
- When the scope is `segment_host`, the `local_backup_dir` is an arbitrary backup directory on the host.

**scope**

The execution scope value indicates the host and number of times the plugin command is executed. `scope` can be one of these values:

- `master` - Execute the plugin command once on the master host.
- `segment_host` - Execute the plugin command once on each of the segment hosts.
- `segment` - Execute the plugin command once for each active segment instance on the host running the segment instance. The `contentID` identifies the segment instance.

The Greenplum Database hosts and segment instances are based on the Greenplum Database configuration when the backup was first initiated.

**contentID**

The contentID of the Greenplum Database master or segment instance corresponding to the scope. `contentID` is passed only when the `scope` is `master` or `segment`.

- When `scope` is `master`, the `contentID` is `-1`.
- When `scope` is `segment`, the `contentID` is the content identifier of an active segment instance.

**Exit Code**

The `cleanup_plugin_for_backup` command must exit with a value of 0 on success, non-zero if an error occurs. In the case of a non-zero exit code, `gpbackup` displays the contents of `stderr` to the user.

**cleanup_plugin_for_restore**

Plugin command to clean up a storage plugin after restore.

**Synopsis**

```
plugin_executable cleanup_plugin_for_restore plugin_config_file local_backup_dir scope
```

**Description**

`gprestore` invokes the `cleanup_plugin_for_restore` plugin command when a `gprestore` operation completes, both in success and failure cases. The `scope` argument specifies the execution scope. `gprestore` will invoke the command with each of the `scope` values.

The `cleanup_plugin_for_restore` implementation should perform the actions necessary to clean up the remote storage system after a restore. Clean up activities may include removing remote directories or temporary files created during the restore, disconnecting from the backup service, etc.

**Arguments**

```
plugin_config_file
```
The absolute path to the plugin configuration YAML file.

**local_backup_dir**
The local directory on the Greenplum Database host (master and segments) from which gprestore reads backup files.

- When `scope` is `master`, the *local_backup_dir* is the backup directory of the Greenplum Database master.
- When `scope` is `segment`, the *local_backup_dir* is the backup directory of a segment instance. The *contentID* identifies the segment instance.
- When the `scope` is `segment_host`, the *local_backup_dir* is an arbitrary backup directory on the host.

**scope**
The execution scope value indicates the host and number of times the plugin command is executed. *scope* can be one of these values:

- *master* - Execute the plugin command once on the master host.
- *segment_host* - Execute the plugin command once on each of the segment hosts.
- *segment* - Execute the plugin command once for each active segment instance on the host running the segment instance. The *contentID* identifies the segment instance.

The Greenplum Database hosts and segment instances are based on the Greenplum Database configuration when the back up was first initiated.

**contentID**
The *contentID* of the Greenplum Database master or segment instance corresponding to the scope. *contentID* is passed only when the *scope* is `master` or `segment`.

- When `scope` is `master`, the *contentID* is `-1`.
- When `scope` is `segment`, the *contentID* is the content identifier of an active segment instance.

**Exit Code**
The `cleanup_plugin_for_restore` command must exit with a value of 0 on success, non-zero if an error occurs. In the case of a non-zero exit code, gprestore displays the contents of `stderr` to the user.

**plugin_api_version**
Plugin command to display the supported Backup Storage Plugin API version.

**Synopsis**
```
plugin_executable plugin_api_version
```

**Description**
gpbackup and gprestore invoke the `plugin_api_version` plugin command before a backup or restore operation to determine Backup Storage Plugin API version compatibility.

**Return Value**
The `plugin_api_version` command must return the Backup Storage Plugin API version number supported by the storage plugin, "0.3.0".

**restore_data**
Plugin command to stream data from the remote storage system to `stdout`. 
Synopsis

```
plugin_executable restore_data plugin_config_file data_filenamekey
```

Description

gprestore invokes the restore_data plugin command on each segment host when a restoring a streaming backup.

The restore_data implementation should read a potentially large data file named or mapped to data_filenamekey from the remote storage system and write the contents to stdout. If the backup_data command modified the data in any way (i.e. compressed), restore_data should perform the reverse operation.

Arguments

- **plugin_config_file**: The absolute path to the plugin configuration YAML file.
- **data_filenamekey**: The mapping key to a backup file on the remote storage system. data_filenamekey is the same key provided to the backup_data command.

Exit Code

The restore_data command must exit with a value of 0 on success, non-zero if an error occurs. In the case of a non-zero exit code, gprestore displays the contents of stderr to the user.

```
restore_file
```

Plugin command to move a backup file from the remote storage system.

Synopsis

```
plugin_executable restore_file plugin_config_file file_to_restore
```

Description

gprestore invokes the restore_file plugin command on the master and each segment host for the file that gprestore will read from a backup directory on local disk.

The restore_file command should process and move the file from the remote storage system to file_to_restore on the local host.

Arguments

- **plugin_config_file**: The absolute path to the plugin configuration YAML file.
- **file_to_restore**: The absolute path to which to move a backup file from the remote storage system.

Exit Code

The restore_file command must exit with a value of 0 on success, non-zero if an error occurs. In the case of a non-zero exit code, gprestore displays the contents of stderr to the user.

```
setup_plugin_for_backup
```

Plugin command to initialize a storage plugin for the backup operation.
Synopsis

```
plugin_executable setup_plugin_for_backup plugin_config_file local_backup_dir scope
```

Description

gpbackup invokes the `setup_plugin_for_backup` plugin command during gpbackup initialization phase. The `scope` argument specifies the execution scope. gpbackup will invoke the command with each of the `scope` values.

The `setup_plugin_for_backup` command should perform the activities necessary to initialize the remote storage system before backup begins. Set up activities may include creating remote directories, validating connectivity to the remote storage system, checking disks, and so forth.

Arguments

`plugin_config_file`

The absolute path to the plugin configuration YAML file.

`local_backup_dir`

The local directory on the Greenplum Database host (master and segments) to which gpbackup will write backup files. gpbackup creates this local directory.

- When `scope` is `master`, the `local_backup_dir` is the backup directory of the Greenplum Database master.
- When `scope` is `segment`, the `local_backup_dir` is the backup directory of a segment instance. The `contentID` identifies the segment instance.
- When the scope is `segment_host`, the `local_backup_dir` is an arbitrary backup directory on the host.

`scope`

The execution scope value indicates the host and number of times the plugin command is executed. `scope` can be one of these values:

- `master` - Execute the plugin command once on the master host.
- `segment_host` - Execute the plugin command once on each of the segment hosts.
- `segment` - Execute the plugin command once for each active segment instance on the host running the segment instance. The `contentID` identifies the segment instance.

The Greenplum Database hosts and segment instances are based on the Greenplum Database configuration when the back up was first initiated.

`contentID`

The `contentID` of the Greenplum Database master or segment instance corresponding to the scope. `contentID` is passed only when the `scope` is `master` or `segment`.

- When `scope` is `master`, the `contentID` is `-1`.
- When `scope` is `segment`, the `contentID` is the content identifier of an active segment instance.

Exit Code

The `setup_plugin_for_backup` command must exit with a value of 0 on success, non-zero if an error occurs. In the case of a non-zero exit code, gpbackup displays the contents of `stderr` to the user.
**setup_plugin_for_restore**

Plugin command to initialize a storage plugin for the restore operation.

**Synopsis**

```
plugin_executable setup_plugin_for_restore plugin_config_file local_backup_dir scope
```

**Description**

gprestore invokes the `setup_plugin_for_restore` plugin command during gprestore initialization phase. The `scope` argument specifies the execution scope. gprestore will invoke the command with each of the `scope` values.

The `setup_plugin_for_restore` command should perform the activities necessary to initialize the remote storage system before a restore operation begins. Set up activities may include creating remote directories, validating connectivity to the remote storage system, etc.

**Arguments**

**plugin_config_file**

The absolute path to the plugin configuration YAML file.

**local_backup_dir**

The local directory on the Greenplum Database host (master and segments) from which gprestore reads backup files. gprestore creates this local directory.

- When `scope` is `master`, the `local_backup_dir` is the backup directory of the Greenplum Database master.
- When `scope` is `segment`, the `local_backup_dir` is the backup directory of a segment instance. The `contentID` identifies the segment instance.
- When the `scope` is `segment_host`, the `local_backup_dir` is an arbitrary backup directory on the host.

**scope**

The execution scope value indicates the host and number of times the plugin command is executed. `scope` can be one of these values:

- `master` - Execute the plugin command once on the master host.
- `segment_host` - Execute the plugin command once on each of the segment hosts.
- `segment` - Execute the plugin command once for each active segment instance on the host running the segment instance. The `contentID` identifies the segment instance.

The Greenplum Database hosts and segment instances are based on the Greenplum Database configuration when the back up was first initiated.

**contentID**

The `contentID` of the Greenplum Database master or segment instance corresponding to the `scope`. `contentID` is passed only when the `scope` is `master` or `segment`.

- When `scope` is `master`, the `contentID` is `-1`.
- When `scope` is `segment`, the `contentID` is the content identifier of an active segment instance.
Exit Code

The `setup_plugin_for_restore` command must exit with a value of 0 on success, non-zero if an error occurs. In the case of a non-zero exit code, `gprestore` displays the contents of `stderr` to the user.

Expanding a Greenplum System

To scale up performance and storage capacity, expand your Greenplum Database system by adding hosts to the system. In general, adding nodes to a Greenplum cluster achieves a linear scaling of performance and storage capacity.

Data warehouses typically grow over time as additional data is gathered and the retention periods increase for existing data. At times, it is necessary to increase database capacity to consolidate different data warehouses into a single database. Additional computing capacity (CPU) may also be needed to accommodate newly added analytics projects. Although it is wise to provide capacity for growth when a system is initially specified, it is not generally possible to invest in resources long before they are required. Therefore, you should expect to execute a database expansion project periodically.

Because of the Greenplum MPP architecture, when you add resources to the system, the capacity and performance are the same as if the system had been originally implemented with the added resources. Unlike data warehouse systems that require substantial downtime in order to dump and restore the data, expanding a Greenplum Database system is a phased process with minimal downtime. Regular and ad hoc workloads can continue while data is redistributed and transactional consistency is maintained. The administrator can schedule the distribution activity to fit into ongoing operations and can pause and resume as needed. Tables can be ranked so that datasets are redistributed in a prioritized sequence, either to ensure that critical workloads benefit from the expanded capacity sooner, or to free disk space needed to redistribute very large tables.

The expansion process uses standard Greenplum Database operations so it is transparent and easy for administrators to troubleshoot. Segment mirroring and any replication mechanisms in place remain active, so fault-tolerance is uncompromised and disaster recovery measures remain effective.

System Expansion Overview

You can perform a Greenplum Database expansion to add segment instances and segment hosts with minimal downtime. In general, adding nodes to a Greenplum cluster achieves a linear scaling of performance and storage capacity.

Data warehouses typically grow over time, often at a continuous pace, as additional data is gathered and the retention period increases for existing data. At times, it is necessary to increase database capacity to consolidate disparate data warehouses into a single database. The data warehouse may also require additional computing capacity (CPU) to accommodate added analytics projects. It is good to provide capacity for growth when a system is initially specified, but even if you anticipate high rates of growth, it is generally unwise to invest in capacity long before it is required. Database expansion, therefore, is a project that you should expect to have to execute periodically.

When you expand your database, you should expect the following qualities:

- Scalable capacity and performance. When you add resources to a Greenplum Database, the capacity and performance are the same as if the system had been originally implemented with the added resources.
- Uninterrupted service during expansion. Regular workloads, both scheduled and ad-hoc, are not interrupted. A short, scheduled downtime period is required to initialize the new servers, similar to downtime required to restart the system. The length of downtime is unrelated to the size of the system before or after expansion.
- Transactional consistency.
- Fault tolerance. During the expansion, standard fault-tolerance mechanisms—such as segment mirroring—remain active, consistent, and effective.
- Replication and disaster recovery. Any existing replication mechanisms continue to function during expansion. Restore mechanisms needed in case of a failure or catastrophic event remain effective.
• Transparency of process. The expansion process employs standard Greenplum Database mechanisms, so administrators can diagnose and troubleshoot any problems.

• Configurable process. Expansion can be a long running process, but it can be fit into a schedule of ongoing operations. The expansion schema's tables allow administrators to prioritize the order in which tables are redistributed, and the expansion activity can be paused and resumed.

The planning and physical aspects of an expansion project are a greater share of the work than expanding the database itself. It will take a multi-discipline team to plan and execute the project. For on-premise installations, space must be acquired and prepared for the new servers. The servers must be specified, acquired, installed, cabled, configured, and tested. For cloud deployments, similar plans should also be made. Planning New Hardware Platforms describes general considerations for deploying new hardware.

After you provision the new hardware platforms and set up their networks, configure the operating systems and run performance tests using Greenplum utilities. The Greenplum Database software distribution includes utilities that are helpful to test and burn-in the new servers before beginning the software phase of the expansion. See Preparing and Adding Nodes for steps to prepare the new hosts for Greenplum Database.

Once the new servers are installed and tested, the software phase of the Greenplum Database expansion process begins. The software phase is designed to be minimally disruptive, transactionally consistent, reliable, and flexible.

• There is a brief period of downtime while the new segment hosts are initialized and the system is prepared for the expansion process. This downtime can be scheduled to occur during a period of low activity to avoid disrupting ongoing business operations. During the initialization process, the following tasks are performed:
  • Greenplum Database software is installed.
  • Databases and database objects are created on the new segment hosts.
  • An expansion schema is created in the master database to control the expansion process.
  • The distribution policy for each table is changed to DISTRIBUTED RANDOMLY.

• The system is restarted and applications resume.
  • New segments are immediately available and participate in new queries and data loads. The existing data, however, is skewed. It is concentrated on the original segments and must be redistributed across the new total number of primary segments.
  • Because tables now have a random distribution policy, the optimizer creates query plans that are not dependent on distribution keys. Some queries will be less efficient because more data motion operators are needed.

• Using the expansion control tables as a guide, tables and partitions are redistributed. For each table:
  • An ALTER TABLE statement is issued to change the distribution policy back to the original policy. This causes an automatic data redistribution operation, which spreads data across all of the servers, old and new, according to the original distribution policy.
  • The table's status is updated in the expansion control tables.
  • The query optimizer creates more efficient execution plans by including the distribution key in the planning.

• When all tables have been redistributed, the expansion is complete.

Redistributing data is a long-running process that creates a large volume of network and disk activity. It can take days to redistribute some very large databases. To minimize the effects of the increased activity on business operations, system administrators can pause and resume expansion activity on an ad hoc basis, or according to a predetermined schedule. Datasets can be prioritized so that critical applications benefit first from the expansion.

In a typical operation, you run the `gpexpand` utility four times with different options during the complete expansion process.
1. To create an expansion input file:
   ```bash
gpexpand -f hosts_file
   ```

2. To initialize segments and create the expansion schema:
   ```bash
gpexpand -i input_file -D database_name
   ```

   *gpexpand* creates a data directory, copies user tables from all existing databases on the new segments, and captures metadata for each table in an expansion schema for status tracking. After this process completes, the expansion operation is committed and irrevocable.

3. To redistribute tables:
   ```bash
gpexpand -d duration
   ```

   At initialization, *gpexpand* nullifies hash distribution policies on tables in all existing databases, except for parent tables of a partitioned table, and sets the distribution policy for all tables to random distribution.

   To complete system expansion, you must run *gpexpand* to redistribute data tables across the newly added segments. Depending on the size and scale of your system, redistribution can be accomplished in a single session during low-use hours, or you can divide the process into batches over an extended period. Each table or partition is unavailable for read or write operations during redistribution. As each table is redistributed across the new segments, database performance should incrementally improve until it exceeds pre-expansion performance levels.

   You may need to run *gpexpand* several times to complete the expansion in large-scale systems that require multiple redistribution sessions. *gpexpand* can benefit from explicit table redistribution ranking; see Planning Table Redistribution.

   Users can access Greenplum Database after initialization completes and the system is back online, but they may experience performance degradation on systems that rely heavily on hash distribution of tables. Normal operations such as ETL jobs, user queries, and reporting can continue, though users might experience slower response times.

   When a table has a random distribution policy, Greenplum Database cannot enforce unique constraints (such as **PRIMARY KEY**). This can affect your ETL and loading processes until table redistribution completes because duplicate rows do not issue a constraint violation error.

4. To remove the expansion schema:
   ```bash
gpexpand -c
   ```

For information about the *gpexpand* utility and the other utilities that are used for system expansion, see the *Greenplum Database Utility Guide*.

**Planning Greenplum System Expansion**

Careful planning will help to ensure a successful Greenplum expansion project.

The topics in this section help to ensure that you are prepared to execute a system expansion.

- **System Expansion Checklist** is a checklist you can use to prepare for and execute the system expansion process.
- **Planning New Hardware Platforms** covers planning for acquiring and setting up the new hardware.
- **Planning New Segment Initialization** provides information about planning to initialize new segment hosts with *gpexpand*.
- **Planning Table Redistribution** provides information about planning the data redistribution after the new segment hosts have been initialized.
**System Expansion Checklist**

This checklist summarizes the tasks for a Greenplum Database system expansion.

**Table 46: Greenplum Database System Expansion Checklist**

<table>
<thead>
<tr>
<th>Online Pre-Expansion Tasks</th>
</tr>
</thead>
<tbody>
<tr>
<td>* System is up and available</td>
</tr>
<tr>
<td>![ ] Devise and execute a plan for ordering, building, and networking new hardware platforms, or provisioning cloud resources.</td>
</tr>
<tr>
<td>![ ] Devise a database expansion plan. Map the number of segments per host, schedule the downtime period for testing performance and creating the expansion schema, and schedule the intervals for table redistribution.</td>
</tr>
<tr>
<td>![ ] Perform a complete schema dump.</td>
</tr>
<tr>
<td>![ ] Install Greenplum Database binaries on new hosts.</td>
</tr>
<tr>
<td>![ ] Copy SSH keys to the new hosts (<em>gpssh-exkeys</em>).</td>
</tr>
<tr>
<td>![ ] Validate the operating system environment of the new hardware or cloud resources (<em>gpcheck</em>).</td>
</tr>
<tr>
<td>![ ] Validate disk I/O and memory bandwidth of the new hardware or cloud resources (<em>gpcheckperf</em>).</td>
</tr>
<tr>
<td>![ ] Validate that the master data directory has no extremely large files in the <em>pg_log</em> or <em>gpperfmon/data</em> directories.</td>
</tr>
<tr>
<td>![ ] Validate that there are no catalog issues (<em>gpcheckcat</em>).</td>
</tr>
<tr>
<td>![ ] Prepare an expansion input file (<em>gpexpand</em>).</td>
</tr>
</tbody>
</table>

Online Expansion and Table Redistribution

* System is up and available

- Before you start table redistribution, stop any automated snapshot processes or other processes that consume disk space.
- Redistribute tables through the expanded system (`gpexpand`).
- Remove expansion schema (`gpexpand -c`).
- Run `analyze` to update distribution statistics.
  During the expansion, use `gpexpand -a`, and post-expansion, use `analyze`.

Planning New Hardware Platforms

A deliberate, thorough approach to deploying compatible hardware greatly minimizes risk to the expansion process.

Hardware resources and configurations for new segment hosts should match those of the existing hosts. Work with Greenplum Platform Engineering before making a hardware purchase to expand Greenplum Database.

The steps to plan and set up new hardware platforms vary for each deployment. Some considerations include how to:

- Prepare the physical space for the new hardware; consider cooling, power supply, and other physical factors.
- Determine the physical networking and cabling required to connect the new and existing hardware.
- Map the existing IP address spaces and developing a networking plan for the expanded system.
- Capture the system configuration (users, profiles, NICs, and so on) from existing hardware to use as a detailed list for ordering new hardware.
- Create a custom build plan for deploying hardware with the desired configuration in the particular site and environment.

After selecting and adding new hardware to your network environment, ensure you perform the burn-in tasks described in Verifying OS Settings.

Planning New Segment Initialization

Expanding Greenplum Database requires a limited period of system downtime. During this period, run `gpexpand` to initialize new segments into the array and create an expansion schema.

The time required depends on the number of schema objects in the Greenplum system and other factors related to hardware performance. In most environments, the initialization of new segments requires less than thirty minutes offline.

**Note:** After you begin initializing new segments, you can no longer restore the system using backup files created for the pre-expansion system. When initialization successfully completes, the expansion is committed and cannot be rolled back.

Planning Mirror Segments

If your existing array has mirror segments, the new segments must have mirroring configured. If there are no mirrors configured for existing segments, you cannot add mirrors to new hosts with the `gpexpand` utility.
For Greenplum Database arrays with mirror segments, ensure you add enough new host machines to accommodate new mirror segments. The number of new hosts required depends on your mirroring strategy:

- **Spread Mirroring** — Add at least one more host to the array than the number of segments per host. The number of separate hosts must be greater than the number of segment instances per host to ensure even spreading.

- **Grouped Mirroring** — Add at least two new hosts so the mirrors for the first host can reside on the second host, and the mirrors for the second host can reside on the first. For more information, see About Segment Mirroring.

*(Increasing Segments Per Host)*

By default, new hosts are initialized with as many primary segments as existing hosts have. You can increase the segments per host or add new segments to existing hosts.

For example, if existing hosts currently have two segments per host, you can use `gpexpand` to initialize two additional segments on existing hosts for a total of four segments and four new segments on new hosts.

The interactive process for creating an expansion input file prompts for this option; you can also specify new segment directories manually in the input configuration file. For more information, see Creating an Input File for System Expansion.

*(About the Expansion Schema)*

At initialization, `gpexpand` creates an expansion schema. If you do not specify a database at initialization (`gpexpand -D`), the schema is created in the database indicated by the `PGDATABASE` environment variable.

The expansion schema stores metadata for each table in the system so its status can be tracked throughout the expansion process. The expansion schema consists of two tables and a view for tracking expansion operation progress:

- `gpexpand.status`
- `gpexpand.status_detail`
- `gpexpand.expansion_progress`

Control expansion process aspects by modifying `gpexpand.status_detail`. For example, removing a record from this table prevents the system from expanding the table across new segments. Control the order in which tables are processed for redistribution by updating the `rank` value for a record. For more information, see Ranking Tables for Redistribution.

*(Planning Table Redistribution)*

Table redistribution is performed while the system is online. For many Greenplum systems, table redistribution completes in a single `gpexpand` session scheduled during a low-use period. Larger systems may require multiple sessions and setting the order of table redistribution to minimize performance impact. Complete the table redistribution in one session if possible.

**Important:** To perform table redistribution, your segment hosts must have enough disk space to temporarily hold a copy of your largest table. All tables are unavailable for read and write operations during redistribution.

The performance impact of table redistribution depends on the size, storage type, and partitioning design of a table. For any given table, redistributing it with `gpexpand` takes as much time as a `CREATE TABLE AS SELECT` operation would. When redistributing a terabyte-scale fact table, the expansion utility can use much of the available system resources, which could affect query performance or other database workloads.
Managing Redistribution in Large-Scale Greenplum Systems

You can manage the order in which tables are redistributed by adjusting their ranking. See Ranking Tables for Redistribution. Manipulating the redistribution order can help adjust for limited disk space and restore optimal query performance for high-priority queries sooner.

When planning the redistribution phase, consider the impact of the exclusive lock taken on each table during redistribution. User activity on a table can delay its redistribution, but also tables are unavailable for user activity during redistribution.

Systems with Abundant Free Disk Space

In systems with abundant free disk space (required to store a copy of the largest table), you can focus on restoring optimum query performance as soon as possible by first redistributing important tables that queries use heavily. Assign high ranking to these tables, and schedule redistribution operations for times of low system usage. Run one redistribution process at a time until large or critical tables have been redistributed.

Systems with Limited Free Disk Space

If your existing hosts have limited disk space, you may prefer to first redistribute smaller tables (such as dimension tables) to clear space to store a copy of the largest table. Available disk space on the original segments increases as each table is redistributed across the expanded array. When enough free space exists on all segments to store a copy of the largest table, you can redistribute large or critical tables. Redistribution of large tables requires exclusive locks; schedule this procedure for off-peak hours.

Also consider the following:

- Run multiple parallel redistribution processes during off-peak hours to maximize available system resources.
- When running multiple processes, operate within the connection limits for your Greenplum system. For information about limiting concurrent connections, see Limiting Concurrent Connections.

Redistributing Append-Optimized and Compressed Tables

gpexpand redistributes append-optimized and compressed append-optimized tables at different rates than heap tables. The CPU capacity required to compress and decompress data tends to increase the impact on system performance. For similar-sized tables with similar data, you may find overall performance differences like the following:

- Uncompressed append-optimized tables expand 10% faster than heap tables.
- zlib-compressed append-optimized tables expand at a significantly slower rate than uncompressed append-optimized tables, potentially up to 80% slower.
- Systems with data compression such as ZFS/LZJB take longer to redistribute.

Important: If your system nodes use data compression, use identical compression on new nodes to avoid disk space shortage.

Redistributing Tables with Primary Key Constraints

There is a time period during which primary key constraints cannot be enforced between the initialization of new segments and successful table redistribution. Duplicate data inserted into tables during this period prevents the expansion utility from redistributing the affected tables.

After a table is redistributed, the primary key constraint is properly enforced again. If an expansion process violates constraints, the expansion utility logs errors and displays warnings when it completes. To fix constraint violations, perform one of the following remedies:

- Clean up duplicate data in the primary key columns, and re-run gpexpand.
- Drop the primary key constraints, and re-run gpexpand.
**Redistributing Tables with User-Defined Data Types**

You cannot perform redistribution with the expansion utility on tables with dropped columns of user-defined data types. To redistribute tables with dropped columns of user-defined types, first re-create the table using `CREATE TABLE AS SELECT`. After this process removes the dropped columns, redistribute the table with `gpexpand`.

**Redistributing Partitioned Tables**

Because the expansion utility can process each individual partition on a large table, an efficient partition design reduces the performance impact of table redistribution. Only the child tables of a partitioned table are set to a random distribution policy. The read/write lock for redistribution applies to only one child table at a time.

**Redistributing Indexed Tables**

Because the `gpexpand` utility must re-index each indexed table after redistribution, a high level of indexing has a large performance impact. Systems with intensive indexing have significantly slower rates of table redistribution.

**Preparing and Adding Nodes**

Verify your new nodes are ready for integration into the existing Greenplum system.

To prepare new system nodes for expansion, install the Greenplum Database software binaries, exchange the required SSH keys, and run performance tests.

Run performance tests first on the new nodes and then all nodes. Run the tests on all nodes with the system offline so user activity does not distort results.

Generally, you should run performance tests when an administrator modifies node networking or other special conditions in the system. For example, if you will run the expanded system on two network clusters, run tests on each cluster.

**Adding New Nodes to the Trusted Host Environment**

New nodes must exchange SSH keys with the existing nodes to enable Greenplum administrative utilities to connect to all segments without a password prompt. Perform the key exchange process twice.

First perform the process as `root`, for administration convenience, and then as the user `gpadmin`, for management utilities. Perform the following tasks in order:

1. To exchange SSH keys as root
2. To create the `gpadmin` user
3. To exchange SSH keys as the `gpadmin` user

   **Note:** The Greenplum Database segment host naming convention is `sdwN` where `sdw` is a prefix and `N` is an integer (`sdw1`, `sdw2` and so on). For hosts with multiple interfaces, the convention is to append a dash (`-`) and number to the host name. For example, `sdw1-1` and `sdw1-2` are the two interface names for host `sdw1`.

**To exchange SSH keys as root**

1. Create a host file with the existing host names in your array and a separate host file with the new expansion host names. For existing hosts, you can use the same host file used to set up SSH keys in the system. In the files, list all hosts (master, backup master, and segment hosts) with one name per line and no extra lines or spaces. Exchange SSH keys using the configured host names for a given host
if you use a multi-NIC configuration. In this example, `mdw` is configured with a single NIC, and `sdw1`, `sdw2`, and `sdw3` are configured with 4 NICs:

```
mdw
sdw1-1
sdw1-2
sdw1-3
sdw1-4
sdw2-1
sdw2-2
sdw2-3
sdw2-4
sdw3-1
sdw3-2
sdw3-3
sdw3-4
```

2. Log in as `root` on the master host, and source the `greenplum_path.sh` file from your Greenplum installation.

```
$ su -
# source /usr/local/greenplum-db/greenplum_path.sh
```

3. Run the `gpssh-exkeys` utility referencing the host list files. For example:

```
# gpssh-exkeys -e /home/gpadmin/existing_hosts_file -x /home/gpadmin/new_hosts_file
```

4. `gpssh-exkeys` checks the remote hosts and performs the key exchange between all hosts. Enter the root user password when prompted. For example:

```
***Enter password for root@hostname: <root_password>
```

### To create the `gpadmin` user

1. Use `gpssh` to create the `gpadmin` user on all the new segment hosts (if it does not exist already). Use the list of new hosts you created for the key exchange. For example:

```
# gpssh -f new_hosts_file '/usr/sbin/useradd gpadmin -d /home/gpadmin -s /bin/bash'
```

2. Set a password for the new `gpadmin` user. On Linux, you can do this on all segment hosts simultaneously using `gpssh`. For example:

```
# gpssh -f new_hosts_file 'echo gpadmin_password | passwd gpadmin --stdin'
```

3. Verify the `gpadmin` user has been created by looking for its home directory:

```
# gpssh -f new_hosts_file ls -l /home
```

### To exchange SSH keys as the `gpadmin` user

1. Log in as `gpadmin` and run the `gpssh-exkeys` utility referencing the host list files. For example:

```
# gpssh-exkeys -e /home/gpadmin/existing_hosts_file -x /home/gpadmin/new_hosts_file
```
2. `gpssh-exkeys` will check the remote hosts and perform the key exchange between all hosts. Enter the `gpadmin` user password when prompted. For example:

```
***Enter password for gpadmin@hostname: <gpadmin_password>
```

**Verifying OS Settings**

Use the `gpcheck` utility to verify all new hosts in your array have the correct OS settings to run Greenplum Database software.

**To run gpcheck**

1. Log in on the master host as the user who will run your Greenplum Database system (for example, `gpadmin`).

   `$ su - gpadmin`

2. Run the `gpcheck` utility using your host file for new hosts. For example:

   `$ gpcheck -f new_hosts_file`

**Validating Disk I/O and Memory Bandwidth**

Use the `gpcheckperf` utility to test disk I/O and memory bandwidth.

**To run gpcheckperf**

1. Run the `gpcheckperf` utility using the host file for new hosts. Use the `-d` option to specify the file systems you want to test on each host. You must have write access to these directories. For example:

   `$ gpcheckperf -f new_hosts_file -d /data1 -d /data2 -v`

2. The utility may take a long time to perform the tests because it is copying very large files between the hosts. When it is finished, you will see the summary results for the Disk Write, Disk Read, and Stream tests.

   For a network divided into subnets, repeat this procedure with a separate host file for each subnet.

**Integrating New Hardware into the System**

Before initializing the system with the new segments, shut down the system with `gpstop` to prevent user activity from skewing performance test results. Then, repeat the performance tests using host files that include all nodes, existing and new:

- **Verifying OS Settings**
- **Validating Disk I/O and Memory Bandwidth**

**Initializing New Segments**

Use the `gxpexpand` utility to initialize the new segments, create the expansion schema, and set a system-wide random distribution policy for the database.

The first time you run `gxpexpand` with a valid input file it creates the expansion schema and sets the distribution policy for all tables to `DISTRIBUTED RANDOMLY`. After these steps are completed, running `gxpexpand` detects if the expansion schema has been created and, if so, performs table redistribution.

- **Creating an Input File for System Expansion**
- **Running gxpexpand to Initialize New Segments**
- **Rolling Back a Failed Expansion Setup**
Creating an Input File for System Expansion

To begin expansion, `gpexpand` requires an input file containing information about the new segments and hosts. If you run `gpexpand` without specifying an input file, the utility displays an interactive interview that collects the required information and automatically creates an input file.

If you create the input file using the interactive interview, you may specify a file with a list of expansion hosts in the interview prompt. If your platform or command shell limits the length of the host list, specifying the hosts with `-f` may be mandatory.

Creating an input file in Interactive Mode

Before you run `gpexpand` to create an input file in interactive mode, ensure you know:

- The number of new hosts (or a hosts file)
- The new hostnames (or a hosts file)
- The mirroring strategy used in existing hosts, if any
- The number of segments to add per host, if any

The utility automatically generates an input file based on this information, `dbid`, `content` ID, and data directory values stored in `gp_segment_configuration`, and saves the file in the current directory.

To create an input file in interactive mode

1. Log in on the master host as the user who will run your Greenplum Database system; for example, `gpadmin`.
2. Run `gpexpand`. The utility displays messages about how to prepare for an expansion operation, and it prompts you to quit or continue.
   
   Optionally, specify a hosts file using `-f`. For example:
   
   ```
   $ gpexpand -f /home/gpadmin/new_hosts_file
   ```

3. At the prompt, select `Y` to continue.
4. Unless you specified a hosts file using `-f`, you are prompted to enter hostnames. Enter a comma separated list of the hostnames of the new expansion hosts. Do not include interface hostnames. For example:

   ```
   > sdw4, sdw5, sdw6, sdw7
   ```

   To add segments to existing hosts only, enter a blank line at this prompt. Do not specify `localhost` or any existing host name.

5. Enter the mirroring strategy used in your system, if any. Options are `spread|grouped|none`. The default setting is `grouped`.
   
   Ensure you have enough hosts for the selected grouping strategy. For more information about mirroring, see `Planning Mirror Segments`.

6. Enter the number of new primary segments to add, if any. By default, new hosts are initialized with the same number of primary segments as existing hosts. Increase segments per host by entering a number greater than zero. The number you enter will be the number of additional segments initialized on all hosts. For example, if existing hosts currently have two segments each, entering a value of 2 initializes two more segments on existing hosts, and four segments on new hosts.

7. If you are adding new primary segments, enter the new primary data directory root for the new segments. Do not specify the actual data directory name, which is created automatically by `gpexpand` based on the existing data directory names.

   For example, if your existing data directories are as follows:

   ```
   /gpdata/primary/gp0
   ```
then enter the following (one at each prompt) to specify the data directories for two new primary segments:

```
/gpdata/primary
```

When the initialization runs, the utility creates the new directories gp2 and gp3 under /gpdata/primary.

**8.** If you are adding new mirror segments, enter the new mirror data directory root for the new segments. Do not specify the data directory name; it is created automatically by gpexpand based on the existing data directory names.

For example, if your existing data directories are as follows:

```
/gpdata/mirror/gp0
/gpdata/mirror/gp1
```

enter the following (one at each prompt) to specify the data directories for two new mirror segments:

```
/gpdata/mirror
```

When the initialization runs, the utility will create the new directories gp2 and gp3 under /gpdata/mirror.

These primary and mirror root directories for new segments must exist on the hosts, and the user running gpexpand must have permissions to create directories in them.

After you have entered all required information, the utility generates an input file and saves it in the current directory. For example:

```
gpexpand_inputfile_yyyymmdd_145134
```

**Expansion Input File Format**

Use the interactive interview process to create your own input file unless your expansion scenario has atypical needs.

The format for expansion input files is:

```
hostname:address:port:fselocation:dbid:content:preferred_role:replication_port
```

For example:

```
sdw5:sdw5-1:50011:/gpdata/primary/gp9:11:9:p:53011
sdw5:sdw5-2:50012:/gpdata/primary/gp10:12:10:p:53011
sdw5:sdw5-1:60012:/gpdata/mirror/gp10:14:10:m:63011
```

For each new segment, this format of expansion input file requires the following:

**Table 47: Data for the expansion configuration file**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Valid Values</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>hostname</td>
<td>Hostname</td>
<td>Hostname for the segment host.</td>
</tr>
<tr>
<td>Parameter</td>
<td>Valid Values</td>
<td>Description</td>
</tr>
<tr>
<td>--------------</td>
<td>--------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>port</td>
<td>An available port number</td>
<td>Database listener port for the segment, incremented on the existing segment port base number.</td>
</tr>
<tr>
<td>fselocation</td>
<td>Directory name</td>
<td>The data directory (filespace) location for a segment as per the pg_filespace_entry system catalog.</td>
</tr>
<tr>
<td>dbid</td>
<td>Integer. Must not conflict with existing dbid values.</td>
<td>Database ID for the segment. The values you enter should be incremented sequentially from existing dbid values shown in the system catalog gp_segment_configuration. For example, to add four nodes to an existing ten-segment array with dbid values of 1-10, list new dbid values of 11, 12, 13 and 14.</td>
</tr>
<tr>
<td>content</td>
<td>Integer. Must not conflict with existing content values.</td>
<td>The content ID of the segment. A primary segment and its mirror should have the same content ID, incremented sequentially from existing values. For more information, see content in the reference for gp_segment_configuration.</td>
</tr>
<tr>
<td>preferred_role</td>
<td>p</td>
<td>m</td>
</tr>
<tr>
<td>replication_port</td>
<td>An available port number</td>
<td>File replication port for the segment, incremented on the existing segment replication_port base number.</td>
</tr>
</tbody>
</table>

**Running gpexpand to Initialize New Segments**

After you have created an input file, run gpexpand to initialize new segments. The utility automatically stops Greenplum Database segment initialization and restarts the system when the process finishes.

**To run gpexpand with an input file**

1. Log in on the master host as the user who will run your Greenplum Database system; for example, gpadmin.
2. Run the gpexpand utility, specifying the input file with -i. Optionally, use -D to specify the database in which to create the expansion schema. For example:

   ```bash
   $ gpexpand -i input_file -D database1
   ```

   The utility detects if an expansion schema exists for the Greenplum Database system. If a schema exists, remove it with gpexpand -c before you start a new expansion operation. See *Removing the Expansion Schema*. |
When the new segments are initialized and the expansion schema is created, the utility prints a success message and exits.

When the initialization process completes, you can connect to Greenplum Database and view the expansion schema. The schema resides in the database you specified with `-D` or in the database specified by the `PGDATABASE` environment variable. For more information, see `About the Expansion Schema`.

**Rolling Back a Failed Expansion Setup**

You can roll back an expansion setup operation only if the operation fails.

If the expansion fails during the initialization step, while the database is down, you must first restart the database in master-only mode by running the `gpstart -m` command.

Roll back the failed expansion with the following command, specifying the database that contains the expansion schema:

```
gpexpand --rollback -D database_name
```

**Redistributing Tables**

Redistribute tables to balance existing data over the newly expanded cluster.

After creating an expansion schema, you can bring Greenplum Database back online and redistribute tables across the entire array with `gpexpand`. Aim to run this during low-use hours when the utility's CPU usage and table locks have minimal impact on operations. Rank tables to redistribute the largest or most critical tables first.

**Note:** When redistributing data, Greenplum Database must be running in production mode. Greenplum Database cannot be restricted mode or in master mode. The `gpstart` options `-R` or `-m` cannot be specified to start Greenplum Database.

While table redistribution is underway, any new tables or partitions created are distributed across all segments exactly as they would be under normal operating conditions. Queries can access all segments, even before the relevant data is redistributed to tables on the new segments. The table or partition being redistributed is locked and unavailable for read or write operations. When its redistribution completes, normal operations resume.

- Ranking Tables for Redistribution
- Redistributing Tables Using `gpexpand`
- Monitoring Table Redistribution

**Ranking Tables for Redistribution**

For large systems, you can control the table redistribution order. Adjust tables' `rank` values in the expansion schema to prioritize heavily-used tables and minimize performance impact. Available free disk space can affect table ranking; see `Managing Redistribution in Large-Scale Greenplum Systems`.

To rank tables for redistribution by updating `rank` values in `gexpand.status_detail`, connect to Greenplum Database using `psql` or another supported client. Update `gexpand.status_detail` with commands such as:

```
=> UPDATE gexpand.status_detail SET rank=10;
=> UPDATE gexpand.status_detail SET rank=1 WHERE fq_name = 'public.lineitem';
=> UPDATE gexpand.status_detail SET rank=2 WHERE fq_name = 'public.orders';
```

These commands lower the priority of all tables to 10 and then assign a rank of 1 to `lineitem` and a rank of 2 to `orders`. When table redistribution begins, `lineitem` is redistributed first, followed by `orders` and
all other tables in `gpexpand.status_detail`. To exclude a table from redistribution, remove the table from `gpexpand.status_detail`.

**Redistributing Tables Using `gpexpand`**

**To redistribute tables with `gpexpand`**

1. Log in on the master host as the user who will run your Greenplum Database system, for example, `gpadmin`.

2. Run the `gpexpand` utility. You can use the `-d` or `-e` option to define the expansion session time period. For example, to run the utility for up to 60 consecutive hours:

   ```
   $ gpexpand -d 60:00:00
   ```

   The utility redistributes tables until the last table in the schema completes or it reaches the specified duration or end time. `gpexpand` updates the status and time in `gpexpand.status` when a session starts and finishes.

**Monitoring Table Redistribution**

You can query the expansion schema during the table redistribution process. The view `gpexpand.expansion_progress` provides a current progress summary, including the estimated rate of table redistribution and estimated time to completion. You can query the table `gpexpand.status_detail` for per-table status information.

**Viewing Expansion Status**

After the first table completes redistribution, `gpexpand.expansion_progress` calculates its estimates and refreshes them based on all tables' redistribution rates. Calculations restart each time you start a table redistribution session with `gpexpand`. To monitor progress, connect to Greenplum Database using `psql` or another supported client; query `gpexpand.expansion_progress` with a command like the following:

```
=# SELECT * FROM gpexpand.expansion_progress;
```

<table>
<thead>
<tr>
<th>name</th>
<th>value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bytes Left</td>
<td>5534842880</td>
</tr>
<tr>
<td>Bytes Done</td>
<td>142475264</td>
</tr>
<tr>
<td>Estimated Expansion Rate</td>
<td>680.75667095996092 MB/s</td>
</tr>
<tr>
<td>Estimated Time to Completion</td>
<td>00:01:01.008047</td>
</tr>
<tr>
<td>Tables Expanded</td>
<td>4</td>
</tr>
<tr>
<td>Tables Left</td>
<td>4</td>
</tr>
</tbody>
</table>

(6 rows)

**Viewing Table Status**

The table `gpexpand.status_detail` stores status, time of last update, and more facts about each table in the schema. To see a table's status, connect to Greenplum Database using `psql` or another supported client and query `gpexpand.status_detail`:

```
=> SELECT status, expansion_started, source_bytes FROM gpexpand.status_detail WHERE fq_name = 'public.sales';
```

<table>
<thead>
<tr>
<th>status</th>
<th>expansion_started</th>
<th>source_bytes</th>
</tr>
</thead>
<tbody>
<tr>
<td>COMPLETED</td>
<td>2017-02-20 10:54:10.043869</td>
<td>4929748992</td>
</tr>
</tbody>
</table>

(1 row)
Removing the Expansion Schema
To clean up after expanding the Greenplum cluster, remove the expansion schema.

You can safely remove the expansion schema after the expansion operation is complete and verified. To run another expansion operation on a Greenplum system, first remove the existing expansion schema.

To remove the expansion schema
1. Log in on the master host as the user who will be running your Greenplum Database system (for example, gpadmin).
2. Run the gpexpand utility with the -c option. For example:
   
   $ gpexpand -c
   $

   **Note:** Some systems require you to press Enter twice.

Migrating Data
Greenplum Database provides utilities that you can use to migrate data between Greenplum Database systems.

The gpcopy utility can migrate data between Greenplum Database systems running software version 5.9.0 or later. The utility can require less disk space to migrate between Greenplum Database systems that co-exist on the same hosts.

The gptransfer utility can migrate data between Greenplum Database installations running any 5.x version software.

   **Note:** gptransfer is deprecated and will be removed in the next major release of Greenplum Database.

Migrating Data with gpcopy
This topic describes how to use the gpcopy utility to transfer data between databases in different Greenplum Database clusters.

gpcopy is a high-performance utility that can copy metadata and data from one Greenplum database to another Greenplum database. You can migrate the entire contents of a database, or just selected tables. The clusters can have different Greenplum Database versions. For example, you can use gpcopy to migrate data from Greenplum 5 to Greenplum 6.

   **Note:** The gpcopy utility is available as a separate download for the commercial release of Pivotal Greenplum Database. See the Pivotal gpcopy Documentation.

Migrating Data with gptransfer
This topic describes how to use the gptransfer utility to transfer data between databases.

   **Note:** Greenplum Database provides two utilities for migrating data between Greenplum Database installations, gpcopy and gptransfer. Use gpcopy to migrate data to a Greenplum Database cluster version 5.9.0 and later. Use the gptransfer utility to migrate data between Greenplum Database installations running software version 5.8.0 or earlier.

   The gptransfer utility is deprecated and will be removed in the next major release of Greenplum Database. For information about migrating data with gpcopy, see Migrating Data with gpcopy.

The gptransfer migration utility transfers Greenplum Database metadata and data from one Greenplum database to another Greenplum database, allowing you to migrate the entire contents of a database, or just selected tables, to another database. The source and destination databases may be in the same or a
different cluster. Data is transferred in parallel across all the segments, using the `gpfdist` data loading utility to attain the highest transfer rates.

`gptransfer` handles the setup and execution of the data transfer. Participating clusters must already exist, have network access between all hosts in both clusters, and have certificate-authenticated ssh access between all hosts in both clusters.

The interface includes options to transfer one or more full databases, or one or more database tables. A full database transfer includes the database schema, table data, indexes, views, roles, user-defined functions, and resource queues. Configuration files, including `postgresql.conf` and `pg_hba.conf`, must be transferred manually by an administrator. Extensions installed in the database with `gppkg`, such as MADlib, must be installed in the destination database by an administrator.

See the *Greenplum Database Utility Guide* for complete syntax and usage information for the `gptransfer` utility.

**Prerequisites**

- The `gptransfer` utility can only be used with Greenplum Database. Apache HAWQ is not supported as a source or destination.
- The source and destination Greenplum clusters must both be version 4.2 or higher.
- At least one Greenplum instance must include the `gptransfer` utility in its distribution. If neither the source or destination includes `gptransfer`, you must upgrade one of the clusters to use `gptransfer`.
- The `gptransfer` utility can be run from the cluster with the source or destination database.
- The number of segments in the destination cluster must be greater than or equal to the number of hosts in the source cluster. The number of segments in the destination may be smaller than the number of segments in the source, but the data will transfer at a slower rate.
- The segment hosts in both clusters must have network connectivity with each other.
- Every host in both clusters must be able to connect to every other host with certificate-authenticated SSH. You can use the `gpssh_exkeys` utility to exchange public keys between the hosts of both clusters.

**What gptransfer Does**

`gptransfer` uses writable and readable external tables, the Greenplum `gpfdist` parallel data-loading utility, and named pipes to transfer data from the source database to the destination database. Segments on the source cluster select from the source database table and insert into a writable external table. Segments in the destination cluster select from a readable external table and insert into the destination database table. The writable and readable external tables are backed by named pipes on the source cluster's segment hosts, and each named pipe has a `gpfdist` process serving the pipe's output to the readable external table on the destination segments.

`gptransfer` orchestrates the process by processing the database objects to be transferred in batches. For each table to be transferred, it performs the following tasks:

- creates a writable external table in the source database
- creates a readable external table in the destination database
- creates named pipes and `gpfdist` processes on segment hosts in the source cluster
- executes a `SELECT INTO` statement in the source database to insert the source data into the writable external table
- executes a `SELECT INTO` statement in the destination database to insert the data from the readable external table into the destination table
- optionally validates the data by comparing row counts or MD5 hashes of the rows in the source and destination
- cleans up the external tables, named pipes, and `gpfdist` processes
Fast Mode and Slow Mode

`gptransfer` sets up data transfer using the `gpfdist` parallel file serving utility, which serves the data evenly to the destination segments. Running more `gpfdist` processes increases the parallelism and the data transfer rate. When the destination cluster has the same or a greater number of segments than the source cluster, `gptransfer` sets up one named pipe and one `gpfdist` process for each source segment. This is the configuration for optimal data transfer rates and is called fast mode. The following figure illustrates a setup on a segment host when the destination cluster has at least as many segments as the source cluster.

The configuration of the input end of the named pipes differs when there are fewer segments in the destination cluster than in the source cluster. `gptransfer` handles this alternative setup automatically. The difference in configuration means that transferring data into a destination cluster with fewer segments than the source cluster is not as fast as transferring into a destination cluster of the same or greater size. It is called slow mode because there are fewer `gpfdist` processes serving the data to the destination cluster, although the transfer is still quite fast with one `gpfdist` per segment host.

When the destination cluster is smaller than the source cluster, there is one named pipe per segment host and all segments on the host send their data through it. The segments on the source host write their data to a writable external web table connected to a `gpfdist` process on the input end of the named pipe. This consolidates the table data into a single named pipe. A `gpfdist` process on the output of the named pipe serves the consolidated data to the destination cluster. The following figure illustrates this configuration.
On the destination side, `gptransfer` defines a readable external table with the `gpfdist` server on the source host as input and selects from the readable external table into the destination table. The data is distributed evenly to all the segments in the destination cluster.

**Batch Size and Sub-batch Size**

The degree of parallelism of a `gptransfer` execution is determined by two command-line options: `--batch-size` and `--sub-batch-size`. The `--batch-size` option specifies the number of tables to transfer in a batch. The default batch size is 2, which means that two table transfers are in process at any time. The minimum batch size is 1 and the maximum is 10. The `--sub-batch-size` parameter specifies the maximum number of parallel sub-processes to start to do the work of transferring a table. The default is 25 and the maximum is 50. The product of the batch size and sub-batch size is the amount of parallelism. If set to the defaults, for example, `gptransfer` can perform 50 concurrent tasks. Each thread is a Python process and consumes memory, so setting these values too high can cause a Python Out of Memory error. For this reason, the batch sizes should be tuned for your environment.

**Preparing Hosts for gptransfer**

When you install a Greenplum Database cluster, you set up all the master and segment hosts so that the Greenplum Database administrative user (`gpadmin`) can connect with SSH from every host in the cluster to any other host in the cluster without providing a password. The `gptransfer` utility requires this capability between every host in the source and destination clusters. First, ensure that the clusters have network connectivity with each other. Then, prepare a hosts file containing a list of all the hosts in both clusters, and use the `gpssh-exkeys` utility to exchange keys. See the reference for `gpssh-exkeys` in the Greenplum Database Utility Guide.

The host map file is a text file that lists the segment hosts in the source cluster. It is used to enable communication between the hosts in Greenplum clusters. The file is specified on the `gptransfer` command line with the `--source-map-file=host_map_file` command option. It is a required option when using `gptransfer` to copy data between two separate Greenplum clusters.
The file contains a list in the following format:

```
host1_name,host1_ip_addr
host2_name,host2_ipaddr
...
```

The file uses IP addresses instead of host names to avoid any problems with name resolution between the clusters.

**Limitations**

gptransfer transfers data from user databases only; the postgres, template0, and template1 databases cannot be transferred. Administrators must transfer configuration files manually and install extensions into the destination database with gppkg.

The destination cluster must have at least as many segments as the source cluster has segment hosts. Transferring data to a smaller cluster is not as fast as transferring data to a larger cluster.

Transferring small or empty tables can be unexpectedly slow. There is significant fixed overhead in setting up external tables and communications processes for parallel data loading between segments that occurs whether or not there is actual data to transfer. It can be more efficient to transfer the schema and smaller tables to the destination database using other methods, then use gptransfer with the -t option to transfer large tables.

When transferring data between databases, you can run only one instance of gptransfer at a time. Running multiple, concurrent instances of gptransfer is not supported.

**Full Mode and Table Mode**

When run with the `--full` option, gptransfer copies all user-created databases, tables, views, indexes, roles, user-defined functions, and resource queues in the source cluster to the destination cluster. The destination system cannot contain any user-defined databases, only the default databases postgres, template0, and template1. If gptransfer finds a database on the destination it fails with a message like the following:

```
[ERROR]:: gptransfer: error: --full option specified but tables exist on
destination system
```

**Note:** The `--full` option cannot be specified with the `-t`, `-d`, `-f`, or `--partition-transfer` options.

To copy tables individually, specify the tables using either the `-t` command-line option (one option per table) or by using the `-f` command-line option to specify a file containing a list of tables to transfer. Tables are specified in the fully-qualified format `database.schema.table`. The table definition, indexes, and table data are copied. The database must already exist on the destination cluster.

By default, gptransfer fails if you attempt to transfer a table that already exists in the destination database:

```
[INFO]::Validating transfer table set...
[CRITICAL]:: gptransfer failed. (Reason='Table database.schema.table exists in database database.') exiting...
```

Override this behavior with the `--skip-existing`, `--truncate`, or `--drop` options.

The following table shows the objects that are copied in full mode and table mode.

<table>
<thead>
<tr>
<th>Object</th>
<th>Full Mode</th>
<th>Table Mode</th>
</tr>
</thead>
<tbody>
<tr>
<td>Data</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>Object</td>
<td>Full Mode</td>
<td>Table Mode</td>
</tr>
<tr>
<td>-------------</td>
<td>-----------</td>
<td>------------</td>
</tr>
<tr>
<td>Indexes</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>Roles</td>
<td>Yes</td>
<td>No</td>
</tr>
<tr>
<td>Functions</td>
<td>Yes</td>
<td>No</td>
</tr>
<tr>
<td>Resource Queues</td>
<td>Yes</td>
<td>No</td>
</tr>
<tr>
<td>postgresql.conf</td>
<td>No</td>
<td>No</td>
</tr>
<tr>
<td>pg_hba.conf</td>
<td>No</td>
<td>No</td>
</tr>
<tr>
<td>gpkg</td>
<td>No</td>
<td>No</td>
</tr>
</tbody>
</table>

The --full option and the --schema-only option can be used together if you want to copy databases in phases, for example, during scheduled periods of downtime or low activity. Run `gptransfer --full --schema-only ...` to create the databases on the destination cluster, but with no data. Then you can transfer the tables in stages during scheduled down times or periods of low activity. Be sure to include the --truncate or --drop option when you later transfer tables to prevent the transfer from failing because the table already exists at the destination.

**Locking**

The -x option enables table locking. An exclusive lock is placed on the source table until the copy and validation, if requested, are complete.

**Validation**

By default, `gptransfer` does not validate the data transferred. You can request validation using the --validate=type option. The validation type can be one of the following:

- count – Compares the row counts for the tables in the source and destination databases.
- md5 – Sorts tables on both source and destination, and then performs a row-by-row comparison of the MD5 hashes of the sorted rows.

If the database is accessible during the transfer, be sure to add the -x option to lock the table. Otherwise, the table could be modified during the transfer, causing validation to fail.

**Failed Transfers**

A failure on a table does not end the `gptransfer` job. When a transfer fails, `gptransfer` displays an error message and adds the table name to a failed transfers file. At the end of the `gptransfer` session, `gptransfer` writes a message telling you there were failures, and providing the name of the failed transfer file. For example:

```
[WARNING]:-Some tables failed to transfer. A list of these tables
[WARNING]:-has been written to the file
  failed_transfer_tables_20140808_101813.txt
[WARNING]:-This file can be used with the -f option to continue
```

The failed transfers file is in the format required by the -f option, so you can use it to start a new `gptransfer` session to retry the failed transfers.

**Best Practices**

Be careful not to exceed host memory by specifying too much parallelism with the --batch-size and --sub-batch-size command line options. Too many sub-processes can exhaust memory, causing a Python Out of Memory error. Start with a smaller batch size and sub-batch size, and increase based on your experiences.
Transfer a database in stages. First, run `gptransfer` with the `--schema-only` and `-d database` options, then transfer the tables in phases. After running `gptransfer` with the `--schema-only` option, be sure to add the `--truncate` or `--drop` option to prevent a failure because a table already exists.

Be careful choosing `gpfdist` and external table parameters such as the delimiter for external table data and the maximum line length. For example, don't choose a delimiter that can appear within table data.

If you have many empty tables to transfer, consider a DDL script instead of `gptransfer`. The `gptransfer` overhead to set up each table for transfer is significant and not an efficient way to transfer empty tables.

`gptransfer` creates table indexes before transferring the data. This slows the data transfer since indexes are updated at the same time the data is inserted in the table. For large tables especially, consider dropping indexes before running `gptransfer` and recreating the indexes when the transfer is complete.

**Monitoring a Greenplum System**

You can monitor a Greenplum Database system using a variety of tools included with the system or available as add-ons. SNMP support allows Greenplum to be integrated with popular system management frameworks.

Observing the Greenplum Database system day-to-day performance helps administrators understand the system behavior, plan workflow, and troubleshoot problems. This chapter discusses tools for monitoring database performance and activity.

Also, be sure to review `Recommended Monitoring and Maintenance Tasks` for monitoring activities you can script to quickly detect problems in the system.

**Monitoring Database Activity and Performance**

Greenplum Database includes an optional system monitoring and management database, `gpperfmon`, that administrators can enable. The `gpperfmon_install` command-line utility creates the `gpperfmon` database and enables data collection agents that collect and store query and system metrics in the database. Administrators can query metrics in the `gpperfmon` database. See the documentation for the `gpperfmon` database in the `Greenplum Database Reference Guide`.

Pivotal Greenplum Command Center, an optional web-based interface, graphically displays the metrics collected in the `gpperfmon` database and provides additional system management tools. Download the Greenplum Command Center package from `Pivotal Network` and view the documentation at the `Greenplum Command Center Documentation` web site.

**Monitoring System State**

As a Greenplum Database administrator, you must monitor the system for problem events such as a segment going down or running out of disk space on a segment host. The following topics describe how to monitor the health of a Greenplum Database system and examine certain state information for a Greenplum Database system.

- Enabling System Alerts and Notifications
- Checking System State
- Checking Disk Space Usage
- Checking for Data Distribution Skew
- Viewing Metadata Information about Database Objects
- Viewing Session Memory Usage Information
- Viewing Query Workfile Usage Information
Enabling System Alerts and Notifications

You can configure a Greenplum Database system to trigger SNMP (Simple Network Management Protocol) alerts or send email notifications to system administrators if certain database events occur. These events include:

- All **PANIC**-level error conditions
- All **FATAL**-level error conditions
- **ERROR**-level conditions that are "internal errors" (for example, SIGSEGV errors)
- Database system shutdown and restart
- Segment failure and recovery
- Standby master out-of-sync conditions
- Master host manual shutdown or other software problem (in certain failure scenarios, Greenplum Database cannot send an alert or notification)

This topic includes the following sub-topics:

- Using SNMP with a Greenplum Database System
- Enabling Email Notifications

Note that SNMP alerts and email notifications report the same event information. There is no difference in the event information that either tool reports. For information about the SNMP event information, see Greenplum Database SNMP OIDs and Error Codes.

Using SNMP with a Greenplum Database System

Greenplum Database supports SNMP to monitor the state of a Greenplum Database system using MIBs (Management Information Bases). MIBs are collections of objects that describe an SNMP-manageable entity — in this case, a Greenplum Database system.

The Greenplum Database SNMP support allows a Network Management System to obtain information about the hardware, operating system, and Greenplum Database from the same port (161) and IP address. It also enables the auto-discovery of Greenplum Database instances.

Prerequisites

Before setting up SNMP support on Greenplum Database, ensure SNMP is installed on the master host. If the `snmpd` file is not present in the `/usr/sbin` directory, then SNMP is not installed on the system. Depending on the platform on which you are running Greenplum Database, install the following:

<table>
<thead>
<tr>
<th>Operating System</th>
<th>Packages¹</th>
</tr>
</thead>
<tbody>
<tr>
<td>Red Hat Enterprise</td>
<td>net-snmp</td>
</tr>
<tr>
<td></td>
<td>net-snmp-libs</td>
</tr>
<tr>
<td></td>
<td>net-snmp-utils</td>
</tr>
<tr>
<td>CentOS</td>
<td>net-snmp</td>
</tr>
<tr>
<td>SUSE</td>
<td>N/A</td>
</tr>
</tbody>
</table>

1. SNMP is installed by default on SUSE platforms.

The `snmp.conf` configuration file is located in `/etc/snmp/`.
**Pre-installation Tasks**

After you establish that SNMP is on the master host, log in as `root`, open a text editor, and edit the `path_to/snmp/snmpd.conf` file. To use SNMP with Greenplum Database, the minimum configuration change required to the `snmpd.conf` file is specifying a community name. For example:

```
rocommunity public
```

**Note:** Replace `public` with the name of your SNMP community. You should also configure `syslocation` and `syscontact`. Configure other SNMP settings as required for your environment and save the file.

For more information about the `snmpd.conf` file, enter:

```
man snmpd.conf
```

**Note:** On SUSE Linux platforms, make sure to review and configure security settings in the `snmp.conf` file so `snmpd` accepts connections from sub-agents and returns all available Object IDs (OIDs).

After you finish configuring the `snmpd.conf` file, start the system `snmpd` daemon:

```
# /sbin/chkconfig snmpd on
```

Then, verify the system `snmpd` daemon is running. Enter:

```
# snmpwalk -v 1 -c community_name localhost .1.3.6.1.2.1.1.1.0
```

For example:

```
# snmpwalk -v 1 -c public localhost .1.3.6.1.2.1.1.1.0
```

If this command returns "Timeout: No Response from localhost", then the system `snmpd` daemon is not running. If the daemon is running, output similar to the following displays:

```
SNMPv2-MIB::sysDescr.0 = STRING: Linux hostname 2.6.18-92.el5 #1 SMP Tue Jun 10 18:51:06 EDT 2016 x86_64
```

**Setting up SNMP Notifications**

1. To configure a Greenplum Database system to send SNMP notifications when alerts occur, set the following parameters on the Greenplum Database master host with the `gpconfig` utility:
   - `gp_snmp_community`: Set this parameter to the community name you specified for your environment.
   - `gp_snmp_monitor_address`: Enter the `hostname:port` of your network monitor application. Typically, the port number is 162. If there are multiple monitor addresses, separate them with a comma.
   - `gp_snmp_use_inform_or_trap`: Enter either `trap` or `inform`. Trap notifications are SNMP messages sent from one application to another (for example, between Greenplum Database and a network monitoring application). These messages are unacknowledged by the monitoring application, but generate less network overhead. Inform notifications are the same as trap messages, except the application sends an acknowledgement to the application that generated the alert. In this case, the monitoring application sends acknowledgement messages to Greenplum Database-generated trap notifications. While inform messages create more overhead, they inform Greenplum Database the monitoring application has received the traps.
The following example commands set the server configuration parameters with the Greenplum Database gpconfig utility:

```bash
$ gpconfig -c gp_snmp_community -v public --masteronly
$ gpconfig -c gp_snmp_monitor_address -v mdw:162 --masteronly
$ gpconfig -c gp_snmp_use_inform_or_trap -v trap --masteronly
```

2. To test SNMP notifications, you can use the `snmptrapd` trap receiver. As root, enter:

```
# /usr/sbin/snmptrapd -m ALL -Lf ~/filename.log
```

`-Lf` indicates that traps are logged to a file. `-Le` indicates that traps are logged to `stderr` instead. `-m` `ALL` loads all available MIBs (you can also specify individual MIBs if required).

### Enabling Email Notifications

Complete the following steps to enable Greenplum Database to send email notifications to system administrators whenever certain database events occur.

1. Open `$MASTER_DATA_DIRECTORY/postgresql.conf` in a text editor.
2. In the `EMAIL ALERTS` section, uncomment the following parameters and enter the appropriate values for your email server and domain. For example:

   ```
gp_email_smtp_server='smtp.company.com:25'
gp_email_smtp_userid='gpadmin@example.com'
gp_email_smtp_password='mypassword'
gp_email_from='Greenplum Database <gpadmin@example.com>'
gp_email_to='dba@example.com;John Smith <jsmith@example.com>'
```

You may create specific email accounts or groups in your email system that send and receive email alerts from the Greenplum Database system. For example:

```
gp_email_from='GPDB Production Instance <gpdb@example.com>'
gp_email_to='gpdb_dba_group@example.com'
```

You can also specify multiple email addresses for both `gp_email` parameters. Use a semi-colon (`;`) to separate each email address. For example:

```
gp_email_to='gpdb_dba_group@example.com;admin@example.com'
```

3. Save and close the `postgresql.conf` file.
4. Reload the Greenplum Database `postgresql.conf` file:

```
$ gpstop -u
```

### Testing Email Notifications

The Greenplum Database master host must be able to connect to the SMTP email server you specify for the `gp_email_smtp_server` parameter. To test connectivity, use the `ping` command:

```
$ ping <my_email_server>
```

If the master host can contact the SMTP server, run this `psql` command to log into a database and test email notification with the `gp_elog` function:

```
$ psql -d <testdb> -U gpadmin -c "SELECT gp_elog('Test GPDB Email',true);"
```

The address you specified for the `gp_email_to` parameter should receive an email with `Test GPDB Email` in the subject line.
Note: If you have difficulty sending and receiving email notifications, verify the security settings for your organization's email server and firewall.

Checking System State

A Greenplum Database system is comprised of multiple PostgreSQL instances (the master and segments) spanning multiple machines. To monitor a Greenplum Database system, you need to know information about the system as a whole, as well as status information of the individual instances. The `gpstate` utility provides status information about a Greenplum Database system.

Viewing Master and Segment Status and Configuration

The default `gpstate` action is to check segment instances and show a brief status of the valid and failed segments. For example, to see a quick status of your Greenplum Database system:

```
$ gpstate
```

To see more detailed information about your Greenplum Database array configuration, use `gpstate` with the `-s` option:

```
$ gpstate -s
```

Viewing Your Mirroring Configuration and Status

If you are using mirroring for data redundancy, you may want to see the list of mirror segment instances in the system, their current synchronization status, and the mirror to primary mapping. For example, to see the mirror segments in the system and their status:

```
$ gpstate -m
```

To see the primary to mirror segment mappings:

```
$ gpstate -c
```

To see the status of the standby master mirror:

```
$ gpstate -f
```

Checking Disk Space Usage

A database administrator's most important monitoring task is to make sure the file systems where the master and segment data directories reside do not grow to more than 70 percent full. A filled data disk will not result in data corruption, but it may prevent normal database activity from continuing. If the disk grows too full, it can cause the database server to shut down.

You can use the `gp_disk_free` external table in the `gp_toolkit` administrative schema to check for remaining free space (in kilobytes) on the segment host file systems. For example:

```
=# SELECT * FROM gp_toolkit.gp_disk_free
    ORDER BY dfsegment;
```

Checking Sizing of Distributed Databases and Tables

The `gp_toolkit` administrative schema contains several views that you can use to determine the disk space usage for a distributed Greenplum Database database, schema, table, or index.

For a list of the available sizing views for checking database object sizes and disk space, see the *Greenplum Database Reference Guide*. 
**Viewing Disk Space Usage for a Database**

To see the total size of a database (in bytes), use the `gp_size_of_database` view in the `gp_toolkit` administrative schema. For example:

```
=> SELECT * FROM gp_toolkit.gp_size_of_database
    ORDER BY sodddatname;
```

**Viewing Disk Space Usage for a Table**

The `gp_toolkit` administrative schema contains several views for checking the size of a table. The table sizing views list the table by object ID (not by name). To check the size of a table by name, you must look up the relation name (`relname`) in the `pg_class` table. For example:

```
=> SELECT relname AS name, sotdsize AS size, sotdtoastsize AS toast
    sotdadditionalsize AS other
    FROM gp_toolkit.gp_size_of_table_disk as sotd, pg_class
    WHERE sotd.sotdoid=pg_class.oid ORDER BY relname;
```

For a list of the available table sizing views, see the *Greenplum Database Reference Guide*.

**Viewing Disk Space Usage for Indexes**

The `gp_toolkit` administrative schema contains a number of views for checking index sizes. To see the total size of all index(es) on a table, use the `gp_size_of_all_table_indexes` view. To see the size of a particular index, use the `gp_size_of_index` view. The index sizing views list tables and indexes by object ID (not by name). To check the size of an index by name, you must look up the relation name (`relname`) in the `pg_class` table. For example:

```
=> SELECT soisize, relname as indexname
    FROM pg_class, gp_toolkit.gp_size_of_index
    WHERE pg_class.oid=gp_size_of_index.soioid
    AND pg_class.relkind='i';
```

**Checking for Data Distribution Skew**

All tables in Greenplum Database are distributed, meaning their data is divided evenly across all of the segments in the system. Unevenly distributed data may diminish query processing performance. A table’s distribution policy is determined at table creation time. For information about choosing the table distribution policy, see the following topics:

- Viewing a Table’s Distribution Key
- Viewing Data Distribution
- Checking for Query Processing Skew

The `gp_toolkit` administrative schema also contains a number of views for checking data distribution skew on a table. For information about how to check for uneven data distribution, see the *Greenplum Database Reference Guide*.

**Viewing a Table’s Distribution Key**

To see the columns used as the data distribution key for a table, you can use the `\d+` meta-command in `psql` to examine the definition of a table. For example:

```
=# \d+ sales

<table>
<thead>
<tr>
<th>Column</th>
<th>Type</th>
<th>Modifiers</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sale_id</td>
<td>integer</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
```

463
Viewing Data Distribution

To see the data distribution of a table’s rows (the number of rows on each segment), you can run a query such as:

```sql
=# SELECT gp_segment_id, count(*)
    FROM table_name
    GROUP BY gp_segment_id;
```

A table is considered to have a balanced distribution if all segments have roughly the same number of rows.

Checking for Query Processing Skew

When a query is being processed, all segments should have equal workloads to ensure the best possible performance. If you identify a poorly-performing query, you may need to investigate further using the `EXPLAIN` command. For information about using the `EXPLAIN` command and query profiling, see Query Profiling.

Query processing workload can be skewed if the table’s data distribution policy and the query predicates are not well matched. To check for processing skew, you can run a query such as:

```sql
=# SELECT gp_segment_id, count(*)
    FROM table_name
    WHERE column='value'
    GROUP BY gp_segment_id;
```

This will show the number of rows returned by segment for the given `WHERE` predicate.

Avoiding an Extreme Skew Warning

You may receive the following warning message while executing a query that performs a hash join operation:

Extreme skew in the innerside of Hashjoin

This occurs when the input to a hash join operator is skewed. It does not prevent the query from completing successfully. You can follow these steps to avoid skew in the plan:

1. Ensure that all fact tables are analyzed.
2. Verify that any populated temporary table used by the query is analyzed.
3. View the `EXPLAIN ANALYZE` plan for the query and look for the following:
   - If there are scans with multi-column filters that are producing more rows than estimated, then set the `gp_selectivity_damping_factor` server configuration parameter to 2 or higher and retest the query.
   - If the skew occurs while joining a single fact table that is relatively small (less than 5000 rows), set the `gp_segments_for_planner` server configuration parameter to 1 and retest the query.
4. Check whether the filters applied in the query match distribution keys of the base tables. If the filters and distribution keys are the same, consider redistributing some of the base tables with different distribution keys.
5. Check the cardinality of the join keys. If they have low cardinality, try to rewrite the query with different joining columns or or additional filters on the tables to reduce the number of rows. These changes could change the query semantics.
**Viewing Metadata Information about Database Objects**

Greenplum Database tracks various metadata information in its system catalogs about the objects stored in a database, such as tables, views, indexes and so on, as well as global objects such as roles and tablespaces.

**Viewing the Last Operation Performed**

You can use the system views `pg_stat_operations` and `pg_stat_partition_operations` to look up actions performed on an object, such as a table. For example, to see the actions performed on a table, such as when it was created and when it was last vacuumed and analyzed:

```sql
=> SELECT schemaname as schema, objname as table, usename as role, actionname as action, subtype as type, statime as time
   FROM pg_stat_operations
   WHERE objname='cust';
```

<table>
<thead>
<tr>
<th>schema</th>
<th>table</th>
<th>role</th>
<th>action</th>
<th>type</th>
<th>time</th>
</tr>
</thead>
<tbody>
<tr>
<td>sales</td>
<td>cust</td>
<td>main</td>
<td>CREATE</td>
<td>TABLE</td>
<td>2016-02-09 18:10:07.867977-08</td>
</tr>
<tr>
<td>sales</td>
<td>cust</td>
<td>main</td>
<td>VACUUM</td>
<td></td>
<td>2016-02-10 13:32:39.068219-08</td>
</tr>
<tr>
<td>sales</td>
<td>cust</td>
<td>main</td>
<td>ANALYZE</td>
<td></td>
<td>2016-02-25 16:07:01.157168-08</td>
</tr>
</tbody>
</table>

(3 rows)

**Viewing the Definition of an Object**

To see the definition of an object, such as a table or view, you can use the `\d+` meta-command when working in `psql`. For example, to see the definition of a table:

```sql
=> \d+ mytable
```

**Viewing Session Memory Usage Information**

You can create and use the `session_level_memory_consumption` view that provides information about the current memory utilization for sessions that are running queries on Greenplum Database. The view contains session information and information such as the database that the session is connected to, the query that the session is currently running, and memory consumed by the session processes.

**Creating the session_level_memory_consumption View**

To create the `session_level_memory_consumption` view in a Greenplum Database, run the script `$GPHOME/share/postgresql/contrib/gp_session_state.sql` once for each database. For example, to install the view in the database `testdb`, use this command:

```bash
$ psql -d testdb -f $GPHOME/share/postgresql/contrib/gp_session_state.sql
```

**The session_level_memory_consumption View**

The `session_level_memory_consumption` view provides information about memory consumption and idle time for sessions that are running SQL queries.

When resource queue-based resource management is active, the column `is_runaway` indicates whether Greenplum Database considers the session a runaway session based on the vmem memory consumption of the session's queries. Under the resource queue-based resource management scheme, Greenplum Database considers the session a runaway when the queries consume an excessive amount of memory. The Greenplum Database server configuration parameter `runaway_detector_activation_percent` governs the conditions under which Greenplum Database considers a session a runaway session.
The `is_runaway`, `runaway_vmem_mb`, and `runaway_command_cnt` columns are not applicable when resource group-based resource management is active.

Table 49: `session_level_memory_consumption`

<table>
<thead>
<tr>
<th>column</th>
<th>type</th>

</tbody>
</table>
**Viewing Query Workfile Usage Information**

The Greenplum Database administrative schema `gp_toolkit` contains views that display information about Greenplum Database workfiles. Greenplum Database creates workfiles on disk if it does not have sufficient memory to execute the query in memory. This information can be used for troubleshooting and tuning queries. The information in the views can also be used to specify the values for the Greenplum Database configuration parameters `gp_workfile_limit_per_query` and `gp_workfile_limit_per_segment`.

These are the views in the schema `gp_toolkit`:

- The `gp_workfile_entries` view contains one row for each operator using disk space for workfiles on a segment at the current time.
- The `gp_workfile_usage_per_query` view contains one row for each query using disk space for workfiles on a segment at the current time.
- The `gp_workfile_usage_per_segment` view contains one row for each segment. Each row displays the total amount of disk space used for workfiles on the segment at the current time.

For information about using `gp_toolkit`, see Using `gp_toolkit`.

**Viewing the Database Server Log Files**

Every database instance in Greenplum Database (master and segments) runs a PostgreSQL database server with its own server log file. Daily log files are created in the `pg_log` directory of the master and each segment data directory.

**Log File Format**

The server log files are written in comma-separated values (CSV) format. Some log entries will not have values for all log fields. For example, only log entries associated with a query worker process will have the `slice_id` populated. You can identify related log entries of a particular query by the query's session identifier (`gp_session_id`) and command identifier (`gp_command_count`).

The following fields are written to the log:

**Table 50: Greenplum Database Server Log Format**

<table>
<thead>
<tr>
<th>#</th>

<td>stack_trace</td>
<td>text</td>
<td>Stack trace text associated with this message</td>
</tr>
</tbody>
</table>

**Searching the Greenplum Server Log Files**

Greenplum Database provides a utility called `gplogfilter` can search through a Greenplum Database log file for entries matching the specified criteria. By default, this utility searches through the Greenplum Database master log file in the default logging location. For example, to display the last three lines of the master log file:

```
$ gplogfilter -n 3
```
To search through all segment log files simultaneously, run `gplogfilter` through the `gpssh` utility. For example, to display the last three lines of each segment log file:

```
$ gpssh -f seg_host_file
=> source /usr/local/greenplum-db/greenplum_path.sh
=> gplogfilter -n 3 /gpdata/gp/*/pg_log/gpdb*.log
```

### Using gp_toolkit

Use the Greenplum Database administrative schema `gp_toolkit` to query the system catalogs, log files, and operating environment for system status information. The `gp_toolkit` schema contains several views you can access using SQL commands. The `gp_toolkit` schema is accessible to all database users. Some objects require superuser permissions. Use a command similar to the following to add the `gp_toolkit` schema to your schema search path:

```
=> ALTER ROLE myrole SET search_path TO myschema,gp_toolkit;
```

For a description of the available administrative schema views and their usages, see the *Greenplum Database Reference Guide*.

### Greenplum Database SNMP OIDs and Error Codes

When a Greenplum Database system is configured to trigger SNMP alerts or send email notifications to system administrators if certain database events occur, the alerts and notifications contain Object IDs (OIDs) and SQL error codes.

- **Greenplum Database SNMP OIDs**
- **SQL Standard Error Codes**

For information about enabling Greenplum Database to use SNMP, see *Enabling System Alerts and Notifications*.

#### Greenplum Database SNMP OIDs

This is the Greenplum Database OID hierarchy structure:

```
iso(1)  
identified-organization(3)  
dod(6)  
internet(1)  
private(4)  
enterprises(1)  
gpdbMIB(31327)  
gpdbObjects(1)  
gpdbAlertMsg(1)
```

- **gpdbAlertMsg**
  ```
  1.3.6.1.4.1.31327.1.1: STRING: alert message text
  ```

- **gpdbAlertSeverity**
  ```
  1.3.6.1.4.1.31327.1.2: INTEGER: severity level
  ```

gpdbAlertSeverity can have one of the following values:

- `gpdbSevUnknown(0)`
gpdbSevOk(1)
gpdbSevWarning(2)
gpdbSevError(3)
gpdbSevFatal(4)
gpdbSevPanic(5)
gpdbSevSystemDegraded(6)
gpdbSevSystemDown(7)

**gpdbAlertSqlstate**

1.3.6.1.4.1.31327.1.3: STRING: SQL standard error codes

For a list of codes, see SQL Standard Error Codes.

**gpdbAlertDetail**

1.3.6.1.4.1.31327.1.4: STRING: detailed alert message text

**gpdbAlertSqlStmt**

1.3.6.1.4.1.31327.1.5: STRING: SQL statement generating this alert if applicable

**gpdbAlertSystemName**

1.3.6.1.4.1.31327.1.6: STRING: hostname

**SQL Standard Error Codes**

The following table lists all the defined error codes. Some are not used, but are defined by the SQL standard. The error classes are also shown. For each error class there is a standard error code having the last three characters 000. This code is used only for error conditions that fall within the class but do not have any more-specific code assigned.

The PL/pgSQL condition name for each error code is the same as the phrase shown in the table, with underscores substituted for spaces. For example, code 22012, DIVISION BY ZERO, has condition name DIVISION_BY_ZERO. Condition names can be written in either upper or lower case.

**Note:** PL/pgSQL does not recognize warning, as opposed to error, condition names; those are classes 00, 01, and 02.

**Table 51: SQL Codes**

<table>
<thead>
<tr>
<th>Error Code</th>

### Routine System Maintenance Tasks

To keep a Greenplum Database system running efficiently, the database must be regularly cleared of expired data and the table statistics must be updated so that the query optimizer has accurate information.

Greenplum Database requires that certain tasks be performed regularly to achieve optimal performance. The tasks discussed here are required, but database administrators can automate them using standard UNIX tools such as `cron` scripts. An administrator sets up the appropriate scripts and checks that they execute successfully. See *Recommended Monitoring and Maintenance Tasks* for additional suggested maintenance activities you can implement to keep your Greenplum system running optimally.

### Routine Vacuum and Analyze

The design of the MVCC transaction concurrency model used in Greenplum Database means that deleted or updated data rows still occupy physical space on disk even though they are not visible to new transactions. If your database has many updates and deletes, many expired rows exist and the space they use must be reclaimed with the `VACUUM` command. The `VACUUM` command also collects table-level statistics, such as numbers of rows and pages, so it is also necessary to vacuum append-optimized tables, even when there is no space to reclaim from updated or deleted rows.

Vacuuming an append-optimized table follows a different process than vacuuming heap tables. On each segment, a new segment file is created and visible rows are copied into it from the current segment. When the segment file has been copied, the original is scheduled to be dropped and the new segment file is made available. This requires sufficient available disk space for a copy of the visible rows until the original segment file is dropped.

If the ratio of hidden rows to total rows in a segment file is less than a threshold value (10, by default), the segment file is not compacted. The threshold value can be configured with the `gp_appendonly_compaction_threshold` server configuration parameter. `VACUUM FULL` ignores the value of `gp_appendonly_compaction_threshold` and rewrites the segment file regardless of the ratio.

You can use the `__gp_aovisimap_compaction_info()` function in the `gp_toolkit` schema to investigate the effectiveness of a `VACUUM` operation on append-optimized tables.

For information about the `__gp_aovisimap_compaction_info()` function see, "Checking Append-Optimized Tables" in the *Greenplum Database Reference Guide*.

`VACUUM` can be disabled for append-optimized tables using the `gp_appendonly_compaction` server configuration parameter.

For details about vacuuming a database, see *Vacuuming the Database*.

For information about the `gp_appendonly_compaction_threshold` server configuration parameter and the `VACUUM` command, see the *Greenplum Database Reference Guide*.

### Transaction ID Management

Greenplum's MVCC transaction semantics depend on comparing transaction ID (XID) numbers to determine visibility to other transactions. Transaction ID numbers are compared using modulo $2^{32}$ arithmetic, so a Greenplum system that runs more than about two billion transactions can experience transaction ID wraparound, where past transactions appear to be in the future. This means past transactions' outputs become invisible. Therefore, it is necessary to `VACUUM` every table in every database at least once per two billion transactions.
Greenplum Database assigns XID values only to transactions that involve DDL or DML operations, which are typically the only transactions that require an XID.

**Important:** Greenplum Database monitors transaction IDs. If you do not vacuum the database regularly, Greenplum Database will generate a warning and error.

Greenplum Database issues the following warning when a significant portion of the transaction IDs are no longer available and before transaction ID wraparound occurs:

WARNING: database "database_name" must be vacuumed within number_of_transactions transactions

When the warning is issued, a VACUUM operation is required. If a VACUUM operation is not performed, Greenplum Database stops creating transactions when it reaches a limit prior to when transaction ID wraparound occurs. Greenplum Database issues this error when it stops creating transactions to avoid possible data loss:

FATAL: database is not accepting commands to avoid wraparound data loss in database "database_name"

The Greenplum Database configuration parameter xid_warn_limit controls when the warning is displayed. The parameter xid_stop_limit controls when Greenplum Database stops creating transactions.

**Recovering from a Transaction ID Limit Error**

When Greenplum Database reaches the xid_stop_limit transaction ID limit due to infrequent VACUUM maintenance, it becomes unresponsive. To recover from this situation, perform the following steps as database administrator:

1. Shut down Greenplum Database.
2. Temporarily lower the xid_stop_limit by 10,000,000.
3. Start Greenplum Database.
4. Run VACUUM FREEZE on all affected databases.
5. Reset the xid_stop_limit to its original value.
6. Restart Greenplum Database.

For information about the configuration parameters, see the Greenplum Database Reference Guide.

For information about transaction ID wraparound see the PostgreSQL documentation.

**System Catalog Maintenance**

Numerous database updates with CREATE and DROP commands increase the system catalog size and affect system performance. For example, running many DROP TABLE statements degrades the overall system performance due to excessive data scanning during metadata operations on catalog tables. The performance loss occurs between thousands to tens of thousands of DROP TABLE statements, depending on the system.

You should run a system catalog maintenance procedure regularly to reclaim the space occupied by deleted objects. If a regular procedure has not been run for a long time, you may need to run a more intensive procedure to clear the system catalog. This topic describes both procedures.

**Regular System Catalog Maintenance**

It is recommended that you periodically run REINDEX and VACUUM on the system catalog to clear the space that deleted objects occupy in the system indexes and tables. If regular database operations include numerous DROP statements, it is safe and appropriate to run a system catalog maintenance procedure with VACUUM daily at off-peak hours. You can do this while the system is available.

These are Greenplum Database system catalog maintenance steps.
1. Perform a `REINDEX` on the system catalog tables to rebuild the system catalog indexes. This removes bloat in the indexes and improves `VACUUM` performance.

   **Note:** When performing `REINDEX` on the system catalog tables, locking will occur on the tables and might have an impact on currently running queries. You can schedule the `REINDEX` operation during a period of low activity to avoid disrupting ongoing business operations.

2. Perform a `VACUUM` on the system catalog tables.

3. Perform an `ANALYZE` on the system catalog tables to update the catalog table statistics.

This example script performs a `REINDEX`, `VACUUM`, and `ANALYZE` of a Greenplum Database system catalog. In the script, replace `<database-name>` with a database name.

```bash
#!/bin/bash
DBNAME="<database-name>"
SYSTABLES="' pg_catalog.' || relname || ';' FROM pg_class a, pg_namespace b WHERE a.relnamespace=b.oid AND b.nspname='pg_catalog' AND a.relkind='r'"

reindexdb --system -d $DBNAME
psql -tc "SELECT 'VACUUM' || $SYSTABLES" $DBNAME | psql -a $DBNAME
analyzedb -s pg_catalog -d $DBNAME
```

**Note:** If you are performing catalog maintenance during a maintenance period and you need to stop a process due to time constraints, run the Greenplum Database function `pg_cancel_backend(<PID>)` to safely stop the Greenplum Database process.

### Intensive System Catalog Maintenance

If system catalog maintenance has not been performed in a long time, the catalog can become bloated with dead space; this causes excessively long wait times for simple metadata operations. A wait of more than two seconds to list user tables, such as with the `\d` metacommand from within `psql`, is an indication of catalog bloat.

If you see indications of system catalog bloat, you must perform an intensive system catalog maintenance procedure with `VACUUM FULL` during a scheduled downtime period. During this period, stop all catalog activity on the system; the `VACUUM FULL` system catalog maintenance procedure takes exclusive locks against the system catalog.

Running regular system catalog maintenance procedures can prevent the need for this more costly procedure.

These are steps for intensive system catalog maintenance.

1. Stop all catalog activity on the Greenplum Database system.
2. Perform a `REINDEX` on the system catalog tables to rebuild the system catalog indexes. This removes bloat in the indexes and improves `VACUUM` performance.
3. Perform a `VACUUM FULL` on the system catalog tables. See the following Note.
4. Perform an `ANALYZE` on the system catalog tables to update the catalog table statistics.

   **Note:** The system catalog table `pg_attribute` is usually the largest catalog table. If the `pg_attribute` table is significantly bloated, a `VACUUM FULL` operation on the table might require a significant amount of time and might need to be performed separately. The presence of both of these conditions indicate a significantly bloated `pg_attribute` table that might require a long `VACUUM FULL` time:

   - The `pg_attribute` table contains a large number of records.
   - The diagnostic message for `pg_attribute` is significant amount of bloat in the `gp_toolkit.gp_bloat_diag` view.
**Vacuum and Analyze for Query Optimization**

Greenplum Database uses a cost-based query optimizer that relies on database statistics. Accurate statistics allow the query optimizer to better estimate selectivity and the number of rows that a query operation retrieves. These estimates help it choose the most efficient query plan. The `ANALYZE` command collects column-level statistics for the query optimizer.

You can run both `VACUUM` and `ANALYZE` operations in the same command. For example:

```sql
=# VACUUM ANALYZE mytable;
```

Running the `VACUUM ANALYZE` command might produce incorrect statistics when the command is run on a table with a significant amount of bloat (a significant amount of table disk space is occupied by deleted or obsolete rows). For large tables, the `ANALYZE` command calculates statistics from a random sample of rows. It estimates the number rows in the table by multiplying the average number of rows per page in the sample by the number of actual pages in the table. If the sample contains many empty pages, the estimated row count can be inaccurate.

For a table, you can view information about the amount of unused disk space (space that is occupied by deleted or obsolete rows) in the `gp_toolkit` view `gp_bloat_diag`. If the `bdidiag` column for a table contains the value `significant amount of bloat suspected`, a significant amount of table disk space consists of unused space. Entries are added to the `gp_bloat_diag` view after a table has been vacuumed.

To remove unused disk space from the table, you can run the command `VACUUM FULL` on the table. Due to table lock requirements, `VACUUM FULL` might not be possible until a maintenance period.

As a temporary workaround, run `ANALYZE` to compute column statistics and then run `VACUUM` on the table to generate an accurate row count. This example runs `ANALYZE` and then `VACUUM` on the `cust_info` table.

```sql
ANALYZE cust_info;
VACUUM cust_info;
```

**Important:** If you intend to execute queries on partitioned tables with GPORCA enabled (the default), you must collect statistics on the partitioned table root partition with the `ANALYZE` command. For information about GPORCA, see Overview of GPORCA.

**Note:** You can use the Greenplum Database utility `analyzedb` to update table statistics. Tables can be analyzed concurrently. For append optimized tables, `analyzedb` updates statistics only if the statistics are not current. See the `analyzedb` utility.

**Routine Reindexing**

For B-tree indexes, a freshly-constructed index is slightly faster to access than one that has been updated many times because logically adjacent pages are usually also physically adjacent in a newly built index. Reindexing older indexes periodically can improve access speed. If all but a few index keys on a page have been deleted, there will be wasted space on the index page. A reindex will reclaim that wasted space.

In Greenplum Database it is often faster to drop an index (`DROP INDEX`) and then recreate it (`CREATE INDEX`) than it is to use the `REINDEX` command.

For table columns with indexes, some operations such as bulk updates or inserts to the table might perform more slowly because of the updates to the indexes. To enhance performance of bulk operations on tables with indexes, you can drop the indexes, perform the bulk operation, and then re-create the index.

**Managing Greenplum Database Log Files**

- **Database Server Log Files**
- **Management Utility Log Files**
Database Server Log Files

Greenplum Database log output tends to be voluminous, especially at higher debug levels, and you do not need to save it indefinitely. Administrators rotate the log files periodically so new log files are started and old ones are removed.

Greenplum Database has log file rotation enabled on the master and all segment instances. Daily log files are created in the `pg_log` subdirectory of the master and each segment data directory using the following naming convention: `gpdb-YYYY-MM-DD_hhmmss.csv`. Although log files are rolled over daily, they are not automatically truncated or deleted. Administrators need to implement scripts or programs to periodically clean up old log files in the `pg_log` directory of the master and each segment instance.

For information about viewing the database server log files, see Viewing the Database Server Log Files.

Management Utility Log Files

Log files for the Greenplum Database management utilities are written to `~/gpAdminLogs` by default. The naming convention for management log files is:

```
script_name_date.log
```

The log entry format is:

```
timestamp:utility:host:user:[INFO|WARN|FATAL]:message
```

The log file for a particular utility execution is appended to its daily log file each time that utility is run.

Recommended Monitoring and Maintenance Tasks

This section lists monitoring and maintenance activities recommended to ensure high availability and consistent performance of your Greenplum Database cluster.

The tables in the following sections suggest activities that a Greenplum System Administrator can perform periodically to ensure that all components of the system are operating optimally. Monitoring activities help you to detect and diagnose problems early. Maintenance activities help you to keep the system up-to-date and avoid deteriorating performance, for example, from bloated system tables or diminishing free disk space.

It is not necessary to implement all of these suggestions in every cluster; use the frequency and severity recommendations as a guide to implement measures according to your service requirements.
# Database State Monitoring Activities

## Table 52: Database State Monitoring Activities

<table>
<thead>
<tr>
<th>Activity</th>
<th>Procedure</th>
<th>Corrective Actions</th>
</tr>
</thead>
<tbody>
<tr>
<td>List segments that are currently down. If any rows are returned, this should generate a warning or alert. Recommended frequency: run every 5 to 10 minutes Severity: IMPORTANT</td>
<td>Run the following query in the postgres database: <code>SELECT * FROM gp_segment_configuration WHERE status &lt;&gt; 'u';</code></td>
<td>If the query returns any rows, follow these steps to correct the problem: 1. Verify that the hosts with down segments are responsive. 2. If hosts are OK, check the pg_log files for the primaries and mirrors of the down segments to discover the root cause of the segments going down. 3. If no unexpected errors are found, run the gprecoverseg utility to bring the segments back online.</td>
</tr>
<tr>
<td>Check for segments that are currently in change tracking mode. If any rows are returned, this should generate a warning or alert. Recommended frequency: run every 5 to 10 minutes Severity: IMPORTANT</td>
<td>Execute the following query in the postgres database: <code>SELECT * FROM gp_segment_configuration WHERE mode = 'c';</code></td>
<td>If the query returns any rows, follow these steps to correct the problem: 1. Verify that hosts with down segments are responsive. 2. If hosts are OK, check the pg_log files for the primaries and mirrors of the down segments to determine the root cause of the segments going down. 3. If no unexpected errors are found, run the gprecoverseg utility to bring the segments back online.</td>
</tr>
<tr>
<td>Check for segments that are currently re-syncing. If rows are returned, this should generate a warning or alert. Recommended frequency: run every 5 to 10 minutes Severity: IMPORTANT</td>
<td>Execute the following query in the postgres database: <code>SELECT * FROM gp_segment_configuration WHERE mode = 'r';</code></td>
<td>When this query returns rows, it implies that the segments are in the process of being re-synched. If the state does not change from 'r' to 's', then check the pg_log files from the primaries and mirrors of the affected segments for errors.</td>
</tr>
<tr>
<td>Activity</td>
<td>Procedure</td>
<td>Corrective Actions</td>
</tr>
<tr>
<td>-------------------------------------------------------------------------</td>
<td>----------------------------------------------------------------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Check for segments that are not operating in their optimal role.</td>
<td>Execute the following query in the postgres database:</td>
<td>When the segments are not running in their preferred role, hosts have uneven numbers of primary segments on each host, implying that processing is skewed. Wait for a potential window and restart the database to bring the segments into their preferred roles.</td>
</tr>
</tbody>
</table>
|                                                                         | ```sql
SELECT * FROM gp_segment_configuration
WHERE preferred_role <> role;
``` |                                                                                                                                                  |
| Recommended frequency: run every 5 to 10 minutes                         |                                                                            |                                                                                                                                                  |
| Severity: IMPORTANT                                                     |                                                                            |                                                                                                                                                  |
| Run a distributed query to test that it runs on all segments. One row   | Execute the following query in the postgres database:                      | If this query fails, there is an issue dispatching to some segments in the cluster. This is a rare event. Check the hosts that are not able to be dispatched to ensure there is no hardware or networking issue. |
|                                                                         | ```sql
SELECT gp_segment_id, count(*)
FROM gp_dist_random('pg_class')
GROUP BY 1;
``` |                                                                                                                                                  |
|                                                                         |                                                                            |                                                                                                                                                  |
| Test the state of master mirroring on a Greenplum Database 4.2 or earlier | Execute the following query in the postgres database:                      | Check the pg_log from the master and standby master for errors. If there are no unexpected errors and the machines are up, run the gpinitstandby utility to bring the standby online. This requires a database restart on GPDB 4.2 and earlier. |
| cluster. If the value is "Not Synchronized", raise an alert or warning. | ```sql
SELECT summary_state
FROM gp_master_mirroring;
``` |                                                                                                                                                  |
| Recommended frequency: run every 5 to 10 minutes                         |                                                                            |                                                                                                                                                  |
| Severity: IMPORTANT                                                     |                                                                            |                                                                                                                                                  |
| Test the state of master mirroring on Greenplum Database. If the value | Run the following psql command:                                             | Check the pg_log file from the master and standby master for errors. If there are no unexpected errors and the machines are up, run the gpinitstandby utility to bring the standby online. |
| is not "STREAMING", raise an alert or warning.                          | ```bash
psql dbname -c 'SELECT procpid, state FROM pg_stat_replication;'
``` |                                                                                                                                                  |
| Recommended frequency: run every 5 to 10 minutes                         |                                                                            |                                                                                                                                                  |
| Severity: IMPORTANT                                                     |                                                                            |                                                                                                                                                  |
| Perform a basic check to see if the master is up and functioning.       | Run the following query in the postgres database:                          | If this query fails the active master may be down. Try again several times and then inspect the active master manually. If the active master is down, reboot or power cycle the active master to ensure no processes remain on the active master and then trigger the activation of the standby master. |
|                                                                         | ```sql
SELECT count(*)
FROM gp_segment_configuration;
``` |                                                                                                                                                  |
| Recommended frequency: run every 5 to 10 minutes                         |                                                                            |                                                                                                                                                  |
| Severity: CRITICAL                                                     |                                                                            |                                                                                                                                                  |
### Database Alert Log Monitoring

**Table 53: Database Alert Log Monitoring Activities**

<table>
<thead>

<td>Corrective Actions</td>
</tr>
<tr>
<td>-------------------------------------------------------------------------</td>
<td>---------------------------------------------------------------------------</td>
<td>------------------------------------------------------------------------------------</td>
</tr>
</tbody>
</table>
| Check disk space usage on volumes used for Greenplum Database data storage and the OS. | Set up a disk space check.  
  • Set a threshold to raise an alert when a disk reaches a percentage of capacity. The recommended threshold is 75% full.  
  • It is not recommended to run the system with capacities approaching 100%. | Free space on the system by removing some data or files. |
| Check for errors or dropped packets on the network interfaces.            | Set up a network interface checks.                                         | Work with network and OS teams to resolve errors.                                  |
| Check for RAID errors or degraded RAID performance.                       | Set up a RAID check.                                                       |  
  • Replace failed disks as soon as possible.  
  • Work with system administration team to resolve other RAID or controller errors as soon as possible. |
| Run the Greenplum gpcheck utility to test that the configuration of the cluster complies with current recommendations. | Run gpcheck.                                                              | Work with system administration team to update configuration according to the recommendations made by the gpcheck utility. |
| Check for adequate I/O bandwidth and I/O skew.                           | Run the Greenplum gpcheckperf utility.                                     | The cluster may be under-specified if data transfer rates are not similar to the following:  
  • 2GB per second disk read  
  • 1 GB per second disk write  
  • 10 Gigabit per second network read and write  
  If transfer rates are lower than expected, consult with your data architect regarding performance expectations.  
  If the machines on the cluster display an uneven performance profile, work with the system administration team to fix faulty machines. |
## Catalog Monitoring

<td>monthly Severity: IMPORTANT</td>
<td>gpcheckcat -R dependency</td>
<td></td>
</tr>
</tbody>
</table>
### Data Maintenance

#### Table 56: Data Maintenance Activities

<table>
<thead>
<tr>
<th>Activity</th>
<th>Procedure</th>
<th>Corrective Actions</th>
</tr>
</thead>
</table>
| Check for missing statistics on tables. | Check the `gp_stats_missing` view in each database:  
`SELECT * FROM gp_toolkit.gp_stats_missing;` | Run `ANALYZE` on tables that are missing statistics. |
| Check for tables that have bloat (dead space) in data files that cannot be recovered by a regular `VACUUM` command.  
Recommended frequency: weekly or monthly  
Severity: WARNING | Check the `gp_bloat_diag` view in each database:  
`SELECT * FROM gp_toolkit.gp_bloat_diag;` | Execute a `VACUUM FULL` statement at a time when users are not accessing the table to remove bloat and compact the data. |

### Database Maintenance

#### Table 57: Database Maintenance Activities

<table>
<thead>
<tr>
<th>Activity</th>
<th>Procedure</th>
<th>Corrective Actions</th>
</tr>
</thead>
</table>
| Mark deleted rows in heap tables so that the space they occupy can be reused.  
Recommended frequency: daily  
Severity: CRITICAL | Vacuum user tables:  
`VACUUM <table>;` | Vacuum updated tables regularly to prevent bloating. |
| Update table statistics.  
Recommended frequency: after loading data and before executing queries  
Severity: CRITICAL | Analyze user tables. You can use the `analyzedb` management utility:  
`analyzedb -d <database> -a` | Analyze updated tables regularly so that the optimizer can produce efficient query execution plans. |
| Backup the database data.  
Recommended frequency: daily, or as required by your backup plan  
Severity: CRITICAL | Run the `gpcrondump` utility to create a backup of the master and segment databases in parallel. | Best practice is to have a current backup ready in case the database must be restored. |
Vacuum, reindex, and analyze system catalogs to maintain an efficient catalog.

Recommended frequency: weekly, or more often if database objects are created and dropped frequently

**Note:** Starting in Greenplum 5.x, VACUUM is supported with persistent table system catalogs, and is required to manage free space.

1. VACUUM the system tables in each database.
2. Run REINDEX SYSTEM in each database, or use the reindexdb command-line utility with the \(-s\) option:
   ```bash
   reindexdb -s <database>
   ```
3. ANALYZE each of the system tables:
   ```bash
   analyzedb -s pg_catalog -d <database>
   ```

The optimizer retrieves information from the system tables to create query plans. If system tables and indexes are allowed to become bloated over time, scanning the system tables increases query execution time. It is important to run ANALYZE after reindexing, because REINDEX leaves indexes with no statistics.

### Patching and Upgrading

**Table 58: Patch and Upgrade Activities**

<table>
<thead>
<tr>
<th>Activity</th>
<th>Procedure</th>
<th>Corrective Actions</th>
</tr>
</thead>
<tbody>
<tr>
<td>Ensure any bug fixes or enhancements are applied to the kernel.</td>
<td>Follow the vendor's instructions to update the Linux kernel.</td>
<td>Keep the kernel current to include bug fixes and security fixes, and to avoid difficult future upgrades.</td>
</tr>
<tr>
<td>Recommended frequency: at least every 6 months</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Severity: IMPORTANT</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Install Greenplum Database minor releases, for example 5.0.x.</td>
<td>Follow upgrade instructions in the Greenplum Database Release Notes. Always upgrade to the latest in the series.</td>
<td>Keep the Greenplum Database software current to incorporate bug fixes, performance enhancements, and feature enhancements into your Greenplum cluster.</td>
</tr>
<tr>
<td>Recommended frequency: quarterly</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Severity: IMPORTANT</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
Managing Greenplum Database Access

Securing Greenplum Database includes protecting access to the database through network configuration, database user authentication, and encryption.

This section contains the following topics:

- Configuring Client Authentication
  - Using LDAP Authentication with TLS/SSL
  - Using Kerberos Authentication
  - Managing Roles and Privileges

Configuring Client Authentication

This topic explains how to configure client connections and authentication for Greenplum Database.

When a Greenplum Database system is first initialized, the system contains one predefined superuser role. This role will have the same name as the operating system user who initialized the Greenplum Database system. This role is referred to as gpadmin. By default, the system is configured to only allow local connections to the database from the gpadmin role. If you want to allow any other roles to connect, or if you want to allow connections from remote hosts, you have to configure Greenplum Database to allow such connections. This section explains how to configure client connections and authentication to Greenplum Database.

Allowing Connections to Greenplum Database

Client access and authentication is controlled by the standard PostgreSQL host-based authentication file, pg_hba.conf. For detailed information about this file, see The pg_hba.conf File in the PostgreSQL documentation.

In Greenplum Database, the pg_hba.conf file of the master instance controls client access and authentication to your Greenplum Database system. The Greenplum Database segments also have pg_hba.conf files, but these are already correctly configured to allow only client connections from the master host. The segments never accept outside client connections, so there is no need to alter the pg_hba.conf file on segments.

The general format of the pg_hba.conf file is a set of records, one per line. Greenplum Database ignores blank lines and any text after the # comment character. A record consists of a number of fields that are separated by spaces or tabs. Fields can contain white space if the field value is quoted. Records cannot be continued across lines. Each remote client access record has the following format:

```
host  database  role  address  authentication-method
```

Each UNIX-domain socket access record is in this format:

```
local  database  role  authentication-method
```

The following table describes meaning of each field.

**Table 59: pg_hba.conf Fields**

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>local</td>
<td>Matches connection attempts using UNIX-domain sockets. Without a record of this type, UNIX-domain socket connections are disallowed.</td>
</tr>
<tr>
<td>Field</td>
<td>Description</td>
</tr>
<tr>
<td>-------</td>
<td>--------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>host</td>
<td>Matches connection attempts made using TCP/IP. Remote TCP/IP connections will not be possible unless the server is started with an appropriate value for the <code>listen_addresses</code> server configuration parameter.</td>
</tr>
<tr>
<td>hostssl</td>
<td>Matches connection attempts made using TCP/IP, but only when the connection is made with SSL encryption. SSL must be enabled at server start time by setting the <code>ssl</code> server configuration parameter.</td>
</tr>
<tr>
<td>hostnossl</td>
<td>Matches connection attempts made over TCP/IP that do not use SSL.</td>
</tr>
<tr>
<td>database</td>
<td>Specifies which database names this record matches. The value <code>all</code> specifies that it matches all databases. Multiple database names can be supplied by separating them with commas. A separate file containing database names can be specified by preceding the file name with a <code>@</code>.</td>
</tr>
<tr>
<td>role</td>
<td>Specifies which database role names this record matches. The value <code>all</code> specifies that it matches all roles. If the specified role is a group and you want all members of that group to be included, precede the role name with a <code>+</code>. Multiple role names can be supplied by separating them with commas. A separate file containing role names can be specified by preceding the file name with a <code>@</code>.</td>
</tr>
<tr>
<td>Field</td>
<td>Description</td>
</tr>
<tr>
<td>--------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>address</td>
<td>Specifies the client machine addresses that this record matches. This field can contain an IP address, an IP address range, or a host name.</td>
</tr>
<tr>
<td></td>
<td>An IP address range is specified using standard numeric notation for the range's starting address, then a slash (/) and a CIDR mask length. The mask length indicates the number of high-order bits of the client IP address that must match. Bits to the right of this should be zero in the given IP address. There must not be any white space between the IP address, the /, and the CIDR mask length.</td>
</tr>
<tr>
<td></td>
<td>Typical examples of an IPv4 address range specified this way are 172.20.143.89/32 for a single host, or 172.20.143.0/24 for a small network, or 10.6.0.0/16 for a larger one. An IPv6 address range might look like ::1/128 for a single host (in this case the IPv6 loopback address) or fe80::7a31:c1ff:0000:0000/96 for a small network. 0.0.0.0/0 represents all IPv4 addresses, and ::0/0 represents all IPv6 addresses. To specify a single host, use a mask length of 32 for IPv4 or 128 for IPv6. In a network address, do not omit trailing zeroes.</td>
</tr>
<tr>
<td></td>
<td>An entry given in IPv4 format will match only IPv4 connections, and an entry given in IPv6 format will match only IPv6 connections, even if the represented address is in the IPv4-in-IPv6 range.</td>
</tr>
<tr>
<td></td>
<td><strong>Note:</strong> Entries in IPv6 format will be rejected if the host system C library does not have support for IPv6 addresses.</td>
</tr>
<tr>
<td></td>
<td>If a host name is specified (an address that is not an IP address or IP range is treated as a host name), that name is compared with the result of a reverse name resolution of the client IP address (for example, reverse DNS lookup, if DNS is used). Host name comparisons are case insensitive. If there is a match, then a forward name resolution (for example, forward DNS lookup) is performed on the host name to check whether any of the addresses it resolves to are equal to the client IP address. If both directions match, then the entry is considered to match.</td>
</tr>
<tr>
<td></td>
<td>Some host name databases allow associating an IP address with multiple host names, but the operating system only returns one host name when asked to resolve an IP address. The host name that is used in <code>pg_hba.conf</code> must be the one that the address-to-name resolution of the client IP address returns, otherwise the line will not be considered a match.</td>
</tr>
<tr>
<td></td>
<td>When host names are specified in <code>pg_hba.conf</code>, you should ensure that name resolution is reasonably fast. It can be of advantage to set up a local name resolution cache such as <code>nscd</code>. Also, you can enable the server configuration parameter <code>log_hostname</code> to see the client host name instead of the IP address in the log.</td>
</tr>
<tr>
<td>IP-address</td>
<td>These fields can be used as an alternative to the CIDR address notation. Instead of specifying the mask length, the actual mask is specified in a separate column. For example, 255.0.0.0 represents an IPv4 CIDR mask length of 8, and 255.255.255.255 represents a CIDR mask length of 32.</td>
</tr>
<tr>
<td>IP-mask</td>
<td></td>
</tr>
<tr>
<td>authentication-method</td>
<td>Specifies the authentication method to use when connecting. Greenplum supports the <a href="https://www.postgresql.org/docs/9.0/auth-methods.html">authentication methods</a> supported by PostgreSQL 9.0.</td>
</tr>
</tbody>
</table>

**Caution:** For a more secure system, consider removing records for remote connections that use trust authentication from the `pg_hba.conf` file. Trust authentication grants any user who can connect to the server access to the database using any role they specify. You can safely replace...
trust authentication with ident authentication for local UNIX-socket connections. You can also use ident authentication for local and remote TCP clients, but the client host must be running an ident service and you must trust the integrity of that machine.

**Editing the pg_hba.conf File**

Initially, the `pg_hba.conf` file is set up with generous permissions for the gpadmin user and no database access for other Greenplum Database roles. You will need to edit the `pg_hba.conf` file to enable users' access to databases and to secure the gpadmin user. Consider removing entries that have trust authentication, since they allow anyone with access to the server to connect with any role they choose. For local (UNIX socket) connections, use ident authentication, which requires the operating system user to match the role specified. For local and remote TCP connections, ident authentication requires the client's host to run an ident service. You can install an ident service on the master host and then use ident authentication for local TCP connections, for example `127.0.0.1/28`. Using ident authentication for remote TCP connections is less secure because it requires you to trust the integrity of the ident service on the client's host.

This example shows how to edit the `pg_hba.conf` file of the master to allow remote client access to all databases from all roles using encrypted password authentication.

**Editing pg_hba.conf**

1. Open the file `$MASTER_DATA_DIRECTORY/pg_hba.conf` in a text editor.
2. Add a line to the file for each type of connection you want to allow. Records are read sequentially, so the order of the records is significant. Typically, earlier records will have tight connection match parameters and weaker authentication methods, while later records will have looser match parameters and stronger authentication methods. For example:

   ```
   # allow the gpadmin user local access to all databases
   # using ident authentication
   local   all   gpadmin   ident         sameuser
   host    all   gpadmin   127.0.0.1/32 ident
   host    all   gpadmin   ::1/128 ident
   # allow the 'dba' role access to any database from any
   # host with IP address 192.168.x.x and use md5 encrypted
   # passwords to authenticate the user
   # Note that to use SHA-256 encryption, replace md5 with
   # password in the line below
   host    all   dba   192.168.0.0/32  md5
   # allow all roles access to any database from any
   # host and use ldap to authenticate the user. Greenplum role
   # names must match the LDAP common name.
   host    all   all   192.168.0.0/32 ldap ldapserver=usldap1 ldapport=1389
   ldapprefix="cn=", ldapsuffix=",ou=People,dc=company,dc=com"
   ```

3. Save and close the file.
4. Reload the `pg_hba.conf` configuration file for your changes to take effect:

   ```
   $ gpstop -u
   ```

**Note:** Note that you can also control database access by setting object privileges as described in *Managing Object Privileges*. The `pg_hba.conf` file just controls who can initiate a database session and how those connections are authenticated.
Limiting Concurrent Connections

Greenplum Database allocates some resources on a per-connection basis, so setting the maximum number of connections allowed is recommended.

To limit the number of active concurrent sessions to your Greenplum Database system, you can configure the `max_connections` server configuration parameter. This is a local parameter, meaning that you must set it in the `postgresql.conf` file of the master, the standby master, and each segment instance (primary and mirror). The recommended value of `max_connections` on segments is 5-10 times the value on the master.

When you set `max_connections`, you must also set the dependent parameter `max_prepared_transactions`. This value must be at least as large as the value of `max_connections` on the master, and segment instances should be set to the same value as the master.

For example:

- In `$MASTER_DATA_DIRECTORY/postgresql.conf` (including standby master):
  
  ```
  max_connections=100
  max_prepared_transactions=100
  ```

- In `$SEGMENT_DATA_DIRECTORY/postgresql.conf` for all segment instances:
  
  ```
  max_connections=500
  max_prepared_transactions=100
  ```

The following steps set the parameter values with the Greenplum Database utility `gpconfig`.

For information about `gpconfig`, see the Greenplum Database Utility Guide.

To change the number of allowed connections

1. Log into the Greenplum Database master host as the Greenplum Database administrator and source the file `$GPHOME/greenplum_path.sh`.

2. Set the value of the `max_connections` parameter. This `gpconfig` command sets the value on the segments to 1000 and the value on the master to 200.

   ```
   $ gpconfig -c max_connections -v 1000 -m 200
   ```

   The value on the segments must be greater than the value on the master. The recommended value of `max_connections` on segments is 5-10 times the value on the master.

3. Set the value of the `max_prepared_transactions` parameter. This `gpconfig` command sets the value to 200 on the master and all segments.

   ```
   $ gpconfig -c max_prepared_transactions -v 200
   ```

   The value of `max_prepared_transactions` must be greater than or equal to `max_connections` on the master.

4. Stop and restart your Greenplum Database system.

   ```
   $ gpstop -r
   ```

5. You can check the value of parameters on the master and segments with the `gpconfig -s` option. This `gpconfig` command displays the values of the `max_connections` parameter.

   ```
   $ gpconfig -s max_connections
   ```
**Note:** Raising the values of these parameters may cause Greenplum Database to request more shared memory. To mitigate this effect, consider decreasing other memory-related parameters such as `gp_cached_segworkers_threshold`.

**Encrypting Client/Server Connections**

Enable SSL for client connections to Greenplum Database to encrypt the data passed over the network between the client and the database.

Greenplum Database has native support for SSL connections between the client and the master server. SSL connections prevent third parties from snooping on the packets, and also prevent man-in-the-middle attacks. SSL should be used whenever the client connection goes through an insecure link, and must be used whenever client certificate authentication is used.

To enable SSL requires that OpenSSL be installed on both the client and the master server systems. Greenplum Database can be started with SSL enabled by setting the server configuration parameter `ssl=on` in the master `postgresql.conf`. When starting in SSL mode, the server will look for the files `server.key` (server private key) and `server.crt` (server certificate) in the master data directory. These files must be set up correctly before an SSL-enabled Greenplum Database system can start.

**Important:** Do not protect the private key with a passphrase. The server does not prompt for a passphrase for the private key, and the database startup fails with an error if one is required.

A self-signed certificate can be used for testing, but a certificate signed by a certificate authority (CA) should be used in production, so the client can verify the identity of the server. Either a global or local CA can be used. If all the clients are local to the organization, a local CA is recommended.

**Creating a Self-signed Certificate without a Passphrase for Testing Only**

To create a quick self-signed certificate for the server for testing, use the following OpenSSL command:

```
# openssl req -new -text -out server.req
```

Enter the information requested by the prompts. Be sure to enter the local host name as *Common Name*. The challenge password can be left blank.

The program will generate a key that is passphrase protected, and does not accept a passphrase that is less than four characters long.

To use this certificate with Greenplum Database, remove the passphrase with the following commands:

```
# openssl rsa -in privkey.pem -out server.key
# rm privkey.pem
```

Enter the old passphrase when prompted to unlock the existing key.

Then, enter the following command to turn the certificate into a self-signed certificate and to copy the key and certificate to a location where the server will look for them.

```
# openssl req -x509 -in server.req -text -key server.key -out server.crt
```

Finally, change the permissions on the key with the following command. The server will reject the file if the permissions are less restrictive than these.

```
# chmod og-rwx server.key
```

For more details on how to create your server private key and certificate, refer to the *OpenSSL documentation*. 
Using LDAP Authentication with TLS/SSL

You can control access to Greenplum Database with an LDAP server and, optionally, secure the connection with encryption by adding parameters to `pg_hba.conf` file entries.

Greenplum Database supports LDAP authentication with the TLS/SSL protocol to encrypt communication with an LDAP server:

- LDAP authentication with STARTTLS and TLS protocol – STARTTLS starts with a clear text connection (no encryption) and upgrades it to a secure connection (with encryption).
- LDAP authentication with a secure connection and TLS/SSL (LDAPS) – Greenplum Database uses the TLS or SSL protocol based on the protocol that is used by the LDAP server.

If no protocol is specified, Greenplum Database communicates with the LDAP server with a clear text connection.

To use LDAP authentication, the Greenplum Database master host must be configured as an LDAP client. See your LDAP documentation for information about configuring LDAP clients.

Enabling LDAP Authentication with STARTTLS and TLS

To enable STARTTLS with the TLS protocol, in the `pg_hba.conf` file, add an `ldap` line and specify the `ldaptls` parameter with the value `1`. The default port is `389`. In this example, the authentication method parameters include the `ldaptls` parameter.

```
ldap ldapserver=myldap.com ldaptls=1 ldapprefix="uid="
ldapsuffix=",,ou=People,dc=example,dc=com"
```

Specify a non-default port with the `ldapport` parameter. In this example, the authentication method includes the `ldaptls` parameter and the `ldapport` parameter to specify the port `550`.

```
ldap ldapserver=myldap.com ldaptls=1 ldapport=500 ldapprefix="uid="
ldapsuffix=",,ou=People,dc=example,dc=com"
```

Enabling LDAP Authentication with a Secure Connection and TLS/SSL

To enable a secure connection with TLS/SSL, add `ldaps://` as the prefix to the LDAP server name specified in the `ldapserver` parameter. The default port is `636`.

This example `ldapserver` parameter specifies a secure connection and the TLS/SSL protocol for the LDAP server `myldap.com`.

```
ldapserver=ldaps://myldap.com
```

To specify a non-default port, add a colon (`:`) and the port number after the LDAP server name. This example `ldapserver` parameter includes the `ldaps://` prefix and the non-default port `550`.

```
ldapserver=ldaps://myldap.com:550
```

Configuring Authentication with a System-wide OpenLDAP System

If you have a system-wide OpenLDAP system and logins are configured to use LDAP with TLS or SSL in the `pg_hba.conf` file, logins may fail with the following message:

```
could not start LDAP TLS session: error code '-11'
```
To use an existing OpenLDAP system for authentication, Greenplum Database must be set up to use the LDAP server’s CA certificate to validate user certificates. Follow these steps on both the master and standby hosts to configure Greenplum Database:

1. Copy the base64-encoded root CA chain file from the Active Directory or LDAP server to the Greenplum Database master and standby master hosts. This example uses the directory `/etc/pki/tls/certs`.

2. Change to the directory where you copied the CA certificate file and, as the root user, generate the hash for OpenLDAP:

```
# cd /etc/pki/tls/certs
# openssl x509 -noout -hash -in <ca-certificate-file>
# ln -s <ca-certificate-file> <ca-certificate-file>.0
```

3. Configure an OpenLDAP configuration file for Greenplum Database with the CA certificate directory and certificate file specified.

As the root user, edit the OpenLDAP configuration file `/etc/openldap/ldap.conf`:

```
SASL_NOCANON on
URI ldaps://ldapA.example.priv ldaps://ldapB.example.priv ldaps://ldapC.example.priv
BASE dc=example,dc=priv
TLS_CACERTDIR /etc/pki/tls/certs
TLS_CACERT /etc/pki/tls/certs/<ca-certificate-file>
```

**Note:** For certificate validation to succeed, the hostname in the certificate must match a hostname in the URI property. Otherwise, you must also add `TLS_REQCERT allow` to the file.

4. As the gpadmin user, edit `/usr/local/greenplum-db/greenplum_path.sh` and add the following line.

```
export LDAPCONF=/etc/openldap/ldap.conf
```

**Notes**

Greenplum Database logs an error if the following are specified in an `pg_hba.conf` file entry:

- If both the `ldaps://` prefix and the `ldaptls=1` parameter are specified.
- If both the `ldaps://` prefix and the `ldapport` parameter are specified.

Enabling encrypted communication for LDAP authentication only encrypts the communication between Greenplum Database and the LDAP server.

See [Encrypting Client/Server Connections](#) for information about encrypting client connections.

**Examples**

These are example entries from an `pg_hba.conf` file.

This example specifies LDAP authentication with no encryption between Greenplum Database and the LDAP server.

```
host all plainuser 0.0.0.0/0 ldap ldapserver=myldap.com ldapprefix="uid=
ldapsuffix=",ou=People,dc=example,dc=com"
```

This example specifies LDAP authentication with the STARTTLS and TLS protocol between Greenplum Database and the LDAP server.

```
host all tlsuser 0.0.0.0/0 ldap ldapserver=myldap.com ldaptls=1
ldapprefix="uid=" ldapsuffix=",ou=People,dc=example,dc=com"
```
This example specifies LDAP authentication with a secure connection and TLS/SSL protocol between Greenplum Database and the LDAP server.

```
host all ldapsuser 0.0.0.0/0 ldap ldaps://myldap.com
ldapprefix="uid=" ldapsuffix=",ou=People,dc=example,dc=com"
```

### Using Kerberos Authentication

You can control access to Greenplum Database with a Kerberos authentication server.

Greenplum Database supports the Generic Security Service Application Program Interface (GSSAPI) with Kerberos authentication. GSSAPI provides automatic authentication (single sign-on) for systems that support it. You specify the Greenplum Database users (roles) that require Kerberos authentication in the Greenplum Database configuration file `pg_hba.conf`. The login fails if Kerberos authentication is not available when a role attempts to log in to Greenplum Database.

Kerberos provides a secure, encrypted authentication service. It does not encrypt data exchanged between the client and database and provides no authorization services. To encrypt data exchanged over the network, you must use an SSL connection. To manage authorization for access to Greenplum databases and objects such as schemas and tables, you use settings in the `pg_hba.conf` file and privileges given to Greenplum Database users and roles within the database. For information about managing authorization privileges, see [Managing Roles and Privileges](#).

For more information about Kerberos, see [http://web.mit.edu/kerberos/](http://web.mit.edu/kerberos/).

### Prerequisites

Before configuring Kerberos authentication for Greenplum Database, ensure that:

- You can identify the KDC server you use for Kerberos authentication and the Kerberos realm for your Greenplum Database system.
  - If you plan to use an MIT Kerberos KDC server but have not yet configured it, see [Installing and Configuring a Kerberos KDC Server](#) for example instructions.
  - If you are using an existing Active Directory KDC server, also ensure that you have:
    - Installed all Active Directory service roles on your AD KDC server.
    - Enabled the LDAP service.
  - System time on the Kerberos Key Distribution Center (KDC) server and Greenplum Database master is synchronized. (For example, install the `ntp` package on both servers.)
  - Network connectivity exists between the KDC server and the Greenplum Database master host.
  - Java 1.7.0_17 or later is installed on all Greenplum Database hosts. Java 1.7.0_17 is required to use Kerberos-authenticated JDBC on Red Hat Enterprise Linux 6.x or 7.x.

### Procedure

Following are the tasks to complete to set up Kerberos authentication for Greenplum Database.

- [Creating Greenplum Database Principals in the KDC Database](#)
- [Installing the Kerberos Client on the Master Host](#)
- [Configuring Greenplum Database to use Kerberos Authentication](#)
- [Mapping Kerberos Principals to Greenplum Database Roles](#)
- [Configuring JDBC Kerberos Authentication for Greenplum Database](#)
- [Configuring Kerberos on Windows for Greenplum Database Clients](#)
- [Configuring Client Authentication with Active Directory](#)
Creating Greenplum Database Principals in the KDC Database

Create a service principal for the Greenplum Database service and a Kerberos admin principal that allows managing the KDC database as the gpadmin user.

1. Log in to the Kerberos KDC server as the root user.

   ```bash
   $ ssh root@<kdc-server>
   ```

2. Create a principal for the Greenplum Database service.

   ```bash
   # kadmin.local -q "addprinc -randkey postgres/mdw@GPDB.KRB"
   ```
   The `−randkey` option prevents the command from prompting for a password.
   The `postgres` part of the principal names matches the value of the Greenplum Database `krb_srvname` server configuration parameter, which is `postgres` by default.
   The host name part of the principal name must match the output of the `hostname` command on the Greenplum Database master host. If the `hostname` command shows the fully qualified domain name (FQDN), use it in the principal name, for example `postgres/mdw.example.com@GPDB.KRB`.
   The `GPDB.KRB` part of the principal name is the Kerberos realm name.

3. Create a principal for the gpadmin/admin role.

   ```bash
   # kadmin.local -q "addprinc gpadmin/admin@GPDB.KRB"
   ```
   This principal allows you to manage the KDC database when you are logged in as gpadmin. Make sure that the Kerberos `kadm.acl` configuration file contains an ACL to grant permissions to this principal. For example, this ACL grants all permissions to any admin user in the GPDB.KRB realm.
   ```bash
   */admin@GPDB.KRB *
   ```

4. Create a keytab file with `kadmin.local`. The following example creates a keytab file `gpdb-kerberos.keytab` in the current directory with authentication information for the Greenplum Database service principal and the gpadmin/admin principal.

   ```bash
   # kadmin.local -q "ktadd -k gpdb-kerberos.keytab postgres/mdw@GPDB.KRB
   gpadmin/admin@GPDB.KRB"
   ```

5. Copy the keytab file to the master host.

   ```bash
   # scp gpdb-kerberos.keytab gpadmin@mdw:~
   ```

Installing the Kerberos Client on the Master Host

Install the Kerberos client utilities and libraries on the Greenplum Database master.

1. Install the Kerberos packages on the Greenplum Database master.

   ```bash
   $ sudo yum install krb5-libs krb5-workstation
   ```

2. Copy the `/etc/krb5.conf` file from the KDC server to `/etc/krb5.conf` on the Greenplum Master host.

Configuring Greenplum Database to use Kerberos Authentication

Configure Greenplum Database to use Kerberos.
1. Log in to the Greenplum Database master host as the gpadmin user.

   $ ssh gpadmin@<master>
   $ source /usr/local/greenplum-db/greenplum_path.sh

2. Set the ownership and permissions of the keytab file you copied from the KDC server.

   $ chown gpadmin:gpadmin /home/gpadmin/gpdb-kerberos.keytab
   $ chmod 400 /home/gpadmin/gpdb-kerberos.keytab

3. Configure the location of the keytab file by setting the Greenplum Database `krb_server_keyfile` server configuration parameter. This `gpconfig` command specifies the folder `/home/gpadmin` as the location of the keytab file `gpdb-kerberos.keytab`.

   $ gpconfig -c krb_server_keyfile -v '/home/gpadmin/gpdb-kerberos.keytab'

4. Modify the Greenplum Database file `pg_hba.conf` to enable Kerberos support. For example, adding the following line to `pg_hba.conf` adds GSSAPI and Kerberos authentication support for connection requests from all users and hosts on the same network to all Greenplum Database databases.

   host all all 0.0.0.0/0 gss include_realm=0 krb_realm=GPDB.KRB

   Setting the `krb_realm` option to a realm name ensures that only users from that realm can successfully authenticate with Kerberos. Setting the `include_realm` option to 0 excludes the realm name from the authenticated user name. For information about the `pg_hba.conf` file, see `The pg_hba.conf file` in the Postgres documentation.

5. Restart Greenplum Database after updating the `krb_server_keyfile` parameter and the `pg_hba.conf` file.

   $ gpstop -ar

6. Create the gpadmin/admin Greenplum Database superuser role.

   $ createuser gpadmin/admin
   Shall the new role be a superuser? (y/n) y

   The Kerberos keys for this database role are in the keyfile you copied from the KDC server.

7. Create a ticket using `kinit` and show the tickets in the Kerberos ticket cache with `klist`.

   $ LD_LIBRARY_PATH= kinit -k -t /home/gpadmin/gpdb-kerberos.keytab gpadmin/admin@GPDB.KRB
   $ LD_LIBRARY_PATH= klist
   Ticket cache: FILE:/tmp/krb5cc_1000
   Default principal: gpadmin/admin@GPDB.KRB
   Valid starting       Expires              Service principal
   06/13/2018 17:37:35  06/14/2018 17:37:35  krbtgt/GPDB.KRB@GPDB.KRB

   Note: When you set up the Greenplum Database environment by sourcing the `greenplum-db_path.sh` script, the `LD_LIBRARY_PATH` environment variable is set to include the Greenplum Database lib directory, which includes Kerberos libraries. This may cause Kerberos utility commands such as `kinit` and `klist` to fail due to version conflicts. The solution is to run Kerberos utilities before you source the `greenplum-db_path.sh` file or temporarily unset the `LD_LIBRARY_PATH` variable when you execute Kerberos utilities, as shown in the example.

8. As a test, log in to the postgres database with the `gpadmin/admin` role:

   $ psql -U "gpadmin/admin" -h mdw postgres
   psql (8.3.23)
   Type "help" for help.
postgres=# select current_user;
  current_user
--------------
gpadmin/admin
(1 row)

**Note:** When you start `psql` on the master host, you must include the `-h <master-hostname>` option to force a TCP connection because Kerberos authentication does not work with local connections.

If a Kerberos principal is not a Greenplum Database user, a message similar to the following is displayed from the `psql` command line when the user attempts to log in to the database:

```
posql: krb5_sendauth: Bad response
```

The principal must be added as a Greenplum Database user.

### Mapping Kerberos Principals to Greenplum Database Roles

To connect to a Greenplum Database system with Kerberos authentication enabled, a user first requests a ticket-granting ticket from the KDC server using the `kinit` utility with a password or a keytab file provided by the Kerberos admin. When the user then connects to the Kerberos-enabled Greenplum Database system, the user's Kerberos principle name will be the Greenplum Database role name, subject to transformations specified in the options field of the `gss` entry in the Greenplum Database `pg_hba.conf` file:

- If the `krb_realm=<realm>` option is present, Greenplum Database only accepts Kerberos principals who are members of the specified realm.
- If the `include_realm=0` option is specified, the Greenplum Database role name is the Kerberos principal name without the Kerberos realm. If the `include_realm=1` option is instead specified, the Kerberos realm is not stripped from the Greenplum Database rolename. The role must have been created with the Greenplum Database `CREATE ROLE` command.
- If the `map=<map-name>` option is specified, the Kerberos principal name is compared to entries labeled with the specified `<map-name>` in the `$MASTER_DATA_DIRECTORY/pg_ident.conf` file and replaced with the Greenplum Database role name specified in the first matching entry.

A user name map is defined in the `$MASTER_DATA_DIRECTORY/pg_ident.conf` configuration file. This example defines a map named `mymap` with two entries.

```
# MAPNAME   SYSTEM-USERNAME        GP-USERNAME
mymap       /^admin@GPDB.KRB$      gpadmin
mymap       /^(.*)_gp)@GPDB.KRB$   \1
```

The map name is specified in the `pg_hba.conf` Kerberos entry in the options field:

```
host all all 0.0.0.0/0 gss include_realm=0 krb_realm=GPDB.KRB map=mymap
```

The first map entry matches the Kerberos principal `admin@GPDB.KRB` and replaces it with the Greenplum Database `gpadmin` role name. The second entry uses a wildcard to match any Kerberos principal in the `GPDB-KRB` realm with a name ending with the characters `_gp` and replaces it with the initial portion of the principal name. Greenplum Database applies the first matching map entry in the `pg_ident.conf` file, so the order of entries is significant.

For more information about using username maps see *Username maps* in the PostgreSQL documentation.
Configuring JDBC Kerberos Authentication for Greenplum Database

Enable Kerberos-authenticated JDBC access to Greenplum Database.

You can configure Greenplum Database to use Kerberos to run user-defined Java functions.

1. Ensure that Kerberos is installed and configured on the Greenplum Database master. See Installing the Kerberos Client on the Master Host.

2. Create the file `.java.login.config` in the folder `/home/gpadmin` and add the following text to the file:

```java
pgjdbc {
    com.sun.security.auth.module.Krb5LoginModule required
doNotPrompt=true
    useTicketCache=true
debug=true
client=true;
};
```

3. Create a Java application that connects to Greenplum Database using Kerberos authentication. The following example database connection URL uses a PostgreSQL JDBC driver and specifies parameters for Kerberos authentication:

```
jdbc:postgresql://mdw:5432/mytest?kerberosServerName=postgres &jaasApplicationName=pgjdbc&user=gpadmin/gpdb-kdc
```

The parameter names and values specified depend on how the Java application performs Kerberos authentication.

4. Test the Kerberos login by running a sample Java application from Greenplum Database.

Installing and Configuring a Kerberos KDC Server

Steps to set up a Kerberos Key Distribution Center (KDC) server on a Red Hat Enterprise Linux host for use with Greenplum Database.

If you do not already have a KDC, follow these steps to install and configure a KDC server on a Red Hat Enterprise Linux host with a `GPDB.KRB` realm. The host name of the KDC server in this example is `gpdb-kdc`.

1. Install the Kerberos server and client packages:

   ```
   $ sudo yum install krb5-libs krb5-server krb5-workstation
   ```

2. Edit the `/etc/krb5.conf` configuration file. The following example shows a Kerberos server configured with a default `GPDB.KRB` realm.

   ```
   [logging]
default = FILE:/var/log/krb5libs.log
  
  kdc = FILE:/var/log/krb5kdc.log
  
  admin_server = FILE:/var/log/kadmind.log

  [libdefaults]
default_realm = GPDB.KRB
dns_lookup_realm = false
dns_lookup_kdc = false
ticket_lifetime = 24h
renew_lifetime = 7d
forwardable = true
default_tgs_enctypes = aes128-cts des3-hmac-shal des-cbc-crc des-cbc-md5
default_tkt_enctypes = aes128-cts des3-hmac-shal des-cbc-crc des-cbc-md5
permitted_enctypes = aes128-cts des3-hmac-shal des-cbc-crc des-cbc-md5
   ```
The `kdc` and `admin_server` keys in the `[realms]` section specify the host (gpdb-kdc) and port where the Kerberos server is running. IP numbers can be used in place of host names.

If your Kerberos server manages authentication for other realms, you would instead add the `GPDB.KRB` realm in the `[realms]` and `[domain_realm]` section of the `kdc.conf` file. See the Kerberos documentation for information about the `kdc.conf` file.

3. To create the Kerberos database, run the `kdb5_util`.

```
# kdb5_util create -s
```

The `kdb5_util create` command creates the database to store keys for the Kerberos realms that are managed by this KDC server. The `-s` option creates a stash file. Without the stash file, every time the KDC server starts it requests a password.

4. Add an administrative user to the KDC database with the `kadmin.local` utility. Because it does not itself depend on Kerberos authentication, the `kadmin.local` utility allows you to add an initial administrative user to the local Kerberos server. To add the user `gpadmin` as an administrative user to the KDC database, run the following command:

```
# kadmin.local -q "addprinc gpadmin/admin"
```

Most users do not need administrative access to the Kerberos server. They can use `kadmin` to manage their own principals (for example, to change their own password). For information about `kadmin`, see the Kerberos documentation.

5. If needed, edit the `/var/kerberos/krb5kdc/kadm5.acl` file to grant the appropriate permissions to `gpadmin`.

6. Start the Kerberos daemons:

```
# /sbin/service krb5kdc start
# /sbin/service kadmin start
```

7. To start Kerberos automatically upon restart:

```
# /sbin/chkconfig krb5kdc on
# /sbin/chkconfig kadmin on
```
Configuring Kerberos for Linux Clients
You can configure Linux client applications to connect to a Greenplum Database system that is configured to authenticate with Kerberos.

If your JDBC application on Red Hat Enterprise Linux uses Kerberos authentication when it connects to your Greenplum Database, your client system must be configured to use Kerberos authentication. If you are not using Kerberos authentication to connect to a Greenplum Database, Kerberos is not needed on your client system.

• **Requirements**
  • **Setting Up Client System with Kerberos Authentication**
  • **Running a Java Application**

For information about enabling Kerberos authentication with Greenplum Database, see the chapter "Setting Up Kerberos Authentication" in the *Greenplum Database Administrator Guide*.

**Requirements**
The following are requirements to connect to a Greenplum Database that is enabled with Kerberos authentication from a client system with a JDBC application.

• **Prerequisites**
  • **Required Software on the Client Machine**

**Prerequisites**
• Kerberos must be installed and configured on the Greenplum Database master host.

  **Important:** Greenplum Database must be configured so that a remote user can connect to Greenplum Database with Kerberos authentication. Authorization to access Greenplum Database is controlled by the `pg_hba.conf` file. For details, see "Editing the pg_hba.conf File" in the *Greenplum Database Administration Guide*, and also see the *Greenplum Database Security Configuration Guide*.

  • The client system requires the Kerberos configuration file `krb5.conf` from the Greenplum Database master.
  • The client system requires a Kerberos keytab file that contains the authentication credentials for the Greenplum Database user that is used to log into the database.
  • The client machine must be able to connect to Greenplum Database master host.

    If necessary, add the Greenplum Database master host name and IP address to the system `hosts` file. On Linux systems, the `hosts` file is in `/etc`.

**Required Software on the Client Machine**
• The Kerberos `kinit` utility is required on the client machine. The `kinit` utility is available when you install the Kerberos packages:
  • `krb5-libs`
  • `krb5-workstation`

    **Note:** When you install the Kerberos packages, you can use other Kerberos utilities such as `klist` to display Kerberos ticket information.

Java applications require this additional software:
• **Java JDK**
  
  Java JDK 1.7.0_17 is supported on Red Hat Enterprise Linux 6.x.
  
  Ensure that `JAVA_HOME` is set to the installation directory of the supported Java JDK.
Setting Up Client System with Kerberos Authentication

To connect to Greenplum Database with Kerberos authentication requires a Kerberos ticket. On client systems, tickets are generated from Kerberos keytab files with the `kinit` utility and are stored in a cache file.

1. Install a copy of the Kerberos configuration file `krb5.conf` from the Greenplum Database master. The file is used by the Greenplum Database client software and the Kerberos utilities.

   Install `krb5.conf` in the directory `/etc`.

   If needed, add the parameter `default_ccache_name` to the `[libdefaults]` section of the `krb5.ini` file and specify location of the Kerberos ticket cache file on the client system.

2. Obtain a Kerberos keytab file that contains the authentication credentials for the Greenplum Database user.

3. Run `kinit` specifying the keytab file to create a ticket on the client machine. For this example, the keytab file `gpdb-kerberos.keytab` is in the the current directory. The ticket cache file is in the `gpadmin` user home directory.

   ```
   > kinit -k -t gpdb-kerberos.keytab -c /home/gpadmin/cache.txt
gpadmin/kerberos-gpdb@KRB.EXAMPLE.COM
   ```

Running psql

From a remote system, you can access a Greenplum Database that has Kerberos authentication enabled.

To connect to Greenplum Database with psql

1. As the `gpadmin` user, open a command window.

2. Start `psql` from the command window and specify a connection to the Greenplum Database specifying the user that is configured with Kerberos authentication.

   The following example logs into the Greenplum Database on the machine `kerberos-gpdb` as the `gpadmin` user with the Kerberos credentials `gpadmin/kerberos-gpdb`:

   ```
   $ psql -U "gpadmin/kerberos-gpdb" -h kerberos-gpdb postgres
   ```

Running a Java Application

Accessing Greenplum Database from a Java application with Kerberos authentication uses the Java Authentication and Authorization Service (JAAS)

1. Create the file `.java.login.config` in the user home folder.

   For example, on a Linux system, the home folder is similar to `/home/gpadmin`.

   Add the following text to the file:

   ```
   pgjdbc {
       com.sun.security.auth.module.Krb5LoginModule required
       doNotPrompt=true
       useTicketCache=true
       ticketCache = "/home/gpadmin/cache.txt"
       debug=true
       client=true;
   };
   ```

2. Create a Java application that connects to Greenplum Database using Kerberos authentication and run the application as the user.
This example database connection URL uses a PostgreSQL JDBC driver and specifies parameters for Kerberos authentication.

```
jdbc:postgresql://kerberos-gpdb:5432/mytest?
  kerberosServerName=postgres&jaasApplicationName=pgjdbc&
  user=gpadmin/kerberos-gpdb
```

The parameter names and values specified depend on how the Java application performs Kerberos authentication.

**Configuring Kerberos For Windows Clients**

You can configure Microsoft Windows client applications to connect to a Greenplum Database system that is configured to authenticate with Kerberos.

- *Configuring Kerberos on Windows for Greenplum Database Clients*
- *Configuring Client Authentication with Active Directory*

For information about configuring Greenplum Database with Kerberos authentication, see *Using Kerberos Authentication*.

**Configuring Kerberos on Windows for Greenplum Database Clients**

When a Greenplum Database system is configured to authenticate with Kerberos, you can configure Kerberos authentication for the Greenplum Database client utilities `gpload` and `psql` on a Microsoft Windows system. The Greenplum Database clients authenticate with Kerberos directly, not with Microsoft Active Directory (AD).

This section contains the following information.

- *Installing Kerberos on a Windows System*
- *Running the psql Utility*
- *Example gpload YAML File*
- *Creating a Kerberos Keytab File*
- *Issues and Possible Solutions*

These topics assume that the Greenplum Database system is configured to authenticate with Kerberos and Microsoft Active Directory. See *Configuring Client Authentication with Active Directory*.

**Installing Kerberos on a Windows System**

To use Kerberos authentication with the Greenplum Database clients on a Windows system, the MIT Kerberos Windows client must be installed on the system. For the clients you can install MIT Kerberos for Windows 4.0.1 (for krb5) that is available at [http://web.mit.edu/kerberos/dist/index.html](http://web.mit.edu/kerberos/dist/index.html).

On the Windows system, you manage Kerberos tickets with the Kerberos `kinit` utility.

The automatic start up of the Kerberos service is not enabled. The service cannot be used to authenticate with Greenplum Database.

Create a copy of the Kerberos configuration file `/etc/krb5.conf` from the Greenplum Database master and place it in the default Kerberos location on the Windows system `C:\ProgramData\MIT\Kerberos5\krb5.ini`. In the file section `[libdefaults]`, remove the location of the Kerberos ticket cache `default_ccache_name`.

On the Windows system, use the environment variable `KRB5CCNAME` to specify the location of the Kerberos ticket. The value for the environment variable is a file, not a directory and should be unique to each login on the server.
This is an example configuration file with default_ccache_name removed. Also, the section [logging] is removed.

```
[libdefaults]
default_etypes = aes256-cts-hmac-sha1-96
default_realm = EXAMPLE.LOCAL
dns_lookup_realm = false
dns_lookup_kdc = false
ticket_lifetime = 24h
renew_lifetime = 7d
forwardable = true

[realms]
EXAMPLE.LOCAL = {
    kdc = bocdc.example.local
    admin_server = bocdc.example.local
}

[domain.realm]
.example.local = EXAMPLE.LOCAL
example.local = EXAMPLE.LOCAL
```

When specifying a Kerberos ticket with KRB5CCNAME, you can specify the value in either a local user environment or within a session. These commands set KRB5CCNAME, runs kinit, and runs the batch file to set the environment variables for the Greenplum Database clients.

```
set KRB5CCNAME=%USERPROFILE%\krb5cache
kinit
"c:\Program Files (x86)\Greenplum\greenplum-clients-<version>\greenplum_clients_path.bat"
```

### Running the psql Utility

After installing and configuring Kerberos and the Kerberos ticket on a Windows system, you can run the Greenplum Database command line client psql.

If you get warnings indicating that the Console code page differs from Windows code page, you can run the Windows utility chcp to change the code page. This is an example of the warning and fix.

```
psql -h prod1.example.local warehouse
psql 8.3.23
WARNING: Console code page (850) differs from Windows code page (1252)
  8-bit characters might not work correctly. See psql reference
  page "Notes for Windows users" for details.
Type "help" for help.

warehouse=# \q

chcp 1252
Active code page: 1252

psql -h prod1.example.local warehouse
psql 8.3.23
Type "help" for help.
```
Creating a Kerberos Keytab File

You can create and use a Kerberos keytab file to avoid entering a password at the command line or the listing a password in a script file when connecting to a Greenplum Database system. You can create a keytab file with these utilities:

- Windows Kerberos utility ktpass
- Java JRE keytab utility ktab

If you use AES256-CTS-HMAC-SHA1-96 encryption, you need to download and install the Java extension Java Cryptography Extension (JCE) Unlimited Strength Jurisdiction Policy Files for JDK/JRE from Oracle. This command creates the keytab file svcPostgresProd1.keytab.

You run the ktpass utility as an AD Domain Administrator. The utility expects a user account to have a Service Principal Name (SPN) defined as an AD user attribute, however, it does not appear to be required. You can specify it as a parameter to ktpass and ignore the warning that it cannot be set.

The Java JRE ktab utility does not require an AD Domain Administrator and does not require an SPN.

Note: When you enter the password to create the keytab file, the password is visible on screen.

This example runs the ktpass utility to create the keytab file dev1.keytab.

```
  ktpass -out dev1.keytab -princ dev1@EXAMPLE.LOCAL -mapUser dev1 -pass your_password -crypto all -ptype KRB5_NT_PRINCIPAL
```

It works despite the warning message Unable to set SPN mapping data.

This example runs the Java ktab.exe to create a keytab file (-a option) and list the keytab name and entries (-l -e -t options).

```
C:\Users\dev1>"\Program Files\Java\jre1.8.0_77\bin\ktab -a dev1
Password for dev1@EXAMPLE.LOCAL:your_password
Done!
Service key for dev1 is saved in C:\Users\dev1\krb5.keytab

C:\Users\dev1>"\Program Files\Java\jre1.8.0_77\bin\ktab -l -e -t
Keytab name: C:\Users\dev1\krb5.keytab
KVNO Timestamp Principal
-----------------------------
4 13/04/16 19:14 dev1@EXAMPLE.LOCAL (18:AES256 CTS mode with HMAC SHA1-96)
4 13/04/16 19:14 dev1@EXAMPLE.LOCAL (17:AES128 CTS mode with HMAC SHA1-96)
4 13/04/16 19:14 dev1@EXAMPLE.LOCAL (16:DES3 CBC mode with SHA1-KD)
4 13/04/16 19:14 dev1@EXAMPLE.LOCAL (23:RC4 with HMAC)
```

You can then use a keytab with the following:

```
kinit -kt dev1.keytab dev1
or
kinit -kt %USERPROFILE%\krb5.keytab dev1
```

Example gpload YAML File

This is an example of running a gpload job with the user dev1 logged onto a Windows desktop with the AD domain.

In the example test.yaml control file, the USER: line has been removed. Kerberos authentication is used.

```
---
VERSION: 1.0.0.1
DATABASE: warehouse
HOST: prod1.example.local
```
PORT: 5432

GPLOAD:
  INPUT:
  - SOURCE:
    PORT_RANGE: [18080,18080]
    FILE:
      - /Users/dev1/Downloads/test.csv
  - FORMAT: text
  - DELIMITER: ','
  - QUOTE: '"'
  - ERROR_LIMIT: 25
  - LOG_ERRORS: true

OUTPUT:
  - TABLE: public.test
  - MODE: INSERT

PRELOAD:
  - REUSE_TABLES: true

These commands run \texttt{kinit} and then \texttt{gpload} with the \texttt{test.yaml} file and displays successful \texttt{gpload} output.

\texttt{kinit -kt \%USERPROFILE\%\krb5.keytab dev1}

\texttt{gpload.py -f test.yaml}

2016-04-10 16:54:12 | INFO | gpload session started 2016-04-10 16:54:12
2016-04-10 16:54:12 | INFO | started gpfdist -p 18080 -P 18080 -f "/Users/dev1/Downloads/test.csv" -t 30
2016-04-10 16:54:13 | INFO | running time: 0.23 seconds
2016-04-10 16:54:13 | INFO | rows Inserted = 3
2016-04-10 16:54:13 | INFO | rows Updated = 0
2016-04-10 16:54:13 | INFO | data formatting errors = 0
2016-04-10 16:54:13 | INFO | gpload succeeded

Issues and Possible Solutions

- This message indicates that Kerberos cannot find your cache file:

  Credentials cache I/O operation failed XXX
  (Kerberos error 193)
  krb5_cc_default() failed

To ensure that Kerberos can find the file set the environment variable \texttt{KRB5CCNAME} and run \texttt{kinit}.

\texttt{set KRB5CCNAME=\%USERPROFILE\%\krb5cache}

\texttt{kinit}

- This \texttt{kinit} message indicates that the \texttt{kinit -k -t} command could not find the keytab.

  kinit: Generic preauthentication failure while getting initial credentials

Confirm the full path and filename for the Kerberos keytab file is correct.

Configuring Client Authentication with Active Directory

You can configure a Microsoft Windows user with a Microsoft Active Directory (AD) account for single sign-on to a Greenplum Database system.

You configure an AD user account to support logging in with Kerberos authentication.
With AD single sign-on, a Windows user can use Active Directory credentials with a Windows client application to log into a Greenplum Database system. For Windows applications that use ODBC, the ODBC driver can use Active Directory credentials to connect to a Greenplum Database system.

Note: Greenplum Database clients that run on Windows, like `gpload`, connect with Greenplum Database directly and do not use Active Directory. For information about connecting Greenplum Database clients on Windows to a Greenplum Database system with Kerberos authentication, see Configuring Kerberos on Windows for Greenplum Database Clients.

This section contains the following information.

- Prerequisites
- Setting Up Active Directory
- Setting Up Greenplum Database for Active Directory
- Single Sign-On Examples
- Issues and Possible Solutions for Active Directory

Prerequisites

These items are required enable AD single sign-on to a Greenplum Database system.

- The Greenplum Database system must be configured to support Kerberos authentication. For information about configuring Greenplum Database with Kerberos authentication, see Configuring Kerberos For Windows Clients.
- You must know the fully-qualified domain name (FQDN) of the Greenplum Database master host. Also, the Greenplum Database master host name must have a domain portion. If the system does not have a domain, you must configure the system to use a domain.

This Linux `hostname` command displays the FQDN.

```bash
hostname --fqdn
```

- You must confirm that the Greenplum Database system has the same date and time as the Active Directory domain. For example, you could set the Greenplum Database system NTP time source to be an AD Domain Controller, or configure the master host to use the same external time source as the AD Domain Controller.
- To support single sign-on, you configure an AD user account as a Managed Service Account in AD. These are requirements for Kerberos authentication.
  
  - You need to add the Service Principal Name (SPN) attribute to the user account information because the Kerberos utilities require the information during Kerberos authentication.
  - Also, as Greenplum Database has unattended startups, you must also provide the account login details in a Kerberos keytab file.

  Note: Setting the SPN and creating the keytab requires AD administrative permissions.

Setting Up Active Directory

The AD naming convention should support multiple Greenplum Database systems. In this example, we create a new AD Managed Service Account `svcPostgresProd1` for our `prod1` Greenplum Database system master host.

The Active Directory domain is `example.local`.

The fully qualified domain name for the Greenplum Database master host is `prod1.example.local`.

We will add the SPN `postgres/prod1.example.local` to this account. Service accounts for other Greenplum Database systems will all be in the form `postgres/fully.qualified.hostname`.
In this example, the AD password is set to never expire and cannot be changed by the user. The AD account password is only used when creating the Kerberos keytab file. There is no requirement to provide it to a database administrator.
An AD administrator must add the Service Principal Name attribute to the account from the command line with the Windows `setspn` command. This example command set the SPN attribute value to `postgres/prod1.example.local` for the AD user `svcPostgresProd1`:

```
setspn -A postgres/prod1.example.local svcPostgresProd1
```

You can see the SPN if Advanced Features are set in the Active Directory Users and Computers view. Find `servicePrincipalName` in the Attribute Editor tab and edit it if necessary.
The next step is to create a Kerberos keytab file.

You can select a specific cryptography method if your security requirements require it, but in the absence of that, it is best to get it to work first and then remove any cryptography methods you do not want.

As an AD Domain Administrator, you can list the types of encryption that your AD domain controller supports with this \texttt{ktpass} command:

\begin{verbatim}
ktpass /?
\end{verbatim}

As an AD Domain Administrator, you can run the \texttt{ktpass} command to create a keytab file. This example command creates the file \texttt{svcPostgresProd1.keytab} with this information:

\begin{verbatim}
ServicePrincipalName (SPN): postgres/prod1.example.local@EXAMPLE.LOCAL
AD user: svcPostgresProd1
Encryption methods: ALL available on AD
Principal Type: KRB5_NT_PRINCIPAL
\end{verbatim}

\begin{verbatim}
ktpass -out svcPostgresProd1.keytab -princ postgres/prod1.example.local@EXAMPLE.LOCAL -mapUser svcPostgresProd1 -pass your_password -crypto all -ptype KRB5_NT_PRINCIPAL
\end{verbatim}

\textbf{Note:} The AD domain \texttt{@EXAMPLE.LOCAL} is appended to the SPN.
You copy the keytab file `svcPostgresProd1.keytab` to the Greenplum Database master host.

As an alternative to running `ktpass` as an AD Domain Administrator, you can run the Java `ktab.exe` utility to generate a keytab file if you have the Java JRE installed on your desktop. When you enter the password using either `ktpass` or `ktab.exe`, the password will be visible on the screen as a command line argument.

This example command creates the keytab file `svcPostgresProd1.keytab`.

```
"c:\Program Files\Java\jre1.8.0_77\bin\ktab.exe" -a svcPostgresprod1 -k svcPostgresProd1.keytab
Password for svcPostgresprod1@EXAMPLE.LOCAL: your_password
Done!
Service key for svcPostgresprod1 is saved in svcPostgresProd1.keytab
```

**Note:** If you use AES256-CTS-HMAC-SHA1-96 encryption, you must download and install the Java extension *Java Cryptography Extension (JCE) Unlimited Strength Jurisdiction Policy Files for JDK/JRE* from Oracle.

### Setting Up Greenplum Database for Active Directory

These instructions assume that the Kerberos workstation utilities `krb5-workstation` are installed on the Greenplum Database master host.

Update `/etc/krb5.conf` with the AD domain name details and the location of an AD domain controller. This is an example configuration.

```
[logging]
default = FILE:/var/log/krb5libs.log
dc = FILE:/var/log/krb5kdc.log
dc = FILE:/var/log/kadmind.log

[libdefaults]
default_realm = EXAMPLE.LOCAL
dns_lookup_realm = false
dns_lookup_kdc = false
ticket_lifetime = 24h
renew_lifetime = 7d
forwardable = true

[realms]
EXAMPLE.LOCAL = {
    kdc = bocdc.example.local
    admin_server = bocdc.example.local
}

[domain_realm]
.example.local = EXAMPLE.LOCAL
example.com = EXAMPLE.LOCAL
```

Copy the Kerberos keytab file that contains the AD user information to the Greenplum Database master directory. This example copies the `svcPostgresProd1.keytab` that was created in *Active Directory Setup*.

```
mv svcPostgresProd1.keytab $MASTER_DATA_DIRECTORY
cshon gpadmin:gpadmin $MASTER_DATA_DIRECTORY/svcPostgresProd1.keytab
chmod 600 $MASTER_DATA_DIRECTORY/svcPostgresProd1.keytab
```
Add this line as the last line in the Greenplum Database `pg_hba.conf` file. This line configures Greenplum Database authentication to use Active Directory for authentication for connection any attempt that is not matched by a previous line.

```
host all all 0.0.0.0/0 gss include_realm=0
```

Update the Greenplum Database `postgresql.conf` file with the location details for the keytab file and the principal name to use. The fully qualified host name and the default realm from `/etc/krb5.conf` forms the full service principal name.

```
krb_server_keyfile = '/data/master/gpseg-1/svcPostgresProd1.keytab'
krb_srvname = 'postgres'
```

Create a database role for the AD user. This example logs into the default database and runs the `CREATE ROLE` command. The user `dev1` was the user specified when creating the keytab file in Active Directory Setup.

```
psql create role dev1 with login superuser;
```

Restart the database to use the updated authentication information:

```
gpstop -a
gpstart
```

**Note:** The Greenplum Database libraries might conflict with the Kerberos workstation utilities such as `kinit`. If you are using these utilities on the Greenplum Database master, you can either run a `gpadmin` shell that does not source the `$GPHOME/greenplum_path.sh` script, or unset the `LD_LIBRARY_PATH` environment variable similar to this example:

```
unset LD_LIBRARY_PATH
kinit
source $GPHOME/greenplum_path.sh
```

Confirm Greenplum Database access with Kerberos authentication:

```
kinit dev1
psql -h prod1.example.local -U dev1
```

**Single Sign-On Examples**

These single sign-on examples that use AD and Kerberos assume that the AD user `dev1` configured for single sign-on is logged into the Windows desktop.

This example configures Aginity Workbench for Greenplum Database. When using single sign-on, you enable Use Integrated Security.
This example configures an ODBC source. When setting up the ODBC source, do not enter a User Name or Password. This DSN can then be used by applications as an ODBC data source.
You can use the DSN `testdata` with an R client. This example configures R to access the DSN.

```r
library("RODBC")
conn <- odbcDriverConnect("testdata")
sql <- "select * from public.data1"
my_data <- sqlQuery(conn, sql)
print(my_data)
```

**Issues and Possible Solutions for Active Directory**

- Kerberos tickets contain a version number that must match the version number for AD.

  To display the version number in your keytab file, use the `klist -ket` command. For example:

  ```bash
  klist -ket svcPostgresProd1.keytab
  ```

  To get the corresponding value from AD domain controller, run this command as an AD Administrator:

  ```bash
  kvno postgres/prod1.example.local@EXAMPLE.LOCAL
  ```

- This login error can occur when there is a mismatch between the Windows ID and the Greenplum Database user role ID. This log file entry shows the login error. A user `dev22` is attempting to login from a Windows desktop where the user is logged in as a different Windows user.

  ```plaintext
  PDT,1917,con32,,seg-1,,,x1917,sx1, "FATAL","28000","authentication failed for user ","dev22": valid
  ```
The error can also occur when the user can be authenticated, but does not have a Greenplum Database user role.

Ensure that the user is using the correct Windows ID and that a Greenplum Database user role is configured for the user ID.

• This error can occur when the Kerberos keytab does not contain a matching cryptographic type to a client attempting to connect.

```sql
psql -h 'hostname' postgres
```

psql: GSSAPI continuation error: Unspecified GSS failure. Minor code may provide more information
GSSAPI continuation error: Key version is not available

The resolution is to add the additional encryption types to the keytab using `ktutil` or recreating the postgres keytab with all crypto systems from AD.

### Managing Roles and Privileges

The Greenplum Database authorization mechanism stores roles and permissions to access database objects in the database and is administered using SQL statements or command-line utilities.

Greenplum Database manages database access permissions using **roles**. The concept of roles subsumes the concepts of **users** and **groups**. A role can be a database user, a group, or both. Roles can own database objects (for example, tables) and can assign privileges on those objects to other roles to control access to the objects. Roles can be members of other roles, thus a member role can inherit the object privileges of its parent role.

Every Greenplum Database system contains a set of database roles (users and groups). Those roles are separate from the users and groups managed by the operating system on which the server runs. However, for convenience you may want to maintain a relationship between operating system user names and Greenplum Database role names, since many of the client applications use the current operating system user name as the default.

In Greenplum Database, users log in and connect through the master instance, which then verifies their role and access privileges. The master then issues commands to the segment instances behind the scenes as the currently logged in role.

Roles are defined at the system level, meaning they are valid for all databases in the system.

In order to bootstrap the Greenplum Database system, a freshly initialized system always contains one predefined **superuser** role (also referred to as the system user). This role will have the same name as the operating system user that initialized the Greenplum Database system. Customarily, this role is named `gpadmin`. In order to create more roles you first have to connect as this initial role.

### Security Best Practices for Roles and Privileges

• **Secure the gpadmin system user.** Greenplum requires a UNIX user id to install and initialize the Greenplum Database system. This system user is referred to as `gpadmin` in the Greenplum documentation. This `gpadmin` user is the default database superuser in Greenplum Database, as well as the file system owner of the Greenplum installation and its underlying data files. This default administrator account is fundamental to the design of Greenplum Database. The system cannot run without it, and there is no way to limit the access of this gpadmin user id. Use roles to manage who has access to the database for specific purposes. You should only use the `gpadmin` account for system maintenance tasks such as expansion and upgrade. Anyone who logs on to a Greenplum host as this user id can read, alter or delete any data; including system catalog data and database access rights. Therefore, it is very important to secure the gpadmin user id and only provide access to essential system administrators. Administrators should only log in to Greenplum as `gpadmin` when performing
certain system maintenance tasks (such as upgrade or expansion). Database users should never log on as gpadmin, and ETL or production workloads should never run as gpadmin.

- Assign a distinct role to each user that logs in. For logging and auditing purposes, each user that is allowed to log in to Greenplum Database should be given their own database role. For applications or web services, consider creating a distinct role for each application or service. See Creating New Roles (Users).

- Use groups to manage access privileges. See Role Membership.

- Limit users who have the SUPERUSER role attribute. Roles that are superusers bypass all access privilege checks in Greenplum Database, as well as resource queuing. Only system administrators should be given superuser rights. See Altering Role Attributes.

Creating New Roles (Users)

A user-level role is considered to be a database role that can log in to the database and initiate a database session. Therefore, when you create a new user-level role using the CREATE ROLE command, you must specify the LOGIN privilege. For example:

```bash
=# CREATE ROLE jsmith WITH LOGIN;
```

A database role may have a number of attributes that define what sort of tasks that role can perform in the database. You can set these attributes when you create the role, or later using the ALTER ROLE command. See Table 60: Role Attributes for a description of the role attributes you can set.

### Altering Role Attributes

A database role may have a number of attributes that define what sort of tasks that role can perform in the database.

#### Table 60: Role Attributes

<table>
<thead>
<tr>
<th>Attributes</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SUPERUSER</td>
<td>NOSUPERUSER</td>
</tr>
<tr>
<td>CREATEDB</td>
<td>NOCREATEDB</td>
</tr>
<tr>
<td>CREATEROLE</td>
<td>NOCREATEROLE</td>
</tr>
<tr>
<td>INHERIT</td>
<td>NOINHERIT</td>
</tr>
<tr>
<td>LOGIN</td>
<td>NOLOGIN</td>
</tr>
<tr>
<td>CONNECTION LIMIT connlimit</td>
<td>If role can log in, this specifies how many concurrent connections the role can make. -1 (the default) means no limit.</td>
</tr>
<tr>
<td>Attributes</td>
<td>Description</td>
</tr>
<tr>
<td>-------------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>CREATEEXTTABLE</td>
<td>NOCREATEEXTTABLE</td>
</tr>
<tr>
<td>PASSWORD 'password'</td>
<td>Sets the role’s password. If you do not plan to use password authentication you can omit this option. If no password is specified, the password will be set to null and password authentication will always fail for that user. A null password can optionally be written explicitly as PASSWORD NULL.</td>
</tr>
<tr>
<td>ENCRYPTED</td>
<td>UNENCRYPTED</td>
</tr>
<tr>
<td>VALID UNTIL 'timestamp'</td>
<td>Sets a date and time after which the role’s password is no longer valid. If omitted the password will be valid for all time.</td>
</tr>
<tr>
<td>RESOURCE QUEUE queue_name</td>
<td>Assigns the role to the named resource queue for workload management. Any statement that role issues is then subject to the resource queue’s limits. Note that the RESOURCE QUEUE attribute is not inherited; it must be set on each user-level (LOGIN) role.</td>
</tr>
<tr>
<td>DENY (deny_interval</td>
<td>deny_point)</td>
</tr>
</tbody>
</table>

You can set these attributes when you create the role, or later using the ALTER ROLE command. For example:

```sql
=# ALTER ROLE jsmith WITH PASSWORD 'passwd123';
=# ALTER ROLE admin VALID UNTIL 'infinity';
=# ALTER ROLE jsmith LOGIN;
=# ALTER ROLE jsmith RESOURCE QUEUE adhoc;
=# ALTER ROLE jsmith DENY DAY 'Sunday';
```

A role can also have role-specific defaults for many of the server configuration settings. For example, to set the default schema search path for a role:

```sql
=# ALTER ROLE admin SET search_path TO myschema, public;
```

**Role Membership**

It is frequently convenient to group users together to ease management of object privileges: that way, privileges can be granted to, or revoked from, a group as a whole. In Greenplum Database this is done by creating a role that represents the group, and then granting membership in the group role to individual user roles.
Use the `CREATE ROLE` SQL command to create a new group role. For example:

```
=# CREATE ROLE admin CREATEROLE CREATEDB;
```

Once the group role exists, you can add and remove members (user roles) using the `GRANT` and `REVOKE` commands. For example:

```
=# GRANT admin TO john, sally;
=# REVOKE admin FROM bob;
```

For managing object privileges, you would then grant the appropriate permissions to the group-level role only (see Table 61: Object Privileges). The member user roles then inherit the object privileges of the group role. For example:

```
=# GRANT ALL ON TABLE mytable TO admin;
=# GRANT ALL ON SCHEMA myschema TO admin;
=# GRANT ALL ON DATABASE mydb TO admin;
```

The role attributes `LOGIN`, `SUPERUSER`, `CREATEDB`, `CREATEROLE`, `CREATEEXTTABLE`, and `RESOURCE QUEUE` are never inherited as ordinary privileges on database objects are. User members must actually `SET ROLE` to a specific role having one of these attributes in order to make use of the attribute. In the above example, we gave `CREATEDB` and `CREATEROLE` to the `admin` role. If `sally` is a member of `admin`, she could issue the following command to assume the role attributes of the parent role:

```
=> SET ROLE admin;
```

### Managing Object Privileges

When an object (table, view, sequence, database, function, language, schema, or tablespace) is created, it is assigned an owner. The owner is normally the role that executed the creation statement. For most kinds of objects, the initial state is that only the owner (or a superuser) can do anything with the object. To allow other roles to use it, privileges must be granted. Greenplum Database supports the following privileges for each object type:

#### Table 61: Object Privileges

<table>
<thead>
<tr>
<th>Object Type</th>
<th>Privileges</th>
</tr>
</thead>
<tbody>
<tr>
<td>Tables, Views, Sequences</td>
<td>SELECT, INSERT, UPDATE, DELETE, RULE, ALL</td>
</tr>
<tr>
<td>External Tables</td>
<td>SELECT, RULE, ALL</td>
</tr>
<tr>
<td>Object Type</td>
<td>Privileges</td>
</tr>
<tr>
<td>----------------------</td>
<td>-----------------------------</td>
</tr>
<tr>
<td>Databases</td>
<td>CONNECT</td>
</tr>
<tr>
<td></td>
<td>CREATE</td>
</tr>
<tr>
<td></td>
<td>TEMPORARY</td>
</tr>
<tr>
<td></td>
<td>ALL</td>
</tr>
<tr>
<td>Functions</td>
<td>EXECUTE</td>
</tr>
<tr>
<td>Procedural Languages</td>
<td>USAGE</td>
</tr>
<tr>
<td>Schemas</td>
<td>CREATE</td>
</tr>
<tr>
<td></td>
<td>USAGE</td>
</tr>
<tr>
<td></td>
<td>ALL</td>
</tr>
<tr>
<td>Custom Protocol</td>
<td>SELECT</td>
</tr>
<tr>
<td></td>
<td>INSERT</td>
</tr>
<tr>
<td></td>
<td>UPDATE</td>
</tr>
<tr>
<td></td>
<td>DELETE</td>
</tr>
<tr>
<td></td>
<td>RULE</td>
</tr>
<tr>
<td></td>
<td>ALL</td>
</tr>
</tbody>
</table>

**Note:** Privileges must be granted for each object individually. For example, granting ALL on a database does not grant full access to the objects within that database. It only grants all of the database-level privileges (CONNECT, CREATE, TEMPORARY) to the database itself.

Use the `GRANT` SQL command to give a specified role privileges on an object. For example:

```sql
=# GRANT INSERT ON mytable TO jsmith;
```

To revoke privileges, use the `REVOKE` command. For example:

```sql
=# REVOKE ALL PRIVILEGES ON mytable FROM jsmith;
```

You can also use the `DROP OWNED` and `REASSIGN OWNED` commands for managing objects owned by deprecated roles (Note: only an object's owner or a superuser can drop an object or reassign ownership). For example:

```sql
=# REASSIGN OWNED BY sally TO bob;
=# DROP OWNED BY visitor;
```

**Simulating Row and Column Level Access Control**

Row-level or column-level access is not supported, nor is labeled security. Row-level and column-level access can be simulated using views to restrict the columns and/or rows that are selected. Row-level labels can be simulated by adding an extra column to the table to store sensitivity information, and then using views to control row-level access based on this column. Roles can then be granted access to the views rather than the base table.

**Encrypting Data**

Greenplum Database is installed with an optional module of encryption/decryption functions called `pgcrypto`. The `pgcrypto` functions allow database administrators to store certain columns of data in...
encrypted form. This adds an extra layer of protection for sensitive data, as data stored in Greenplum Database in encrypted form cannot be read by anyone who does not have the encryption key, nor can it be read directly from the disks.

**Note:** The *pgcrypto* functions run inside the database server, which means that all the data and passwords move between *pgcrypto* and the client application in clear-text. For optimal security, consider also using SSL connections between the client and the Greenplum master server.

To use *pgcrypto* functions, run the installation script `$GPHOME/share/postgresql/contrib/pgcrypto.sql` in each database where you want the ability to query other databases:

```
$ psql -d testdb -f $GPHOME/share/postgresql/contrib/pgcrypto.sql
```

See *pgcrypto* in the PostgreSQL documentation for more information about individual functions.

## Protecting Passwords in Greenplum Database

In its default configuration, Greenplum Database saves MD5 hashes of login users' passwords in the `pg_authid` system catalog rather than saving clear text passwords. Anyone who is able to view the `pg_authid` table can see hash strings, but no passwords. This also ensures that passwords are obscured when the database is dumped to backup files.

The hash function executes when the password is set by using any of the following commands:

- `CREATE USER name WITH ENCRYPTED PASSWORD 'password'
- `CREATE ROLE name WITH LOGIN ENCRYPTED PASSWORD 'password'
- `ALTER USER name WITH ENCRYPTED PASSWORD 'password'
- `ALTER ROLE name WITH ENCRYPTED PASSWORD 'password'

The `ENCRYPTED` keyword may be omitted when the `password_encryption` system configuration parameter is `on`, which is the default value. The `password_encryption` configuration parameter determines whether clear text or hashed passwords are saved when the `ENCRYPTED` or `UNENCRYPTED` keyword is not present in the command.

**Note:** The SQL command syntax and `password_encryption` configuration variable include the term `encrypt`, but the passwords are not technically encrypted. They are hashed and therefore cannot be decrypted.

The hash is calculated on the concatenated clear text password and role name. The MD5 hash produces a 32-byte hexadecimal string prefixed with the characters `md5`. The hashed password is saved in the `rolpassword` column of the `pg_authid` system table.

Although it is not recommended, passwords may be saved in clear text in the database by including the `UNENCRYPTED` keyword in the command or by setting the `password_encryption` configuration variable to `off`. Note that changing the configuration value has no effect on existing passwords, only newly created or updated passwords.

To set `password_encryption` globally, execute these commands in a shell as the `gpadmin` user:

```
$ gpconfig -c password_encryption -v 'off'
$ gpstop -u
```

To set `password_encryption` in a session, use the SQL `SET` command:

```sql
=# SET password_encryption = 'on';
```

Passwords may be hashed using the SHA-256 hash algorithm instead of the default MD5 hash algorithm. The algorithm produces a 64-byte hexadecimal string prefixed with the characters `sha256`.

**Note:**
Although SHA-256 uses a stronger cryptographic algorithm and produces a longer hash string, it cannot be used with the MD5 authentication method. To use SHA-256 password hashing the authentication method must be set to `password` in the `pg_hba.conf` configuration file so that clear text passwords are sent to Greenplum Database. Because clear text passwords are sent over the network, it is very important to use SSL for client connections when you use SHA-256. The default `md5` authentication method, on the other hand, hashes the password twice before sending it to Greenplum Database, once on the password and role name and then again with a salt value shared between the client and server, so the clear text password is never sent on the network.

To enable SHA-256 hashing, change the `password_hash_algorithm` configuration parameter from its default value, `md5`, to `sha-256`. The parameter can be set either globally or at the session level. To set `password_hash_algorithm` globally, execute these commands in a shell as the `gpadmin` user:

```
$ gpconfig -c password_hash_algorithm -v 'sha-256'
$ gpstop -u
```

To set `password_hash_algorithm` in a session, use the SQL `SET` command:

```
=# SET password_hash_algorithm = 'sha-256';
```

**Time-based Authentication**

Greenplum Database enables the administrator to restrict access to certain times by role. Use the `CREATE ROLE` or `ALTER ROLE` commands to specify time-based constraints.

For details, refer to the *Greenplum Database Security Configuration Guide*. 
Defining Database Objects

This section covers data definition language (DDL) in Greenplum Database and how to create and manage database objects.

Creating objects in a Greenplum Database includes making up-front choices about data distribution, storage options, data loading, and other Greenplum features that will affect the ongoing performance of your database system. Understanding the options that are available and how the database will be used will help you make the right decisions.

Most of the advanced Greenplum features are enabled with extensions to the SQL `CREATE DDL` statements.

Creating and Managing Databases

A Greenplum Database system is a single instance of Greenplum Database. There can be several separate Greenplum Database systems installed, but usually just one is selected by environment variable settings. See your Greenplum administrator for details.

There can be multiple databases in a Greenplum Database system. This is different from some database management systems (such as Oracle) where the database instance is the database. Although you can create many databases in a Greenplum system, client programs can connect to and access only one database at a time — you cannot cross-query between databases.

About Template Databases

Each new database you create is based on a template. Greenplum provides a default database, `template1`. Use `postgres` to connect to Greenplum Database for the first time. Greenplum Database uses `template1` to create databases unless you specify another template. Do not create any objects in `template1` unless you want those objects to be in every database you create.

Greenplum Database uses another database templates, `template0`, internally. Do not drop or modify `template0`. You can use `template0` to create a completely clean database containing only the standard objects predefined by Greenplum Database at initialization, especially if you modified `template1`.

Creating a Database

The `CREATE DATABASE` command creates a new database. For example:

```
=> CREATE DATABASE new_dbname;
```

To create a database, you must have privileges to create a database or be a Greenplum Database superuser. If you do not have the correct privileges, you cannot create a database. Contact your Greenplum Database administrator to either give you the necessary privilege or to create a database for you.

You can also use the client program `createdb` to create a database. For example, running the following command in a command line terminal connects to Greenplum Database using the provided host name and port and creates a database named `mydatabase`:

```
$ createdb -h masterhost -p 5432 mydatabase
```

The host name and port must match the host name and port of the installed Greenplum Database system.

Some objects, such as roles, are shared by all the databases in a Greenplum Database system. Other objects, such as tables that you create, are known only in the database in which you create them.

**Warning:** The `CREATE DATABASE` command is not transactional.
**Cloning a Database**

By default, a new database is created by cloning the standard system database template, `template1`. Any database can be used as a template when creating a new database, thereby providing the capability to ‘clone’ or copy an existing database and all objects and data within that database. For example:

```
=> CREATE DATABASE new_dbname TEMPLATE old_dbname;
```

**Creating a Database with a Different Owner**

Another database owner can be assigned when a database is created:

```
=> CREATE DATABASE new_dbname WITH owner=new_user;
```

**Viewing the List of Databases**

If you are working in the `psql` client program, you can use the `\l` meta-command to show the list of databases and templates in your Greenplum Database system. If using another client program and you are a superuser, you can query the list of databases from the `pg_database` system catalog table. For example:

```
=> SELECT datname from pg_database;
```

**Altering a Database**

The `ALTER DATABASE` command changes database attributes such as owner, name, or default configuration attributes. For example, the following command alters a database by setting its default schema search path (the `search_path` configuration parameter):

```
=> ALTER DATABASE mydatabase SET search_path TO myschema, public, pg_catalog;
```

To alter a database, you must be the owner of the database or a superuser.

**Dropping a Database**

The `DROP DATABASE` command drops (or deletes) a database. It removes the system catalog entries for the database and deletes the database directory on disk that contains the data. You must be the database owner or a superuser to drop a database, and you cannot drop a database while you or anyone else is connected to it. Connect to `postgres` (or another database) before dropping a database. For example:

```
=> \c postgres
=> DROP DATABASE mydatabase;
```

You can also use the client program `dropdb` to drop a database. For example, the following command connects to Greenplum Database using the provided host name and port and drops the database `mydatabase`:

```
$ dropdb -h masterhost -p 5432 mydatabase
```

**Warning:** Dropping a database cannot be undone.

The `DROP DATABASE` command is not transactional.
Creating and Managing Tablespaces

Tablespaces allow database administrators to have multiple file systems per machine and decide how to best use physical storage to store database objects. They are named locations within a filespace in which you can create objects. Tablespaces allow you to assign different storage for frequently and infrequently used database objects or to control the I/O performance on certain database objects. For example, place frequently-used tables on file systems that use high performance solid-state drives (SSD), and place other tables on standard hard drives.

A tablespace requires a file system location to store its database files. In Greenplum Database, the master and each segment (primary and mirror) require a distinct storage location. The collection of file system locations for all components in a Greenplum system is a filespace. Filespaces can be used by one or more tablespaces.

Creating a Filespace

A filespace sets aside storage for your Greenplum system. A filespace is a symbolic storage identifier that maps onto a set of locations in your Greenplum hosts’ file systems. To create a filespace, prepare the logical file systems on all of your Greenplum hosts, then use the gpfilespace utility to define the filespace. You must be a database superuser to create a filespace.

Note: Greenplum Database is not directly aware of the file system boundaries on your underlying systems. It stores files in the directories that you tell it to use. You cannot control the location on disk of individual files within a logical file system.

To create a filespace using gpfilespace

1. Log in to the Greenplum Database master as the gpadmin user.
   ```
   $ su - gpadmin
   ```

2. Create a filespace configuration file:
   ```
   $ gpfilespace -o gpfilespace_config
   ```

3. At the prompt, enter a name for the filespace, the primary segment file system locations, the mirror segment file system locations, and a master file system location. Primary and mirror locations refer to directories on segment hosts; the master location refers to a directory on the master host and standby master, if configured. For example, if your configuration has 2 primary and 2 mirror segments per host:
   ```
   Enter a name for this filespace> fastdisk
   primary location 1> /gpfs1/seg1
   primary location 2> /gpfs1/seg2
   mirror location 1> /gpfs2/mir1
   mirror location 2> /gpfs2/mir2
   master location> /gpfs1/master
   ```

4. gpfilespace creates a configuration file. Examine the file to verify that the gpfilespace configuration is correct.

5. Run gpfilespace again to create the filespace based on the configuration file:
   ```
   $ gpfilespace -c gpfilespace_config
   ```

Moving the Location of Temporary or Transaction Files

You can move temporary or transaction files to a specific filespace to improve database performance when running queries, creating backups, and to store data more sequentially.
The dedicated filespace for temporary and transaction files is tracked in two separate flat files called `gp_temporary_files_filespace` and `gp_transaction_files_filespace`. These are located in the `pg_system` directory on each primary and mirror segment, and on master and standby. You must be a superuser to move temporary or transaction files. Only the `gpfilespace` utility can write to this file.

**About Temporary and Transaction Files**

Unless otherwise specified, temporary and transaction files are stored together with all user data. The default location of temporary files, `<filespace_directory>/<tablespace_oid>/<database_oid>/pgsql_tmp` is changed when you use `gpfilespace --movetempfiles` for the first time.

Also note the following information about temporary or transaction files:

- You can dedicate only one filespace for temporary or transaction files, although you can use the same filespace to store other types of files.
- You cannot drop a filespace if it used by temporary files.
- You must create the filespace in advance. See Creating a Filespace.

**To move temporary files using gpfilespace**

1. Check that the filespace exists and is different from the filespace used to store all other user data.
2. Issue smart shutdown to bring the Greenplum Database offline.
   
   If any connections are still in progress, the `gpfilespace --movetempfiles` utility will fail.
3. Bring Greenplum Database online with no active session and run the following command:

```
    gpfilespace --movetempfilespace filespace_name
```

   The location of the temporary files is stored in the segment configuration shared memory (PMModuleState) and used whenever temporary files are created, opened, or dropped.

**To move transaction files using gpfilespace**

1. Check that the filespace exists and is different from the filespace used to store all other user data.
2. Issue smart shutdown to bring the Greenplum Database offline.
   
   If any connections are still in progress, the `gpfilespace --movetransfiles` utility will fail.
3. Bring Greenplum Database online with no active session and run the following command:

```
    gpfilespace --movetransfilespace filespace_name
```

   The location of the transaction files is stored in the segment configuration shared memory (PMModuleState) and used whenever transaction files are created, opened, or dropped.

**Creating a Tablespace**

After you create a filespace, use the `CREATE TABLESPACE` command to define a tablespace that uses that filespace. For example:

```
    # CREATE TABLESPACE fastspace FILESPACE fastdisk;
```

Database superusers define tablespaces and grant access to database users with the `GRANT CREATE` command. For example:

```
    # GRANT CREATE ON TABLESPACE fastspace TO admin;
```
Using a Tablespace to Store Database Objects

Users with the `CREATE` privilege on a tablespace can create database objects in that tablespace, such as tables, indexes, and databases. The command is:

```
CREATE TABLE tablename(options) TABLESPACE spacename
```

For example, the following command creates a table in the tablespace `space1`:

```
CREATE TABLE foo(i int) TABLESPACE space1;
```

You can also use the `default_tablespace` parameter to specify the default tablespace for `CREATE TABLE` and `CREATE INDEX` commands that do not specify a tablespace:

```
SET default_tablespace = space1;
CREATE TABLE foo(i int);
```

The tablespace associated with a database stores that database's system catalogs, temporary files created by server processes using that database, and is the default tablespace selected for tables and indexes created within the database, if no `TABLESPACE` is specified when the objects are created. If you do not specify a tablespace when you create a database, the database uses the same tablespace used by its template database.

You can use a tablespace from any database if you have appropriate privileges.

Viewing Existing Tablespaces and Filespaces

Every Greenplum Database system has the following default tablespaces.

- `pg_global` for shared system catalogs.
- `pg_default`, the default tablespace. Used by the `template1` and `template0` databases.

These tablespaces use the system default filesystem, `pg_system`, the data directory location created at system initialization.

To see filesystem information, look in the `pg_filespace` and `pg_filespace_entry` catalog tables. You can join these tables with `pg_tablespace` to see the full definition of a tablespace. For example:

```
=# SELECT spcname as tblspc, fsname as filespc,
    fsedbid as seg_dbid, fselocation as datadir
    FROM   pg_tablespace pgts, pg_filespace pgfs,
            pg_filespace_entry pgfse
    WHERE  pgts.spcfsoid=pgfse.fsefsoid
                AND pgfse.fsefsoid=pgfs.oid
    ORDER BY tblspc, seg_dbid;
```

Dropping Tablespaces and Filespaces

To drop a tablespace, you must be the tablespace owner or a superuser. You cannot drop a tablespace until all objects in all databases using the tablespace are removed.

Only a superuser can drop a filesystem. A filesystem cannot be dropped until all tablespaces using that filesystem are removed.

The `DROP TABLESPACE` command removes an empty tablespace.

The `DROP FILESPACE` command removes an empty filesystem.

**Note:** You cannot drop a filesystem if it stores temporary or transaction files.
Creating and Managing Schemas

Schemas logically organize objects and data in a database. Schemas allow you to have more than one object (such as tables) with the same name in the database without conflict if the objects are in different schemas.

The Default "Public" Schema

Every database has a default schema named public. If you do not create any schemas, objects are created in the public schema. All database roles (users) have CREATE and USAGE privileges in the public schema. When you create a schema, you grant privileges to your users to allow access to the schema.

Creating a Schema

Use the CREATE SCHEMA command to create a new schema. For example:

```sql
=> CREATE SCHEMA myschema;
```

To create or access objects in a schema, write a qualified name consisting of the schema name and table name separated by a period. For example:

`myschema.table`

See Schema Search Paths for information about accessing a schema.

You can create a schema owned by someone else, for example, to restrict the activities of your users to well-defined namespaces. The syntax is:

```sql
=> CREATE SCHEMA schemaname  AUTHORIZATION username ;
```

Schema Search Paths

To specify an object's location in a database, use the schema-qualified name. For example:

```sql
=> SELECT * FROM myschema.mytable;
```

You can set the search_path configuration parameter to specify the order in which to search the available schemas for objects. The schema listed first in the search path becomes the default schema. If a schema is not specified, objects are created in the default schema.

Setting the Schema Search Path

The search_path configuration parameter sets the schema search order. The ALTER DATABASE command sets the search path. For example:

```sql
=> ALTER DATABASE mydatabase SET search_path TO myschema, public, pg_catalog;
```

You can also set search_path for a particular role (user) using the ALTER ROLE command. For example:

```sql
=> ALTER ROLE sally SET search_path TO myschema, public, pg_catalog;
```
**Viewing the Current Schema**

Use the `current_schema()` function to view the current schema. For example:

```sql
=> SELECT current_schema();
```

Use the `SHOW` command to view the current search path. For example:

```sql
=> SHOW search_path;
```

**Dropping a Schema**

Use the `DROP SCHEMA` command to drop (delete) a schema. For example:

```sql
=> DROP SCHEMA myschema;
```

By default, the schema must be empty before you can drop it. To drop a schema and all of its objects (tables, data, functions, and so on) use:

```sql
=> DROP SCHEMA myschema CASCADE;
```

**System Schemas**

The following system-level schemas exist in every database:

- `pg_catalog` contains the system catalog tables, built-in data types, functions, and operators. It is always part of the schema search path, even if it is not explicitly named in the search path.
- `information_schema` consists of a standardized set of views that contain information about the objects in the database. These views get system information from the system catalog tables in a standardized way.
- `pg_toast` stores large objects such as records that exceed the page size. This schema is used internally by the Greenplum Database system.
- `pg_bitmapindex` stores bitmap index objects such as lists of values. This schema is used internally by the Greenplum Database system.
- `pg_aoseg` stores append-optimized table objects. This schema is used internally by the Greenplum Database system.
- `gp_toolkit` is an administrative schema that contains external tables, views, and functions that you can access with SQL commands. All database users can access `gp_toolkit` to view and query the system log files and other system metrics.

**Creating and Managing Tables**

Greenplum Database tables are similar to tables in any relational database, except that table rows are distributed across the different segments in the system. When you create a table, you specify the table’s distribution policy.

**Creating a Table**

The `CREATE TABLE` command creates a table and defines its structure. When you create a table, you define:

- The columns of the table and their associated data types. See *Choosing Column Data Types*.
- Any table or column constraints to limit the data that a column or table can contain. See *Setting Table and Column Constraints*.
• The distribution policy of the table, which determines how Greenplum Database divides data is across the segments. See Choosing the Table Distribution Policy.
• The way the table is stored on disk. See Choosing the Table Storage Model.
• The table partitioning strategy for large tables. See Creating and Managing Databases.

Choosing Column Data Types

The data type of a column determines the types of data values the column can contain. Choose the data type that uses the least possible space but can still accommodate your data and that best constrains the data. For example, use character data types for strings, date or timestamp data types for dates, and numeric data types for numbers.

For table columns that contain textual data, specify the data type VARCHAR or TEXT. Specifying the data type CHAR is not recommended. In Greenplum Database, the data types VARCHAR or TEXT handles padding added to the data (space characters added after the last non-space character) as significant characters, the data type CHAR does not. For information on the character data types, see the CREATE TABLE command in the Greenplum Database Reference Guide.

Use the smallest numeric data type that will accommodate your numeric data and allow for future expansion. For example, using BIGINT for data that fits in INT or SMALLINT wastes storage space. If you expect that your data values will expand over time, consider that changing from a smaller datatype to a larger datatype after loading large amounts of data is costly. For example, if your current data values fit in a SMALLINT but it is likely that the values will expand, INT is the better long-term choice.

Use the same data types for columns that you plan to use in cross-table joins. Cross-table joins usually use the primary key in one table and a foreign key in the other table. When the data types are different, the database must convert one of them so that the data values can be compared correctly, which adds unnecessary overhead.

Greenplum Database has a rich set of native data types available to users. See the Greenplum Database Reference Guide for information about the built-in data types.

Setting Table and Column Constraints

You can define constraints on columns and tables to restrict the data in your tables. Greenplum Database support for constraints is the same as PostgreSQL with some limitations, including:

• CHECK constraints can refer only to the table on which they are defined.
• UNIQUE and PRIMARY KEY constraints must be compatible with their table’s distribution key and partitioning key, if any.

  Note: UNIQUE and PRIMARY KEY constraints are not allowed on append-optimized tables because the UNIQUE indexes that are created by the constraints are not allowed on append-optimized tables.
• FOREIGN KEY constraints are allowed, but not enforced.
• Constraints that you define on partitioned tables apply to the partitioned table as a whole. You cannot define constraints on the individual parts of the table.

Check Constraints

Check constraints allow you to specify that the value in a certain column must satisfy a Boolean (truth-value) expression. For example, to require positive product prices:

```sql
=> CREATE TABLE products
   ( product_no integer,
     name text,
     price numeric CHECK (price > 0) );
```
**Not-Null Constraints**

Not-null constraints specify that a column must not assume the null value. A not-null constraint is always written as a column constraint. For example:

```sql
=> CREATE TABLE products
   ( product_no integer NOT NULL,
     name text NOT NULL,
     price numeric );
```

**Unique Constraints**

Unique constraints ensure that the data contained in a column or a group of columns is unique with respect to all the rows in the table. The table must be hash-distributed (not DISTRIBUTED RANDOMLY), and the constraint columns must be the same as (or a superset of) the table's distribution key columns. For example:

```sql
=> CREATE TABLE products
   ( product_no integer UNIQUE,
     name text,
     price numeric )
   DISTRIBUTED BY (product_no);
```

**Primary Keys**

A primary key constraint is a combination of a UNIQUE constraint and a NOT NULL constraint. The table must be hash-distributed (not DISTRIBUTED RANDOMLY), and the primary key columns must be the same as (or a superset of) the table's distribution key columns. If a table has a primary key, this column (or group of columns) is chosen as the distribution key for the table by default. For example:

```sql
=> CREATE TABLE products
   ( product_no integer PRIMARY KEY,
     name text,
     price numeric )
   DISTRIBUTED BY (product_no);
```

**Foreign Keys**

Foreign keys are not supported. You can declare them, but referential integrity is not enforced.

Foreign key constraints specify that the values in a column or a group of columns must match the values appearing in some row of another table to maintain referential integrity between two related tables. Referential integrity checks cannot be enforced between the distributed table segments of a Greenplum database.

**Choosing the Table Distribution Policy**

All Greenplum Database tables are distributed. When you create or alter a table, you optionally specify DISTRIBUTED BY (hash distribution) or DISTRIBUTED RANDOMLY (round-robin distribution) to determine the table row distribution.

**Note:** The Greenplum Database server configuration parameter `gp_create_table_random_default_distribution` controls the table distribution policy if the DISTRIBUTED BY clause is not specified when you create a table.

For information about the parameter, see “Server Configuration Parameters” of the *Greenplum Database Reference Guide*.

Consider the following points when deciding on a table distribution policy.
• **Even Data Distribution** — For the best possible performance, all segments should contain equal portions of data. If the data is unbalanced or skewed, the segments with more data must work harder to perform their portion of the query processing. Choose a distribution key that is unique for each record, such as the primary key.

• **Local and Distributed Operations** — Local operations are faster than distributed operations. Query processing is fastest if the work associated with join, sort, or aggregation operations is done locally, at the segment level. Work done at the system level requires distributing tuples across the segments, which is less efficient. When tables share a common distribution key, the work of joining or sorting on their shared distribution key columns is done locally. With a random distribution policy, local join operations are not an option.

• **Even Query Processing** — For best performance, all segments should handle an equal share of the query workload. Query workload can be skewed if a table's data distribution policy and the query predicates are not well matched. For example, suppose that a sales transactions table is distributed on the customer ID column (the distribution key). If a predicate in a query references a single customer ID, the query processing work is concentrated on just one segment.

### Declaring Distribution Keys

CREATE TABLE’s optional clauses DISTRIBUTED BY and DISTRIBUTED RANDOMLY specify the distribution policy for a table. The default is a hash distribution policy that uses either the PRIMARY KEY (if the table has one) or the first column of the table as the distribution key. Columns with geometric or user-defined data types are not eligible as Greenplum distribution key columns. If a table does not have an eligible column, Greenplum distributes the rows randomly or in round-robin fashion.

To ensure even distribution of data, choose a distribution key that is unique for each record. If that is not possible, choose DISTRIBUTED RANDOMLY. For example:

```sql
=> CREATE TABLE products
   (name varchar(40),
    prod_id integer,
    supplier_id integer)
   DISTRIBUTED BY (prod_id);

=> CREATE TABLE random_stuff
   (things text,
    doodads text,
    etc text)
   DISTRIBUTED RANDOMLY;
```

**Important:** A Primary Key is always the Distribution Key for a table. If no Primary Key exists, but a Unique Key exists, this is the Distribution Key for the table.

### Choosing the Table Storage Model

Greenplum Database supports several storage models and a mix of storage models. When you create a table, you choose how to store its data. This topic explains the options for table storage and how to choose the best storage model for your workload.

• **Heap Storage**
• **Append-Optimized Storage**
• **Choosing Row or Column-Oriented Storage**
• **Using Compression (Append-Optimized Tables Only)**
• **Checking the Compression and Distribution of an Append-Optimized Table**
• **Altering a Table**
• **Dropping a Table**
Note: To simplify the creation of database tables, you can specify the default values for some table storage options with the Greenplum Database server configuration parameter `gp_default_storage_options`.

For information about the parameter, see "Server Configuration Parameters" in the Greenplum Database Reference Guide.

Heap Storage

By default, Greenplum Database uses the same heap storage model as PostgreSQL. Heap table storage works best with OLTP-type workloads where the data is often modified after it is initially loaded. `UPDATE` and `DELETE` operations require storing row-level versioning information to ensure reliable database transaction processing. Heap tables are best suited for smaller tables, such as dimension tables, that are often updated after they are initially loaded.

Append-Optimized Storage

Append-optimized table storage works best with denormalized fact tables in a data warehouse environment. Denormalized fact tables are typically the largest tables in the system. Fact tables are usually loaded in batches and accessed by read-only queries. Moving large fact tables to an append-optimized storage model eliminates the storage overhead of the per-row update visibility information, saving about 20 bytes per row. This allows for a leaner and easier-to-optimize page structure. The storage model of append-optimized tables is optimized for bulk data loading. Single row `INSERT` statements are not recommended.

To create a heap table

Row-oriented heap tables are the default storage type.

```sql
=> CREATE TABLE foo (a int, b text) DISTRIBUTED BY (a);
```

To create an append-optimized table

Use the `WITH` clause of the `CREATE TABLE` command to declare the table storage options. The default is to create the table as a regular row-oriented heap-storage table. For example, to create an append-optimized table with no compression:

```sql
=> CREATE TABLE bar (a int, b text)
    WITH (appendonly=true)
    DISTRIBUTED BY (a);
```

`UPDATE` and `DELETE` are not allowed on append-optimized tables in a serializable transaction and will cause the transaction to abort. `CLUSTER`, `DECLARE...FOR UPDATE`, and triggers are not supported with append-optimized tables.

Choosing Row or Column-Oriented Storage

Greenplum provides a choice of storage orientation models: row, column, or a combination of both. This topic provides general guidelines for choosing the optimum storage orientation for a table. Evaluate performance using your own data and query workloads.

- Row-oriented storage: good for OLTP types of workloads with many iterative transactions and many columns of a single row needed all at once, so retrieving is efficient.
- Column-oriented storage: good for data warehouse workloads with aggregations of data computed over a small number of columns, or for single columns that require regular updates without modifying other column data.
For most general purpose or mixed workloads, row-oriented storage offers the best combination of flexibility and performance. However, there are use cases where a column-oriented storage model provides more efficient I/O and storage. Consider the following requirements when deciding on the storage orientation model for a table:

- **Updates of table data.** If you load and update the table data frequently, choose a row-oriented heap table. Column-oriented table storage is only available on append-optimized tables. See **Heap Storage** for more information.

- **Frequent INSERTs.** If rows are frequently inserted into the table, consider a row-oriented model. Column-oriented tables are not optimized for write operations, as column values for a row must be written to different places on disk.

- **Number of columns requested in queries.** If you typically request all or the majority of columns in the `SELECT` list or `WHERE` clause of your queries, consider a row-oriented model. Column-oriented tables are best suited to queries that aggregate many values of a single column where the `WHERE` or `HAVING` predicate is also on the aggregate column. For example:

  ```sql
  SELECT SUM(salary)...
  ```

  ```sql
  SELECT AVG(salary)... WHERE salary > 10000
  ```

  Or where the `WHERE` predicate is on a single column and returns a relatively small number of rows. For example:

  ```sql
  SELECT salary, dept ... WHERE state='CA'
  ```

- **Number of columns in the table.** Row-oriented storage is more efficient when many columns are required at the same time, or when the row-size of a table is relatively small. Column-oriented tables can offer better query performance on tables with many columns where you access a small subset of columns in your queries.

- **Compression.** Column data has the same data type, so storage size optimizations are available in column-oriented data that are not available in row-oriented data. For example, many compression schemes use the similarity of adjacent data to compress. However, the greater adjacent compression achieved, the more difficult random access can become, as data must be uncompressed to be read.

**To create a column-oriented table**

The `WITH` clause of the `CREATE TABLE` command specifies the table's storage options. The default is a row-oriented heap table. Tables that use column-oriented storage must be append-optimized tables. For example, to create a column-oriented table:

```sql
=> CREATE TABLE bar (a int, b text)
    WITH (appendonly=true, orientation=column)
    DISTRIBUTED BY (a);
```

**Using Compression (Append-Optimized Tables Only)**

There are two types of in-database compression available in the Greenplum Database for append-optimized tables:

- Table-level compression is applied to an entire table.
- Column-level compression is applied to a specific column. You can apply different column-level compression algorithms to different columns.

The following table summarizes the available compression algorithms.
### Table 62: Compression Algorithms for Append-Optimized Tables

<table>
<thead>
<tr>
<th>Table Orientation</th>
<th>Available Compression Types</th>
<th>Supported Algorithms</th>
</tr>
</thead>
<tbody>
<tr>
<td>Row</td>
<td>Table</td>
<td>ZLIB and QUICKLZ(^1)</td>
</tr>
<tr>
<td>Column</td>
<td>Column and Table</td>
<td>RLE_TYPE, ZLIB, and QUICKLZ(^1)</td>
</tr>
</tbody>
</table>

\(^1\)QuickLZ compression is not available in the open source version of Greenplum Database.

When choosing a compression type and level for append-optimized tables, consider these factors:

- **CPU usage.** Your segment systems must have the available CPU power to compress and uncompress the data.
- **Compression ratio/disk size.** Minimizing disk size is one factor, but also consider the time and CPU capacity required to compress and scan data. Find the optimal settings for efficiently compressing data without causing excessively long compression times or slow scan rates.
- **Speed of compression.** QuickLZ compression generally uses less CPU capacity and compresses data faster at a lower compression ratio than zlib. zlib provides higher compression ratios at lower speeds.

For example, at compression level 1 (`compresslevel=1`), QuickLZ and zlib have comparable compression ratios, though at different speeds. Using zlib with `compresslevel=6` can significantly increase the compression ratio compared to QuickLZ, though with lower compression speed.

- **Speed of decompression/scan rate.** Performance with compressed append-optimized tables depends on hardware, query tuning settings, and other factors. Perform comparison testing to determine the actual performance in your environment.

**Note:** Do not create compressed append-optimized tables on file systems that use compression. If the file system on which your segment data directory resides is a compressed file system, your append-optimized table must not use compression.

Performance with compressed append-optimized tables depends on hardware, query tuning settings, and other factors. You should perform comparison testing to determine the actual performance in your environment.

**Note:** QuickLZ compression level can only be set to level 1; no other options are available. Compression level with zlib can be set at values from 1 - 9. Compression level with RLE can be set at values from 1 - 4.

An **ENCODING** clause specifies compression type and level for individual columns. When an **ENCODING** clause conflicts with a **WITH** clause, the **ENCODING** clause has higher precedence than the **WITH** clause.

### To create a compressed table

The **WITH** clause of the **CREATE TABLE** command declares the table storage options. Tables that use compression must be append-optimized tables. For example, to create an append-optimized table with zlib compression at a compression level of 5:

```sql
=> CREATE TABLE foo (a int, b text)
   WITH (appendonly=true, compressstype=zlib, compresslevel=5);
```

### Checking the Compression and Distribution of an Append-Optimized Table

Greenplum provides built-in functions to check the compression ratio and the distribution of an append-optimized table. The functions take either the object ID or a table name. You can qualify the table name with a schema name.
Table 63: Functions for compressed append-optimized table metadata

<table>
<thead>
<tr>
<th>Function</th>
<th>Return Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>get_ao_distribution(name)</td>
<td>Set of (dbid, tuplecount) rows</td>
<td>Shows the distribution of an append-optimized table’s rows across the array. Returns a set of rows, each of which includes a segment dbid and the number of tuples stored on the segment.</td>
</tr>
<tr>
<td>get_ao_distribution(oid)</td>
<td></td>
<td></td>
</tr>
<tr>
<td>get_ao_compression_ratio(name)</td>
<td>float8</td>
<td>Calculates the compression ratio for a compressed append-optimized table. If information is not available, this function returns a value of -1.</td>
</tr>
<tr>
<td>get_ao_compression_ratio(oid)</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

The compression ratio is returned as a common ratio. For example, a returned value of 3.19, or 3.19:1, means that the uncompressed table is slightly larger than three times the size of the compressed table.

The distribution of the table is returned as a set of rows that indicate how many tuples are stored on each segment. For example, in a system with four primary segments with dbid values ranging from 0 - 3, the function returns four rows similar to the following:

```
=# SELECT get_ao_distribution('lineitem_comp');
get_ao_distribution
---------------------
(0,7500721)
(1,7501365)
(2,7499978)
(3,7497731)
(4 rows)
```

Support for Run-length Encoding

Greenplum Database supports Run-length Encoding (RLE) for column-level compression. RLE data compression stores repeated data as a single data value and a count. For example, in a table with two columns, a date and a description, that contains 200,000 entries containing the value date1 and 400,000 entries containing the value date2, RLE compression for the date field is similar to date1 200000 date2 400000. RLE is not useful with files that do not have large sets of repeated data as it can greatly increase the file size.

There are four levels of RLE compression available. The levels progressively increase the compression ratio, but decrease the compression speed.

Greenplum Database versions 4.2.1 and later support column-oriented RLE compression. To backup a table with RLE compression that you intend to restore to an earlier version of Greenplum Database, alter the table to have no compression or a compression type supported in the earlier version (ZLIB or QUICKLZ) before you start the backup operation.

Greenplum Database combines delta compression with RLE compression for data in columns of type BIGINT, INTEGER, DATE, TIME, or TIMESTAMP. The delta compression algorithm is based on the change between consecutive column values and is designed to improve compression when data is loaded in sorted order or when the compression is applied to data in sorted order.

Adding Column-level Compression

You can add the following storage directives to a column for append-optimized tables with column orientation:
- Compression type
- Compression level
- Block size for a column

Add storage directives using the `CREATE TABLE`, `ALTER TABLE`, and `CREATE TYPE` commands.

The following table details the types of storage directives and possible values for each.

### Table 64: Storage Directives for Column-level Compression

<table>
<thead>
<tr>
<th>Name</th>
<th>Definition</th>
<th>Values</th>
<th>Comment</th>
</tr>
</thead>
<tbody>
<tr>
<td>COMPRESSTYPE</td>
<td>Type of compression.</td>
<td>zlib: deflate algorithm quicklz: fast compression RLE_TYPE: run-length encoding none: no compression</td>
<td>Values are not case-sensitive.</td>
</tr>
<tr>
<td>COMPRESSLEVEL</td>
<td>Compression level.</td>
<td>zlib compression: 1-9 RLE_TYPE compression: 1 – use compression</td>
<td>1 is the fastest method with the least compression. 1 is the default. 9 is the slowest method with the most compression.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>RLE_TYPE compression: 1 – 4</td>
<td>1 is the default. 4 is the slowest method with the most compression.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>1 - apply RLE only</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>2 - apply RLE then apply zlib compression level 1</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>3 - apply RLE then apply zlib compression level 5</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>4 - apply RLE then apply zlib compression level 9</td>
<td></td>
</tr>
<tr>
<td>BLOCKSIZE</td>
<td>The size in bytes for each block in the table</td>
<td>8192 – 2097152</td>
<td>The value must be a multiple of 8192.</td>
</tr>
</tbody>
</table>

The following is the format for adding storage directives.

```
[ ENCODING ( storage_directive [,...] ) ]
```

where the word `ENCODING` is required and the storage directive has three parts:

- The name of the directive
- An equals sign
- The specification
Separate multiple storage directives with a comma. Apply a storage directive to a single column or designate it as the default for all columns, as shown in the following `CREATE TABLE` clauses.

**General Usage:**

```
column_name  data_type  ENCODING (storage_directive [, ... ] ), ...
```

```
COLUMN  column_name  ENCODING (storage_directive [, ... ] ), ...
```

```
DEFAULT COLUMN  ENCODING (storage_directive [, ... ] )
```

**Example:**

```
C1  char  ENCODING (compressstype=quicklz, blocksize=65536)
```

```
COLUMN  C1  ENCODING (compressstype=zlib, compresslevel=6, blocksize=65536)
```

```
DEFAULT COLUMN  ENCODING (compressstype=quicklz)
```

**Default Compression Values**

If the compression type, compression level and block size are not defined, the default is no compression, and the block size is set to the Server Configuration Parameter `block_size`.

**Precedence of Compression Settings**

Column compression settings are inherited from the table level to the partition level to the subpartition level. The lowest-level settings have priority.

- Column compression settings specified at the table level override any compression settings for the entire table.
- Column compression settings specified for partitions override any compression settings at the column or table levels.
- Column compression settings specified for subpartitions override any compression settings at the partition, column or table levels.
- When an `ENCODING` clause conflicts with a `WITH` clause, the `ENCODING` clause has higher precedence than the `WITH` clause.

**Note:** The `INHERITS` clause is not allowed in a table that contains a storage directive or a column reference storage directive.

Tables created using the `LIKE` clause ignore storage directive and column reference storage directives.

**Optimal Location for Column Compression Settings**

The best practice is to set the column compression settings at the level where the data resides. See **Example 5**, which shows a table with a partition depth of 2. `RLE_TYPE` compression is added to a column at the subpartition level.

**Storage Directives Examples**

The following examples show the use of storage directives in `CREATE TABLE` statements.
Example 1

In this example, column c1 is compressed using zlib and uses the block size defined by the system. Column c2 is compressed with quicklz, and uses a block size of 65536. Column c3 is not compressed and uses the block size defined by the system.

```sql
CREATE TABLE T1 (c1 int ENCODING (compresstype=zlib),
    c2 char ENCODING (compresstype=quicklz, blocksize=65536),
    c3 char     WITH (appendonly=true, orientation=column);
```

Example 2

In this example, column c1 is compressed using zlib and uses the block size defined by the system. Column c2 is compressed with quicklz, and uses a block size of 65536. Column c3 is compressed using RLE_TYPE and uses the block size defined by the system.

```sql
CREATE TABLE T2 (c1 int ENCODING (compresstype=zlib),
    c2 char ENCODING (compresstype=quicklz, blocksize=65536),
    c3 char,
    COLUMN c3 ENCODING (compresstype=RLE_TYPE)
) WITH (appendonly=true, orientation=column)
```

Example 3

In this example, column c1 is compressed using zlib and uses the block size defined by the system. Column c2 is compressed with quicklz, and uses a block size of 65536. Column c3 is compressed using zlib and uses the block size defined by the system. Note that column c3 uses zlib (not RLE_TYPE) in the partitions, because the column storage in the partition clause has precedence over the storage directive in the column definition for the table.

```sql
CREATE TABLE T3 (c1 int ENCODING (compresstype=zlib),
    c2 char ENCODING (compresstype=quicklz, blocksize=65536),
    c3 char, COLUMN c3 ENCODING (compresstype=zlib))
PARTITION BY RANGE (c3) (START ('1900-01-01'::DATE)
    END ('2100-12-31'::DATE),
    COLUMN c3 ENCODING (zlib));
```

Example 4

In this example, CREATE TABLE assigns the zlib compressstype storage directive to c1. Column c2 has no storage directive and inherits the compression type (quicklz) and block size (65536) from the DEFAULT COLUMN ENCODING clause.

Column c3’s ENCODING clause defines its compression type, RLE_TYPE. The DEFAULT COLUMN ENCODING clause defines c3’s block size, 65536.

The ENCODING clause defined for a specific column overrides the DEFAULT ENCODING clause, so column c4 has a compress type of none and the default block size.

```sql
CREATE TABLE T4 (c1 int ENCODING (compresstype=zlib),
    c2 char,
    c4 smallint ENCODING (compresstype=none),
    DEFAULT COLUMN ENCODING (compresstype=quicklz, blocksize=65536),
    COLUMN c3 ENCODING (compresstype=RLE_TYPE)
)
```
WITH (appendonly=true, orientation=column);

**Example 5**

This example creates an append-optimized, column-oriented table, T5. T5 has two partitions, p1 and p2, each of which has subpartitions. Each subpartition has `ENCODING` clauses:

- The `ENCODING` clause for partition p1’s subpartition sp1 defines column i’s compression type as `zlib` and block size as 65536.
- The `ENCODING` clauses for partition p2’s subpartition sp1 defines column i’s compression type as `rle_type` and block size is the default value. Column k uses the default compression and its block size is 8192.

```sql
CREATE TABLE T5(i int, j int, k int, l int)
    WITH (appendonly=true, orientation=column)
    PARTITION BY range(i) SUBPARTITION BY range(j)
    (p1 start(1) end(2)
    ( subpartition sp1 start(1) end(2)
        column i encoding(compressstype=zlib, blocksize=65536)
    ),
    partition p2 start(2) end(3)
    ( subpartition sp1 start(1) end(2)
        column i encoding(compressstype=rle_type)
        column k encoding(blocksize=8192)
    )
);
```

For an example showing how to add a compressed column to an existing table with the `ALTER TABLE` command, see [Adding a Compressed Column to Table](#).

**Adding Compression in a TYPE Command**

You can define a compression type to simplify column compression statements. For example, the following `CREATE TYPE` command defines a compression type, `comptype`, that specifies `quicklz` compression.

where `comptype` is defined as:

```sql
CREATE TYPE comptype (
    internallength = 4,
    input = comptype_in,
    output = comptype_out,
    alignment = int4,
    default = 123,
    passedbyvalue,
    compressstype="quicklz",
    blocksize=65536,
    compresslevel=1
);
```

You can then use `comptype` in a `CREATE TABLE` command to specify `quicklz` compression for a column:

```sql
CREATE TABLE t2 (c1 comptype)
    WITH (APPENDONLY=true, ORIENTATION=column);
```

For information about creating and adding compression parameters to a type, see [CREATE TYPE](#). For information about changing compression specifications in a type, see [ALTER TYPE](#).
Choosing Block Size

The blocksize is the size, in bytes, for each block in a table. Block sizes must be between 8192 and 2097152 bytes, and be a multiple of 8192. The default is 32768.

Specifying large block sizes can consume large amounts of memory. Block size determines buffering in the storage layer. Greenplum maintains a buffer per partition, and per column in column-oriented tables. Tables with many partitions or columns consume large amounts of memory.

Altering a Table

The `ALTER TABLE` command changes the definition of a table. Use `ALTER TABLE` to change table attributes such as column definitions, distribution policy, storage model, and partition structure (see also *Maintaining Partitioned Tables*). For example, to add a not-null constraint to a table column:

```sql
=> ALTER TABLE address ALTER COLUMN street SET NOT NULL;
```

Altering Table Distribution

`ALTER TABLE` provides options to change a table's distribution policy. When the table distribution options change, the table data is redistributed on disk, which can be resource intensive. You can also redistribute table data using the existing distribution policy.

Changing the Distribution Policy

For partitioned tables, changes to the distribution policy apply recursively to the child partitions. This operation preserves the ownership and all other attributes of the table. For example, the following command redistributes the table sales across all segments using the customer_id column as the distribution key:

```sql
ALTER TABLE sales SET DISTRIBUTED BY (customer_id);
```

When you change the hash distribution of a table, table data is automatically redistributed. Changing the distribution policy to a random distribution does not cause the data to be redistributed. For example, the following `ALTER TABLE` command has no immediate effect:

```sql
ALTER TABLE sales SET DISTRIBUTED RANDOMLY;
```

Redistributing Table Data

To redistribute table data for tables with a random distribution policy (or when the hash distribution policy has not changed) use `REORGANIZE=TRUE`. Reorganizing data may be necessary to correct a data skew problem, or when segment resources are added to the system. For example, the following command redistributes table data across all segments using the current distribution policy, including random distribution.

```sql
ALTER TABLE sales SET WITH (REORGANIZE=TRUE);
```

Altering the Table Storage Model

Table storage, compression, and orientation can be declared only at creation. To change the storage model, you must create a table with the correct storage options, load the original table data into the new table, drop the original table, and rename the new table with the original table's name. You must also re-grant any table permissions. For example:

```sql
CREATE TABLE sales2 (LIKE sales)
```
WITH (appendonly=true, compressstype=quicklz, compresslevel=1, orientation=column);
INSERT INTO sales2 SELECT * FROM sales;
DROP TABLE sales;
ALTER TABLE sales2 RENAME TO sales;
GRANT ALL PRIVILEGES ON sales TO admin;
GRANT SELECT ON sales TO guest;

See Splitting a Partition to learn how to change the storage model of a partitioned table.

**Adding a Compressed Column to Table**

Use the `ALTER TABLE` command to add a compressed column to a table. All of the options and constraints for compressed columns described in Adding Column-level Compression apply to columns added with the `ALTER TABLE` command.

The following example shows how to add a column with `zlib` compression to a table, `T1`.

```sql
ALTER TABLE T1
ADD COLUMN c4 int DEFAULT 0
ENCODING (COMPRESSTYPE=zlib);
```

**Inheritance of Compression Settings**

A partition that is added to a table that has subpartitions with compression settings inherits the compression settings from the subpartition. The following example shows how to create a table with subpartition encodings, then alter it to add a partition.

```sql
CREATE TABLE ccddl (i int, j int, k int, l int)
WITH
  (APPENDONLY = TRUE, ORIENTATION=COLUMN)
PARTITION BY range(j)
SUBPARTITION BY list (k)
SUBPARTITION template{
  SUBPARTITION sp1 values(1, 2, 3, 4, 5),
  COLUMN i ENCODING(COMPRESSTYPE=ZLIB),
  COLUMN j ENCODING(COMPRESSTYPE=QUICKLZ),
  COLUMN k ENCODING(COMPRESSTYPE=ZLIB),
  COLUMN l ENCODING(COMPRESSTYPE=ZLIB))
(PARTITION p1 START(1) END(10),
  PARTITION p2 START(10) END(20))
;
ALTER TABLE ccddl
ADD PARTITION p3 START(20) END(30)
;
```

Running the `ALTER TABLE` command creates partitions of table `ccddl` named `ccddl_1_prt_p3` and `ccddl_1_prt_p3_2_prt_sp1`. Partition `ccddl_1_prt_p3` inherits the different compression encodings of subpartition `sp1`.

**Dropping a Table**

The `DROP TABLE` command removes tables from the database. For example:

```sql
DROP TABLE mytable;
```

To empty a table of rows without removing the table definition, use `DELETE` or `TRUNCATE`. For example:

```sql
DELETE FROM mytable;
```
Partitioning Large Tables

Table partitioning enables supporting very large tables, such as fact tables, by logically dividing them into smaller, more manageable pieces. Partitioned tables can improve query performance by allowing the Greenplum Database query optimizer to scan only the data needed to satisfy a given query instead of scanning all the contents of a large table.

- About Table Partitioning
- Deciding on a Table Partitioning Strategy
- Creating Partitioned Tables
- Loading Partitioned Tables
- Verifying Your Partition Strategy
- Viewing Your Partition Design
- Maintaining Partitioned Tables

About Table Partitioning

Partitioning does not change the physical distribution of table data across the segments. Table distribution is physical: Greenplum Database physically divides partitioned tables and non-partitioned tables across segments to enable parallel query processing. Table partitioning is logical: Greenplum Database logically divides big tables to improve query performance and facilitate data warehouse maintenance tasks, such as rolling old data out of the data warehouse.

Greenplum Database supports:

- range partitioning: division of data based on a numerical range, such as date or price.
- list partitioning: division of data based on a list of values, such as sales territory or product line.
- A combination of both types.

Figure 22: Example Multi-level Partition Design

Table Partitioning in Greenplum Database

Greenplum Database divides tables into parts (also known as partitions) to enable massively parallel processing. Tables are partitioned during CREATE TABLE using the PARTITION BY (and optionally the
SUBPARTITION BY) clause. Partitioning creates a top-level (or parent) table with one or more levels of sub-tables (or child tables). Internally, Greenplum Database creates an inheritance relationship between the top-level table and its underlying partitions, similar to the functionality of the INHERITS clause of PostgreSQL.

Greenplum uses the partition criteria defined during table creation to create each partition with a distinct CHECK constraint, which limits the data that the table can contain. The query optimizer uses CHECK constraints to determine which table partitions to scan to satisfy a given query predicate.

The Greenplum system catalog stores partition hierarchy information so that rows inserted into the top-level parent table propagate correctly to the child table partitions. To change the partition design or table structure, alter the parent table using ALTER TABLE with the PARTITION clause.

To insert data into a partitioned table, you specify the root partitioned table, the table created with the CREATE TABLE command. You also can specify a leaf child table of the partitioned table in an INSERT command. An error is returned if the data is not valid for the specified leaf child table. Specifying a non-leaf or a non-root partition table in the DML command is not supported.

Deciding on a Table Partitioning Strategy

Not all tables are good candidates for partitioning. If the answer is *yes* to all or most of the following questions, table partitioning is a viable database design strategy for improving query performance. If the answer is *no* to most of the following questions, table partitioning is not the right solution for that table. Test your design strategy to ensure that query performance improves as expected.

- **Is the table large enough?** Large fact tables are good candidates for table partitioning. If you have millions or billions of records in a table, you may see performance benefits from logically breaking that data up into smaller chunks. For smaller tables with only a few thousand rows or less, the administrative overhead of maintaining the partitions will outweigh any performance benefits you might see.

- **Are you experiencing unsatisfactory performance?** As with any performance tuning initiative, a table should be partitioned only if queries against that table are producing slower response times than desired.

- **Do your query predicates have identifiable access patterns?** Examine the WHERE clauses of your query workload and look for table columns that are consistently used to access data. For example, if most of your queries tend to look up records by date, then a monthly or weekly date-partitioning design might be beneficial. Or if you tend to access records by region, consider a list-partitioning design to divide the table by region.

- **Does your data warehouse maintain a window of historical data?** Another consideration for partition design is your organization's business requirements for maintaining historical data. For example, your data warehouse may require that you keep data for the past twelve months. If the data is partitioned by month, you can easily drop the oldest monthly partition from the warehouse and load current data into the most recent monthly partition.

- **Can the data be divided into somewhat equal parts based on some defining criteria?** Choose partitioning criteria that will divide your data as evenly as possible. If the partitions contain a relatively equal number of records, query performance improves based on the number of partitions created. For example, by dividing a large table into 10 partitions, a query will execute 10 times faster than it would against the unpartitioned table, provided that the partitions are designed to support the query's criteria.

Do not create more partitions than are needed. Creating too many partitions can slow down management and maintenance jobs, such as vacuuming, recovering segments, expanding the cluster, checking disk usage, and others.

Partitioning does not improve query performance unless the query optimizer can eliminate partitions based on the query predicates. Queries that scan every partition run slower than if the table were not partitioned, so avoid partitioning if few of your queries achieve partition elimination. Check the explain plan for queries to make sure that partitions are eliminated. See [Query Profiling](#) for more about partition elimination.

**Warning:** Be very careful with multi-level partitioning because the number of partition files can grow very quickly. For example, if a table is partitioned by both day and city, and there are 1,000
days of data and 1,000 cities, the total number of partitions is one million. Column-oriented tables store each column in a physical table, so if this table has 100 columns, the system would be required to manage 100 million files for the table.

Before settling on a multi-level partitioning strategy, consider a single level partition with bitmap indexes. Indexes slow down data loads, so performance testing with your data and schema is recommended to decide on the best strategy.

Creating Partitioned Tables

You partition tables when you create them with `CREATE TABLE`. This topic provides examples of SQL syntax for creating a table with various partition designs.

To partition a table:

1. Decide on the partition design: date range, numeric range, or list of values.
2. Choose the column(s) on which to partition the table.
3. Decide how many levels of partitions you want. For example, you can create a date range partition table by month and then subpartition the monthly partitions by sales region.

• Defining Date Range Table Partitions
• Defining Numeric Range Table Partitions
• Defining List Table Partitions
• Defining Multi-level Partitions
• Partitioning an Existing Table

Defining Date Range Table Partitions

A date range partitioned table uses a single `date` or `timestamp` column as the partition key column. You can use the same partition key column to create subpartitions if necessary, for example, to partition by month and then subpartition by day. Consider partitioning by the most granular level. For example, for a table partitioned by day, you can partition by day and have 365 daily partitions, rather than partition by year then subpartition by month then subpartition by day. A multi-level design can reduce query planning time, but a flat partition design runs faster.

You can have Greenplum Database automatically generate partitions by giving a `START value`, an `END value`, and an `EVERY` clause that defines the partition increment value. By default, `START` values are always inclusive and `END` values are always exclusive. For example:

```sql
CREATE TABLE sales (id int, date date, amt decimal(10,2))
DISTRIBUTED BY (id)
PARTITION BY RANGE (date)
  ( START (date '2016-01-01') INCLUSIVE
    END (date '2017-01-01') EXCLUSIVE
    EVERY (INTERVAL '1 day') );
```

You can also declare and name each partition individually. For example:

```sql
CREATE TABLE sales (id int, date date, amt decimal(10,2))
DISTRIBUTED BY (id)
PARTITION BY RANGE (date)
  ( PARTITION Jan16 START (date '2016-01-01') INCLUSIVE ,
    PARTITION Feb16 START (date '2016-02-01') INCLUSIVE ,
    PARTITION Mar16 START (date '2016-03-01') INCLUSIVE ,
    PARTITION Apr16 START (date '2016-04-01') INCLUSIVE ,
    PARTITION May16 START (date '2016-05-01') INCLUSIVE ,
    PARTITION Jun16 START (date '2016-06-01') INCLUSIVE ,
    PARTITION Jul16 START (date '2016-07-01') INCLUSIVE ,
    PARTITION Aug16 START (date '2016-08-01') INCLUSIVE ,
    PARTITION Sep16 START (date '2016-09-01') INCLUSIVE );
```
PARTITION Oct16 START (date '2016-10-01') INCLUSIVE,  
PARTITION Nov16 START (date '2016-11-01') INCLUSIVE,  
PARTITION Dec16 START (date '2016-12-01') INCLUSIVE  
END (date '2017-01-01') EXCLUSIVE );

You do not have to declare an END value for each partition, only the last one. In this example, Jan16 ends where Feb16 starts.

**Defining Numeric Range Table Partitions**

A numeric range partitioned table uses a single numeric data type column as the partition key column. For example:

```
CREATE TABLE rank (id int, rank int, year int, gender char(1), count int)  
DISTRIBUTED BY (id)  
PARTITION BY RANGE (year)  
  DEFAULT PARTITION extra );
```

For more information about default partitions, see [Adding a Default Partition](#).

**Defining List Table Partitions**

A list partitioned table can use any data type column that allows equality comparisons as its partition key column. A list partition can also have a multi-column (composite) partition key, whereas a range partition only allows a single column as the partition key. For list partitions, you must declare a partition specification for every partition (list value) you want to create. For example:

```
CREATE TABLE rank (id int, rank int, year int, gender char(1), count int)  
DISTRIBUTED BY (id)  
PARTITION BY LIST (gender)  
( PARTITION girls VALUES ('F'),  
  PARTITION boys VALUES ('M'),  
  DEFAULT PARTITION other );
```

**Note:** The current Greenplum Database legacy optimizer allows list partitions with multi-column (composite) partition keys. A range partition only allows a single column as the partition key. The Greenplum Query Optimizer does not support composite keys, so you should not use composite partition keys.

For more information about default partitions, see [Adding a Default Partition](#).

**Defining Multi-level Partitions**

You can create a multi-level partition design with subpartitions of partitions. Using a subpartition template ensures that every partition has the same subpartition design, including partitions that you add later. For example, the following SQL creates the two-level partition design shown in [Figure 22: Example Multi-level Partition Design](#):

```
CREATE TABLE sales (trans_id int, date date, amount decimal(9,2), region text)  
DISTRIBUTED BY (trans_id)  
PARTITION BY RANGE (date)  
SUBPARTITION BY LIST (region)  
SUBPARTITION TEMPLATE  
( SUBPARTITION usa VALUES ('usa'),  
  SUBPARTITION asia VALUES ('asia'),  
  SUBPARTITION europe VALUES ('europe'),  
  DEFAULT SUBPARTITION other_regions)
```
The following example shows a three-level partition design where the sales table is partitioned by year, then month, then region. The SUBPARTITION TEMPLATE clauses ensure that each yearly partition has the same subpartition structure. The example declares a DEFAULT partition at each level of the hierarchy.

```
CREATE TABLE p3_sales (id int, year int, month int, day int, region text)
DISTRIBUTED BY (id)
PARTITION BY RANGE (year)
    SUBPARTITION BY RANGE (month)
        SUBPARTITION TEMPLATE (START (1) END (13) EVERY (1), DEFAULT SUBPARTITION other_months )
        SUBPARTITION BY LIST (region)
            SUBPARTITION usa VALUES ('usa'),
            SUBPARTITION europe VALUES ('europe'),
            SUBPARTITION asia VALUES ('asia'),
            DEFAULT SUBPARTITION other_regions )
    ( START (2002) END (2012) EVERY (1), DEFAULT PARTITION outlying_years );
```

**Caution:** When you create multi-level partitions on ranges, it is easy to create a large number of subpartitions, some containing little or no data. This can add many entries to the system tables, which increases the time and memory required to optimize and execute queries. Increase the range interval or choose a different partitioning strategy to reduce the number of subpartitions created.

### Partitioning an Existing Table

Tables can be partitioned only at creation. If you have a table that you want to partition, you must create a partitioned table, load the data from the original table into the new table, drop the original table, and rename the partitioned table with the original table's name. You must also re-grant any table permissions. For example:

```
CREATE TABLE sales2 (LIKE sales)
PARTITION BY RANGE (date)
    ( START (date '2016-01-01') INCLUSIVE
        END (date '2017-01-01') EXCLUSIVE
        EVERY (INTERVAL '1 month') );
INSERT INTO sales2 SELECT * FROM sales;
DROP TABLE sales;
ALTER TABLE sales2 RENAME TO sales;
GRANT ALL PRIVILEGES ON sales TO admin;
GRANT SELECT ON sales TO guest;
```

### Limitations of Partitioned Tables

For each partition level, a partitioned table can have a maximum of 32,767 partitions.

A primary key or unique constraint on a partitioned table must contain all the partitioning columns. A unique index can omit the partitioning columns; however, it is enforced only on the parts of the partitioned table, not on the partitioned table as a whole.

GPORCA, the Greenplum next generation query optimizer, supports uniform multi-level partitioned tables. If GPORCA is enabled (the default) and the multi-level partitioned table is not uniform, Greenplum Database executes queries against the table with the legacy query optimizer. For information about uniform multi-level partitioned tables, see About Uniform Multi-level Partitioned Tables.
For information about exchanging a leaf child partition with an external table, see *Exchanging a Leaf Child Partition with an External Table*.

These are limitations for partitioned tables when a leaf child partition of the table is an external table:

- Queries that run against partitioned tables that contain external table partitions are executed with the legacy query optimizer.
- The external table partition is a read only external table. Commands that attempt to access or modify data in the external table partition return an error. For example:
  - `INSERT`, `DELETE`, and `UPDATE` commands that attempt to change data in the external table partition return an error.
  - `TRUNCATE` commands return an error.
  - `COPY` commands cannot copy data to a partitioned table that updates an external table partition.
  - `COPY` commands that attempt to copy from an external table partition return an error unless you specify the `IGNORE EXTERNAL PARTITIONS` clause with `COPY` command. If you specify the clause, data is not copied from external table partitions.

To use the `COPY` command against a partitioned table with a leaf child table that is an external table, use an SQL query to copy the data. For example, if the table `my_sales` contains a with a leaf child table that is an external table, this command sends the data to `stdout`:

```sql
COPY (SELECT * from my_sales ) TO stdout
```

- `VACUUM` commands skip external table partitions.
- The following operations are supported if no data is changed on the external table partition. Otherwise, an error is returned.
  - Adding or dropping a column.
  - Changing the data type of column.
- These `ALTER PARTITION` operations are not supported if the partitioned table contains an external table partition:
  - Setting a subpartition template.
  - Altering the partition properties.
  - Creating a default partition.
  - Setting a distribution policy.
  - Setting or dropping a `NOT NULL` constraint of column.
  - Adding or dropping constraints.
  - Splitting an external partition.
- The Greenplum Database utility `gpcrondump` does not back up data from a leaf child partition of a partitioned table if the leaf child partition is a readable external table.

### Loading Partitioned Tables

After you create the partitioned table structure, top-level parent tables are empty. Data is routed to the bottom-level child table partitions. In a multi-level partition design, only the subpartitions at the bottom of the hierarchy can contain data.

Rows that cannot be mapped to a child table partition are rejected and the load fails. To avoid unmapped rows being rejected at load time, define your partition hierarchy with a `DEFAULT` partition. Any rows that do not match a partition’s `CHECK` constraints load into the `DEFAULT` partition. See *Adding a Default Partition*.

At runtime, the query optimizer scans the entire table inheritance hierarchy and uses the `CHECK` table constraints to determine which of the child table partitions to scan to satisfy the query's conditions. The `DEFAULT` partition (if your hierarchy has one) is always scanned. `DEFAULT` partitions that contain data slow down the overall scan time.
When you use `COPY` or `INSERT` to load data into a parent table, the data is automatically rerouted to the correct partition, just like a regular table.

Best practice for loading data into partitioned tables is to create an intermediate staging table, load it, and then exchange it into your partition design. See [Exchanging a Partition](#).

### Verifying Your Partition Strategy

When a table is partitioned based on the query predicate, you can use `EXPLAIN` to verify that the query optimizer scans only the relevant data to examine the query plan.

For example, suppose a `sales` table is date-range partitioned by month and subpartitioned by region as shown in Figure 22: Example Multi-level Partition Design. For the following query:

```sql
EXPLAIN SELECT * FROM sales WHERE date='01-07-12' AND region='usa';
```

The query plan for this query should show a table scan of only the following tables:

- the default partition returning 0-1 rows (if your partition design has one)
- the January 2012 partition (`sales_1_prt_1`) returning 0-1 rows
- the USA region subpartition (`sales_1_2_prt_usa`) returning *some number* of rows.

The following example shows the relevant portion of the query plan.

```
-> Seq Scan on sales_1_prt_1 sales (cost=0.00..0.00 rows=0
   width=0)
   Filter: "date"=01-07-12::date AND region='USA'::text
-> Seq Scan on sales_1_2_prt_usa sales (cost=0.00..9.87
   rows=20
   width=40)
```

Ensure that the query optimizer does not scan unnecessary partitions or subpartitions (for example, scans of months or regions not specified in the query predicate), and that scans of the top-level tables return 0-1 rows.

### Troubleshooting Selective Partition Scanning

The following limitations can result in a query plan that shows a non-selective scan of your partition hierarchy.

- The query optimizer can selectively scan partitioned tables only when the query contains a direct and simple restriction of the table using immutable operators such as:
  
  
  
  ```
  =, <, <=, >, >=, and <>
  ```

- Selective scanning recognizes `STABLE` and `IMMUTABLE` functions, but does not recognize `VOLATILE` functions within a query. For example, `WHERE` clauses such as `date > CURRENT_DATE` cause the query optimizer to selectively scan partitioned tables, but `time > TIMEOFDAY` does not.

### Viewing Your Partition Design

You can look up information about your partition design using the `pg_partitions` system view. For example, to see the partition design of the `sales` table:

```sql
SELECT partitionboundary, partitiotablename, partitionname, partitionlevel, partitionrank
FROM pg_partitions
WHERE tablename='sales';
```

The following table and views also show information about partitioned tables.
• `pg_partition` - Tracks partitioned tables and their inheritance level relationships.
• `pg_partition_templates` - Shows the subpartitions created using a subpartition template.
• `pg_partition_columns` - Shows the partition key columns used in a partition design.

For information about Greenplum Database system catalog tables and views, see the *Greenplum Database Reference Guide*.

**Maintaining Partitioned Tables**

To maintain a partitioned table, use the `ALTER TABLE` command against the top-level parent table. The most common scenario is to drop old partitions and add new ones to maintain a rolling window of data in a range partition design. You can convert (exchange) older partitions to the append-optimized compressed storage format to save space. If you have a default partition in your partition design, you add a partition by splitting the default partition.

- Adding a Partition
- Renaming a Partition
- Adding a Default Partition
- Dropping a Partition
- Truncating a Partition
- Exchanging a Partition
- Splitting a Partition
- Modifying a Subpartition Template
- Exchanging a Leaf Child Partition with an External Table

**Important:** When defining and altering partition designs, use the given partition name, not the table object name. The given partition name is the `partitionname` column value in the `pg_partitions` system view. Although you can query and load any table (including partitioned tables) directly using SQL commands, you can only modify the structure of a partitioned table using the `ALTER TABLE...PARTITION` clauses.

Partitions are not required to have names. If a partition does not have a name, use one of the following expressions to specify a partition: `PARTITION FOR (value)` or `PARTITION FOR (RANK(number))`.

For a multi-level partitioned table, you identify a specific partition to change with `ALTER PARTITION` clauses. For each partition level in the table hierarchy that is above the target partition, specify the partition that is related to the target partition in an `ALTER PARTITION` clause. For example, if you have a partitioned table that consists of three levels, year, quarter, and region, this `ALTER TABLE` command exchanges a leaf partition `region` with the table `region_new`.

```
ALTER TABLE sales ALTER PARTITION year_1 ALTER PARTITION quarter_4 EXCHANGE PARTITION region WITH TABLE region_new ;
```

The two `ALTER PARTITION` clauses identify which `region` partition to exchange. Both clauses are required to identify the specific leaf partition to exchange.

**Adding a Partition**

You can add a partition to a partition design with the `ALTER TABLE` command. If the original partition design included subpartitions defined by a `subpartition template`, the newly added partition is subpartitioned according to that template. For example:

```
ALTER TABLE sales ADD PARTITION
  START (date '2017-02-01') INCLUSIVE
  END (date '2017-03-01') EXCLUSIVE;
```
If you did not use a subpartition template when you created the table, you define subpartitions when adding a partition:

```sql
ALTER TABLE sales ADD PARTITION
   START (date '2017-02-01') INCLUSIVE
   END (date '2017-03-01') EXCLUSIVE
   ( SUBPARTITION usa VALUES ('usa'),
     SUBPARTITION asia VALUES ('asia'),
     SUBPARTITION europe VALUES ('europe') );
```

When you add a subpartition to an existing partition, you can specify the partition to alter. For example:

```sql
ALTER TABLE sales ALTER PARTITION FOR (RANK(12))
   ADD PARTITION africa VALUES ('africa');
```

**Note:** You cannot add a partition to a partition design that has a default partition. You must split the default partition to add a partition. See *Splitting a Partition*.

### Renaming a Partition

Partitioned tables use the following naming convention. Partitioned subtable names are subject to uniqueness requirements and length limitations.

```plaintext
<parentname>_<level>_prt_<partition_name>
```

For example:

```plaintext
sales_1_prt_jan16
```

For auto-generated range partitions, where a number is assigned when no name is given):

```plaintext
sales_1_prt_l
```

To rename a partitioned child table, rename the top-level parent table. The `<parentname>` changes in the table names of all associated child table partitions. For example, the following command:

```sql
ALTER TABLE sales RENAME TO globalsales;
```

Changes the associated table names:

```plaintext
globalsales_1_prt_l
```

You can change the name of a partition to make it easier to identify. For example:

```sql
ALTER TABLE sales RENAME PARTITION FOR ('2016-01-01') TO jan16;
```

Changes the associated table name as follows:

```plaintext
sales_1_prt_jan16
```

When altering partitioned tables with the `ALTER TABLE` command, always refer to the tables by their partition name *(jan16)* and not their full table name *(sales_1_prt_jan16)*.

**Note:** The table name cannot be a partition name in an `ALTER TABLE` statement. For example, `ALTER TABLE sales... is correct, ALTER TABLE sales_1_prt_jan16... is not allowed.`
**Adding a Default Partition**

You can add a default partition to a partition design with the `ALTER TABLE` command.

```
ALTER TABLE sales ADD DEFAULT PARTITION other;
```

If your partition design is multi-level, each level in the hierarchy must have a default partition. For example:

```
ALTER TABLE sales ALTER PARTITION FOR (RANK(1)) ADD DEFAULT PARTITION other;
ALTER TABLE sales ALTER PARTITION FOR (RANK(2)) ADD DEFAULT PARTITION other;
ALTER TABLE sales ALTER PARTITION FOR (RANK(3)) ADD DEFAULT PARTITION other;
```

If incoming data does not match a partition's `CHECK` constraint and there is no default partition, the data is rejected. Default partitions ensure that incoming data that does not match a partition is inserted into the default partition.

**Dropping a Partition**

You can drop a partition from your partition design using the `ALTER TABLE` command. When you drop a partition that has subpartitions, the subpartitions (and all data in them) are automatically dropped as well. For range partitions, it is common to drop the older partitions from the range as old data is rolled out of the data warehouse. For example:

```
ALTER TABLE sales DROP PARTITION FOR (RANK(1));
```

**Truncating a Partition**

You can truncate a partition using the `ALTER TABLE` command. When you truncate a partition that has subpartitions, the subpartitions are automatically truncated as well.

```
ALTER TABLE sales TRUNCATE PARTITION FOR (RANK(1));
```

**Exchanging a Partition**

You can exchange a partition using the `ALTER TABLE` command. Exchanging a partition swaps one table in place of an existing partition. You can exchange partitions only at the lowest level of your partition hierarchy (only partitions that contain data can be exchanged).

Exchanging a partition with a partitioned table or a child partition of a partitioned table is not supported.

Partition exchange can be useful for data loading. For example, load a staging table and swap the loaded table into your partition design. You can use partition exchange to change the storage type of older partitions to append-optimized tables. For example:

```
CREATE TABLE jan12 (LIKE sales) WITH (appendonly=true);
INSERT INTO jan12 SELECT * FROM sales_1_prt_1 ;
ALTER TABLE sales EXCHANGE PARTITION FOR (DATE '2012-01-01')
WITH TABLE jan12;
```

**Note:** This example refers to the single-level definition of the table `sales`, before partitions were added and altered in the previous examples.
Warning: If you specify the WITHOUT VALIDATION clause, you must ensure that the data in table that you are exchanging for an existing partition is valid against the constraints on the partition. Otherwise, queries against the partitioned table might return incorrect results.

The Greenplum Database server configuration parameter `gp_enable_exchange_default_partition` controls availability of the EXCHANGE DEFAULT PARTITION clause. The default value for the parameter is off, the clause is not available and Greenplum Database returns an error if the clause is specified in an ALTER TABLE command.

For information about the parameter, see "Server Configuration Parameters" in the Greenplum Database Reference Guide.

Warning: Before you exchange the default partition, you must ensure the data in the table to be exchanged, the new default partition, is valid for the default partition. For example, the data in the new default partition must not contain data that would be valid in other leaf child partitions of the partitioned table. Otherwise, queries against the partitioned table with the exchanged default partition that are executed by GPORCA might return incorrect results.

### Splitting a Partition

Splitting a partition divides a partition into two partitions. You can split a partition using the ALTER TABLE command. You can split partitions only at the lowest level of your partition hierarchy (partitions that contain data). For a multi-level partition, only range partitions can be split, not list partitions. The split value you specify goes into the latter partition.

For example, to split a monthly partition into two with the first partition containing dates January 1-15 and the second partition containing dates January 16-31:

```sql
ALTER TABLE sales SPLIT PARTITION FOR ('2017-01-01')
AT ('2017-01-16')
INTO (PARTITION jan171to15, PARTITION jan1716to31);
```

If your partition design has a default partition, you must split the default partition to add a partition.

When using the INTO clause, specify the current default partition as the second partition name. For example, to split a default range partition to add a new monthly partition for January 2017:

```sql
ALTER TABLE sales SPLIT DEFAULT PARTITION
START ('2017-01-01') INCLUSIVE
END ('2017-02-01') EXCLUSIVE
INTO (PARTITION jan17, default partition);
```

### Modifying a Subpartition Template

Use ALTER TABLE SET SUBPARTITION TEMPLATE to modify the subpartition template of a partitioned table. Partitions added after you set a new subpartition template have the new partition design. Existing partitions are not modified.

The following example alters the subpartition template of this partitioned table:

```sql
CREATE TABLE sales (trans_id int, date date, amount decimal(9,2), region text)
    DISTRIBUTED BY (trans_id)
    PARTITION BY RANGE (date)
    SUBPARTITION BY LIST (region)
    SUBPARTITION TEMPLATE
        ( SUBPARTITION usa VALUES ('usa'),
          SUBPARTITION asia VALUES ('asia'),
          SUBPARTITION europe VALUES ('europe'),
          DEFAULT SUBPARTITION other_regions )
    ( START (date '2014-01-01') INCLUSIVE
```
This ALTER TABLE command modifies the subpartition template.

```
ALTER TABLE sales SET SUBPARTITION TEMPLATE
( SUBPARTITION usa VALUES ('usa'),
  SUBPARTITION asia VALUES ('asia'),
  SUBPARTITION europe VALUES ('europe'),
  SUBPARTITION africa VALUES ('africa'),
  DEFAULT SUBPARTITION regions );
```

When you add a date-range partition of the table sales, it includes the new regional list subpartition for Africa. For example, the following command creates the subpartitions usa, asia, europe, africa, and a default partition named other:

```
ALTER TABLE sales ADD PARTITION "4"
  START ('2014-04-01') INCLUSIVE
  END ('2014-05-01') EXCLUSIVE ;
```

To view the tables created for the partitioned table sales, you can use the command \dt sales* from the psql command line.

To remove a subpartition template, use SET SUBPARTITION TEMPLATE with empty parentheses. For example, to clear the sales table subpartition template:

```
ALTER TABLE sales SET SUBPARTITION TEMPLATE ();
```

### Exchanging a Leaf Child Partition with an External Table

You can exchange a leaf child partition of a partitioned table with a readable external table. The external table data can reside on a host file system, an NFS mount, or a Hadoop file system (HDFS).

For example, if you have a partitioned table that is created with monthly partitions and most of the queries against the table only access the newer data, you can copy the older, less accessed data to external tables and exchange older partitions with the external tables. For queries that only access the newer data, you could create queries that use partition elimination to prevent scanning the older, unneeded partitions.

Exchanging a leaf child partition with an external table is not supported if the partitioned table contains a column with a check constraint or a NOT NULL constraint.

For information about exchanging and altering a leaf child partition, see the ALTER TABLE command in the Greenplum Database Command Reference.

For information about limitations of partitioned tables that contain a external table partition, see Limitations of Partitioned Tables.

#### Example Exchanging a Partition with an External Table

This is a simple example that exchanges a leaf child partition of this partitioned table for an external table. The partitioned table contains data for the years 2010 through 2013.

```
CREATE TABLE sales (id int, year int, qtr int, day int, region text)
  DISTRIBUTED BY (id)
  PARTITION BY RANGE (year)
  ( PARTITION yr START (2010) END (2014) EVERY (1) ) ;
```

There are four leaf child partitions for the partitioned table. Each leaf child partition contains the data for a single year. The leaf child partition table sales_l_prt_yr_1 contains the data for the year 2010. These steps exchange the table sales_l_prt_yr_1 with an external table the uses the gpfdist protocol:
1. Ensure that the external table protocol is enabled for the Greenplum Database system.
   
   This example uses the `gpfdist` protocol. This command starts the `gpfdist` protocol.

   ```bash
   $ gpfdist
   ```

2. Create a writable external table.
   
   This `CREATE WRITABLE EXTERNAL TABLE` command creates a writable external table with the same columns as the partitioned table.

   ```sql
   CREATE WRITABLE EXTERNAL TABLE my_sales_ext ( LIKE sales_1_prt_yr_1 )
   LOCATION ( 'gpfdist://gpdb_test/sales_2010' )
   FORMAT 'csv'
   DISTRIBUTED BY (id) ;
   ```

3. Create a readable external table that reads the data from that destination of the writable external table created in the previous step.
   
   This `CREATE EXTERNAL TABLE` create a readable external that uses the same external data as the writable external data.

   ```sql
   CREATE EXTERNAL TABLE sales_2010_ext ( LIKE sales_1_prt_yr_1)
   LOCATION ( 'gpfdist://gpdb_test/sales_2010' )
   FORMAT 'csv' ;
   ```

4. Copy the data from the leaf child partition into the writable external table.
   
   This `INSERT` command copies the data from the child leaf partition table of the partitioned table into the external table.

   ```sql
   INSERT INTO my_sales_ext SELECT * FROM sales_1_prt_yr_1 ;
   ```

5. Exchange the existing leaf child partition with the external table.
   
   This `ALTER TABLE` command specifies the `EXCHANGE PARTITION` clause to switch the readable external table and the leaf child partition.

   ```sql
   ALTER TABLE sales ALTER PARTITION yr_1
   EXCHANGE PARTITION yr_1
   WITH TABLE sales_2010_ext WITHOUT VALIDATION;
   ```

   The external table becomes the leaf child partition with the table name `sales_1_prt_yr_1` and the old leaf child partition becomes the table `sales_2010_ext`.

   **Warning:** In order to ensure queries against the partitioned table return the correct results, the external table data must be valid against the `CHECK` constraints on the leaf child partition. In this case, the data was taken from the child leaf partition table on which the `CHECK` constraints were defined.

6. Drop the table that was rolled out of the partitioned table.

   ```sql
   DROP TABLE sales_2010_ext ;
   ```

You can rename the name of the leaf child partition to indicate that `sales_1_prt_yr_1` is an external table.

This example command changes the `partitionname` to `yr_1_ext` and the name of the child leaf partition table to `sales_1_prt_yr_1_ext`.

```sql
ALTER TABLE sales RENAME PARTITION yr_1 TO yr_1_ext ;
```
Creating and Using Sequences

A Greenplum Database sequence object is a special single row table that functions as a number generator. You can use a sequence to generate unique integer identifiers for a row that you add to a table. Declaring a column of type `SERIAL` implicitly creates a sequence counter for use in that table column.

Greenplum Database provides commands to create, alter, and drop a sequence. Greenplum Database also provides built-in functions to return the next value in the sequence (`nextval()`) or to set the sequence to a specific start value (`setval()`).

**Note:** The PostgreSQL `currval()` and `lastval()` sequence functions are not supported in Greenplum Database.

Attributes of a sequence object include the name of the sequence, its increment value, and the last, minimum, and maximum values of the sequence counter. Sequences also have a special boolean attribute named `is_called` that governs the auto-increment behavior of a `nextval()` operation on the sequence counter. When a sequence's `is_called` attribute is `true`, `nextval()` increments the sequence counter before returning the value. When the `is_called` attribute value of a sequence is `false`, `nextval()` does not increment the counter before returning the value.

Creating a Sequence

The `CREATE SEQUENCE` command creates and initializes a sequence with the given sequence name and optional start value. The sequence name must be distinct from the name of any other sequence, table, index, or view in the same schema. For example:

```
CREATE SEQUENCE myserial START 101;
```

When you create a new sequence, Greenplum Database sets the sequence `is_called` attribute to `false`. Invoking `nextval()` on a newly-created sequence does not increment the sequence counter, but returns the sequence start value and sets `is_called` to `true`.

Using a Sequence

After you create a sequence with the `CREATE SEQUENCE` command, you can examine the sequence and use the sequence built-in functions.

Examining Sequence Attributes

To examine the current attributes of a sequence, query the sequence directly. For example, to examine a sequence named `myserial`:

```
SELECT * FROM myserial;
```

Returning the Next Sequence Counter Value

You can invoke the `nextval()` built-in function to return and use the next value in a sequence. The following command inserts the next value of the sequence named `myserial` into the first column of a table named `vendors`:

```
INSERT INTO vendors VALUES (nextval('myserial'), 'acme');
```

`nextval()` uses the sequence's `is_called` attribute value to determine whether or not to increment the sequence counter before returning the value. `nextval()` advances the counter when `is_called` is `true`. `nextval()` sets the sequence `is_called` attribute to `true` before returning.
A `nextval()` operation is never rolled back. A fetched value is considered used, even if the transaction that performed the `nextval()` fails. This means that failed transactions can leave unused holes in the sequence of assigned values.

**Note:** You cannot use the `nextval()` function in `UPDATE` or `DELETE` statements if mirroring is enabled in Greenplum Database.

### Setting the Sequence Counter Value

You can use the Greenplum Database `setval()` built-in function to set the counter value for a sequence. For example, the following command sets the counter value of the sequence named `myserial` to 201:

```sql
SELECT setval('myserial', 201);
```

`setval()` has two function signatures: `setval(sequence, start_val)` and `setval(sequence, start_val, is_called)`. The default behaviour of `setval(sequence, start_val)` sets the sequence `is_called` attribute value to `true`.

If you do not want the sequence counter advanced on the next `nextval()` call, use the `setval(sequence, start_val, is_called)` function signature, passing a `false` argument:

```sql
SELECT setval('myserial', 201, false);
```

`setval()` operations are never rolled back.

### Altering a Sequence

The `ALTER SEQUENCE` command changes the attributes of an existing sequence. You can alter the sequence minimum, maximum, and increment values. You can also restart the sequence at a specific value.

Any parameters not set in the `ALTER SEQUENCE` command retain their prior settings.

The following command restarts the sequence named `myserial` at value 105:

```sql
ALTER SEQUENCE myserial RESTART WITH 105;
```

When you alter a sequence start value with the `ALTER SEQUENCE` command, Greenplum Database sets the sequence’s `is_called` attribute to `false`. The first `nextval()` invoked after restarting a sequence does not advance the sequence counter, but returns the sequence restart value and sets `is_called` to `true`.

### Dropping a Sequence

The `DROP SEQUENCE` command removes a sequence. For example, the following command removes the sequence named `myserial`:

```sql
DROP SEQUENCE myserial;
```

### Specifying a Sequence as the Default Value for a Column

You can reference a sequence directly in the `CREATE TABLE` command in addition to using the `SERIAL` or `BIGSERIAL` types. For example:

```sql
CREATE TABLE tablename ( id INT4 DEFAULT nextval('myserial'), name text );
```
You can also alter a table column to set its default value to a sequence counter:

```
ALTER TABLE tablenam ALTER COLUMN id SET DEFAULT nextval('myserial');
```

**Sequence Wraparound**

By default, a sequence does not wrap around. That is, when a sequence reaches the max value (+32767 for SMALLSERIAL, +2147483647 for SERIAL, +9223372036854775807 for BIGSERIAL), every subsequent `nextval()` call produces an error. You can alter a sequence to make it cycle around and start at 1 again:

```
ALTER SEQUENCE myserial CYCLE;
```

You can also specify the wraparound behaviour when you create the sequence:

```
CREATE SEQUENCE myserial CYCLE;
```

**Using Indexes in Greenplum Database**

In most traditional databases, indexes can greatly improve data access times. However, in a distributed database such as Greenplum, indexes should be used more sparingly. Greenplum Database performs very fast sequential scans; indexes use a random seek pattern to locate records on disk. Greenplum data is distributed across the segments, so each segment scans a smaller portion of the overall data to get the result. With table partitioning, the total data to scan may be even smaller. Because business intelligence (BI) query workloads generally return very large data sets, using indexes is not efficient.

First try your query workload without adding indexes. Indexes are more likely to improve performance for OLTP workloads, where the query is returning a single record or a small subset of data. Indexes can also improve performance on compressed append-optimized tables for queries that return a targeted set of rows, as the optimizer can use an index access method rather than a full table scan when appropriate. For compressed data, an index access method means only the necessary rows are uncompressed.

Greenplum Database automatically creates PRIMARY KEY constraints for tables with primary keys. To create an index on a partitioned table, create an index on the partitioned table that you created. The index is propagated to all the child tables created by Greenplum Database. Creating an index on a table that is created by Greenplum Database for use by a partitioned table is not supported.

Note that a UNIQUE CONSTRAINT (such as a PRIMARY KEY CONSTRAINT) implicitly creates a UNIQUE INDEX that must include all the columns of the distribution key and any partitioning key. The UNIQUE CONSTRAINT is enforced across the entire table, including all table partitions (if any).

Indexes add some database overhead — they use storage space and must be maintained when the table is updated. Ensure that the query workload uses the indexes that you create, and check that the indexes you add improve query performance (as compared to a sequential scan of the table). To determine whether indexes are being used, examine the query EXPLAIN plans. See Query Profiling.

Consider the following points when you create indexes.

- **Your Query Workload.** Indexes improve performance for workloads where queries return a single record or a very small data set, such as OLTP workloads.
- **Compressed Tables.** Indexes can improve performance on compressed append-optimized tables for queries that return a targeted set of rows. For compressed data, an index access method means only the necessary rows are uncompressed.
- **Avoid indexes on frequently updated columns.** Creating an index on a column that is frequently updated increases the number of writes required when the column is updated.
- **Create selective B-tree indexes.** Index selectivity is a ratio of the number of distinct values a column has divided by the number of rows in a table. For example, if a table has 1000 rows and a column has 800 distinct values, the selectivity of the index is 0.8, which is considered good. Unique indexes always
have a selectivity ratio of 1.0, which is the best possible. Greenplum Database allows unique indexes only on distribution key columns.

- **Use Bitmap indexes for low selectivity columns.** The Greenplum Database Bitmap index type is not available in regular PostgreSQL. See [About Bitmap Indexes](#).

- **Index columns used in joins.** An index on a column used for frequent joins (such as a foreign key column) can improve join performance by enabling more join methods for the query optimizer to use.

- **Index columns frequently used in predicates.** Columns that are frequently referenced in `WHERE` clauses are good candidates for indexes.

- **Avoid overlapping indexes.** Indexes that have the same leading column are redundant.

- **Drop indexes for bulk loads.** For mass loads of data into a table, consider dropping the indexes and re-creating them after the load completes. This is often faster than updating the indexes.

- **Consider a clustered index.** Clustering an index means that the records are physically ordered on disk according to the index. If the records you need are distributed randomly on disk, the database has to seek across the disk to fetch the records requested. If the records are stored close together, the fetching operation is more efficient. For example, a clustered index on a date column where the data is ordered sequentially by date. A query against a specific date range results in an ordered fetch from the disk, which leverages fast sequential access.

### To cluster an index in Greenplum Database

Using the `CLUSTER` command to physically reorder a table based on an index can take a long time with very large tables. To achieve the same results much faster, you can manually reorder the data on disk by creating an intermediate table and loading the data in the desired order. For example:

```sql
CREATE TABLE new_table (LIKE old_table)
    AS SELECT * FROM old_table ORDER BY myixcolumn;
DROP old_table;
ALTER TABLE new_table RENAME TO old_table;
CREATE INDEX myixcolumn_ix ON old_table;
VACUUM ANALYZE old_table;
```

### Index Types

Greenplum Database supports the Postgres index types B-tree and GiST. Hash and GIN indexes are not supported. Each index type uses a different algorithm that is best suited to different types of queries. B-tree indexes fit the most common situations and are the default index type. See [Index Types](#) in the PostgreSQL documentation for a description of these types.

**Note:** Greenplum Database allows unique indexes only if the columns of the index key are the same as (or a superset of) the Greenplum distribution key. Unique indexes are not supported on append-optimized tables. On partitioned tables, a unique index cannot be enforced across all child table partitions of a partitioned table. A unique index is supported only within a partition.

### About Bitmap Indexes

Greenplum Database provides the Bitmap index type. Bitmap indexes are best suited to data warehousing applications and decision support systems with large amounts of data, many ad hoc queries, and few data modification (DML) transactions.

An index provides pointers to the rows in a table that contain a given key value. A regular index stores a list of tuple IDs for each key corresponding to the rows with that key value. Bitmap indexes store a bitmap for each key value. Regular indexes can be several times larger than the data in the table, but bitmap indexes provide the same functionality as a regular index and use a fraction of the size of the indexed data.

Each bit in the bitmap corresponds to a possible tuple ID. If the bit is set, the row with the corresponding tuple ID contains the key value. A mapping function converts the bit position to a tuple ID. Bitmaps are compressed for storage. If the number of distinct key values is small, bitmap indexes are much smaller,
compress better, and save considerable space compared with a regular index. The size of a bitmap index is proportional to the number of rows in the table times the number of distinct values in the indexed column.

Bitmap indexes are most effective for queries that contain multiple conditions in the \texttt{WHERE} clause. Rows that satisfy some, but not all, conditions are filtered out before the table is accessed. This improves response time, often dramatically.

\textbf{When to Use Bitmap Indexes}

Bitmap indexes are best suited to data warehousing applications where users query the data rather than update it. Bitmap indexes perform best for columns that have between 100 and 100,000 distinct values and when the indexed column is often queried in conjunction with other indexed columns. Columns with fewer than 100 distinct values, such as a gender column with two distinct values (male and female), usually do not benefit much from any type of index. On a column with more than 100,000 distinct values, the performance and space efficiency of a bitmap index decline.

Bitmap indexes can improve query performance for ad hoc queries. \texttt{AND} and \texttt{OR} conditions in the \texttt{WHERE} clause of a query can be resolved quickly by performing the corresponding Boolean operations directly on the bitmaps before converting the resulting bitmap to tuple ids. If the resulting number of rows is small, the query can be answered quickly without resorting to a full table scan.

\textbf{When Not to Use Bitmap Indexes}

Do not use bitmap indexes for unique columns or columns with high cardinality data, such as customer names or phone numbers. The performance gains and disk space advantages of bitmap indexes start to diminish on columns with 100,000 or more unique values, regardless of the number of rows in the table.

Bitmap indexes are not suitable for OLTP applications with large numbers of concurrent transactions modifying the data.

Use bitmap indexes sparingly. Test and compare query performance with and without an index. Add an index only if query performance improves with indexed columns.

\textbf{Creating an Index}

The \texttt{CREATE INDEX} command defines an index on a table. A B-tree index is the default index type. For example, to create a B-tree index on the column \texttt{gender} in the table \texttt{employee}:

\begin{verbatim}
CREATE INDEX gender_idx ON employee (gender);
\end{verbatim}

To create a bitmap index on the column \texttt{title} in the table \texttt{films}:

\begin{verbatim}
CREATE INDEX title_bmp_idx ON films USING bitmap (title);
\end{verbatim}

\textbf{Examining Index Usage}

Greenplum Database indexes do not require maintenance and tuning. You can check which indexes are used by the real-life query workload. Use the \texttt{EXPLAIN} command to examine index usage for a query.

The query plan shows the steps or \texttt{plan nodes} that the database will take to answer a query and time estimates for each plan node. To examine the use of indexes, look for the following query plan node types in your \texttt{EXPLAIN} output:

\begin{itemize}
  \item \textbf{Index Scan} - A scan of an index.
  \item \textbf{Bitmap Heap Scan} - Retrieves all
      from the bitmap generated by BitmapAnd, BitmapOr, or BitmapIndexScan and accesses the heap to retrieve the relevant rows.
  \item \textbf{Bitmap Index Scan} - Compute a bitmap by OR-ing all bitmaps that satisfy the query predicates from the underlying index.
\end{itemize}
• **BitmapAnd** or **BitmapOr** - Takes the bitmaps generated from multiple BitmapIndexScan nodes, ANDs or ORs them together, and generates a new bitmap as its output.

You have to experiment to determine the indexes to create. Consider the following points.

• Run **ANALYZE** after you create or update an index. **ANALYZE** collects table statistics. The query optimizer uses table statistics to estimate the number of rows returned by a query and to assign realistic costs to each possible query plan.

• Use real data for experimentation. Using test data for setting up indexes tells you what indexes you need for the test data, but that is all.

• Do not use very small test data sets as the results can be unrealistic or skewed.

• Be careful when developing test data. Values that are similar, completely random, or inserted in sorted order will skew the statistics away from the distribution that real data would have.

• You can force the use of indexes for testing purposes by using run-time parameters to turn off specific plan types. For example, turn off sequential scans (**enable_seqscan**) and nested-loop joins (**enable_nestloop**), the most basic plans, to force the system to use a different plan. Time your query with and without indexes and use the **EXPLAIN ANALYZE** command to compare the results.

**Managing Indexes**

Use the **REINDEX** command to rebuild a poorly-performing index. **REINDEX** rebuilds an index using the data stored in the index's table, replacing the old copy of the index.

**To rebuild all indexes on a table**

```
REINDEX my_table;
```

**To rebuild a particular index**

```
REINDEX my_index;
```

**Dropping an Index**

The **DROP INDEX** command removes an index. For example:

```
DROP INDEX title_idx;
```

When loading data, it can be faster to drop all indexes, load, then recreate the indexes.

**Creating and Managing Views**

Views enable you to save frequently used or complex queries, then access them in a **SELECT** statement as if they were a table. A view is not physically materialized on disk: the query runs as a subquery when you access the view.

If a subquery is associated with a single query, consider using the **WITH** clause of the **SELECT** command instead of creating a seldom-used view.

**Creating Views**

The **CREATE VIEW** command defines a view of a query. For example:

```
CREATE VIEW comedies AS SELECT * FROM films WHERE kind = 'comedy';
```

Views ignore **ORDER BY** and **SORT** operations stored in the view.
Dropping Views

The `DROP VIEW` command removes a view. For example:

```
DROP VIEW topten;
```

The `DROP VIEW ... CASCADE` command also removes all dependent objects. As example, if another view depends on the view which is about to be dropped, the other view will be dropped as well. Without the `CASCADE` option, the `DROP VIEW` command will fail.
Distribution and Skew

Greenplum Database relies on even distribution of data across segments.

In an MPP shared nothing environment, overall response time for a query is measured by the completion time for all segments. The system is only as fast as the slowest segment. If the data is skewed, segments with more data will take more time to complete, so every segment must have an approximately equal number of rows and perform approximately the same amount of processing. Poor performance and out of memory conditions may result if one segment has significantly more data to process than other segments.

Optimal distributions are critical when joining large tables together. To perform a join, matching rows must be located together on the same segment. If data is not distributed on the same join column, the rows needed from one of the tables are dynamically redistributed to the other segments. In some cases a broadcast motion, in which each segment sends its individual rows to all other segments, is performed rather than a redistribution motion, where each segment rehashes the data and sends the rows to the appropriate segments according to the hash key.

Local (Co-located) Joins

Using a hash distribution that evenly distributes table rows across all segments and results in local joins can provide substantial performance gains. When joined rows are on the same segment, much of the processing can be accomplished within the segment instance. These are called local or co-located joins. Local joins minimize data movement; each segment operates independently of the other segments, without network traffic or communications between segments.

To achieve local joins for large tables commonly joined together, distribute the tables on the same column. Local joins require that both sides of a join be distributed on the same columns (and in the same order) and that all columns in the distribution clause are used when joining tables. The distribution columns must also be the same data type—although some values with different data types may appear to have the same representation, they are stored differently and hash to different values, so they are stored on different segments.

Data Skew

Data skew may be caused by uneven data distribution due to the wrong choice of distribution keys or single tuple table insert or copy operations. Present at the table level, data skew, is often the root cause of poor query performance and out of memory conditions. Skewed data affects scan (read) performance, but it also affects all other query execution operations, for instance, joins and group by operations.

It is very important to validate distributions to ensure that data is evenly distributed after the initial load. It is equally important to continue to validate distributions after incremental loads.

The following query shows the number of rows per segment as well as the variance from the minimum and maximum numbers of rows:

```sql
SELECT 'Example Table' AS "Table Name",
       max(c) AS "Max Seg Rows", min(c) AS "Min Seg Rows",
       (max(c)-min(c))*100.0/max(c) AS "Percentage Difference Between Max & Min"
FROM (SELECT count(*) c, gp_segment_id FROM facts GROUP BY 2) AS a;
```

The gp_toolkit schema has two views that you can use to check for skew.

- The gp_toolkit.gp_skew_coefficients view shows data distribution skew by calculating the coefficient of variation (CV) for the data stored on each segment. The skccoeff column shows the coefficient of variation (CV), which is calculated as the standard deviation divided by the average. It
takes into account both the average and variability around the average of a data series. The lower the value, the better. Higher values indicate greater data skew.

- The `gp_toolkit.gp_skew_idle_fractions` view shows data distribution skew by calculating the percentage of the system that is idle during a table scan, which is an indicator of computational skew. The `siffraction` column shows the percentage of the system that is idle during a table scan. This is an indicator of uneven data distribution or query processing skew. For example, a value of 0.1 indicates 10% skew, a value of 0.5 indicates 50% skew, and so on. Tables that have more than 10% skew should have their distribution policies evaluated.

**Processing Skew**

Processing skew results when a disproportionate amount of data flows to, and is processed by, one or a few segments. It is often the culprit behind Greenplum Database performance and stability issues. It can happen with operations such join, sort, aggregation, and various OLAP operations. Processing skew happens in flight while a query is executing and is not as easy to detect as data skew.

If single segments are failing, that is, not all segments on a host, it may be a processing skew issue. Identifying processing skew is currently a manual process. First look for spill files. If there is skew, but not enough to cause spill, it will not become a performance issue. If you determine skew exists, then find the query responsible for the skew. Following are the steps and commands to use. (Change names like the host file name passed to `gpssh` accordingly):

1. Find the OID for the database that is to be monitored for skew processing:

   ```sql
   SELECT oid, datname FROM pg_database;
   ```

   Example output:

<table>
<thead>
<tr>
<th>oid</th>
<th>datname</th>
</tr>
</thead>
<tbody>
<tr>
<td>17088</td>
<td>gpadmin</td>
</tr>
<tr>
<td>10899</td>
<td>postgres</td>
</tr>
<tr>
<td>1</td>
<td>template1</td>
</tr>
<tr>
<td>10898</td>
<td>template0</td>
</tr>
<tr>
<td>38817</td>
<td>pws</td>
</tr>
<tr>
<td>39682</td>
<td>gpperfmon</td>
</tr>
</tbody>
</table>
   (6 rows)

2. Run a `gpssh` command to check file sizes across all of the segment nodes in the system. Replace `<OID>` with the OID of the database from the prior command:

   ```bash
   [gpadmin@mdw kend]$ gpssh -f ~/hosts -e "
   "du -b /data[1-2]/primary/gpseg*/base/<OID>/pgsql_tmp/*" | \n   grep -v "du -b" | sort | awk -F" " '{ arr[$1] += $2; tot += $2 }; END \n   { for ( i in arr ) print "Segment node" i, arr[i], "bytes (" arr[i]/(1024**3) " GB)"; \n     print "Total", tot, "bytes (" tot/(1024**3) " GB)" }' -
   ```

   Example output:

   Segment node[sdw1] 2443370457 bytes (2.27557 GB)
   Segment node[sdw2] 1766575328 bytes (1.64525 GB)
   Segment node[sdw3] 1761686551 bytes (1.6407 GB)
   Segment node[sdw4] 1780301617 bytes (1.65804 GB)
   Segment node[sdw5] 1742543599 bytes (1.62287 GB)
   Segment node[sdw6] 1830073754 bytes (1.70439 GB)
   Segment node[sdw7] 1767310099 bytes (1.64594 GB)
   Segment node[sdw8] 1765105802 bytes (1.64388 GB)
   Total 14856967207 bytes (13.8366 GB)
If there is a **significant and sustained** difference in disk usage, then the queries being executed should be investigated for possible skew (the example output above does not reveal significant skew). In monitoring systems, there will always be some skew, but often it is transient and will be **short in duration**.

3. **If significant and sustained skew appears, the next task is to identify the offending query.**

The command in the previous step sums up the entire node. This time, find the actual segment directory. You can do this from the master or by logging into the specific node identified in the previous step. Following is an example run from the master.

This example looks specifically for sort files. Not all spill files or skew situations are caused by sort files, so you will need to customize the command:

```bash
$ gpssh -f ~/hosts -e
  "ls -l /data[1-2]/primary/gpseg*/base/19979/pgsql_tmp/*"  
| grep -i sort | awk '{sub(/base.*tmp//, ".../", $10); print $1,$6, $10}' | sort -k2 -n
```

Here is output from this command:

```
[sdw1]  288718848 /data1/primary/gpseg2/.../pgsql_tmp_slice0_sort_17758_0001.0[sdw1]  
291176448 /data2/primary/gpseg5/.../pgsql_tmp_slice0_sort_17764_0001.0[sdw8]  
924581888 /data2/primary/gpseg45/.../pgsql_tmp_slice10_sort_15673_0010.9[sdw4]  
980582400 /data1/primary/gpseg18/.../pgsql_tmp_slice10_sort_29425_0001.0[sdw6]  
986447872 /data2/primary/gpseg35/.../pgsql_tmp_slice10_sort_29602_0001.0...  
[sdw5]  999620608 /data1/primary/gpseg26/.../pgsql_tmp_slice10_sort_28637_0001.0[sdw2]  
999751680 /data2/primary/gpseg9/.../pgsql_tmp_slice10_sort_3969_0001.0[sdw3]  
1000112128 /data1/primary/gpseg13/.../pgsql_tmp_slice10_sort_24723_0001.0[sdw3]  
1000898560 /data2/primary/gpseg28/.../pgsql_tmp_slice10_sort_28641_0001.0...  
[sdw8]  1008009216 /data1/primary/gpseg44/.../pgsql_tmp_slice10_sort_15671_0001.0[sdw5]  
1008566272 /data1/primary/gpseg24/.../pgsql_tmp_slice10_sort_28633_0001.0[sdw4]  
1009451008 /data1/primary/gpseg19/.../pgsql_tmp_slice10_sort_29427_0001.0[sdw7]  
1011187712 /data1/primary/gpseg37/.../pgsql_tmp_slice10_sort_18526_0001.0[sdw8]  
1573741824 /data2/primary/gpseg45/.../pgsql_tmp_slice10_sort_15673_0001.0[sdw8]  
1573741824 /data2/primary/gpseg13/.../pgsql_tmp_slice10_sort_15673_0002.1[sdw8]  
1573741824 /data2/primary/gpseg45/.../pgsql_tmp_slice10_sort_15673_0003.2[sdw8]  
1573741824 /data2/primary/gpseg45/.../pgsql_tmp_slice10_sort_15673_0004.3[sdw8]  
1573741824 /data2/primary/gpseg45/.../pgsql_tmp_slice10_sort_15673_0005.4[sdw8]  
1573741824 /data2/primary/gpseg45/.../pgsql_tmp_slice10_sort_15673_0006.5[sdw8]  
1573741824 /data2/primary/gpseg45/.../pgsql_tmp_slice10_sort_15673_0007.6[sdw8]  
1573741824
```
Scanning this output reveals that segment gpseg45 on host sdw8 is the culprit, as its sort files are larger than the others in the output.

4. Log in to the offending node with `ssh` and become root. Use the `lsof` command to find the PID for the process that owns one of the sort files:

```
[root@sdw8 ~]# lsof /data2/primary/gpseg45/base/19979/pgsql_tmp/
pql_tmp_slice10_sort_15673_0002.1
```

The PID, 15673, is also part of the file name, but this may not always be the case.

5. Use the `ps` command with the PID to identify the database and connection information:

```
[root@sdw8 ~]# ps -eaf | grep 15673
```

The remedy for processing skew in almost all cases is to rewrite the query. Creating temporary tables can eliminate skew. Temporary tables can be randomly distributed to force a two-stage aggregation.
Inserting, Updating, and Deleting Data

This section provides information about manipulating data and concurrent access in Greenplum Database. This topic includes the following subtopics:

- About Concurrency Control in Greenplum Database
- Inserting Rows
- Updating Existing Rows
- Deleting Rows
- Working With Transactions
- Vacuuming the Database

About Concurrency Control in Greenplum Database

Greenplum Database and PostgreSQL do not use locks for concurrency control. They maintain data consistency using a multiversion model, Multiversion Concurrency Control (MVCC). MVCC achieves transaction isolation for each database session, and each query transaction sees a snapshot of data. This ensures the transaction sees consistent data that is not affected by other concurrent transactions.

Because MVCC does not use explicit locks for concurrency control, lock contention is minimized and Greenplum Database maintains reasonable performance in multiuser environments. Locks acquired for querying (reading) data do not conflict with locks acquired for writing data.

Greenplum Database provides multiple lock modes to control concurrent access to data in tables. Most Greenplum Database SQL commands automatically acquire the appropriate locks to ensure that referenced tables are not dropped or modified in incompatible ways while a command executes. For applications that cannot adapt easily to MVCC behavior, you can use the \texttt{LOCK} command to acquire explicit locks. However, proper use of MVCC generally provides better performance.

Table 65: Lock Modes in Greenplum Database

<table>
<thead>
<tr>
<th>Lock Mode</th>
<th>Associated SQL Commands</th>
<th>Conflicts With</th>
</tr>
</thead>
<tbody>
<tr>
<td>ACCESS SHARE</td>
<td>\texttt{SELECT}</td>
<td>ACCESS EXCLUSIVE</td>
</tr>
<tr>
<td>ROW SHARE</td>
<td>\texttt{SELECT FOR SHARE, SELECT FOR UPDATE}</td>
<td>EXCLUSIVE, ACCESS EXCLUSIVE</td>
</tr>
<tr>
<td>ROW EXCLUSIVE</td>
<td>\texttt{INSERT, COPY}</td>
<td>SHARE, SHARE ROW EXCLUSIVE, EXCLUSIVE, ACCESS EXCLUSIVE</td>
</tr>
<tr>
<td></td>
<td>\texttt{UPDATE, DELETE} on non-partitioned tables, see \texttt{Note.}</td>
<td></td>
</tr>
<tr>
<td>SHARE UPDATE EXCLUSIVE</td>
<td>\texttt{VACUUM (without FULL), ANALYZE}</td>
<td>SHARE UPDATE EXCLUSIVE, SHARE, SHARE ROW EXCLUSIVE, EXCLUSIVE, ACCESS EXCLUSIVE</td>
</tr>
<tr>
<td>SHARE</td>
<td>\texttt{CREATE INDEX}</td>
<td>ROW EXCLUSIVE, SHARE UPDATE EXCLUSIVE, SHARE ROW EXCLUSIVE, EXCLUSIVE, ACCESS EXCLUSIVE</td>
</tr>
<tr>
<td>SHARE ROW EXCLUSIVE</td>
<td></td>
<td>ROW EXCLUSIVE, SHARE UPDATE EXCLUSIVE, SHARE ROW EXCLUSIVE, EXCLUSIVE, ACCESS EXCLUSIVE</td>
</tr>
</tbody>
</table>
**Lock Mode** | **Associated SQL Commands** | **Conflicts With**
--- | --- | ---
EXCLUSIVE | SELECT FOR UPDATE DELETE, UPDATE on partitioned tables. See Note. | ROW SHARE, ROW EXCLUSIVE, SHARE UPDATE EXCLUSIVE, SHARE, SHARE ROW EXCLUSIVE, EXCLUSIVE, ACCESS EXCLUSIVE
ACCESS EXCLUSIVE | ALTER TABLE, DROP TABLE, TRUNCATE, REINDEX, CLUSTER, VACUUM FULL | ACCESS SHARE, ROW SHARE, ROW EXCLUSIVE, SHARE UPDATE EXCLUSIVE, SHARE, SHARE ROW EXCLUSIVE, EXCLUSIVE, ACCESS EXCLUSIVE

**Note:** Greenplum Database acquires an **EXCLUSIVE** lock for SELECT FOR UPDATE. PostgreSQL acquires a less restrictive **ROW EXCLUSIVE** lock.

For an **UPDATE** or **DELETE** command on a partitioned table, Greenplum Database acquires an **EXCLUSIVE** lock on the root partition table. On a non-partitioned table, Greenplum Database acquires a **ROW EXCLUSIVE** lock.

### Inserting Rows

Use the **INSERT** command to create rows in a table. This command requires the table name and a value for each column in the table; you may optionally specify the column names in any order. If you do not specify column names, list the data values in the order of the columns in the table, separated by commas.

For example, to specify the column names and the values to insert:

```sql
INSERT INTO products (name, price, product_no) VALUES ('Cheese', 9.99, 1);
```

To specify only the values to insert:

```sql
INSERT INTO products VALUES (1, 'Cheese', 9.99);
```

Usually, the data values are literals (constants), but you can also use scalar expressions. For example:

```sql
INSERT INTO films SELECT * FROM tmp_films WHERE date_prod < '2016-05-07';
```

You can insert multiple rows in a single command. For example:

```sql
INSERT INTO products (product_no, name, price) VALUES
(1, 'Cheese', 9.99),
(2, 'Bread', 1.99),
(3, 'Milk', 2.99);
```

To insert data into a partitioned table, you specify the root partitioned table, the table created with the **CREATE TABLE** command. You also can specify a leaf child table of the partitioned table in an **INSERT** command. An error is returned if the data is not valid for the specified leaf child table. Specifying a child table that is not a leaf child table in the **INSERT** command is not supported.

To insert large amounts of data, use external tables or the **COPY** command. These load mechanisms are more efficient than **INSERT** for inserting large quantities of rows. See *Loading and Unloading Data* for more information about bulk data loading.

The storage model of append-optimized tables is optimized for bulk data loading. Greenplum does not recommend single row **INSERT** statements for append-optimized tables. For append-optimized tables,
Greenplum Database supports a maximum of 127 concurrent INSERT transactions into a single append-optimized table.

**Updating Existing Rows**

The `UPDATE` command updates rows in a table. You can update all rows, a subset of all rows, or individual rows in a table. You can update each column separately without affecting other columns.

To perform an update, you need:
- The name of the table and columns to update
- The new values of the columns
- One or more conditions specifying the row or rows to be updated.

For example, the following command updates all products that have a price of 5 to have a price of 10:

```sql
UPDATE products SET price = 10 WHERE price = 5;
```

Using `UPDATE` in Greenplum Database has the following restrictions:
- While GPORCA supports updates to Greenplum distribution key columns, the Postgres planner does not.
- If mirrors are enabled, you cannot use `STABLE` or `VOLATILE` functions in an `UPDATE` statement.
- Greenplum Database does not support the `RETURNING` clause.
- Greenplum Database partitioning columns cannot be updated.

**Deleting Rows**

The `DELETE` command deletes rows from a table. Specify a `WHERE` clause to delete rows that match certain criteria. If you do not specify a `WHERE` clause, all rows in the table are deleted. The result is a valid, but empty, table. For example, to remove all rows from the products table that have a price of 10:

```sql
DELETE FROM products WHERE price = 10;
```

To delete all rows from a table:

```sql
DELETE FROM products;
```

Using `DELETE` in Greenplum Database has similar restrictions to using `UPDATE`:
- If mirrors are enabled, you cannot use `STABLE` or `VOLATILE` functions in an `UPDATE` statement.
- The `RETURNING` clause is not supported in Greenplum Database.

**Truncating a Table**

Use the `TRUNCATE` command to quickly remove all rows in a table. For example:

```sql
TRUNCATE mytable;
```

This command empties a table of all rows in one operation. Note that `TRUNCATE` does not scan the table, therefore it does not process inherited child tables or `ON DELETE` rewrite rules. The command truncates only rows in the named table.

**Working With Transactions**

Transactions allow you to bundle multiple SQL statements in one all-or-nothing operation.

The following are the Greenplum Database SQL transaction commands:
• **BEGIN** or **START TRANSACTION** starts a transaction block.
• **END** or **COMMIT** commits the results of a transaction.
• **ROLLBACK** abandons a transaction without making any changes.
• **SAVEPOINT** marks a place in a transaction and enables partial rollback. You can roll back commands executed after a savepoint while maintaining commands executed before the savepoint.
• **ROLLBACK TO SAVEPOINT** rolls back a transaction to a savepoint.
• **RELEASE SAVEPOINT** destroys a savepoint within a transaction.

**Transaction Isolation Levels**

Greenplum Database accepts the standard SQL transaction levels as follows:

• **read uncommitted** and **read committed** behave like the standard **read committed**
• **repeatable read** is disallowed. If the behavior of **repeatable read** is required, use **serializable**.
• **serializable** behaves in a manner similar to SQL standard **serializable**

The following information describes the behavior of the Greenplum transaction levels:

• **read committed/read uncommitted** — Provides fast, simple, partial transaction isolation. With read committed and read uncommitted transaction isolation, **SELECT**, **UPDATE**, and **DELETE** transactions operate on a snapshot of the database taken when the query started.

  A **SELECT** query:
  • Sees data committed before the query starts.
  • Sees updates executed within the transaction.
  • Does not see uncommitted data outside the transaction.
  • Can possibly see changes that concurrent transactions made if the concurrent transaction is committed after the initial read in its own transaction.

  Successive **SELECT** queries in the same transaction can see different data if other concurrent transactions commit changes before the queries start. **UPDATE** and **DELETE** commands find only rows committed before the commands started.

Read committed or read uncommitted transaction isolation allows concurrent transactions to modify or lock a row before **UPDATE** or **DELETE** finds the row. Read committed or read uncommitted transaction isolation may be inadequate for applications that perform complex queries and updates and require a consistent view of the database.

• **serializable** — Provides strict transaction isolation in which transactions execute as if they run one after another rather than concurrently. Applications on the serializable level must be designed to retry transactions in case of serialization failures. In Greenplum Database, **SERIALIZABLE** prevents dirty reads, non-repeatable reads, and phantom reads without expensive locking, but there are other interactions that can occur between some **SERIALIZABLE** transactions in Greenplum Database that prevent them from being truly serializable. Transactions that run concurrently should be examined to identify interactions that are not prevented by disallowing concurrent updates of the same data. Problems identified can be prevented by using explicit table locks or by requiring the conflicting transactions to update a dummy row introduced to represent the conflict.

  A **SELECT** query:
  • Sees a snapshot of the data as of the start of the transaction (not as of the start of the current query within the transaction).
  • Sees only data committed before the query starts.
  • Sees updates executed within the transaction.
  • Does not see uncommitted data outside the transaction.
  • Does not see changes that concurrent transactions made.

  Successive **SELECT** commands within a single transaction always see the same data.
UPDATE, DELETE, SELECT FOR UPDATE, and SELECT FOR SHARE commands find only rows committed before the command started. If a concurrent transaction has already updated, deleted, or locked a target row when the row is found, the serializable or repeatable read transaction waits for the concurrent transaction to update the row, delete the row, or roll back.

If the concurrent transaction updates or deletes the row, the serializable or repeatable read transaction rolls back. If the concurrent transaction rolls back, then the serializable or repeatable read transaction updates or deletes the row.

The default transaction isolation level in Greenplum Database is read committed. To change the isolation level for a transaction, declare the isolation level when you BEGIN the transaction or use the SET TRANSACTION command after the transaction starts.

Vacuuming the Database

Deleted or updated data rows occupy physical space on disk even though new transactions cannot see them. Periodically running the VACUUM command removes these expired rows. For example:

```
VACUUM mytable;
```

The VACUUM command collects table-level statistics such as the number of rows and pages. Vacuum all tables after loading data, including append-optimized tables. For information about recommended routine vacuum operations, see Routine Vacuum and Analyze.

**Important:** The VACUUM, VACUUM FULL, and VACUUM ANALYZE commands should be used to maintain the data in a Greenplum database especially if updates and deletes are frequently performed on your database data. See the VACUUM command in the Greenplum Database Reference Guide for information about using the command.

**Configuring the Free Space Map**

Expired rows are held in the free space map. The free space map must be sized large enough to hold all expired rows in your database. If not, a regular VACUUM command cannot reclaim space occupied by expired rows that overflow the free space map.

VACUUM FULL reclaims all expired row space, but it is an expensive operation and can take an unacceptably long time to finish on large, distributed Greenplum Database tables. If the free space map overflows, you can recreate the table with a CREATE TABLE AS statement and drop the old table. Using VACUUM FULL is discouraged.

Size the free space map with the following server configuration parameters:

- `max_fsm_pages`
- `max_fsm_relations`
**Querying Data**

This topic provides information about using SQL in Greenplum databases.

You enter SQL statements called queries to view, change, and analyze data in a database using the `psql` interactive SQL client and other client tools.

**About Greenplum Query Processing**

This topic provides an overview of how Greenplum Database processes queries. Understanding this process can be useful when writing and tuning queries.

Users issue queries to Greenplum Database as they would to any database management system. They connect to the database instance on the Greenplum master host using a client application such as `psql` and submit SQL statements.

**Understanding Query Planning and Dispatch**

The master receives, parses, and optimizes the query. The resulting query plan is either parallel or targeted. The master dispatches parallel query plans to all segments, as shown in Figure 23: Dispatching the Parallel Query Plan. The master dispatches targeted query plans to a single segment, as shown in Figure 24: Dispatching a Targeted Query Plan. Each segment is responsible for executing local database operations on its own set of data.

Most database operations—such as table scans, joins, aggregations, and sorts—execute across all segments in parallel. Each operation is performed on a segment database independent of the data stored in the other segment databases.

---

**Figure 23: Dispatching the Parallel Query Plan**
Certain queries may access only data on a single segment, such as single-row `INSERT`, `UPDATE`, `DELETE`, or `SELECT` operations or queries that filter on the table distribution key column(s). In queries such as these, the query plan is not dispatched to all segments, but is targeted at the segment that contains the affected or relevant row(s).

**Figure 24: Dispatching a Targeted Query Plan**

**Understanding Greenplum Query Plans**

A query plan is the set of operations Greenplum Database will perform to produce the answer to a query. Each node or step in the plan represents a database operation such as a table scan, join, aggregation, or sort. Plans are read and executed from bottom to top.

In addition to common database operations such as table scans, joins, and so on, Greenplum Database has an additional operation type called **motion**. A motion operation involves moving tuples between the segments during query processing. Note that not every query requires a motion. For example, a targeted query plan does not require data to move across the interconnect.

To achieve maximum parallelism during query execution, Greenplum divides the work of the query plan into **slices**. A slice is a portion of the plan that segments can work on independently. A query plan is sliced wherever a motion operation occurs in the plan, with one slice on each side of the motion.

For example, consider the following simple query involving a join between two tables:

```sql
SELECT customer, amount
FROM sales JOIN customer USING (cust_id)
WHERE dateCol = '04-30-2016';
```

**Figure 25: Query Slice Plan** shows the query plan. Each segment receives a copy of the query plan and works on it in parallel.

The query plan for this example has a **redistribute motion** that moves tuples between the segments to complete the join. The redistribute motion is necessary because the customer table is distributed across the segments by `cust_id`, but the sales table is distributed across the segments by `sale_id`. To perform
the join, the sales tuples must be redistributed by cust_id. The plan is sliced on either side of the redistribute motion, creating slice 1 and slice 2.

This query plan has another type of motion operation called a gather motion. A gather motion is when the segments send results back up to the master for presentation to the client. Because a query plan is always sliced wherever a motion occurs, this plan also has an implicit slice at the very top of the plan (slice 3). Not all query plans involve a gather motion. For example, a `CREATE TABLE x AS SELECT ...` statement would not have a gather motion because tuples are sent to the newly created table, not to the master.

![Figure 25: Query Slice Plan](image)

**Understanding Parallel Query Execution**

Greenplum creates a number of database processes to handle the work of a query. On the master, the query worker process is called the query dispatcher (QD). The QD is responsible for creating and dispatching the query plan. It also accumulates and presents the final results. On the segments, a query worker process is called a query executor (QE). A QE is responsible for completing its portion of work and communicating its intermediate results to the other worker processes.

There is at least one worker process assigned to each slice of the query plan. A worker process works on its assigned portion of the query plan independently. During query execution, each segment will have a number of processes working on the query in parallel.

Related processes that are working on the same slice of the query plan but on different segments are called gangs. As a portion of work is completed, tuples flow up the query plan from one gang of processes
Greenplum Database uses GPORCA by default to generate an execution plan for a query when possible. GPORCA also enhances Greenplum Database query performance tuning in the following areas:

- Queries against partitioned tables
- Queries that contain a common table expression (CTE)
- Queries that contain subqueries

About GPORCA

In Greenplum Database, the default GPORCA optimizer co-exists with the legacy query optimizer. These sections describe GPORCA functionality and usage:

- Overview of GPORCA
- Enabling and Disabling GPORCA
- Considerations when Using GPORCA
- GPORCA Features and Enhancements
- Changed Behavior with the GPORCA
- GPORCA Limitations
- Determining the Query Optimizer that is Used
- About Uniform Multi-level Partitioned Tables

Overview of GPORCA

GPORCA extends the planning and optimization capabilities of the Greenplum Database legacy optimizer. GPORCA is extensible and achieves better optimization in multi-core architecture environments. Greenplum Database uses GPORCA by default to generate an execution plan for a query when possible.

Figure 26: Query Worker Processes

Figure 26: Query Worker Processes shows the query worker processes on the master and two segment instances for the query plan illustrated in Figure 25: Query Slice Plan.
In Greenplum Database, GPORCA co-exists with the legacy query optimizer. By default, Greenplum Database uses GPORCA. If GPORCA cannot be used, then the legacy query optimizer is used. The following figure shows how GPORCA fits into the query planning architecture.

**Note:** All legacy query optimizer (planner) server configuration parameters are ignored by GPORCA. However, if Greenplum Database falls back to the legacy optimizer, the planner server configuration parameters will impact the query plan generation. For a list of legacy query optimizer (planner) server configuration parameters, see *Query Tuning Parameters*.

### Enabling and Disabling GPORCA

By default, Greenplum Database uses GPORCA instead of the legacy query planner. Server configuration parameters enable or disable GPORCA.

Although GPORCA is on by default, you can configure GPORCA usage at the system, database, session, or query level using the `optimizer` parameter. Refer to one of the following sections if you want to change the default behavior:

- *Enabling GPORCA for a System*
- *Enabling GPORCA for a Database*
- *Enabling GPORCA for a Session or a Query*

**Note:** You can disable the ability to enable or disable GPORCA with the server configuration parameter `optimizer_control`. For information about the server configuration parameters, see the *Greenplum Database Reference Guide*.

### Enabling GPORCA for a System

Set the server configuration parameter `optimizer` for the Greenplum Database system.

1. Log into the Greenplum Database master host as `gpadmin`, the Greenplum Database administrator.
2. Set the values of the server configuration parameters. These Greenplum Database `gpconfig` utility commands sets the value of the parameters to `on`:

   ```bash
   $ gpconfig -c optimizer -v on --masteronly
   ```
3. Restart Greenplum Database. This Greenplum Database gpstop utility command reloads the postgresql.conf files of the master and segments without shutting down Greenplum Database.

```
gpstop -u
```

**Enabling GPORCA for a Database**

Set the server configuration parameter `optimizer` for individual Greenplum databases with the `ALTER DATABASE` command. For example, this command enables GPORCA for the database `test_db`.

```
> ALTER DATABASE test_db SET OPTIMIZER = ON ;
```

**Enabling GPORCA for a Session or a Query**

You can use the `SET` command to set `optimizer` server configuration parameter for a session. For example, after you use the `psql` utility to connect to Greenplum Database, this `SET` command enables GPORCA:

```
> set optimizer = on ;
```

To set the parameter for a specific query, include the `SET` command prior to running the query.

**Collecting Root Partition Statistics**

For a partitioned table, GPORCA uses statistics of the table root partition to generate query plans. These statistics are used for determining the join order, for splitting and joining aggregate nodes, and for costing the query steps. In contrast, the legacy planner uses the statistics of each leaf partition.

If you execute queries on partitioned tables, you should collect statistics on the root partition and periodically update those statistics to ensure that GPORCA can generate optimal query plans. If the root partition statistics are not up-to-date or do not exist, GPORCA still performs dynamic partition elimination for queries against the table. However, the query plan might not be optimal.

**Running ANALYZE**

By default, running the `ANALYZE` command on the root partition of a partitioned table samples the leaf partition data in the table, and stores the statistics for the root partition. `ANALYZE` collects statistics on the root and leaf partitions, including HyperLogLog (HLL) statistics on the leaf partitions. `ANALYZE` collects statistics only on the root partition. The server configuration parameter `optimizer_analyze_root_partition` controls whether the `ROOTPARTITION` keyword is required to collect root statistics for the root partition of a partitioned table. See the `ANALYZE` command for information about collecting statistics on partitioned tables.

Keep in mind that `ANALYZE` always scans the entire table before updating the root partition statistics. If your table is very large, this operation can take a significant amount of time. `ANALYZE` also uses an `ACCESS SHARE` lock that prevents certain operations, such as `TRUNCATE` and `VACUUM` operations, during execution. For these reasons, you should schedule `ANALYZE` operations periodically, or when there are significant changes to leaf partition data.

Follow these best practices for running `ANALYZE` or `ANALYZE` on partitioned tables in your system:

- Run `ANALYZE <root_partition>` on a new partitioned table after adding initial data. Run `ANALYZE <leaf_partition>` on a new leaf partition or a leaf partition where data has changed. By default, running the command on a leaf partition updates the root partition statistics if the other leaf partitions have statistics.
- Update root partition statistics when you observe query performance regression in `EXPLAIN` plans against the table, or after significant changes to leaf partition data. For example, if you add a new leaf partition at some point after generating root partition statistics, consider running `ANALYZE` or `ANALYZE`.
**ROOTPARTITION** to update root partition statistics with the new tuples inserted from the new leaf partition.

- For very large tables, run **ANALYZE** or **ANALYZE ROOTPARTITION** only weekly, or at some interval longer than daily.
- Avoid running **ANALYZE** with no arguments, because doing so executes the command on all database tables including partitioned tables. With large databases, these global **ANALYZE** operations are difficult to monitor, and it can be difficult to predict the time needed for completion.
- Consider running multiple **ANALYZE <table_name>** or **ANALYZE ROOTPARTITION <table_name>** operations in parallel to speed the operation of statistics collection, if your I/O throughput can support the load.
- You can also use the Greenplum Database utility **analyzedb** to update table statistics. Using **analyzedb** ensures that tables that were previously analyzed are not re-analyzed if no modifications were made to the leaf partition.

**GPORCA and Leaf Partition Statistics**

Although creating and maintaining root partition statistics is crucial for GPORCA query performance with partitioned tables, maintaining leaf partition statistics is also important. If GPORCA cannot generate a plan for a query against a partitioned table, then the legacy planner is used and leaf partition statistics are needed to produce the optimal plan for that query.

GPORCA itself also uses leaf partition statistics for any queries that access leaf partitions directly, instead of using the root partition with predicates to eliminate partitions. For example, if you know which partitions hold necessary tuples for a query, you can directly query the leaf partition table itself; in this case GPORCA uses the leaf partition statistics.

**Disabling Automatic Root Partition Statistics Collection**

If you do not intend to execute queries on partitioned tables with GPORCA (setting the server configuration parameter **optimizer** to **off**), then you can disable the automatic collection of statistics on the root partition of the partitioned table. The server configuration parameter **optimizer_analyze_root_partition** controls whether the **ROOTPARTITION** keyword is required to collect root statistics for the root partition of a partitioned table. The default setting for the parameter is **on**, the **ANALYZE** command can collect root partition statistics without the **ROOTPARTITION** keyword. You can disable automatic collection of root partition statistics by setting the parameter to **off**. When the value is **off**, you must run **ANALYZE ROOTPARTITION** to collect root partition statistics.

1. Log into the Greenplum Database master host as **gpadmin**, the Greenplum Database administrator.
2. Set the values of the server configuration parameters. These Greenplum Database **gpconfig** utility commands sets the value of the parameters to **off**:

   ```bash
   $ gpconfig -c optimizer_analyze_root_partition -v off --masteronly
   ```

3. Restart Greenplum Database. This Greenplum Database **gpstop** utility command reloads the *postgresql.conf* files of the master and segments without shutting down Greenplum Database.

   ```bash
   gpstop -u
   ```

**Considerations when Using GPORCA**

To execute queries optimally with GPORCA, query criteria to consider.

Ensure the following criteria are met:

- The table does not contain multi-column partition keys.
- The multi-level partitioned table is a uniform multi-level partitioned table. See [About Uniform Multi-level Partitioned Tables](#).
The server configuration parameter `optimizer_enable_master_only_queries` is set to on when running against master only tables such as the system table `pg_attribute`. For information about the parameter, see the `Greenplum Database Reference Guide`.

**Note:** Enabling this parameter decreases performance of short running catalog queries. To avoid this issue, set this parameter only for a session or a query.

Statistics have been collected on the root partition of a partitioned table. If the partitioned table contains more than 20,000 partitions, consider a redesign of the table schema.

These server configuration parameters affect GPORCA query processing.

- `optimizer_cte_inlining_bound` controls the amount of inlining performed for common table expression (CTE) queries (queries that contain a `WHERE` clause).
- `optimizer_force_multistage_agg` forces GPORCA to choose a 3 stage aggregate plan for a scalar distinct qualified aggregate.
- `optimizer_force_three_stage_scalar_dqa` forces GPORCA to choose a plan with multistage aggregates when such a plan alternative is generated.
- `optimizer_join_order` sets the query optimization level for join ordering by specifying which types of join ordering alternatives to evaluate.
- `optimizer_join_order_threshold` specifies the maximum number of join children for which GPORCA uses the dynamic programming-based join ordering algorithm.
- `optimizer_nestloop_factor` controls nested loop join cost factor to apply to during query optimization.
- `optimizer_parallel_union` controls the amount of parallelization that occurs for queries that contain a `UNION` or `UNION ALL` clause. When the value is on, GPORCA can generate a query plan the child operations of a `UNION` or `UNION ALL` operation execute in parallel on segment instances.
- `optimizer_sort_factor` controls the cost factor that GPORCA applies to sorting operations during query optimization. The cost factor can be adjusted for queries when data skew is present.
- `gp_enable_relsize_collection` controls how GPORCA (and the legacy query optimizer) handle a table without statistics. By default, GPORCA uses a default value to estimate the number of rows if statistics are not available. When this value is on, GPORCA uses the estimated size of a table if there are no statistics for the table.

This parameter is ignored for a root partition of a partitioned table. If the root partition does not have statistics, GPORCA always uses the default value. You can use `ANALYZE ROOTPARTITION` to collect statistics on the root partition. See `ANALYZE`.

These server configuration parameters control the display and logging of information.

- `optimizer_print_missing_stats` controls the display of column information about columns with missing statistics for a query (default is true)
- `optimizer_print_optimization_stats` controls the logging of GPORCA query optimization metrics for a query (default is off)

For information about the parameters, see the `Greenplum Database Reference Guide`.

GPORCA generates minidumps to describe the optimization context for a given query. The minidump files are used by Pivotal support to analyze Greenplum Database issues. The information in the file is not in a format that can be easily used for debugging or troubleshooting. The minidump file is located under the master data directory and uses the following naming format:

`Minidump_`\_`date_time.mdp`

For information about the minidump file, see the server configuration parameter `optimizer_minidump` in the `Greenplum Database Reference Guide`.

When the `EXPLAIN ANALYZE` command uses GPORCA, the `EXPLAIN` plan shows only the number of partitions that are being eliminated. The scanned partitions are not shown. To show
the name of the scanned partitions in the segment logs set the server configuration parameter `gp_log_dynamic_partition_pruning` to `on`. This example SET command enables the parameter.

```
SET gp_log_dynamic_partition_pruning = on;
```

### GPORCA Features and Enhancements

GPORCA, the Greenplum next generation query optimizer, includes enhancements for specific types of queries and operations:

- Queries Against Partitioned Tables
- Queries that Contain Subqueries
- Queries that Contain Common Table Expressions
- DML Operation Enhancements with GPORCA

GPORCA also includes these optimization enhancements:

- Improved join ordering
- Join-Aggregate reordering
- Sort order optimization
- Data skew estimates included in query optimization

### Queries Against Partitioned Tables

GPORCA includes these enhancements for queries against partitioned tables:

- Partition elimination is improved.
- Uniform multi-level partitioned tables are supported. For information about uniform multi-level partitioned tables, see About Uniform Multi-level Partitioned Tables
- Query plan can contain the Partition selector operator.
- Partitions are not enumerated in EXPLAIN plans.

For queries that involve static partition selection where the partitioning key is compared to a constant, GPORCA lists the number of partitions to be scanned in the EXPLAIN output under the Partition Selector operator. This example Partition Selector operator shows the filter and number of partitions selected:

```
Partition Selector for Part_Table (dynamic scan id: 1)
Filter: a > 10
Partitions selected:  1 (out of 3)
```

For queries that involve dynamic partition selection where the partitioning key is compared to a variable, the number of partitions that are scanned will be known only during query execution. The partitions selected are not shown in the EXPLAIN output.

- Plan size is independent of number of partitions.
- Out of memory errors caused by number of partitions are reduced.

This example `CREATE TABLE` command creates a range partitioned table.

```
CREATE TABLE sales(order_id int, item_id int, amount numeric(15,2),
                    date date, yr_qtr int)
    range partitioned by yr_qtr;
```

GPORCA improves on these types of queries against partitioned tables:

- Full table scan. Partitions are not enumerated in plans.

```
SELECT * FROM sales;
```
• Query with a constant filter predicate. Partition elimination is performed.

```sql
SELECT * FROM sales WHERE yr_qtr = 201501;
```

• Range selection. Partition elimination is performed.

```sql
SELECT * FROM sales WHERE yr_qtr BETWEEN 201601 AND 201704;
```

• Joins involving partitioned tables. In this example, the partitioned dimension table `date_dim` is joined with fact table `catalog_sales`:

```sql
SELECT * FROM catalog_sales
WHERE date_id IN (SELECT id FROM date_dim WHERE month=12);
```

### Queries that Contain Subqueries

GPORCA handles subqueries more efficiently. A subquery is query that is nested inside an outer query block. In the following query, the `SELECT` in the `WHERE` clause is a subquery.

```sql
SELECT * FROM part
WHERE price > (SELECT avg(price) FROM part);
```

GPORCA also handles queries that contain a correlated subquery (CSQ) more efficiently. A correlated subquery is a subquery that uses values from the outer query. In the following query, the `price` column is used in both the outer query and the subquery.

```sql
SELECT * FROM part p1
WHERE price > (SELECT avg(price) FROM part p2
               WHERE p2.brand = p1.brand);
```

GPORCA generates more efficient plans for the following types of subqueries:

• CSQ in the `SELECT` list.

```sql
SELECT *,
   (SELECT min(price) FROM part p2 WHERE p1.brand = p2.brand)
AS foo
FROM part p1;
```

• CSQ in disjunctive (OR) filters.

```sql
SELECT FROM part p1 WHERE p_size > 40 OR
   p_retailprice >
   (SELECT avg(p_retailprice)
    FROM part p2
    WHERE p2.p_brand = p1.p_brand)
```

• Nested CSQ with skip level correlations

```sql
SELECT * FROM part p1 WHERE p1.p_partkey
IN (SELECT p_partkey FROM part p2 WHERE p2.p_retailprice =
    (SELECT min(p_retailprice)
     FROM part p3
     WHERE p3.p_brand = p1.p_brand)
    );
```

**Note:** Nested CSQ with skip level correlations are not supported by the legacy query optimizer.

• CSQ with aggregate and inequality. This example contains a CSQ with an inequality.

```sql
SELECT * FROM part p1 WHERE p1.p_retailprice =
```
(SELECT min(p_retailprice) FROM part p2 WHERE p2.p_brand <> p1.p_brand);

- CSQ that must return one row.

SELECT p_partkey,
    (SELECT p_retailprice FROM part p2 WHERE p2.p_brand = p1.p_brand)
FROM part p1;

Queries that Contain Common Table Expressions

GPORCA handles queries that contain the WITH clause. The WITH clause, also known as a common table expression (CTE), generates temporary tables that exist only for the query. This example query contains a CTE.

```sql
WITH v AS (SELECT a, sum(b) as s FROM T where c < 10 GROUP BY a)
SELECT *FROM  v AS v1 ,  v AS v2
WHERE v1.a <> v2.a AND v1.s < v2.s;
```

As part of query optimization, GPORCA can push down predicates into a CTE. For example query, GPORCA pushes the equality predicates to the CTE.

```
WITH v AS (SELECT a, sum(b) as s FROM T GROUP BY a)
SELECT *
FROM v as v1, v as v2, v as v3
WHERE v1.a < v2.a
    AND v1.s < v3.s
    AND v1.a = 10
    AND v2.a = 20
    AND v3.a = 30;
```

GPORCA can handle these types of CTEs:

- CTE that defines one or multiple tables. In this query, the CTE defines two tables.

```
WITH cte1 AS (SELECT a, sum(b) as s FROM T
    where c < 10 GROUP BY a),
      cte2 AS (SELECT a, s FROM cte1 where s > 1000)
SELECT *
FROM cte1 as v1, cte2 as v2, cte2 as v3
WHERE v1.a < v2.a AND v1.s < v3.s;
```

- Nested CTEs.

```
WITH v AS (WITH w AS (SELECT a, b FROM foo
    WHERE b < 5)
    SELECT w1.a, w2.b
    FROM w AS w1, w AS w2
    WHERE w1.a = w2.a AND w1.a > 2)
SELECT v1.a, v2.a, v2.b
FROM v as v1, v as v2
WHERE v1.a < v2.a;
```

DML Operation Enhancements with GPORCA

GPORCA contains enhancements for DML operations such as INSERT, UPDATE, and DELETE.

- A DML node in a query plan is a query plan operator.
  - Can appear anywhere in the plan, as a regular node (top slice only for now)
  - Can have consumers
- UPDATE operations use the query plan operator Split and supports these operations:
• UPDATE operations on the table distribution key columns.
• UPDATE operations on the table on the partition key column.

This example plan shows the Split operator.

```
UPDATE (cost=0.00..5.46 rows=1 width=1)
  -> Redistribute Motion 2:2 (slice1; segments: 2)
    Hash Key: a
    -> Result (cost=0.00..3.23 rows=1 width=48)
      -> Split (cost=0.00..2.13 rows=1 width=40)
        -> Result (cost=0.00..1.05 rows=1 width=40)
          -> Table Scan on dmltest
```

• New query plan operator Assert is used for constraints checking.

This example plan shows the Assert operator.

```
Insert (cost=0.00..4.61 rows=3 width=8)
  -> Assert (cost=0.00..3.37 rows=3 width=24)
    Assert Cond: (dmlsource.a > 2) IS DISTINCT FROM false
  -> Assert (cost=0.00..2.25 rows=3 width=24)
    Assert Cond: NOT dmlsource.b IS NULL
  -> Result (cost=0.00..1.14 rows=3 width=24)
    -> Table Scan on dmlsource
```

**Changed Behavior with the GPORCA**

There are changes to Greenplum Database behavior with the GPORCA optimizer enabled (the default) as compared to the legacy planner.

• UPDATE operations on distribution keys are allowed.
• UPDATE operations on partitioned keys are allowed.
• Queries against uniform partitioned tables are supported.
• Queries against partitioned tables that are altered to use an external table as a leaf child partition fall back to the legacy query optimizer.
• Except for INSERT, DML operations directly on partition (child table) of a partitioned table are not supported.

For the INSERT command, you can specify a leaf child table of the partitioned table to insert data into a partitioned table. An error is returned if the data is not valid for the specified leaf child table. Specifying a child table that is not a leaf child table is not supported.

• The command CREATE TABLE AS distributes table data randomly if the DISTRIBUTED BY clause is not specified and no primary or unique keys are specified.
• Non-deterministic updates not allowed. The following UPDATE command returns an error.

```
update r set b = r.b + 1 from s where r.a in (select a from s);
```

• Statistics are required on the root table of a partitioned table. The ANALYZE command generates statistics on both root and individual partition tables (leaf child tables). See the ROOTPARTITION clause for ANALYZE command.
• Additional Result nodes in the query plan:
  • Query plan Assert operator.
  • Query plan Partition selector operator.
  • Query plan Split operator.
• When running EXPLAIN, the query plan generated by GPORCA is different than the plan generated by the legacy query optimizer.
• Greenplum Database adds the log file message Planner produced plan when GPORCA is enabled and Greenplum Database falls back to the legacy query optimizer to generate the query plan.
• Greenplum Database issues a warning when statistics are missing from one or more table columns. When executing an SQL command with GPORCA, Greenplum Database issues a warning if the command performance could be improved by collecting statistics on a column or set of columns referenced by the command. The warning is issued on the command line and information is added to the Greenplum Database log file. For information about collecting statistics on table columns, see the ANALYZE command in the Greenplum Database Reference Guide.

GPORCA Limitations
There are limitations in Greenplum Database when using the default GPORCA optimizer. GPORCA and the legacy query optimizer currently coexist in Greenplum Database because GPORCA does not support all Greenplum Database features.

This section describes the limitations.

• Unsupported SQL Query Features
• Performance Regressions

Unsupported SQL Query Features
Certain query features are not supported with the default GPORCA optimizer. When an unsupported query is executed, Greenplum logs this notice along with the query text:

Feature not supported by the Pivotal Query Optimizer: UTILITY command

These features are unsupported when GPORCA is enabled (the default):
• Indexed expressions (an index defined as expression based on one or more columns of the table)
• GIN indexing method. GPORCA supports only B-tree, bitmap, and GiST indexes. GPORCA ignores indexes created with unsupported methods.
• External parameters
• These types of partitioned tables:
  • Non-uniform partitioned tables.
  • Partitioned tables that have been altered to use an external table as a leaf child partition.
• SortMergeJoin (SMJ).
• Ordered aggregations.
• These analytics extensions:
  • CUBE
  • Multiple grouping sets
• These scalar operators:
  • ROW
  • ROWCOMPARE
  • FIELDSELECT
• Aggregate functions that take set operators as input arguments.
• percentile_* window functions (Greenplum Database does not support ordered-set aggregate functions).
• Inverse distribution functions.
• Queries that contain UNICODE characters in metadata names, such as table names, and the characters are not compatible with the host system locale.
• SELECT, UPDATE, and DELETE commands where a table name is qualified by the ONLY keyword.
**Performance Regressions**

The following features are known performance regressions that occur with GPORCA enabled:

- **Short running queries** - For GPORCA, short running queries might encounter additional overhead due to GPORCA enhancements for determining an optimal query execution plan.
- **ANALYZE** - For GPORCA, the `ANALYZE` command generates root partition statistics for partitioned tables. For the legacy optimizer, these statistics are not generated.
- **DML operations** - For GPORCA, DML enhancements including the support of updates on partition and distribution keys might require additional overhead.

Also, enhanced functionality of the features from previous versions could result in additional time required when Greenplum Database executes SQL statements with the features.

**Determining the Query Optimizer that is Used**

When GPORCA is enabled (the default), you can determine if Greenplum Database is using GPORCA or is falling back to the legacy query optimizer.

You can examine the EXPLAIN query plan for the query determine which query optimizer was used by Greenplum Database to execute the query:

- **When GPORCA generates the query plan**, the setting `optimizer=on` and GPORCA version are displayed at the end of the query plan. For example.

  ```
  Settings: optimizer=on
  Optimizer status: PQO version 1.584
  ```

- **When Greenplum Database falls back to the legacy optimizer to generate the plan**, the setting `optimizer=on` and `legacy query optimizer` are displayed at the end of the query plan. For example.

  ```
  Settings: optimizer=on
  Optimizer status: legacy query optimizer
  ```

- **When the server configuration parameter OPTIMIZER is off**, these lines are displayed at the end of a query plan.

  ```
  Settings: optimizer=off
  Optimizer status: legacy query optimizer
  ```

- These plan items appear only in the EXPLAIN plan output generated by GPORCA. The items are not supported in a legacy optimizer query plan.
  - Assert operator
  - Sequence operator
  - DynamicIndexScan
  - DynamicTableScan
  - Table Scan
  - When a query against a partitioned table is generated by GPORCA, the EXPLAIN plan displays only the number of partitions that are being eliminated is listed. The scanned partitions are not shown. The EXPLAIN plan generated by the legacy optimizer lists the scanned partitions.

  The log file contains messages that indicate which query optimizer was used. If Greenplum Database falls back to the legacy optimizer, a message with NOTICE information is added to the log file that indicates the unsupported feature. Also, the label Planner produced plan: appears before the query in the query execution log message when Greenplum Database falls back to the legacy optimizer.
**Note:** You can configure Greenplum Database to display log messages on the psql command line by setting the Greenplum Database server configuration parameter `client_min_messages` to `LOG`. See the *Greenplum Database Reference Guide* for information about the parameter.

**Examples**

This example shows the differences for a query that is run against partitioned tables when GPORCA is enabled.

This `CREATE TABLE` statement creates a table with single level partitions:

```sql
CREATE TABLE sales (trans_id int, date date, amount decimal(9,2), region text)
DISTRIBUTED BY (trans_id)
PARTITION BY RANGE (date)
  (START (date '20160101') INCLUSIVE END (date '20170101') EXCLUSIVE EVERY (INTERVAL '1 month'),
  DEFAULT PARTITION outlying_dates )#
```

This query against the table is supported by GPORCA and does not generate errors in the log file:

```sql
select * from sales ;
```

The `EXPLAIN` plan output lists only the number of selected partitions.

```sql
->  Partition Selector for sales (dynamic scan id: 1)  (cost=10.00..100.00
  rows=50 width=4)
  Partitions selected:  13 (out of 13)
```

If a query against a partitioned table is not supported by GPORCA, Greenplum Database falls back to the legacy optimizer. The `EXPLAIN` plan generated by the legacy optimizer lists the selected partitions. This example shows a part of the explain plan that lists some selected partitions.

```sql
->  Append  (cost=0.00..0.00 rows=26 width=53)
  ->  Seq Scan on sales2_1_prt_7_2_prt_usa sales2  (cost=0.00..0.00
    rows=1 width=53)
  ->  Seq Scan on sales2_1_prt_7_2_prt_asia sales2  (cost=0.00..0.00
    rows=1 width=53)
...```

This example shows the log output when the Greenplum Database falls back to the legacy query optimizer from GPORCA.

When this query is run, Greenplum Database falls back to the legacy query optimizer.

```sql
explain select * from pg_class;
```

A message is added to the log file. The message contains this `NOTICE` information that indicates the reason GPORCA did not execute the query:

```sql
NOTICE,""Feature not supported: Queries on master-only tables"
```

**About Uniform Multi-level Partitioned Tables**

GPORCA supports queries on a multi-level partitioned (MLP) table if the MLP table is a uniform partitioned table. A multi-level partitioned table is a partitioned table that was created with the `SUBPARTITION` clause. A uniform partitioned table must meet these requirements.
• The partitioned table structure is uniform. Each partition node at the same level must have the same hierarchical structure.
• The partition key constraints must be consistent and uniform. At each subpartition level, the sets of constraints on the child tables created for each branch must match.

You can display information about partitioned tables in several ways, including displaying information from these sources:
• The `pg_partitions` system view contains information on the structure of a partitioned table.
• The `pg_constraint` system catalog table contains information on table constraints.
• The `psql` meta command `\d+ tablename` displays the table constraints for child leaf tables of a partitioned table.

**Example**

This `CREATE TABLE` command creates a uniform partitioned table.

```sql
CREATE TABLE mlp (id int, year int, month int, day int, region text)
    DISTRIBUTED BY (id)
    PARTITION BY RANGE (year)
    SUBPARTITION BY LIST (region)
    SUBPARTITION TEMPLATE (
        SUBPARTITION usa VALUES ('usa'),
        SUBPARTITION europe VALUES ('europe'),
        SUBPARTITION asia VALUES ('asia'))
    (START (2006) END (2016) EVERY (5));
```

These are child tables and the partition hierarchy that are created for the table `mlp`. This hierarchy consists of one subpartition level that contains two branches.

```sql
mlp_1_prt_11
    mlp_1_prt_11_2_prt_usa
    mlp_1_prt_11_2_prt_europe
    mlp_1_prt_11_2_prt_asia

mlp_1_prt_21
    mlp_1_prt_21_2_prt_usa
    mlp_1_prt_21_2_prt_europe
    mlp_1_prt_21_2_prt_asia
```

The hierarchy of the table is uniform, each partition contains a set of three child tables (subpartitions). The constraints for the region subpartitions are uniform, the set of constraints on the child tables for the branch table `mlp_1_prt_11` are the same as the constraints on the child tables for the branch table `mlp_1_prt_21`.

As a quick check, this query displays the constraints for the partitions.

```sql
WITH tbl AS (SELECT oid, partitionlevel AS level,
                partitiontablename AS part
        FROM pg_partitions, pg_class
        WHERE tablename = 'mlp' AND partitiontablename=reiname
        AND partitionlevel=1 )
SELECT tbl.part, consrc
        FROM tbl, pg_constraint
        WHERE tbl.oid = conrelid ORDER BY consrc;
```

**Note:** You will need modify the query for more complex partitioned tables. For example, the query does not account for table names in different schemas.
The `consrc` column displays constraints on the subpartitions. The set of region constraints for the subpartitions in `mlp_1_prt_1` match the constraints for the subpartitions in `mlp_1_prt_2`. The constraints for year are inherited from the parent branch tables.

<table>
<thead>
<tr>
<th>part</th>
<th>consrc</th>
</tr>
</thead>
<tbody>
<tr>
<td>mlp_1_prt_2_2_prt_asia</td>
<td>(<code>region = 'asia'::text</code>)</td>
</tr>
<tr>
<td>mlp_1_prt_1_2_prt_asia</td>
<td>(<code>region = 'asia'::text</code>)</td>
</tr>
<tr>
<td>mlp_1_prt_2_2_prt_europe</td>
<td>(<code>region = 'europe'::text</code>)</td>
</tr>
<tr>
<td>mlp_1_prt_1_2_prt_europe</td>
<td>(<code>region = 'europe'::text</code>)</td>
</tr>
<tr>
<td>mlp_1_prt_2_2_prt_usa</td>
<td>(<code>region = 'usa'::text</code>)</td>
</tr>
<tr>
<td>mlp_1_prt_1_2_prt_usa</td>
<td>(<code>region = 'usa'::text</code>)</td>
</tr>
<tr>
<td>mlp_1_prt_2_2_prt_usa</td>
<td>(<code>year &gt;= 2006) AND (year &lt; 2011)</code>)</td>
</tr>
<tr>
<td>mlp_1_prt_1_2_prt_usa</td>
<td>(<code>year &gt;= 2006) AND (year &lt; 2011)</code>)</td>
</tr>
<tr>
<td>mlp_1_prt_1_2_prt_europe</td>
<td>(<code>year &gt;= 2006) AND (year &lt; 2011)</code>)</td>
</tr>
<tr>
<td>mlp_1_prt_2_2_prt_usa</td>
<td>(<code>year &gt;= 2011) AND (year &lt; 2016)</code>)</td>
</tr>
<tr>
<td>mlp_1_prt_2_2_prt_asia</td>
<td>(<code>year &gt;= 2011) AND (year &lt; 2016)</code>)</td>
</tr>
<tr>
<td>mlp_1_prt_2_2_prt_europe</td>
<td>(<code>year &gt;= 2011) AND (year &lt; 2016)</code>)</td>
</tr>
</tbody>
</table>

(12 rows)

If you add a default partition to the example partitioned table with this command:

```sql
ALTER TABLE mlp ADD DEFAULT PARTITION def
```

The partitioned table remains a uniform partitioned table. The branch created for default partition contains three child tables and the set of constraints on the child tables match the existing sets of child table constraints.

In the above example, if you drop the subpartition `mlp_1_prt_21_2_prt_asia` and add another subpartition for the region `canada`, the constraints are no longer uniform.

```sql
ALTER TABLE mlp ALTER PARTITION FOR (RANK(2))
DROP PARTITION asia ;
ALTER TABLE mlp ALTER PARTITION FOR (RANK(2))
ADD PARTITION canada VALUES ('canada');
```

Also, if you add a partition `canada` under `mlp_1_prt_21`, the partitioning hierarchy is not uniform.

However, if you add the subpartition `canada` to both `mlp_1_prt_21` and `mlp_1_prt_11` the of the original partitioned table, it remains a uniform partitioned table.

**Note:** Only the constraints on the sets of partitions at a partition level must be the same. The names of the partitions can be different.

### Defining Queries

Greenplum Database is based on the PostgreSQL implementation of the SQL standard.

This topic describes how to construct SQL queries in Greenplum Database.

- **SQL Lexicon**
- **SQL Value Expressions**

#### SQL Lexicon

SQL is a standard language for accessing databases. The language consists of elements that enable data storage, retrieval, analysis, viewing, manipulation, and so on. You use SQL commands to construct queries and commands that the Greenplum Database engine understands. SQL queries consist of a sequence of commands. Commands consist of a sequence of valid tokens in correct syntax order, terminated by a semicolon (`;`).
For more information about SQL commands, see *SQL Command Reference* in the *Greenplum Database Reference Guide*.

Greenplum Database uses PostgreSQL's structure and syntax, with some exceptions. For more information about SQL rules and concepts in PostgreSQL, see "SQL Syntax" in the PostgreSQL documentation.

**SQL Value Expressions**

SQL value expressions consist of one or more values, symbols, operators, SQL functions, and data. The expressions compare data or perform calculations and return a value as the result. Calculations include logical, arithmetic, and set operations.

The following are value expressions:

- An aggregate expression
- An array constructor
- A column reference
- A constant or literal value
- A correlated subquery
- A field selection expression
- A function call
- A new column value in an INSERT or UPDATE
- An operator invocation column reference
- A positional parameter reference, in the body of a function definition or prepared statement
- A row constructor
- A scalar subquery
- A search condition in a WHERE clause
- A target list of a SELECT command
- A type cast
- A value expression in parentheses, useful to group sub-expressions and override precedence
- A window expression

SQL constructs such as functions and operators are expressions but do not follow any general syntax rules. For more information about these constructs, see *Using Functions and Operators*.

**Column References**

A column reference has the form:

```
correlation.columnname
```

Here, *correlation* is the name of a table (possibly qualified with a schema name) or an alias for a table defined with a `FROM` clause or one of the keywords `NEW` or `OLD`. `NEW` and `OLD` can appear only in rewrite rules, but you can use other correlation names in any SQL statement. If the column name is unique across all tables in the query, you can omit the "*correlation." part of the column reference.

**Positional Parameters**

Positional parameters are arguments to SQL statements or functions that you reference by their positions in a series of arguments. For example, $1 refers to the first argument, $2 to the second argument, and so on. The values of positional parameters are set from arguments external to the SQL statement or supplied when SQL functions are invoked. Some client libraries support specifying data values separately from the
SQL command, in which case parameters refer to the out-of-line data values. A parameter reference has the form:

\$number

For example:

```sql
CREATE FUNCTION dept(text) RETURNS dept
AS $$ SELECT * FROM dept WHERE name = $1 $$
LANGUAGE SQL;
```

Here, the $1 references the value of the first function argument whenever the function is invoked.

**Subscripts**

If an expression yields a value of an array type, you can extract a specific element of the array value as follows:

```sql
expression[subscript]
```

You can extract multiple adjacent elements, called an array slice, as follows (including the brackets):

```sql
expression[lower_subscript:upper_subscript]
```

Each subscript is an expression and yields an integer value.

Array expressions usually must be in parentheses, but you can omit the parentheses when the expression to be subscripted is a column reference or positional parameter. You can concatenate multiple subscripts when the original array is multidimensional. For example (including the parentheses):

```sql
mytable.arraycolumn[4]
```

```sql
mytable.two_d_column[17][34]
```

```sql
$1[10:42]
```

```sql
(arrayfunction(a,b))[42]
```

**Field Selection**

If an expression yields a value of a composite type (row type), you can extract a specific field of the row as follows:

```sql
expression.fieldname
```

The row expression usually must be in parentheses, but you can omit these parentheses when the expression to be selected from is a table reference or positional parameter. For example:

```sql
mytable.mycolumn
```

```sql
$1.somecolumn
```

```sql
(rowfunction(a,b)).col3
```

A qualified column reference is a special case of field selection syntax.
**Operator Invocations**

Operator invocations have the following possible syntaxes:

- `expression operator expression` (binary infix operator)
- `operator expression` (unary prefix operator)
- `expression operator` (unary postfix operator)

Where `operator` is an operator token, one of the key words `AND`, `OR`, or `NOT`, or qualified operator name in the form:

```
OPERATOR(schema.operatorsname)
```

Available operators and whether they are unary or binary depends on the operators that the system or user defines. For more information about built-in operators, see *Built-in Functions and Operators*.

**Function Calls**

The syntax for a function call is the name of a function (possibly qualified with a schema name), followed by its argument list enclosed in parentheses:

```
function ([expression [, expression ... ]])
```

For example, the following function call computes the square root of 2:

```
sqrt(2)
```

See *Summary of Built-in Functions* in the *Greenplum Database Reference Guide* for lists of the built-in functions by category. You can add custom functions, too.

**Aggregate Expressions**

An aggregate expression applies an aggregate function across the rows that a query selects. An aggregate function performs a calculation on a set of values and returns a single value, such as the sum or average of the set of values. The syntax of an aggregate expression is one of the following:

- `aggregate_name(expression [, ... ] )` — operates across all input rows for which the expected result value is non-null. `ALL` is the default.
- `aggregate_name(ALL expression [, ... ] )` — operates identically to the first form because `ALL` is the default.
- `aggregate_name(DISTINCT expression [, ... ] )` — operates across all distinct non-null values of input rows.
- `aggregate_name(*)` — operates on all rows with values both null and non-null. Generally, this form is most useful for the `count(*)` aggregate function.

Where `aggregate_name` is a previously defined aggregate (possibly schema-qualified) and `expression` is any value expression that does not contain an aggregate expression.

For example, `count(*)` yields the total number of input rows, `count(f1)` yields the number of input rows in which `f1` is non-null, and `count(distinct f1)` yields the number of distinct non-null values of `f1`.

For predefined aggregate functions, see *Built-in Functions and Operators*. You can also add custom aggregate functions.
Greenplum Database provides the `MEDIAN` aggregate function, which returns the fiftieth percentile of the `PERCENTILE_CONT` result and special aggregate expressions for inverse distribution functions as follows:

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>PERCENTILE_CONT(_percentage_) WITHIN GROUP (ORDER BY _expression_)</code></td>
<td>Returns the fiftieth percentile of the result.</td>
</tr>
<tr>
<td><code>PERCENTILE_DISC(_percentage_) WITHIN GROUP (ORDER BY _expression_)</code></td>
<td>Special aggregate expressions for inverse distribution functions.</td>
</tr>
</tbody>
</table>

Currently you can use only these two expressions with the keyword `WITHIN GROUP`.

**Limitations of Aggregate Expressions**

The following are current limitations of the aggregate expressions:

- Greenplum Database does not support the following keywords: `ALL`, `DISTINCT`, `FILTER` and `OVER`. See Table 69: Advanced Aggregate Functions for more details.
- An aggregate expression can appear only in the result list or `HAVING` clause of a `SELECT` command. It is forbidden in other clauses, such as `WHERE`, because those clauses are logically evaluated before the results of aggregates form. This restriction applies to the query level to which the aggregate belongs.
- When an aggregate expression appears in a subquery, the aggregate is normally evaluated over the rows of the subquery. If the aggregate's arguments contain only outer-level variables, the aggregate belongs to the nearest such outer level and evaluates over the rows of that query. The aggregate expression as a whole is then an outer reference for the subquery in which it appears, and the aggregate expression acts as a constant over any one evaluation of that subquery. See Scalar Subqueries and Table 67: Built-in functions and operators.
- Greenplum Database does not support `DISTINCT` with multiple input expressions.
- Greenplum Database does not support specifying an aggregate function as an argument to another aggregate function.
- Greenplum Database does not support specifying a window function as an argument to an aggregate function.

**Window Expressions**

Window expressions allow application developers to more easily compose complex online analytical processing (OLAP) queries using standard SQL commands. For example, with window expressions, users can calculate moving averages or sums over various intervals, reset aggregations and ranks as selected column values change, and express complex ratios in simple terms.

A window expression represents the application of a `window function` applied to a `window frame`, which is defined in a special `OVER()` clause. A window partition is a set of rows that are grouped together to apply a window function. Unlike aggregate functions, which return a result value for each group of rows, window functions return a result value for every row, but that value is calculated with respect to the rows in a particular window partition. If no partition is specified, the window function is computed over the complete intermediate result set.

Greenplum Database does not support specifying a window function as an argument to another window function.

The syntax of a window expression is:

```
window_function ( [expression [, ...]] ) OVER ( window_specification )
```

Where `window_function` is one of the functions listed in Table 68: Window functions, `expression` is any value expression that does not contain a window expression, and `window_specification` is:

```
[window_name]
[PARTITION BY expression [, ...]]
```
Greenplum Database Administrator Guide

[[ORDER BY expression [ASC | DESC | USING operator] [NULLS {FIRST | LAST}]
[, ...]
{{RANGE | ROWS}
{ UNBOUNDED PRECEDING
| expression PRECEDING
| CURRENT ROW
| BETWEEN window_frame_bound AND window_frame_bound }}]]

and where window_frame_bound can be one of:

UNBOUNDED PRECEDING
expression PRECEDING
CURRENT ROW
expression FOLLOWING
UNBOUNDED FOLLOWING

A window expression can appear only in the select list of a SELECT command. For example:

```
SELECT count(*) OVER(PARTITION BY customer_id), * FROM sales;
```

The OVER clause differentiates window functions from other aggregate or reporting functions. The OVER clause defines the window specification to which the window function is applied. A window specification has the following characteristics:

- The PARTITION BY clause defines the window partitions to which the window function is applied. If omitted, the entire result set is treated as one partition.
- The ORDER BY clause defines the expression(s) for sorting rows within a window partition. The ORDER BY clause of a window specification is separate and distinct from the ORDER BY clause of a regular query expression. The ORDER BY clause is required for the window functions that calculate rankings, as it identifies the measure(s) for the ranking values. For OLAP aggregations, the ORDER BY clause is required to use window frames (the ROWS | RANGE clause).

  **Note:** Columns of data types without a coherent ordering, such as time, are not good candidates for use in the ORDER BY clause of a window specification. Time, with or without a specified time zone, lacks a coherent ordering because addition and subtraction do not have the expected effects. For example, the following is not generally true: \( x::\text{time} < x::\text{time} + '2 hour'::\text{interval} \)

- The ROWS/RANGE clause defines a window frame for aggregate (non-ranking) window functions. A window frame defines a set of rows within a window partition. When a window frame is defined, the window function computes on the contents of this moving frame rather than the fixed contents of the entire window partition. Window frames are row-based (ROWS) or value-based (RANGE).

**Type Casts**

A type cast specifies a conversion from one data type to another. A cast applied to a value expression of a known type is a run-time type conversion. The cast succeeds only if a suitable type conversion function is defined. This differs from the use of casts with constants. A cast applied to a string literal represents the initial assignment of a type to a literal constant value, so it succeeds for any type if the contents of the string literal are acceptable input syntax for the data type.

Greenplum Database supports three types of casts applied to a value expression:

- **Explicit cast** - Greenplum Database applies a cast when you explicitly specify a cast between two data types. Greenplum Database accepts two equivalent syntaxes for explicit type casts:

  ```
  CAST ( expression AS type )
  expression::type
  ```

  The CAST syntax conforms to SQL; the syntax with :: is historical PostgreSQL usage.
• **Assignment cast** - Greenplum Database implicitly invokes a cast in assignment contexts, when assigning a value to a column of the target data type. For example, a `CREATE CAST` command with the AS ASSIGNMENT clause creates a cast that is applied implicitly in the assignment context. This example assignment cast assumes that `tbl1.f1` is a column of type `text`. The `INSERT` command is allowed because the value is implicitly cast from the integer to text type.

```
INSERT INTO tbl1 (f1) VALUES (42);
```

• **Implicit cast** - Greenplum Database implicitly invokes a cast in assignment or expression contexts. For example, a `CREATE CAST` command with the AS IMPLICIT clause creates an implicit cast, a cast that is applied implicitly in both the assignment and expression context. This example implicit cast assumes that `tbl1.c1` is a column of type `int`. For the calculation in the predicate, the value of `c1` is implicitly cast from `int` to a `decimal` type.

```
SELECT * FROM tbl1 WHERE tbl1.c2 = (4.3 + tbl1.c1);
```

You can usually omit an explicit type cast if there is no ambiguity about the type a value expression must produce; for example, when it is assigned to a table column, the system automatically applies a type cast. Greenplum Database implicitly applies casts only to casts where the is defined with the cast context of assignment or implicit in the system catalogs. Other casts must be invoked with explicit casting syntax to prevent unexpected conversions from being applied without the user's knowledge.

You can display cast information with the `psql` metacommand `\dC`. Cast information is stored in the catalog table `pg_cast`, and type information is stored in the catalog table `pg_type`.

### Scalar Subqueries

A scalar subquery is a `SELECT` query in parentheses that returns exactly one row with one column. Do not use a `SELECT` query that returns multiple rows or columns as a scalar subquery. The query runs and uses the returned value in the surrounding value expression. A correlated scalar subquery contains references to the outer query block.

### Correlated Subqueries

A correlated subquery (CSQ) is a `SELECT` query with a `WHERE` clause or target list that contains references to the parent outer clause. CSQs efficiently express results in terms of results of another query. Greenplum Database supports correlated subqueries that provide compatibility with many existing applications. A CSQ is a scalar or table subquery, depending on whether it returns one or multiple rows. Greenplum Database does not support correlated subqueries with skip-level correlations.

### Correlated Subquery Examples

**Example 1 – Scalar correlated subquery**

```
SELECT * FROM t1 WHERE t1.x > (SELECT MAX(t2.x) FROM t2 WHERE t2.y = t1.y);
```

**Example 2 – Correlated EXISTS subquery**

```
SELECT * FROM t1 WHERE EXISTS (SELECT 1 FROM t2 WHERE t2.x = t1.x);
```

Greenplum Database uses one of the following methods to run CSQs:

- Unnest the CSQ into join operations – This method is most efficient, and it is how Greenplum Database runs most CSQs, including queries from the TPC-H benchmark.
• Run the CSQ on every row of the outer query – This method is relatively inefficient, and it is how Greenplum Database runs queries that contain CSQs in the \texttt{SELECT} list or are connected by \texttt{OR} conditions.

The following examples illustrate how to rewrite some of these types of queries to improve performance.

\textbf{Example 3 - CSQ in the Select List}

\textit{Original Query}

\begin{verbatim}
SELECT T1.a,
    (SELECT COUNT(DISTINCT T2.z) FROM t2 WHERE t1.x = t2.y) dt2
FROM t1;
\end{verbatim}

Rewrite this query to perform an inner join with \texttt{t1} first and then perform a left join with \texttt{t1} again. The rewrite applies for only an equijoin in the correlated condition.

\textit{Rewritten Query}

\begin{verbatim}
SELECT t1.a, dt2 FROM t1
LEFT JOIN
    (SELECT t2.y AS csq_y, COUNT(DISTINCT t2.z) AS dt2
    FROM t1, t2 WHERE t1.x = t2.y
    GROUP BY t1.x)
ON (t1.x = csq_y);
\end{verbatim}

\textbf{Example 4 - CSQs connected by OR Clauses}

\textit{Original Query}

\begin{verbatim}
SELECT * FROM t1
WHERE
    x > (SELECT COUNT(*) FROM t2 WHERE t1.x = t2.x)
    OR x < (SELECT COUNT(*) FROM t3 WHERE t1.y = t3.y)
\end{verbatim}

Rewrite this query to separate it into two parts with a union on the \texttt{OR} conditions.

\textit{Rewritten Query}

\begin{verbatim}
SELECT * FROM t1
WHERE x > (SELECT count(*) FROM t2 WHERE t1.x = t2.x)
UNION
SELECT * FROM t1
WHERE x < (SELECT count(*) FROM t3 WHERE t1.y = t3.y)
\end{verbatim}

To view the query plan, use \texttt{EXPLAIN SELECT} or \texttt{EXPLAIN ANALYZE SELECT}. Subplan nodes in the query plan indicate that the query will run on every row of the outer query, and the query is a candidate for rewriting. For more information about these statements, see \textit{Query Profiling}.

\textbf{Array Constructors}

An array constructor is an expression that builds an array value from values for its member elements. A simple array constructor consists of the key word \texttt{ARRAY}, a left square bracket [, one or more expressions separated by commas for the array element values, and a right square bracket ]. For example,

\begin{verbatim}
SELECT ARRAY[1,2,3+4];
array
  {1,2,7}
\end{verbatim}
The array element type is the common type of its member expressions, determined using the same rules as for UNION or CASE constructs.

You can build multidimensional array values by nesting array constructors. In the inner constructors, you can omit the keyword ARRAY. For example, the following two SELECT statements produce the same result:

```sql
SELECT ARRAY[ARRAY[1,2], ARRAY[3,4]];  
SELECT ARRAY[[1,2],[3,4]];  
array  
-------------  
{(1,2), (3,4)}
```

Since multidimensional arrays must be rectangular, inner constructors at the same level must produce sub-arrays of identical dimensions.

Multidimensional array constructor elements are not limited to a sub-ARRAY construct; they are anything that produces an array of the proper kind. For example:

```sql
CREATE TABLE arr(f1 int[], f2 int[]);  
INSERT INTO arr VALUES (ARRAY[[1,2],[3,4]],  
ARRAY[[5,6],[7,8]]);  
SELECT ARRAY[f1, f2, '((9,10),(11,12))':int[]] FROM arr;  
array  
-------------  
{{{1,2},{3,4}},{{5,6},{7,8}},{{9,10},{11,12}}}
```

You can construct an array from the results of a subquery. Write the array constructor with the keyword ARRAY followed by a subquery in parentheses. For example:

```sql
SELECT ARRAY(SELECT oid FROM pg_proc WHERE proname LIKE 'bytea%');  
?column?  
-------------  
```

The subquery must return a single column. The resulting one-dimensional array has an element for each row in the subquery result, with an element type matching that of the subquery's output column. The subscripts of an array value built with ARRAY always begin with 1.

### Row Constructors

A row constructor is an expression that builds a row value (also called a composite value) from values for its member fields. For example,

```sql
SELECT ROW(1,2.5,'this is a test');
```

Row constructors have the syntax rowvalue.*, which expands to a list of the elements of the row value, as when you use the syntax .* at the top level of a SELECT list. For example, if table t has columns f1 and f2, the following queries are the same:

```sql
SELECT ROW(t.*, 42) FROM t;  
SELECT ROW(t.f1, t.f2, 42) FROM t;
```

By default, the value created by a ROW expression has an anonymous record type. If necessary, it can be cast to a named composite type — either the row type of a table, or a composite type created with CREATE TYPE AS. To avoid ambiguity, you can explicitly cast the value if necessary. For example:

```sql
CREATE TABLE mytable(f1 int, f2 float, f3 text);  
CREATE FUNCTION getf1(mytable) RETURNS int AS 'SELECT $1.f1'  
LANGUAGE SQL;
```
In the following query, you do not need to cast the value because there is only one `getf1()` function and therefore no ambiguity:

```sql
SELECT getf1(ROW(1,2.5,'this is a test'));
getf1
-----
  1
```

```sql
CREATE TYPE myrowtype AS (f1 int, f2 text, f3 numeric);
CREATE FUNCTION getf1(myrowtype) RETURNS int AS 'SELECT $1.f1' LANGUAGE SQL;
```

Now we need a cast to indicate which function to call:

```sql
SELECT getf1(ROW(1,2.5,'this is a test'));
ERROR:  function getf1(record) is not unique
```

```sql
SELECT getf1(ROW(1,2.5,'this is a test')::mytable);
getf1
-----
  1
SELECT getf1(CAST(ROW(1,2.5,'this is a test') AS myrowtype));
getf1
-----
 11
```

You can use row constructors to build composite values to be stored in a composite-type table column or to be passed to a function that accepts a composite parameter.

**Expression Evaluation Rules**

The order of evaluation of subexpressions is undefined. The inputs of an operator or function are not necessarily evaluated left-to-right or in any other fixed order.

If you can determine the result of an expression by evaluating only some parts of the expression, then other subexpressions might not be evaluated at all. For example, in the following expression:

```sql
SELECT true OR somefunc();
```

`somefunc()` would probably not be called at all. The same is true in the following expression:

```sql
SELECT somefunc() OR true;
```

This is not the same as the left-to-right evaluation order that Boolean operators enforce in some programming languages.

Do not use functions with side effects as part of complex expressions, especially in WHERE and HAVING clauses, because those clauses are extensively reprocessed when developing an execution plan. Boolean expressions (AND/OR/NOT combinations) in those clauses can be reorganized in any manner that Boolean algebra laws allow.

Use a CASE construct to force evaluation order. The following example is an untrustworthy way to avoid division by zero in a WHERE clause:

```sql
SELECT ... WHERE x <> 0 AND y/x > 1.5;
```

The following example shows a trustworthy evaluation order:

```sql
SELECT ... WHERE CASE WHEN x <> 0 THEN y/x > 1.5 ELSE false END;
```
This `CASE` construct usage defeats optimization attempts; use it only when necessary.

**WITH Queries (Common Table Expressions)**

The `WITH` clause of the `SELECT` command provides a way to write subqueries for use in a larger `SELECT` query.

The subqueries, which are often referred to as Common Table Expressions or CTEs, can be thought of as defining temporary tables that exist just for the query. One use of this feature is to break down complicated queries into simpler parts. This example query displays per-product sales totals in only the top sales regions:

```sql
WITH regional_sales AS (
    SELECT region, SUM(amount) AS total_sales
    FROM orders
    GROUP BY region
), top_regions AS (
    SELECT region
    FROM regional_sales
    WHERE total_sales > (SELECT SUM(total_sales)/10 FROM regional_sales)
) SELECT region,
        product,
        SUM(quantity) AS product_units,
        SUM(amount) AS product_sales
FROM orders
WHERE region IN (SELECT region FROM top_regions)
GROUP BY region, product;
```

The query could have been written without the `WITH` clause, but would have required two levels of nested sub-`SELECT`s. It is easier to follow with the `WITH` clause.

The `RECURSIVE` keyword can be enabled by setting the server configuration parameter `gp_recursive_cte_prototype` to `on`.

**Note:** The `RECURSIVE` keyword is a Beta feature.

The optional `RECURSIVE` keyword changes `WITH` accomplishes things not otherwise possible in standard SQL. Using `RECURSIVE`, a query in the `WITH` clause can refer to its own output. This is a simple example that computes the sum the integers from 1 through 100:

```sql
WITH RECURSIVE t(n) AS (
    VALUES (1)
    UNION ALL
    SELECT n+1 FROM t WHERE n < 100
) SELECT sum(n) FROM t;
```

The required form of a recursive `WITH` clause is a `non-recursive term`, followed by a `UNION` (or `UNION ALL`), and then a `recursive term`, where only the `recursive term` can contain a reference to the query output.

`non_recursive_term UNION [ ALL ] recursive_term`

A recursive `WITH` query is executed as follows:

1. Evaluate the non-recursive term. For `UNION` (but not `UNION ALL`), discard duplicate rows. Include all remaining rows in the result of the recursive query, and also place them in a temporary `working table`.
2. As long as the working table is not empty, repeat these steps:
   a. Evaluate the recursive term, substituting the current contents of the working table for the recursive self-reference. For `UNION` (but not `UNION ALL`), discard duplicate rows and rows that duplicate any
previous result row. Include all remaining rows in the result of the recursive query, and also place them in a temporary intermediate table.

b. Replace the contents of the working table with the contents of the intermediate table, then empty the intermediate table.

Note: Strictly speaking, the process is iteration not recursion, but RECURSIVE is the terminology chosen by the SQL standards committee.

Recursive WITH queries are typically used to deal with hierarchical or tree-structured data. An example is this query to find all the direct and indirect sub-parts of a product, given only a table that shows immediate inclusions:

```sql
WITH RECURSIVE included_parts(sub_part, part, quantity) AS (
    SELECT sub_part, part, quantity FROM parts WHERE part = 'our_product'
    UNION ALL
    SELECT p.sub_part, p.part, p.quantity
    FROM included_parts pr, parts p
    WHERE p.part = pr.sub_part
) SELECT sub_part, SUM(quantity) as total_quantity
FROM included_parts
GROUP BY sub_part
```

When working with recursive WITH queries, you must ensure that the recursive part of the query eventually returns no tuples, or else the query loops indefinitely. In the example that computes the sum the integers, the working table contains a single row in each step, and it takes on the values from 1 through 100 in successive steps. In the 100th step, there is no output because of the WHERE clause, and the query terminates.

For some queries, using UNION instead of UNION ALL can ensure that the recursive part of the query eventually returns no tuples by discarding rows that duplicate previous output rows. However, often a cycle does not involve output rows that are complete duplicates: it might sufficient to check just one or a few fields to see if the same point has been reached before. The standard method for handling such situations is to compute an array of the visited values. For example, consider the following query that searches a table graph using a link field:

```sql
WITH RECURSIVE search_graph(id, link, data, depth) AS (
    SELECT g.id, g.link, g.data, 1
    FROM graph g
    UNION ALL
    SELECT g.id, g.link, g.data, sg.depth + 1
    FROM graph g, search_graph sg
    WHERE g.id = sg.link
) SELECT * FROM search_graph;
```

This query loops if the link relationships contain cycles. Because the query requires a depth output, changing UNION ALL to UNION does not eliminate the looping. Instead the query needs to recognize whether it has reached the same row again while following a particular path of links. This modified query adds two columns path and cycle to the loop-prone query:

```sql
WITH RECURSIVE search_graph(id, link, data, depth, path, cycle) AS (
    SELECT g.id, g.link, g.data, 1,
    ARRAY[g.id],
    false
    FROM graph g
    UNION ALL
    SELECT g.id, g.link, g.data, sg.depth + 1,
    path || g.id,
    g.id = ANY(path)
    FROM graph g, search_graph sg
)
```
WHERE g.id = sg.link AND NOT cycle
)
SELECT * FROM search_graph;

Aside from detecting cycles, the array value of path is useful in its own right since it represents the path taken to reach any particular row.

In the general case where more than one field needs to be checked to recognize a cycle, an array of rows can be used. For example, if we needed to compare fields \( f_1 \) and \( f_2 \):

```sql
WITH RECURSIVE search_graph(id, link, data, depth, path, cycle) AS (
    SELECT g.id, g.link, g.data, 1,
          ARRAY[ROW(g.f1, g.f2)],
          false
    FROM graph g
    UNION ALL
    SELECT g.id, g.link, g.data, sg.depth + 1,
          path || ROW(g.f1, g.f2),
          ROW(g.f1, g.f2) = ANY(path)
    FROM graph g, search_graph sg
    WHERE g.id = sg.link AND NOT cycle
)
SELECT * FROM search_graph;
```

**Tip:** Omit the `ROW()` syntax in the case where only one field needs to be checked to recognize a cycle. This uses a simple array rather than a composite-type array to be used, gaining efficiency.

**Tip:** The recursive query evaluation algorithm produces its output in breadth-first search order. You can display the results in depth-first search order by making the outer query `ORDER BY` a path column constructed in this way.

A helpful technique for testing a query when you are not certain if it might loop indefinitely is to place a `LIMIT` in the parent query. For example, this query would loop forever without the `LIMIT` clause:

```sql
WITH RECURSIVE t(n) AS (
    SELECT 1
    UNION ALL
    SELECT n+1 FROM t
)
SELECT n FROM t LIMIT 100;
```

The technique works because the recursive `WITH` implementation evaluates only as many rows of a `WITH` query as are actually fetched by the parent query. Using this technique in production is not recommended, because other systems might work differently. Also, the technique might not work if the outer query sorts the recursive `WITH` results or join the results to another table.

### Using Functions and Operators

Description of user-defined and built-in functions and operators in Greenplum Database.

- **Using Functions in Greenplum Database**
- **User-Defined Functions**
- **Built-in Functions and Operators**
- **Window Functions**
- **Advanced Aggregate Functions**
## Using Functions in Greenplum Database

### Table 66: Functions in Greenplum Database

<table>
<thead>
<tr>
<th>Function Type</th>
<th>Greenplum Support</th>
<th>Description</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>IMMUTABLE</td>
<td>Yes</td>
<td>Relies only on information directly in its argument list. Given the same argument values, always returns the same result.</td>
<td></td>
</tr>
<tr>
<td>STABLE</td>
<td>Yes, in most cases</td>
<td>Within a single table scan, returns the same result for same argument values, but results change across SQL statements.</td>
<td>Results depend on database lookups or parameter values. current_timestamp family of functions is STABLE; values do not change within an execution.</td>
</tr>
<tr>
<td>VOLATILE</td>
<td>Restricted</td>
<td>Function values can change within a single table scan. For example: random(), timeofday().</td>
<td>Any function with side effects is volatile, even if its result is predictable. For example: setval().</td>
</tr>
</tbody>
</table>

Refer to the PostgreSQL Function Volatility Categories documentation for additional information about the Greenplum Database function volatility classifications.

In Greenplum Database, data is divided up across segments — each segment is a distinct PostgreSQL database. To prevent inconsistent or unexpected results, do not execute functions classified as VOLATILE at the segment level if they contain SQL commands or modify the database in any way. For example, functions such as setval() are not allowed to execute on distributed data in Greenplum Database because they can cause inconsistent data between segment instances.

To ensure data consistency, you can safely use VOLATILE and STABLE functions in statements that are evaluated on and run from the master. For example, the following statements run on the master (statements without a `FROM` clause):

```sql
SELECT setval('myseq', 201);
SELECT foo();
```

If a statement has a `FROM` clause containing a distributed table and the function in the `FROM` clause returns a set of rows, the statement can run on the segments:

```sql
SELECT * from foo();
```

Greenplum Database does not support functions that return a table reference (`rangeFuncs`) or functions that use the `refCursor` datatype.

### Function Volatility and Plan Caching

There is relatively little difference between the STABLE and IMMUTABLE function volatility categories for simple interactive queries that are planned and immediately executed. It does not matter much whether a function is executed once during planning or once during query execution startup. But there is a big difference when you save the plan and reuse it later. If you mislabel a function IMMUTABLE, Greenplum Database may prematurely fold it to a constant during planning, possibly reusing a stale value during subsequent execution of the plan. You may run into this hazard when using PREPARED statements, or when using languages such as PL/pgSQL that cache plans.
User-Defined Functions

Greenplum Database supports user-defined functions. See Extending SQL in the PostgreSQL documentation for more information.

Use the `CREATE FUNCTION` statement to register user-defined functions that are used as described in Using Functions in Greenplum Database. By default, user-defined functions are declared as VOLATILE, so if your user-defined function is IMMUTABLE or STABLE, you must specify the correct volatility level when you register your function.

When you create user-defined functions, avoid using fatal errors or destructive calls. Greenplum Database may respond to such errors with a sudden shutdown or restart.

In Greenplum Database, the shared library files for user-created functions must reside in the same library path location on every host in the Greenplum Database array (masters, segments, and mirrors).

You can also create and execute anonymous code blocks that are written in a Greenplum Database procedural language such as PL/pgSQL. The anonymous blocks run as transient anonymous functions. For information about creating and executing anonymous blocks, see the `DO` command.

Built-in Functions and Operators

The following table lists the categories of built-in functions and operators supported by PostgreSQL. All functions and operators are supported in Greenplum Database as in PostgreSQL with the exception of STABLE and VOLATILE functions, which are subject to the restrictions noted in Using Functions in Greenplum Database. See the Functions and Operators section of the PostgreSQL documentation for more information about these built-in functions and operators.

Greenplum Database includes JSON processing functions that manipulate values the `json` data type. For information about JSON data, see Working with JSON Data.

Table 67: Built-in functions and operators

<table>
<thead>
<tr>
<th>Operator/Function Category</th>
<th>VOLATILE Functions</th>
<th>STABLE Functions</th>
<th>Restrictions</th>
</tr>
</thead>
<tbody>

**Advanced Aggregate Functions**

The following built-in advanced aggregate functions are Greenplum extensions of the PostgreSQL database. These functions are immutable. Greenplum Database does not support the PostgreSQL ordered-set aggregate functions.

**Note:** The Greenplum MADlib Extension for Analytics provides additional advanced functions to perform statistical analysis and machine learning with Greenplum Database data. See Greenplum MADlib Extension for Analytics in the Greenplum Database Reference Guide.

### Working with JSON Data

Greenplum Database supports the `json` data type that stores JSON (JavaScript Object Notation) data. Greenplum Database supports JSON as specified in the [RFC 7159](https://tools.ietf.org/html/rfc7159) document and enforces data validity according to the JSON rules. There are also JSON-specific functions and operators available for `json` data. See [JSON Functions and Operators](https://greenplum-db-docs.s3.amazonaws.com/GPDB-17.3/GPDB17.3.1.0/docs/func-ref/json.html).

This section contains the following topics:

- About JSON Data
- JSON Input and Output Syntax
- Designing JSON documents
- JSON Functions and Operators

### About JSON Data

When Greenplum Database stores data as `json` data type, an exact copy of the input text is stored and the JSON processing functions reparse the data on each execution.

- Semantically-insignificant white space between tokens is retained, as well as the order of keys within JSON objects.
- All key/value pairs are kept even if a JSON object contains duplicate keys. For duplicate keys, JSON processing functions consider the last value as the operative one.

Greenplum Database allows only one character set encoding per database. It is not possible for the `json` type to conform rigidly to the JSON specification unless the database encoding is UTF8. Attempts to...
include characters that cannot be represented in the database encoding will fail. Characters that can be
represented in the database encoding but not in UTF8 are allowed.

The RFC 7159 document permits JSON strings to contain Unicode escape sequences denoted by \uXXXX. For the json type, the Greenplum Database input function allows Unicode escapes regardless of
the database encoding and checks Unicode escapes only for syntactic correctness (a \u followed by four
hex digits).

**Note:** Many of the JSON processing functions described in JSON Functions and Operators convert
Unicode escapes to regular characters. The functions throw an error for characters that cannot be
represented in the database encoding. You should avoid mixing Unicode escapes in JSON with a
non-UTF8 database encoding, if possible.

### JSON Input and Output Syntax

The input and output syntax for the json data type is as specified in RFC 7159.

The following are all valid json expressions:

-- Simple scalar/primitive value
-- Primitive values can be numbers, quoted strings, true, false, or null
SELECT '5'::json;

-- Array of zero or more elements (elements need not be of same type)
SELECT '[1, 2, "foo", null]':json;

-- Object containing pairs of keys and values
-- Note that object keys must always be quoted strings
SELECT '{"bar": "baz", "balance": 7.77, "active": false}':json;

-- Arrays and objects can be nested arbitrarily
SELECT '{"foo": [true, "bar"], "tags": {"a": 1, "b": null}}':json;

### Designing JSON documents

Representing data as JSON can be considerably more flexible than the traditional relational data model,
which is compelling in environments where requirements are fluid. It is quite possible for both approaches
to co-exist and complement each other within the same application. However, even for applications
where maximal flexibility is desired, it is still recommended that JSON documents have a somewhat fixed
structure. The structure is typically unenforced (though enforcing some business rules declaratively is
possible), but having a predictable structure makes it easier to write queries that usefully summarize a set
of "documents" (datums) in a table.

JSON data is subject to the same concurrency-control considerations as any other data type when stored
in a table. Although storing large documents is practicable, keep in mind that any update acquires a row-
level lock on the whole row. Consider limiting JSON documents to a manageable size in order to decrease
lock contention among updating transactions. Ideally, JSON documents should each represent an atomic
datum that business rules dictate cannot reasonably be further subdivided into smaller datums that could
be modified independently.

### JSON Functions and Operators

Built-in functions and operators that create and manipulate JSON data.

- **JSON Operators**
- **JSON Creation Functions**
- **JSON Processing Functions**

**Note:** For json values, all key/value pairs are kept even if a JSON object contains duplicate keys.
For duplicate keys, JSON processing functions consider the last value as the operative one.
**JSON Operators**

This table describes the operators that are available for use with the `json` data type.

**Table 70: json Operators**

<table>
<thead>
<tr>
<th>Operator</th>
<th>Right Operand Type</th>
<th>Description</th>
<th>Example</th>
<th>Example Result</th>
</tr>
</thead>

</table>
| `array_to_json(anyarray [, pretty_bool])` | Returns the array as a JSON array. A Greenplum Database multidimensional array becomes a JSON array of arrays. Line feeds are added between dimension 1 elements if `pretty_bool` is true. | `array_to_json('{{1,5},
{99,100}}':::int[])` | `[[1,5],[99,100]]` |
| `row_to_json(record [, pretty_bool])` | Returns the row as a JSON object. Line feeds are added between level 1 elements if `pretty_bool` is true. | `row_to_json(row(1,'foo'))` | `{"f1":1,"f2":"foo"}` |
Greenplum Database Administrator Guide

OpenTopic

JSON Processing Functions
This table describes the functions that process json values.
Table 72: JSON Processing Functions
Function

Return Type

Description

Example

json_
each(json)

setof key
text, value
json

Expands the
outermost JSON
object into a set of
key/value pairs.

select *
key | value
from json_
-----+------| "foo"
each('{"a":"foo", a
b
| "bar"
"b":"bar"}')

setof key
text, value
jsonb

Example Result

json_each_
text(json)

setof key
text, value
text

Expands the
outermost JSON
object into a set
of key/value pairs.
The returned
values are of type
text.

select * from
key | value
json_each_
-----+------| foo
text('{"a":"foo", a
b
| bar
"b":"bar"}')

json_extract_
path(from_json
json, VARIADIC
path_elems
text[])

json

Returns the JSON
value specified to
by path_elems.
Equivalent to #>
operator.

json_extract_
{"f5":99,"f6":"foo"}
path('{"f2":
{"f3":1},"f4":
{"f5":99,"f6":"foo"}}','f4')

json_
extract_path_
text(from_json
json, VARIADIC
path_elems
text[])

text

Returns the JSON
value specified to
by path_elems
as text. Equivalent
to #>> operator.

json_extract_
foo
path_text('{"f2":
{"f3":1},"f4":
{"f5":99,"f6":"foo"}}','f4',
'f6')

json_object_
keys(json)

setof text

Returns set
of keys in the
outermost JSON
object.

json_object_
json_object_
keys('{"f1":"abc","f2":
keys
-----------------{"f3":"a",
f1
"f4":"b"}}')
f2

json_populate_
record(base
anyelement,
from_json
json)

anyelement

Expands the
object in from_
json to a row
whose columns
match the record
type defined by
base. See Note.

select * from
a | b
json_populate_
---+--1 | 2
record(null::myrowtype,
'{"a":1,"b":2}')

615


### Working with XML Data

Greenplum Database supports the `xml` data type that stores XML data.

The `xml` data type checks the input values for well-formedness, providing an advantage over simply storing XML data in a text field. Additionally, support functions allow you to perform type-safe operations on this data; refer to XML Function Reference, below.

The `xml` type can store well-formed "documents", as defined by the XML standard, as well as "content" fragments, which are defined by the production `XMLDecl? content` in the XML standard. Roughly, this means that content fragments can have more than one top-level element or character node. The expression `xmlvalue IS DOCUMENT` can be used to evaluate whether a particular `xml` value is a full document or only a content fragment.

This section contains the following topics:

- Creating XML Values
- Encoding Handling
- Accessing XML Values
- Processing XML
- Mapping Tables to XML
- Using XML Functions and Expressions

### Creating XML Values

To produce a value of type `xml` from character data, use the function `xmlparse`:

```
xmllparse ( { DOCUMENT | CONTENT } value)
```
For example:

```
XMLPARSE (DOCUMENT '<?xml version="1.0"?><book><title>Manual</title><chapter>...</chapter></book>')
XMLPARSE (CONTENT 'abc<foo>bar</foo><bar>foo</bar>')
```

The above method converts character strings into XML values according to the SQL standard, but you can also use Greenplum Database syntax like the following:

```
xml '<foo>bar</foo>'
'<foo>bar</foo>'::xml
```

The `xml` type does not validate input values against a document type declaration (DTD), even when the input value specifies a DTD. There is also currently no built-in support for validating against other XML schema languages such as XML schema.

The inverse operation, producing a character string value from `xml`, uses the function `xmlserialize`:

```
xmserialize ( { DOCUMENT | CONTENT } value AS type )
```

`type` can be `character`, `character varying`, or `text` (or an alias for one of those). Again, according to the SQL standard, this is the only way to convert between type `xml` and character types, but Greenplum Database also allows you to simply cast the value.

When a character string value is cast to or from type `xml` without going through `XMLPARSE` or `XMLSERIALIZE`, respectively, the choice of `DOCUMENT` versus `CONTENT` is determined by the `XML` option session configuration parameter, which can be set using the standard command:

```
SET XML OPTION { DOCUMENT | CONTENT };
```

or simply like Greenplum Database:

```
SET XML OPTION TO { DOCUMENT | CONTENT };
```

The default is `CONTENT`, so all forms of XML data are allowed.

**Note:**

With the default XML option setting, you cannot directly cast character strings to type `xml` if they contain a document type declaration, because the definition of XML content fragment does not accept them. If you need to do that, either use `XMLPARSE` or change the `XML` option.

### Encoding Handling

Be careful when dealing with multiple character encodings on the client, server, and in the XML data passed through them. When using the text mode to pass queries to the server and query results to the client (which is the normal mode), Greenplum Database converts all character data passed between the client and the server, and vice versa, to the character encoding of the respective endpoint; see Character Set Support. This includes string representations of XML values, such as in the above examples.

Ordinarily, this means that encoding declarations contained in XML data can become invalid, as the character data is converted to other encodings while travelling between client and server, because the embedded encoding declaration is not changed. To cope with this behavior, encoding declarations contained in character strings presented for input to the `xml` type are ignored, and content is assumed to be in the current server encoding. Consequently, for correct processing, character strings of XML data must be sent from the client in the current client encoding. It is the responsibility of the client to either convert documents to the current client encoding before sending them to the server, or to adjust the client encoding appropriately. On output, values of type `xml` will not have an encoding declaration, and clients should assume all data is in the current client encoding.
When using binary mode to pass query parameters to the server and query results back to the client, no character set conversion is performed, so the situation is different. In this case, an encoding declaration in the XML data will be observed, and if it is absent, the data will be assumed to be in UTF-8 (as required by the XML standard; note that Greenplum Database does not support UTF-16). On output, data will have an encoding declaration specifying the client encoding, unless the client encoding is UTF-8, in which case it will be omitted.

Note:
Processing XML data with Greenplum Database will be less error-prone and more efficient if the XML data encoding, client encoding, and server encoding are the same. Because XML data is internally processed in UTF-8, computations will be most efficient if the server encoding is also UTF-8.

Accessing XML Values
The xml data type is unusual in that it does not provide any comparison operators. This is because there is no well-defined and universally useful comparison algorithm for XML data. One consequence of this is that you cannot retrieve rows by comparing an xml column against a search value. XML values should therefore typically be accompanied by a separate key field such as an ID. An alternative solution for comparing XML values is to convert them to character strings first, but note that character string comparison has little to do with a useful XML comparison method.

Because there are no comparison operators for the xml data type, it is not possible to create an index directly on a column of this type. If speedy searches in XML data are desired, possible workarounds include casting the expression to a character string type and indexing that, or indexing an XPath expression. Of course, the actual query would have to be adjusted to search by the indexed expression.

Processing XML
To process values of data type xml, Greenplum Database offers the functions xpath and xpath_exists, which evaluate XPath 1.0 expressions.

\[
\text{xpath}(\text{xpath}, \text{xml} [, \text{nsarray}])
\]

The function xpath evaluates the XPath expression xpath (a text value) against the XML value xml. It returns an array of XML values corresponding to the node set produced by the XPath expression.

The second argument must be a well formed XML document. In particular, it must have a single root node element.

The optional third argument of the function is an array of namespace mappings. This array should be a two-dimensional text array with the length of the second axis being equal to 2 (i.e., it should be an array of arrays, each of which consists of exactly 2 elements). The first element of each array entry is the namespace name (alias), the second the namespace URI. It is not required that aliases provided in this array be the same as those being used in the XML document itself (in other words, both in the XML document and in the xpath function context, aliases are local).

Example:

```
ARRAY[ARRAY['my', 'http://example.com']]);
```

```
xpath
--------
{test}
(1 row)
```
To deal with default (anonymous) namespaces, do something like this:

```sql
SELECT xpath('//mydefns:b/text()', '<a xmlns="http://example.com"><b>test</b></a>', ARRAY[ARRAY['mydefns', 'http://example.com']]));
```

```
xpath
--------
{test}
(1 row)
```

`xpath_exists(xpath, xml [, nsarray])`

The function `xpath_exists` is a specialized form of the `xpath` function. Instead of returning the individual XML values that satisfy the XPath, this function returns a Boolean indicating whether the query was satisfied or not. This function is equivalent to the standard `XMLEXISTS` predicate, except that it also offers support for a namespace mapping argument.

Example:

```sql
```

```
xpath_exists
----------
t
(1 row)
```

**Mapping Tables to XML**

The following functions map the contents of relational tables to XML values. They can be thought of as XML export functionality:

- `table_to_xml(tbl regclass, nulls boolean, tableforest boolean, targetns text)`
- `query_to_xml(query text, nulls boolean, tableforest boolean, targetns text)`
- `cursor_to_xml(cursor refcursor, count int, nulls boolean, tableforest boolean, targetns text)`

The return type of each function is `xml`.

`table_to_xml` maps the content of the named table, passed as parameter `tbl`. The `regclass` type accepts strings identifying tables using the usual notation, including optional schema qualifications and double quotes. `query_to_xml` executes the query whose text is passed as parameter `query` and maps the result set. `cursor_to_xml` fetches the indicated number of rows from the cursor specified by the parameter `cursor`. This variant is recommended if large tables have to be mapped, because the result value is built up in memory by each function.

If `tableforest` is false, then the resulting XML document looks like this:

```xml
<tablename>
  <row>
    <columnname1>data</columnname1>
    <columnname2>data</columnname2>
  </row>
  ...
</row>
```
If tableforest is true, the result is an XML content fragment that looks like this:

```
<tablename>
  <columnname1>data</columnname1>
  <columnname2>data</columnname2>
</tablename>
<tablename>
  ...
</tablename>
```

If no table name is available, that is, when mapping a query or a cursor, the string table is used in the first format, row in the second format.

The choice between these formats is up to the user. The first format is a proper XML document, which will be important in many applications. The second format tends to be more useful in the `cursor_to_xml` function if the result values are to be later reassembled into one document. The functions for producing XML content discussed above, in particular `xmlelement`, can be used to alter the results as desired.

The data values are mapped in the same way as described for the function `xmlelement`, above.

The parameter `nulls` determines whether null values should be included in the output. If true, null values in columns are represented as:

```
<columnname xsi:nil="true"/>
```

where `xsi` is the XML namespace prefix for XML schema Instance. An appropriate namespace declaration will be added to the result value. If false, columns containing null values are simply omitted from the output.

The parameter `targetns` specifies the desired XML namespace of the result. If no particular namespace is wanted, an empty string should be passed.

The following functions return XML schema documents describing the mappings performed by the corresponding functions above:

```
able_to_xmlschema(tbl regclass, nulls boolean, tableforest boolean, targetns text)
query_to_xmlschema(query text, nulls boolean, tableforest boolean, targetns text)
cursor_to_xmlschema(cursor refcursor, nulls boolean, tableforest boolean, targetns text)
```

It is essential that the same parameters are passed in order to obtain matching XML data mappings and XML schema documents.

The following functions produce XML data mappings and the corresponding XML schema in one document (or forest), linked together. They can be useful where self-contained and self-describing results are desired:

```
table_to_xml_and_xmlschema(tbl regclass, nulls boolean, tableforest boolean, targetns text)
query_to_xml_and_xmlschema(query text, nulls boolean, tableforest boolean, targetns text)
```
In addition, the following functions are available to produce analogous mappings of entire schemas or the entire current database:

```
    schema_to_xml(schema name, nulls boolean, tableforest boolean, targetns text)
    schema_to_xmlschema(schema name, nulls boolean, tableforest boolean, targetns text)
    schema_to_xml_and_xmlschema(schema name, nulls boolean, tableforest boolean, targetns text)
    
    database_to_xml(nulls boolean, tableforest boolean, targetns text)
    database_to_xmlschema(nulls boolean, tableforest boolean, targetns text)
    database_to_xml_and_xmlschema(nulls boolean, tableforest boolean, targetns text)
```

Note that these potentially produce large amounts of data, which needs to be built up in memory. When requesting content mappings of large schemas or databases, consider mapping the tables separately instead, possibly even through a cursor.

The result of a schema content mapping looks like this:

```
    <schema name>
    table1-mapping
    table2-mapping
    ...
    </schema name>
```

where the format of a table mapping depends on the `tableforest` parameter, as explained above.

The result of a database content mapping looks like this:

```
    <dbname>
    <schema1 name>
    ...
    </schema1 name>
    ...
    <schema2 name>
    ...
    </schema2 name>
    ...
    </dbname>
```

where the schema mapping is as above.

The example below demonstrates using the output produced by these functions, The example shows an XSLT stylesheet that converts the output of `table_to_xml_and_xmlschema` to an HTML document containing a tabular rendition of the table data. In a similar manner, the results from these functions can be converted into other XML-based formats.

```
<?xml version="1.0"?>
<xsl:stylesheet version="1.0"
    xmlns:xsl="http://www.w3.org/1999/XSL/Transform"
    xmlns:xsd="http://www.w3.org/2001/XMLSchema"
    xmlns="http://www.w3.org/1999/xhtml"
>
```
XML Function Reference

The functions described in this section operate on values of type xml. The section XML Predicates also contains information about the xml functions and function-like expressions.

Function:
xmlcomment

Synopsis:

xmlcomment(text)

The function xmlcomment creates an XML value containing an XML comment with the specified text as content. The text cannot contain "--" or end with a "-" so that the resulting construct is a valid XML comment. If the argument is null, the result is null.

Example:

SELECT xmlcomment('hello');
**Function:**

xmlconcat

**Synopsis:**

xmlconcat(xml[, ...])

The function `xmlconcat` concatenates a list of individual XML values to create a single value containing an XML content fragment. Null values are omitted; the result is only null if there are no nonnull arguments.

**Example:**

```sql
SELECT xmlconcat('<abc/>', '<bar>foo</bar>');
```

XML declarations, if present, are combined as follows:

- If all argument values have the same XML version declaration, that version is used in the result, else no version is used.
- If all argument values have the standalone declaration value "yes", then that value is used in the result.
- If all argument values have a standalone declaration value and at least one is "no", then that is used in the result. Otherwise, the result will have no standalone declaration.
- If the result is determined to require a standalone declaration but no version declaration, a version declaration with version 1.0 will be used because XML requires an XML declaration to contain a version declaration.

Encoding declarations are ignored and removed in all cases.

**Example:**

```sql
SELECT xmlconcat('<?xml version="1.1"?><foo/>', '<?xml version="1.1" standalone="no"?><bar/>');
```

**Function:**

xmlelement

**Synopsis:**

xmlelement(name name [, xmlattributes(value [AS attname] [, ... ])] [, content, ...])

The `xmlelement` expression produces an XML element with the given name, attributes, and content.

**Examples:**

```sql
SELECT xmlelement(name foo);
```

```sql
xmlelement
-----------
<foo/>
```
SELECT xmlelement(name foo, xmlattributes('xyz' as bar));

xmlelement
------------------
<foo bar="xyz"/>

SELECT xmlelement(name foo, xmlattributes(current_date as bar), 'cont', 'ent');

-------------------------------------
<foo bar="2017-01-26">content</foo>

Element and attribute names that are not valid XML names are escaped by replacing the offending characters by the sequence \_xHHHH\_, where HHHH is the character's Unicode codepoint in hexadecimal notation. For example:

SELECT xmlelement(name "foo\$bar", xmlattributes('xyz' as "a&b"));

----------------------------------
<foo_x0024_bar a_x0026_b="xyz"/>

An explicit attribute name need not be specified if the attribute value is a column reference, in which case the column's name will be used as the attribute name by default. In other cases, the attribute must be given an explicit name. So this example is valid:

CREATE TABLE test (a xml, b xml);
SELECT xmlelement(name test, xmlattributes(a, b)) FROM test;

But these are not:

SELECT xmlelement(name test, xmlattributes('constant'), a, b) FROM test;
SELECT xmlelement(name test, xmlattributes(func(a, b))) FROM test;

Element content, if specified, will be formatted according to its data type. If the content is itself of type xml, complex XML documents can be constructed. For example:

SELECT xmlelement(name foo, xmlattributes('xyz' as bar),
    xmlelement(name abc),
    xmlcomment('test'),
    xmlelement(name xyz));

----------------------------------------------
<foo bar="xyz"><abc/><!--test--><xyz/></foo>

Content of other types will be formatted into valid XML character data. This means in particular that the characters <, >, and & will be converted to entities. Binary data (data type bytea) will be represented in base64 or hex encoding, depending on the setting of the configuration parameter xmlbinary. The particular behavior for individual data types is expected to evolve in order to align the SQL and Greenplum Database data types with the XML schema specification, at which point a more precise description will appear.

Function:
xmlforest

Synopsis:

xmlforest(content [AS name] [, ...])
The `xmlforest` expression produces an XML forest (sequence) of elements using the given names and content.

Examples:

```sql
SELECT xmlforest('abc' AS foo, 123 AS bar);
```

```xml
<foo>abc</foo><bar>123</bar>
```

```sql
SELECT xmlforest(table_name, column_name)
FROM information_schema.columns
WHERE table_schema = 'pg_catalog';
```

```xml
<table_name>pg_authid</table_name><column_name>rolname</column_name>
<table_name>pg_authid</table_name><column_name>rolsuper</column_name>
```

As seen in the second example, the element name can be omitted if the content value is a column reference, in which case the column name is used by default. Otherwise, a name must be specified.

Element names that are not valid XML names are escaped as shown for `xmlelement` above. Similarly, content data is escaped to make valid XML content, unless it is already of type `xml`.

Note that XML forests are not valid XML documents if they consist of more than one element, so it might be useful to wrap `xmlforest` expressions in `xmlelement`.

**Function:**

`xmlpi`

**Synopsis:**

```sql
xmlpi(name target [, content])
```

The `xmlpi` expression creates an XML processing instruction. The content, if present, must not contain the character sequence `?>`.

Example:

```sql
SELECT xmlpi(name php, 'echo "hello world";');
```

```xml
<?php echo "hello world";?>
```

**Function:**

`xmlroot`

**Synopsis:**

```sql
xmlroot(xml, version text | no value [, standalone yes|no|no value])
```

The `xmlroot` expression alters the properties of the root node of an XML value. If a version is specified, it replaces the value in the root node's version declaration; if a standalone setting is specified, it replaces the value in the root node's standalone declaration.

Example:

```sql
SELECT xmlroot(xmlparse(document '<?xml version="1.1"?><content>abc</content>'),
```

```xml
<?xml version="1.1"?><content>abc</content>
```
version '1.0', standalone yes);
xmlroot

<?xml version="1.0" standalone="yes"?>
<content>abc</content>

**Function:**

xmlagg

xmlagg (xml)

The function `xmlagg` is, unlike the other functions described here, an aggregate function. It concatenates the input values to the aggregate function call, much like `xmlconcat` does, except that concatenation occurs across rows rather than across expressions in a single row. See *Using Functions and Operators* for additional information about aggregate functions.

**Example:**

```sql
CREATE TABLE test (y int, x xml);
INSERT INTO test VALUES (1, '<foo>abc</foo>');
INSERT INTO test VALUES (2, '<bar/>');
SELECT xmlagg(x) FROM test;
```

```
xmllag
----------------------
<foo>abc</foo><bar/>
```

To determine the order of the concatenation, an `ORDER BY` clause may be added to the aggregate call. For example:

```sql
SELECT xmlagg(x ORDER BY y DESC) FROM test;
```

```
xmllag
----------------------
<bar/><foo>abc</foo>
```

The following non-standard approach used to be recommended in previous versions, and may still be useful in specific cases:

```sql
SELECT xmlagg(x) FROM (SELECT * FROM test ORDER BY y DESC) AS tab;
```

```
xmllag
----------------------
<bar/><foo>abc</foo>
```

**XML Predicates**

The expressions described in this section check properties of `xml` values.

**Expression:**

**IS DOCUMENT**

**Synopsis:**

```
xml IS DOCUMENT
```

The expression `IS DOCUMENT` returns true if the argument XML value is a proper XML document, false if it is not (that is, it is a content fragment), or null if the argument is null.

**Expression:**

**XMLEXISTS**
Synopsis:

\texttt{XMLEXISTS(\texttt{text} \ \texttt{PASSING \ [BY \ REF]} \ \texttt{xml} \ [BY \ REF])}

The function \texttt{xmlexists} returns true if the XPath expression in the first argument returns any nodes, and false otherwise. (If either argument is null, the result is null.)

Example:

\begin{verbatim}
SELECT xmlexists('//town[text()] = ''Toronto'']' PASSING BY REF '<towns><town>Toronto</town><town>Ottawa</town></towns>');
\end{verbatim}

\begin{verbatim}
xmlexists
----------
t
(1 row)
\end{verbatim}

The \texttt{BY \ REF} clauses have no effect in Greenplum Database, but are allowed for SQL conformance and compatibility with other implementations. Per SQL standard, the first \texttt{BY \ REF} is required, the second is optional. Also note that the SQL standard specifies the \texttt{xmlexists} construct to take an XQuery expression as first argument, but Greenplum Database currently only supports XPath, which is a subset of XQuery.

Expression:

\texttt{xml_is_well_formed}

Synopsis:

\begin{verbatim}
xml_is_well_formed(text)
xml_is_well_formed_document(text)
xml_is_well_formed_content(text)
\end{verbatim}

These functions check whether a text string is well-formed XML, returning a Boolean result. \texttt{xml_is_well_formed_document} checks for a well-formed document, while \texttt{xml_is_well_formed_content} checks for well-formed content. \texttt{xml_is_well_formed} does the former if the \texttt{xmloption} configuration parameter is set to \texttt{DOCUMENT}, or the latter if it is set to \texttt{CONTENT}. This means that \texttt{xml_is_well_formed} is useful for seeing whether a simple cast to type \texttt{xml} will succeed, whereas the other two functions are useful for seeing whether the corresponding variants of \texttt{XMLPARSE} will succeed.

Examples:

\begin{verbatim}
SET xmloption TO DOCUMENT;
SELECT xml_is_well_formed('<>');
 xml_is_well_formed
---------
 f
(1 row)

SELECT xml_is_well_formed('<abc/>');
 xml_is_well_formed
---------
 t
(1 row)

SET xmloption TO CONTENT;
SELECT xml_is_well_formed('abc');
 xml_is_well_formed
---------
 t
(1 row)
\end{verbatim}
Greenplum Database dynamically eliminates irrelevant partitions in a table and optimally allocates memory for different operators in a query. These enhancements scan less data for a query, accelerate query processing, and support more concurrency.

- **Dynamic Partition Elimination**
  
  In Greenplum Database, values available only when a query runs are used to dynamically prune partitions, which improves query processing speed. Enable or disable dynamic partition elimination by setting the server configuration parameter `gp_dynamic_partition_pruning` to `ON` or `OFF`; it is `ON` by default.

- **Memory Optimizations**
  
  Greenplum Database allocates memory optimally for different operators in a query and frees and reallocates memory during the stages of processing a query.

  **Note:** Greenplum Database uses GPORCA, the Greenplum next generation query optimizer, by default. GPORCA extends the planning and optimization capabilities of the Greenplum Database legacy optimizer. For information about the features and limitations of GPORCA, see *Overview of GPORCA*.

## Managing Spill Files Generated by Queries

Greenplum Database creates spill files, also known as workfiles, on disk if it does not have sufficient memory to execute an SQL query in memory. The default value of 100,000 spill files is sufficient for the majority of queries. However, if a query creates more than the specified number of spill files, Greenplum Database returns this error:

```
ERROR: number of workfiles per query limit exceeded
```

Reasons that cause a large number of spill files to be generated include:

- Data skew is present in the queried data.
- The amount memory allocated for the query is too low.

You might be able to run the query successfully by changing the query, changing the data distribution, or changing the system memory configuration. You can use the `gp_workfile_*` views to see spill file usage information. You can control the maximum amount of memory that can be used by a query with the Greenplum Database server configuration parameters `max_statement_mem`, `statement_mem`, or through resource queues.

*Monitoring a Greenplum System* contains the following information:

- Information about skew and how to check for data skew
• Information about using the `gp_workfile_*` views

For information about server configuration parameters, see the *Greenplum Database Reference Guide*. For information about resource queues, see *Using Resource Queues*.

If you have determined that the query must create more spill files than allowed by the value of server configuration parameter `gp_workfile_limit_files_per_query`, you can increase the value of the parameter.

**Query Profiling**

Examine the query plans of poorly performing queries to identify possible performance tuning opportunities.

Greenplum Database devises a *query plan* for each query. Choosing the right query plan to match the query and data structure is necessary for good performance. A query plan defines how Greenplum Database will run the query in the parallel execution environment.

The query optimizer uses data statistics maintained by the database to choose a query plan with the lowest possible cost. Cost is measured in disk I/O, shown as units of disk page fetches. The goal is to minimize the total execution cost for the plan.

View the plan for a given query with the `EXPLAIN` command. `EXPLAIN` shows the query optimizer's estimated cost for the query plan. For example:

```sql
EXPLAIN SELECT * FROM names WHERE id=22;
```

`EXPLAIN ANALYZE` runs the statement in addition to displaying its plan. This is useful for determining how close the optimizer's estimates are to reality. For example:

```sql
EXPLAIN ANALYZE SELECT * FROM names WHERE id=22;
```

**Note:** In Greenplum Database, the default GPORCA optimizer co-exists with the legacy query optimizer. The `EXPLAIN` output generated by GPORCA is different than the output generated by the legacy query optimizer.

By default, Greenplum Database uses GPORCA to generate an execution plan for a query when possible.

When the `EXPLAIN ANALYZE` command uses GPORCA, the `EXPLAIN` plan shows only the number of partitions that are being eliminated. The scanned partitions are not shown. To show name of the scanned partitions in the segment logs set the server configuration parameter `gp_log_dynamic_partition_pruning` to `on`. This example `SET` command enables the parameter.

```sql
SET gp_log_dynamic_partition_pruning = on;
```

For information about GPORCA, see *Querying Data*.

**Reading EXPLAIN Output**

A query plan is a tree of nodes. Each node in the plan represents a single operation, such as a table scan, join, aggregation, or sort.

Read plans from the bottom to the top: each node feeds rows into the node directly above it. The bottom nodes of a plan are usually table scan operations: sequential, index, or bitmap index scans. If the query requires joins, aggregations, sorts, or other operations on the rows, there are additional nodes above the scan nodes to perform these operations. The topmost plan nodes are usually Greenplum Database motion nodes: redistribute, explicit redistribute, broadcast, or gather motions. These operations move rows between segment instances during query processing.
The output of `EXPLAIN` has one line for each node in the plan tree and shows the basic node type and the following execution cost estimates for that plan node:

- **cost** — Measured in units of disk page fetches. 1.0 equals one sequential disk page read. The first estimate is the start-up cost of getting the first row and the second is the total cost of getting all rows. The total cost assumes all rows will be retrieved, which is not always true; for example, if the query uses `LIMIT`, not all rows are retrieved.

  **Note:** The cost values generated by the Pivotal Query Optimizer and the Postgres Planner are not directly comparable. The two optimizers use different cost models, as well as different algorithms, to determine the cost of an execution plan. Nothing can or should be inferred by comparing cost values between the two optimizers.

  In addition, the cost generated for any given optimizer is valid only for comparing plan alternatives for a given single query and set of statistics. Different queries can generate plans with different costs, even when keeping the optimizer a constant.

  To summarize, the cost is essentially an internal number used by a given optimizer, and nothing should be inferred by examining only the cost value displayed in the `EXPLAIN` plans.

- **rows** — The total number of rows output by this plan node. This number is usually less than the number of rows processed or scanned by the plan node, reflecting the estimated selectivity of any `WHERE` clause conditions. Ideally, the estimate for the topmost node approximates the number of rows that the query actually returns, updates, or deletes.

- **width** — The total bytes of all the rows that this plan node outputs.

Note the following:

- The cost of a node includes the cost of its child nodes. The topmost plan node has the estimated total execution cost for the plan. This is the number the optimizer intends to minimize.

- The cost reflects only the aspects of plan execution that the query optimizer takes into consideration. For example, the cost does not reflect time spent transmitting result rows to the client.

**EXPLAIN Example**

The following example describes how to read an `EXPLAIN` query plan for a query:

```sql
EXPLAIN SELECT * FROM names WHERE name = 'Joelle';
```

```
---
Gather Motion 2:1 (slice1) (cost=0.00..20.88 rows=1 width=13)
  -> Seq Scan on 'names' (cost=0.00..20.88 rows=1 width=13)
    Filter: name::text ~~ 'Joelle'::text
---
```

Read the plan from the bottom to the top. To start, the query optimizer sequentially scans the `names` table. Notice the `WHERE` clause is applied as a `filter` condition. This means the scan operation checks the condition for each row it scans and outputs only the rows that satisfy the condition.

The results of the scan operation are passed to a `gather motion` operation. In Greenplum Database, a gather motion is when segments send rows to the master. In this example, we have two segment instances that send to one master instance. This operation is working on `slice1` of the parallel query execution plan. A query plan is divided into `slices` so the segments can work on portions of the query plan in parallel.

The estimated startup cost for this plan is **00.00** (no cost) and a total cost of **20.88** disk page fetches. The optimizer estimates this query will return one row.

**Reading EXPLAIN ANALYZE Output**

`EXPLAIN ANALYZE` plans and runs the statement. The `EXPLAIN ANALYZE` plan shows the actual execution cost along with the optimizer’s estimates. This allows you to see if the optimizer’s estimates are close to reality. `EXPLAIN ANALYZE` also shows the following:
• The total runtime (in milliseconds) in which the query executed.
• The memory used by each slice of the query plan, as well as the memory reserved for the whole query statement.
• The number of workers (segments) involved in a plan node operation. Only segments that return rows are counted.
• The maximum number of rows returned by the segment that produced the most rows for the operation. If multiple segments produce an equal number of rows, EXPLAIN ANALYZE shows the segment with the longest <time> to end.
• The segment id of the segment that produced the most rows for an operation.
• For relevant operations, the amount of memory (work_mem) used by the operation. If the work_mem was insufficient to perform the operation in memory, the plan shows the amount of data spilled to disk for the lowest-performing segment. For example:

| Work_mem used: 64K bytes avg, 64K bytes max (seg0). |
| Work_mem wanted: 90K bytes avg, 90K bytes max (seg0) to lessen workfile I/O affecting 2 workers. |

• The time (in milliseconds) in which the segment that produced the most rows retrieved the first row, and the time taken for that segment to retrieve all rows. The result may omit <time> to first row if it is the same as the <time> to end.

**EXPLAIN ANALYZE Examples**

This example describes how to read an EXPLAIN ANALYZE query plan using the same query. The bold parts of the plan show actual timing and rows returned for each plan node, as well as memory and time statistics for the whole query.

```
EXPLAIN ANALYZE SELECT * FROM names WHERE name = 'Joelle';
QUERY PLAN
------------------------------------------------------------
Gather Motion 2:1 (slice1; segments: 2) (cost=0.00..20.88 rows=1 width=13)
   Rows out: 1 rows at destination with 0.305 ms to first row, 0.537 ms to end, start offset by 0.289 ms.
      -> Seq Scan on names (cost=0.00..20.88 rows=1 width=13)
         Rows out: Avg 1 rows x 2 workers. Max 1 rows (seg0) with 0.255 ms to first row, 0.486 ms to end, start offset by 0.968 ms.
            Filter: name = 'Joelle '::text
Slice statistics:
   (slice0) Executor memory: 135K bytes.
   (slice1) Executor memory: 151K bytes avg x 2 workers, 151K bytes max (seg0).
Statement statistics:
   Memory used: 128000K bytes
   Total runtime: 22.548 ms
```

Read the plan from the bottom to the top. The total elapsed time to run this query was **22.548 milliseconds**.

The sequential scan operation had only one segment (seg0) that returned rows, and it returned just 1 row. It took 0.255 milliseconds to find the first row and 0.486 to scan all rows. This result is close to the optimizer's estimate: the query optimizer estimated it would return one row for this query. The gather motion (segments sending data to the master) received 1 row. The total elapsed time for this operation was **0.537 milliseconds**.

**Determining the Query Optimizer**

You can view EXPLAIN output to determine if GPORCA is enabled for the query plan and whether GPORCA or the legacy query optimizer generated the explain plan. The information appears at the end
of the EXPLAIN output. The Settings line displays the setting of the server configuration parameter OPTIMIZER. The Optimizer status line displays whether GPORCA or the legacy query optimizer generated the explain plan.

For these two example query plans, GPORCA is enabled, the server configuration parameter OPTIMIZER is on. For the first plan, GPORCA generated the EXPLAIN plan. For the second plan, Greenplum Database fell back to the legacy query optimizer to generate the query plan.

<table>
<thead>
<tr>
<th>QUERY PLAN</th>

</tbody>
</table>

**Examining Query Plans to Solve Problems**

If a query performs poorly, examine its query plan and ask the following questions:

- **Do operations in the plan take an exceptionally long time?** Look for an operation consumes the majority of query processing time. For example, if an index scan takes longer than expected, the index could be out-of-date and need to be reindexed. Or, adjust enable_<operator> parameters to see if you can force the legacy query optimizer (planner) to choose a different plan by disabling a particular query plan operator for that query.
• **Are the optimizer's estimates close to reality?** Run `EXPLAIN ANALYZE` and see if the number of rows the optimizer estimates is close to the number of rows the query operation actually returns. If there is a large discrepancy, collect more statistics on the relevant columns.

  See the *Greenplum Database Reference Guide* for more information on the `EXPLAIN ANALYZE` and `ANALYZE` commands.

• **Are selective predicates applied early in the plan?** Apply the most selective filters early in the plan so fewer rows move up the plan tree. If the query plan does not correctly estimate query predicate selectivity, collect more statistics on the relevant columns. See the `ANALYZE` command in the *Greenplum Database Reference Guide* for more information collecting statistics. You can also try reordering the `WHERE` clause of your SQL statement.

• **Does the optimizer choose the best join order?** When you have a query that joins multiple tables, make sure that the optimizer chooses the most selective join order. Joins that eliminate the largest number of rows should be done earlier in the plan so fewer rows move up the plan tree.

  If the plan is not choosing the optimal join order, set `joinCollapseLimit=1` and use explicit `JOIN` syntax in your SQL statement to force the legacy query optimizer (planner) to the specified join order. You can also collect more statistics on the relevant join columns.

  See the `ANALYZE` command in the *Greenplum Database Reference Guide* for more information collecting statistics.

• **Does the optimizer selectively scan partitioned tables?** If you use table partitioning, is the optimizer selectively scanning only the child tables required to satisfy the query predicates? Scans of the parent tables should return 0 rows since the parent tables do not contain any data. See *Verifying Your Partition Strategy* for an example of a query plan that shows a selective partition scan.

• **Does the optimizer choose hash aggregate and hash join operations where applicable?** Hash operations are typically much faster than other types of joins or aggregations. Row comparison and sorting is done in memory rather than reading/writing from disk. To enable the query optimizer to choose hash operations, there must be sufficient memory available to hold the estimated number of rows. Try increasing work memory to improve performance for a query. If possible, run an `EXPLAIN ANALYZE` for the query to show which plan operations spilled to disk, how much work memory they used, and how much memory was required to avoid spilling to disk. For example:

  ```
  Work_mem used: 23430K bytes avg, 23430K bytes max (seg0). Work_mem wanted: 33649K bytes avg, 33649K bytes max (seg0) to lessen workfile I/O affecting 2 workers.
  ```

  The "bytes wanted" message from `EXPLAIN ANALYZE` is based on the amount of data written to work files and is not exact. The minimum `work_mem` needed can differ from the suggested value.
Working with External Data

External tables provide access to data stored in data sources outside of Greenplum Database as if the data were stored in regular database tables. Data can be read from or written to external tables.

An external table is a Greenplum database table backed with data that resides outside of the database. An external table is either readable or writable. It can be used like a regular database table in SQL commands such as `SELECT` and `INSERT` and joined with other tables. External tables are most often used to load and unload database data.

Web-based external tables provide access to data served by an HTTP server or an operating system process. See Creating and Using External Web Tables for more about web-based tables.

Defining External Tables

External tables enable accessing external data as if it were a regular database table. They are often used to move data into and out of a Greenplum database.

To create an external table definition, you specify the format of your input files and the location of your external data sources. For information about input file formats, see Formatting Data Files.

Use one of the following protocols to access external table data sources. You cannot mix protocols in `CREATE EXTERNAL TABLE` statements:

- `file://` accesses external data files on segment hosts that the Greenplum Database superuser (`gpadmin`) can access. See file:/// Protocol.
- `gpfdist://` points to a directory on the file host and serves external data files to all Greenplum Database segments in parallel. See gpfdist:// Protocol.
- `gpfdists://` is the secure version of gpfdist. See gpfdists:// Protocol.

  Note: The gphdfs external table protocol is deprecated and will be removed in the next major release of Greenplum Database.

- `s3://` accesses files in an Amazon S3 bucket. See s3:// Protocol.

  Note: The gphdfs:/// (deprecated), s3://, and pxf:// protocols are custom data access protocols, where the `file://`, `gpfdist://`, and `gpfdists://` protocols are implemented internally in Greenplum Database. The custom and internal protocols differ in these ways:

  • Custom protocols must be registered using the `CREATE PROTOCOL` command. The gphdfs:// protocol (deprecated) is preregistered when you install Greenplum Database. Registering the PXF extension in a database creates the `pxf://` protocol. (See Accessing External Data with PXF.) You can optionally register the `s3://` protocol. (See Configuring and Using S3 External Tables.) Internal protocols are always present and cannot be unregistered.

  • When a custom protocol is registered, a row is added to the `pg_extprotocol` catalog table to specify the handler functions that implement the protocol. The protocol's shared libraries must have been installed on all Greenplum Database hosts. The internal protocols are not represented in the `pg_extprotocol` table and have no additional libraries to install.

  • To grant users permissions on custom protocols, you use `GRANT [SELECT | INSERT | ALL] ON PROTOCOL`. To allow (or deny) users permissions on the internal protocols, you use `CREATE ROLE` or `ALTER ROLE` to add the `CREATEEXTABLE` (or `NOCREATEEXTABLE`) attribute to each user’s role.
External tables access external files from within the database as if they are regular database tables. External tables defined with the `gpfdist/gpfdists`, `gphdfs` (deprecated), and `s3` protocols utilize Greenplum parallelism by using the resources of all Greenplum Database segments to load or unload data. The `gphdfs` protocol (deprecated) leverages the parallel architecture of the Hadoop Distributed File System to access files on that system. The `s3` protocol utilizes the Amazon Web Services (AWS) capabilities.

You can query external table data directly and in parallel using SQL commands such as `SELECT`, `JOIN`, or `SORT EXTERNAL TABLE DATA`, and you can create views for external tables.

The steps for using external tables are:

1. Define the external table.
   
   To use the `s3` protocol, you must also configure Greenplum Database and enable the protocol. See `s3:// Protocol`.

2. Do one of the following:
   
   • Start the Greenplum Database file server(s) when using the `gpfdist` or `gpdists` protocols.
   • Verify that you have already set up the required one-time configuration for the `gphdfs` protocol (deprecated).
   • Verify the Greenplum Database configuration for the `s3` protocol.

3. Place the data files in the correct locations.

4. Query the external table with SQL commands.

Greenplum Database provides readable and writable external tables:

- **Readable external tables for data loading.** Readable external tables support:
  
  • Basic extraction, transformation, and loading (ETL) tasks common in data warehousing
  • Reading external table data in parallel from multiple Greenplum database segment instances, to optimize large load operations
  • Filter pushdown. If a query contains a `WHERE` clause, it may be passed to the external data source. Refer to the `gp_external_enable_filter_pushdown` server configuration parameter discussion for more information. Note that this feature is currently supported only with the `pxf` protocol (see `pxf:// Protocol`).

  Readable external tables allow only `SELECT` operations.

- **Writable external tables for data unloading.** Writable external tables support:
  
  • Selecting data from database tables to insert into the writable external table
  • Sending data to an application as a stream of data. For example, unload data from Greenplum Database and send it to an application that connects to another database or ETL tool to load the data elsewhere
  • Receiving output from Greenplum parallel MapReduce calculations.

  Writable external tables allow only `INSERT` operations.

External tables can be file-based or web-based. External tables using the `file://` protocol are read-only tables.

- Regular (file-based) external tables access static flat files. Regular external tables are rescannable: the data is static while the query runs.
- Web (web-based) external tables access dynamic data sources, either on a web server with the `http://` protocol or by executing OS commands or scripts. External web tables are not rescannable: the data can change while the query runs.

Dump and restore operate only on external and external web table definitions, not on the data sources.
**file:// Protocol**

The `file://` protocol is used in a URI that specifies the location of an operating system file.

The URI includes the host name, port, and path to the file. Each file must reside on a segment host in a location accessible by the Greenplum Database superuser (`gpadmin`). The host name used in the URI must match a segment host name registered in the `gp_segment_configuration` system catalog table.

The `LOCATION` clause can have multiple URIs, as shown in this example:

```sql
CREATE EXTERNAL TABLE ext_expenses (  
    name text, date date, amount float4, category text, desc1 text  
)  
LOCATION ('file://host1:5432/data/expense/*.csv',  
    'file://host2:5432/data/expense/*.csv',  
    'file://host3:5432/data/expense/*.csv')  
FORMAT 'CSV' (HEADER);  
```

The number of URIs you specify in the `LOCATION` clause is the number of segment instances that will work in parallel to access the external table. For each URI, Greenplum assigns a primary segment on the specified host to the file. For maximum parallelism when loading data, divide the data into as many equally sized files as you have primary segments. This ensures that all segments participate in the load. The number of external files per segment host cannot exceed the number of primary segment instances on that host. For example, if your array has four primary segment instances per segment host, you can place four external files on each segment host. Tables based on the `file://` protocol can only be readable tables.

The system view `pg_max_external_files` shows how many external table files are permitted per external table. This view lists the available file slots per segment host when using the `file://` protocol. The view is only applicable for the `file://` protocol. For example:

```sql
SELECT * FROM pg_max_external_files;  
```

**gpfdist:// Protocol**

The `gpfdist://` protocol is used in a URI to reference a running `gpfdist` instance.

The `gpfdist` utility serves external data files from a directory on a file host to all Greenplum Database segments in parallel.

`gpfdist` is located in the `$GPHOME/bin` directory on your Greenplum Database master host and on each segment host.

Run `gpfdist` on the host where the external data files reside. `gpfdist` uncompresses `gzip (.gz)` and `bzip2 (.bz2)` files automatically. You can use the wildcard character (*) or other C-style pattern matching to denote multiple files to read. The files specified are assumed to be relative to the directory that you specified when you started the `gpfdist` instance.

All primary segments access the external file(s) in parallel, subject to the number of segments set in the `gp_external_max_segments` server configuration parameter. Use multiple `gpfdist` data sources in a `CREATE EXTERNAL TABLE` statement to scale the external table’s scan performance.

`gpfdist` supports data transformations. You can write a transformation process to convert external data from or to a format that is not directly supported with Greenplum Database external tables.

For more information about configuring `gpfdist`, see *Using the Greenplum Parallel File Server (gpfdist)*.

See the `gpfdist` reference documentation for more information about using `gpfdist` with external tables.
gpfdists:// Protocol

The gpfdists:// protocol is a secure version of the gpfdist:// protocol. To use it, you run the gpfdist utility with the --ssl option. When specified in a URI, the gpfdists:// protocol enables encrypted communication and secure identification of the file server and the Greenplum Database to protect against attacks such as eavesdropping and man-in-the-middle attacks.

The gpfdists protocol implements SSL security in a client/server scheme with the following attributes and limitations:

- Client certificates are required.
- Multilingual certificates are not supported.
- A Certificate Revocation List (CRL) is not supported.
- The TLSv1 protocol is used with the TLS_RSA_WITH_AES_128_CBC_SHA encryption algorithm.
- SSL parameters cannot be changed.
- SSL renegotiation is supported.
- The SSL ignore host mismatch parameter is set to false.
- Private keys containing a passphrase are not supported for the gpfdist file server (server.key) and for the Greenplum Database (client.key).
- Issuing certificates that are appropriate for the operating system in use is the user's responsibility. Generally, converting certificates as shown in https://www.sslshopper.com/ssl-converter.html is supported.

Note: A server started with the gpfdist --ssl option can only communicate with the gpfdists protocol. A server that was started with gpfdist without the --ssl option can only communicate with the gpfdist protocol.

- The client certificate file, client.crt
- The client private key file, client.key

Use one of the following methods to invoke the gpfdists protocol.

- Run gpfdist with the --ssl option and then use the gpfdists protocol in the LOCATION clause of a CREATE EXTERNAL TABLE statement.
- Use a gpload YAML control file with the SSL option set to true. Running gpload starts the gpfdist server with the --ssl option, then uses the gpfdists protocol.

Using gpfdists requires that the following client certificates reside in the $PGDATA/gpfdists directory on each segment.

- The client certificate file, client.crt
- The client private key file, client.key
- The trusted certificate authorities, root.crt

For an example of loading data into an external table security, see Example 3—Multiple gpfdists instances.

The server configuration parameter verify_gpfds_cert controls whether SSL certificate authentication is enabled when Greenplum Database communicates with the gpfdist utility to either read data from or write data to an external data source. You can set the parameter value to false to disable authentication when testing the communication between the Greenplum Database external table and the gpfdist utility that is serving the external data. If the value is false, these SSL exceptions are ignored:

- The self-signed SSL certificate that is used by gpfdist is not trusted by Greenplum Database.
- The host name contained in the SSL certificate does not match the host name that is running gpfdist.

Warning: Disabling SSL certificate authentication exposes a security risk by not validating the gpfdists SSL certificate.
**gphdfs:// Protocol (Deprecated)**

The `gphdfs://` protocol specifies an external file path on a Hadoop Distributed File System (HDFS).

**Note:** The `gphdfs` external table protocol is deprecated and will be removed in the next major release of Greenplum Database. Consider using the Greenplum Platform Extension Framework (PXF) `pxf` external table protocol to access data stored in a Hadoop file system.

The protocol allows specifying external files in Hadoop clusters configured with or without Hadoop HA (high availability) and in MapR clusters. File names may contain wildcard characters and the files can be in CSV, TEXT, or custom formats.

When Greenplum links with HDFS files, all the data is read in parallel from the HDFS data nodes into the Greenplum segments for rapid processing. Greenplum determines the connections between the segments and nodes.

Each Greenplum segment reads one set of Hadoop data blocks. For writing, each Greenplum segment writes only the data it contains. The following figure illustrates an external table located on a HDFS file system.

![Figure 27: External Table Located on a Hadoop Distributed File System](image)

The `FORMAT` clause describes the format of the external table files. Valid file formats are similar to the formatting options available with the PostgreSQL `COPY` command and user-defined formats for the `gphdfs` protocol. If the data in the file does not use the default column delimiter, escape character, null string and so on, you must specify the additional formatting options so that Greenplum Database reads the data in the external file correctly. The `gphdfs` protocol requires a one-time setup. See One-time HDFS Protocol Installation.
pxf:// Protocol
You can use the Greenplum Platform Extension Framework (PXF) pxf:// protocol to access data residing on external Hadoop systems (HDFS, Hive, HBase), object store systems (Azure, Google Cloud Storage, Minio, S3), and SQL databases.

The PXF pxf protocol is packaged as a Greenplum Database extension. The pxf protocol supports reading from external data stores. You can also write text, binary, and parquet-format data with the pxf protocol.

When you use the pxf protocol to query an external data store, you specify the directory, file, or table that you want to access. PXF requests the data from the data store and delivers the relevant portions in parallel to each Greenplum Database segment instance serving the query.

You must explicitly initialize and start PXF before you can use the pxf protocol to read or write external data. You must also enable PXF in each database in which you want to allow users to create external tables to access external data, and grant permissions on the pxf protocol to those Greenplum Database users.

For detailed information about configuring and using PXF and the pxf protocol, refer to Accessing External Data with PXF.

s3:// Protocol
The s3 protocol is used in a URL that specifies the location of an Amazon S3 bucket and a prefix to use for reading or writing files in the bucket.

Amazon Simple Storage Service (Amazon S3) provides secure, durable, highly-scalable object storage. For information about Amazon S3, see Amazon S3.

You can define read-only external tables that use existing data files in the S3 bucket for table data, or writable external tables that store the data from INSERT operations to files in the S3 bucket. Greenplum Database uses the S3 URL and prefix specified in the protocol URL either to select one or more files for a read-only table, or to define the location and filename format to use when uploading S3 files for INSERT operations to writable tables.

The s3 protocol also supports Dell EMC Elastic Cloud Storage (ECS), an Amazon S3 compatible service.

This topic contains the sections:
- Configuring and Using S3 External Tables
- About the S3 Protocol URL
- About S3 Data Files
- s3 Protocol AWS Server-Side Encryption Support
- s3 Protocol Proxy Support
- About the s3 Protocol config Parameter
- s3 Protocol Configuration File
- s3 Protocol Limitations
- Using the gpcheckcloud Utility

Configuring and Using S3 External Tables
Follow these basic steps to configure the S3 protocol and use S3 external tables, using the available links for more information. See also s3 Protocol Limitations to better understand the capabilities and limitations of S3 external tables:

1. Configure each database to support the s3 protocol:
a. In each database that will access an S3 bucket with the s3 protocol, create the read and write functions for the s3 protocol library:

```
CREATE OR REPLACE FUNCTION write_to_s3() RETURNS integer AS
    $libdir/gps3ext.so', 's3_export' LANGUAGE C STABLE;
CREATE OR REPLACE FUNCTION read_from_s3() RETURNS integer AS
    $libdir/gps3ext.so', 's3_import' LANGUAGE C STABLE;
```

b. In each database that will access an S3 bucket, declare the s3 protocol and specify the read and write functions you created in the previous step:

```
CREATE PROTOCOL s3 (writefunc = write_to_s3, readfunc = read_from_s3);
```

**Note:** The protocol name s3 must be the same as the protocol of the URL specified for the external table you create to access an S3 resource.

The corresponding function is called by every Greenplum Database segment instance. All segment hosts must have access to the S3 bucket.

2. On each Greenplum Database segment, create and install the s3 protocol configuration file:

a. Create a template s3 protocol configuration file using the gpcheckcloud utility:

```
gpcheckcloud -t > ./mytest_s3.config
```

b. Edit the template file to specify the accessid and secret required to connect to the S3 location. See **s3 Protocol Configuration File** for information about other s3 protocol configuration parameters.

c. Copy the file to the same location and filename for all Greenplum Database segments on all hosts. The default file location is gpseg_data_dir/gpseg_prefix/N/s3/s3.conf. gpseg_data_dir is the path to the Greenplum Database segment data directory, gpseg_prefix is the segment prefix, and N is the segment ID. The segment data directory, prefix, and ID are set when you initialize a Greenplum Database system.

If you copy the file to a different location or filename, then you must specify the location with the config parameter in the s3 protocol URL. See **About the s3 Protocol config Parameter**.

d. Use the gpcheckcloud utility to validate connectivity to the S3 bucket:

```
gpcheckcloud -c "s3://<s3-endpoint>/<s3-bucket> config=./mytest_s3.config"
```

Specify the correct path to the configuration file for your system, as well as the S3 endpoint name and bucket that you want to check. gpcheckcloud attempts to connect to the S3 endpoint and lists any files in the S3 bucket, if available. A successful connection ends with the message:

```
Your configuration works well.
```

You can optionally use gpcheckcloud to validate uploading to and downloading from the S3 bucket, as described in **Using the gpcheckcloud Utility**.

3. After completing the previous steps to create and configure the s3 protocol, you can specify an s3 protocol URL in the CREATE EXTERNAL TABLE command to define S3 external tables. For read-only S3 tables, the URL defines the location and prefix used to select existing data files that comprise the S3 table. For example:

```
CREATE READABLE EXTERNAL TABLE S3TBL (date text, time text, amt int)
    LOCATION('s3://s3-us-west-2.amazonaws.com/s3test.example.com/dataset1/normal/ config=/home/gpadmin/aws_s3/s3.conf')
    FORMAT 'csv';
```
For writable S3 tables, the protocol URL defines the S3 location in which Greenplum database stores data files for the table, as well as a prefix to use when creating files for table INSERT operations. For example:

```sql
CREATE WRITABLE EXTERNAL TABLE S3WRIT (LIKE S3TBL)
    LOCATION('s3://s3-us-west-2.amazonaws.com/s3test.example.com/dataset1/normal/config=/home/gpadmin/aws_s3/s3.conf')
    FORMAT 'csv';
```

See [About the S3 Protocol URL](#) for more information.

### About the S3 Protocol URL

For the s3 protocol, you specify a location for files and an optional configuration file location in the LOCATION clause of the `CREATE EXTERNAL TABLE` command. This is the syntax:

```sql
's3://S3_endpoint[:port]/bucket_name/[S3_prefix] [region=S3_region] [config=config_file_location]'```

The s3 protocol requires that you specify the S3 endpoint and S3 bucket name. Each Greenplum Database segment instance must have access to the S3 location. The optional S3_prefix value is used to select files for read-only S3 tables, or as a filename prefix to use when uploading files for S3 writable tables.

**Note:** The Greenplum Database s3 protocol URL must include the S3 endpoint hostname.

To specify an ECS endpoint (an Amazon S3 compatible service) in the LOCATION clause, you must set the s3 configuration file parameter `version` to 2. The version parameter controls whether the region parameter is used in the LOCATION clause. You can also specify an Amazon S3 location when the version parameter is 2. For information about version parameter, see [s3 Protocol Configuration File](#).

**Note:** Although the S3_prefix is an optional part of the syntax, you should always include an S3 prefix for both writable and read-only S3 tables to separate datasets as part of the CREATE EXTERNAL TABLE syntax.

For writable S3 tables, the s3 protocol URL specifies the endpoint and bucket name where Greenplum Database uploads data files for the table. The S3 bucket permissions must be Upload/Delete for the S3 user ID that uploads the files. The S3 file prefix is used for each new file uploaded to the S3 location as a result of inserting data to the table. See [About S3 Data Files](#).

For read-only S3 tables, the S3 file prefix is optional. If you specify an S3_prefix, then the s3 protocol selects all files that start with the specified prefix as data files for the external table. The s3 protocol does not use the slash character (\/) as a delimiter, so a slash character following a prefix is treated as part of the prefix itself.

For example, consider the following 5 files that each have the S3_endpoint named s3-us-west-2.amazonaws.com and the bucket_name test1:

- `s3://s3-us-west-2.amazonaws.com/test1/abc`
- `s3://s3-us-west-2.amazonaws.com/test1/abc/`
- `s3://s3-us-west-2.amazonaws.com/test1/abc/xx`
- `s3://s3-us-west-2.amazonaws.com/test1/abcdef`
- `s3://s3-us-west-2.amazonaws.com/test1/abcdefff`

- If the S3 URL is provided as `s3://s3-us-west-2.amazonaws.com/test1/abc`, then the abc prefix selects all 5 files.
- If the S3 URL is provided as `s3://s3-us-west-2.amazonaws.com/test1/abc/`, then the abc/ prefix selects the files `s3://s3-us-west-2.amazonaws.com/test1/abc/` and `s3://s3-us-west-2.amazonaws.com/test1/abc/xx`.  

• If the S3 URL is provided as `s3://s3-us-west-2.amazonaws.com/test1/abcd`, then the `abcd` prefix selects the files `s3://s3-us-west-2.amazonaws.com/test1/abcdef` and `s3://s3-us-west-2.amazonaws.com/test1/abcdefff`.

Wildcard characters are not supported in an `S3_prefix`; however, the S3 prefix functions as if a wildcard character immediately followed the prefix itself.

All of the files selected by the S3 URL (`S3_endpoint/bucket_name/S3_prefix`) are used as the source for the external table, so they must have the same format. Each file must also contain complete data rows. A data row cannot be split between files. The S3 file permissions must be Open/Download and View for the S3 user ID that is accessing the files.

For information about the Amazon S3 endpoints see [http://docs.aws.amazon.com/general/latest/gr/rande.html#s3_region](http://docs.aws.amazon.com/general/latest/gr/rande.html#s3_region). For information about S3 buckets and folders, see the Amazon S3 documentation [https://aws.amazon.com/documentation/s3/](https://aws.amazon.com/documentation/s3/). For information about the S3 file prefix, see the Amazon S3 documentation [Listing Keys Hierarchically Using a Prefix and Delimiter](https://docs.aws.amazon.com/AmazonS3/latest/userguide/ListingObjects.html).

The `config` parameter specifies the location of the required `s3` protocol configuration file that contains AWS connection credentials and communication parameters. See About the `s3` Protocol config Parameter.

### About S3 Data Files

For each `INSERT` operation to a writable S3 table, each Greenplum Database segment uploads a single file to the configured S3 bucket using the filename format `<prefix><segment_id><random>.<extension>[.gz]` where:

- `<prefix>` is the prefix specified in the S3 URL.
- `<segment_id>` is the Greenplum Database segment ID.
- `<random>` is a random number that is used to ensure that the filename is unique.
- `<extension>` describes the file type (`.txt` or `.csv`, depending on the value you provide in the `FORMAT` clause of CREATE WRITABLE EXTERNAL TABLE). Files created by the `gpcheckcloud` utility always uses the extension `.data`.
- `.gz` is appended to the filename if compression is enabled for S3 writable tables (the default).

For writable S3 tables, you can configure the buffer size and the number of threads that segments use for uploading files. See `s3` Protocol Configuration File.

For read-only S3 tables, all of the files specified by the S3 file location (`S3_endpoint/bucket_name/S3_prefix`) are used as the source for the external table and must have the same format. Each file must also contain complete data rows. If the files contain an optional header row, the column names in the header row cannot contain a newline character (`\n`) or a carriage return (`\r`). Also, the column delimiter cannot be a newline character (`\n`) or a carriage return character (`\r`).

The `s3` protocol recognizes the gzip format and uncompress the files. Only the gzip compression format is supported.

The S3 file permissions must be Open/Download and View for the S3 user ID that is accessing the files. Writable S3 tables require the S3 user ID to have Upload/Delete permissions.

For read-only S3 tables, each segment can download one file at a time from S3 location using several threads. To take advantage of the parallel processing performed by the Greenplum Database segments, the files in the S3 location should be similar in size and the number of files should allow for multiple segments to download the data from the S3 location. For example, if the Greenplum Database system consists of 16 segments and there was sufficient network bandwidth, creating 16 files in the S3 location allows each segment to download a file from the S3 location. In contrast, if the location contained only 1 or 2 files, only 1 or 2 segments download data.

### s3 Protocol AWS Server-Side Encryption Support

Greenplum Database supports server-side encryption using Amazon S3-managed keys (SSE-S3) for AWS S3 files you access with readable and writable external tables created using the `s3` protocol. SSE-S3
encrypts your object data as it writes to disk, and transparently decrypts the data for you when you access it.

**Note:** The s3 protocol supports SSE-S3 only for Amazon Web Services S3 files. SS3-SE is not supported when accessing files in S3 compatible services.

Your S3 accessid and secret permissions govern your access to all S3 bucket objects, whether the data is encrypted or not. However, you must configure your client to use S3-managed keys for accessing encrypted data.

**Configuring S3 Server-Side Encryption**

s3 protocol server-side encryption is disabled by default. To take advantage of server-side encryption on AWS S3 objects you write using the Greenplum Database s3 protocol, you must set the `server_side_encryption` configuration parameter in your s3 configuration file to the value `sse-s3`:

```
server_side_encryption = sse-s3
```

When the configuration file you provide to a `CREATE WRITABLE EXTERNAL TABLE` call using the s3 protocol includes the `server_side_encryption = sse-s3` setting, Greenplum Database applies encryption headers for you on all `INSERT` operations on that external table. S3 then encrypts on write the object(s) identified by the URI you provided in the `LOCATION` clause.

S3 transparently decrypts data during read operations of encrypted files accessed via readable external tables you create using the s3 protocol. No additional configuration is required.

For further encryption configuration granularity, you may consider creating Amazon Web Services S3 Bucket Policy(s), identifying the objects you want to encrypt and the write actions on those objects as described in the [Protecting Data Using Server-Side Encryption with Amazon S3-Managed Encryption Keys (SSE-S3)](https://docs.aws.amazon.com/AmazonS3/latest/dev/ServerSideEncryptionWithS3ManagedKeys.html) AWS documentation.

**s3 Protocol Proxy Support**

You can specify a URL that is the proxy that S3 uses to connect to a data source. S3 supports these protocols: HTTP, HTTPS, and SOCKS (4, 4a, 5, 5h). You can specify a proxy with the s3 protocol configuration parameter `proxy` or an environment variable. If the configuration parameter is set, the environment variables are ignored.

To specify proxy with an environment variable, you set the environment variable based on the protocol: `http_proxy`, `https_proxy`, or `socks_proxy`. You can specify a different URL for each protocol by setting the appropriate environment variable. S3 supports these environment variables.

- `all_proxy` specifies the proxy URL that is used if an environment variable for a specific protocol is not set.
- `no_proxy` specifies a comma-separated list of hosts names that do not use the proxy specified by an environment variable.

The environment variables must be set must and must be accessible to Greenplum Database on all Greenplum Database hosts.

For information about the configuration parameter `proxy`, see s3 Protocol Configuration File.

**About the s3 Protocol config Parameter**

The optional `config` parameter specifies the location of the required s3 protocol configuration file. The file contains Amazon Web Services (AWS) connection credentials and communication parameters. For information about the file, see s3 Protocol Configuration File.
The configuration file is required on all Greenplum Database segment hosts. This is default location is a location in the data directory of each Greenplum Database segment instance.

```
gpseg_data_dir/gpseg_prefixN/s3/s3.conf
```

The `gpseg_data_dir` is the path to the Greenplum Database segment data directory, the `gpseg_prefix` is the segment prefix, and \( N \) is the segment ID. The segment data directory, prefix, and ID are set when you initialize a Greenplum Database system.

If you have multiple segment instances on segment hosts, you can simplify the configuration by creating a single location on each segment host. Then you specify the absolute path to the location with the `config` parameter in the `s3` protocol LOCATION clause. This example specifies a location in the `gpadmin` home directory.

```
LOCATION ('s3://s3-us-west-2.amazonaws.com/test/my_data config=/home/gpadmin/s3.conf')
```

All segment instances on the hosts use the file `/home/gpadmin/s3.conf`.

**s3 Protocol Configuration File**

When using the `s3` protocol, an `s3` protocol configuration file is required on all Greenplum Database segments. The default location is:

```
gpseg_data_dir/gpseg-prefixN/s3/s3.conf
```

The `gpseg_data_dir` is the path to the Greenplum Database segment data directory, the `gpseg-prefix` is the segment prefix, and \( N \) is the segment ID. The segment data directory, prefix, and ID are set when you initialize a Greenplum Database system.

If you have multiple segment instances on segment hosts, you can simplify the configuration by creating a single location on each segment host. Then you can specify the absolute path to the location with the `config` parameter in the `s3` protocol LOCATION clause. However, note that both read-only and writable S3 external tables use the same parameter values for their connections. If you want to configure protocol parameters differently for read-only and writable S3 tables, then you must use two different `s3` protocol configuration files and specify the correct file in the `CREATE EXTERNAL TABLE` statement when you create each table.

This example specifies a single file location in the `/s3` directory of the `gpadmin` home directory:

```
config=/home/gpadmin/s3/s3.conf
```

All segment instances on the hosts use the file `/home/gpadmin/s3/s3.conf`.

The `s3` protocol configuration file is a text file that consists of a `[default]` section and parameters. This is an example configuration file:

```
[default]
secret = "secret"
accessid = "user access id"
threadnum = 3
chunksize = 67108864
```

You can use the Greenplum Database `gpcheckcloud` utility to test the S3 configuration file. See [Using the `gpcheckcloud` Utility](#).

**s3 Configuration File Parameters**

**accessid**

Required. AWS S3 ID to access the S3 bucket.
secret
Required. AWS S3 passcode for the S3 ID to access the S3 bucket.

autocompress
For writable S3 external tables, this parameter specifies whether to compress files (using gzip) before uploading to S3. Files are compressed by default if you do not specify this parameter.

chunksize
The buffer size that each segment thread uses for reading from or writing to the S3 server. The default is 64 MB. The minimum is 8MB and the maximum is 128MB.

When inserting data to a writable S3 table, each Greenplum Database segment writes the data into its buffer (using multiple threads up to the threadnum value) until it is full, after which it writes the buffer to a file in the S3 bucket. This process is then repeated as necessary on each segment until the insert operation completes.

Because Amazon S3 allows a maximum of 10,000 parts for multipart uploads, the minimum chunksize value of 8MB supports a maximum insert size of 80GB per Greenplum database segment. The maximum chunksize value of 128MB supports a maximum insert size 1.28TB per segment. For writable S3 tables, you must ensure that the chunksize setting can support the anticipated table size of your table. See Multipart Upload Overview in the S3 documentation for more information about uploads to S3.

enryption
Use connections that are secured with Secure Sockets Layer (SSL). Default value is true. The values true, t, on, yes, and y (case insensitive) are treated as true. Any other value is treated as false.

If the port is not specified in the URL in the LOCATION clause of the CREATE EXTERNAL TABLE command, the configuration file encryption parameter affects the port used by the s3 protocol (port 80 for HTTP or port 443 for HTTPS). If the port is specified, that port is used regardless of the encryption setting.

gpcheckcloud_newline
When downloading files from an S3 location, the gpcheckcloud utility appends a newline character to last line of a file if the last line of a file does not have an EOL (end of line) character. The default character is \n (newline). The value can be \n, \r (carriage return), or \n\r (newline/carriage return).

Adding an EOL character prevents the last line of one file from being concatenated with the first line of next file.

low_speed_limit
The upload/download speed lower limit, in bytes per second. The default speed is 10240 (10K). If the upload or download speed is slower than the limit for longer than the time specified by low_speed_time, then the connection is aborted and retried. After 3 retries, the s3 protocol returns an error. A value of 0 specifies no lower limit.

low_speed_time
When the connection speed is less than low_speed_limit, this parameter specified the amount of time, in seconds, to wait before aborting an upload to or a download from the S3 bucket. The default is 60 seconds. A value of 0 specifies no time limit.

proxy
Specify a URL that is the proxy that S3 uses to connect to a data source. S3 supports these protocols: HTTP, HTTPS, and SOCKS (4, 4a, 5, 5h). This is the format for the parameter.

proxy = protocol://[user:password@]proxyhost[:port]
If this parameter is not set or is an empty string (proxy = ""), S3 uses the proxy specified by the environment variable http_proxy, https_proxy, or socks_proxy (and the environment variables all_proxy and no_proxy). The environment variable that S3 uses depends on the protocol. For information about the environment variables, see s3 Protocol Proxy Support in the Greenplum Database Administrator Guide.

There can be at most one proxy parameter in the configuration file. The URL specified by the parameter is the proxy for all supported protocols.

**server_side_encryption**

The S3 server-side encryption method that has been configured for the bucket. Greenplum Database supports only server-side encryption with Amazon S3-managed keys, identified by the configuration parameter value sse-s3. Server-side encryption is disabled (none) by default.

**threadnum**

The maximum number of concurrent threads a segment can create when uploading data to or downloading data from the S3 bucket. The default is 4. The minimum is 1 and the maximum is 8.

**verifycert**

Controls how the s3 protocol handles authentication when establishing encrypted communication between a client and an S3 data source over HTTPS. The value is either true or false. The default value is true.

- verifycert=false - Ignores authentication errors and allows encrypted communication over HTTPS.
- verifycert=true - Requires valid authentication (a proper certificate) for encrypted communication over HTTPS.

Setting the value to false can be useful in testing and development environments to allow communication without changing certificates.

**Warning:** Setting the value to false exposes a security risk by ignoring invalid credentials when establishing communication between a client and a S3 data store.

**version**

Specifies the version of the information specified in the LOCATION clause of the CREATE EXTERNAL TABLE command. The value is either 1 or 2. The default value is 1.

If the value is 1, the LOCATION clause supports an Amazon S3 URL, and does not contain the region parameter. If the value is 2, the LOCATION clause supports S3 compatible services and must include the region parameter. The region parameter specifies the S3 data source region. For this S3 URL s3://s3-us-west-2.amazonaws.com/s3test.example.com/dataset1/normal/, the AWS S3 region is us-west-2.

If version is 1 or is not specified, this is an example of the LOCATION clause of the CREATE EXTERNAL TABLE command that specifies an Amazon S3 endpoint.

```
LOCATION ('s3://s3-us-west-2.amazonaws.com/s3test.example.com/dataset1/normal/ config=/home/gpadmin/aws_s3/s3.conf')
```

If version is 2, this is an example LOCATION clause with the region parameter for an AWS S3 compatible service.

```
LOCATION ('s3://test.company.com/s3test.company/test1/normal/ region=local-test config=/home/gpadmin/aws_s3/s3.conf')
```
If version is 2, the LOCATION clause can also specify an Amazon S3 endpoint. This example specifies an Amazon S3 endpoint that uses the region parameter.

```sql
LOCATION ('s3://s3-us-west-2.amazonaws.com/s3test.example.com/dataset1/normal/ region=us-west-2 config=/home/gpadmin/aws_s3/s3.conf')
```

**Note:** Greenplum Database can require up to `threadnum * chunksize` memory on each segment host when uploading or downloading S3 files. Consider this S3 protocol memory requirement when you configure overall Greenplum Database memory.

### s3 Protocol Limitations

These are s3 protocol limitations:

- Only the S3 path-style URL is supported.
- Only the S3 endpoint is supported. The protocol does not support virtual hosting of S3 buckets (binding a domain name to an S3 bucket).
- AWS signature version 4 signing process is supported. For information about the S3 endpoints supported by each signing process, see [http://docs.aws.amazon.com/general/latest/gr/rande.html#s3_region](http://docs.aws.amazon.com/general/latest/gr/rande.html#s3_region).
- Only a single URL and optional configuration file is supported in the LOCATION clause of the CREATE EXTERNAL TABLE command.
- If the NEWLINE parameter is not specified in the CREATE EXTERNAL TABLE command, the newline character must be identical in all data files for specific prefix. If the newline character is different in some data files with the same prefix, read operations on the files might fail.
- For writable S3 external tables, only the INSERT operation is supported. UPDATE, DELETE, and TRUNCATE operations are not supported.
- Because Amazon S3 allows a maximum of 10,000 parts for multipart uploads, the maximum chunksize value of 128MB supports a maximum insert size of 1.28TB per Greenplum database segment for writable s3 tables. You must ensure that the chunksize setting can support the anticipated table size of your table. See [Multipart Upload Overview](http://docs.aws.amazon.com/general/latest/gr/rande.html#s3_region) in the S3 documentation for more information about uploads to S3.
- To take advantage of the parallel processing performed by the Greenplum Database segment instances, the files in the S3 location for read-only S3 tables should be similar in size and the number of files should allow for multiple segments to download the data from the S3 location. For example, if the Greenplum Database system consists of 16 segments and there was sufficient network bandwidth, creating 16 files in the S3 location allows each segment to download a file from the S3 location. In contrast, if the location contained only 1 or 2 files, only 1 or 2 segments download data.

### Using the gpcheckcloud Utility

The Greenplum Database utility `gpcheckcloud` helps users create an s3 protocol configuration file and test a configuration file. You can specify options to test the ability to access an S3 bucket with a configuration file, and optionally upload data to or download data from files in the bucket.

If you run the utility without any options, it sends a template configuration file to STDOUT. You can capture the output and create an s3 configuration file to connect to Amazon S3.

The utility is installed in the Greenplum Database $GPHOME/bin directory.

**Syntax**

```
gpcheckcloud { -c | -d } "s3://S3_endpoint/bucketname/[S3_prefix] [config=path_to_config_file]"
```
gpcheckcloud -u <file_to_upload> "s3://S3_endpoint/bucketname/[S3_prefix] [config=path_to_config_file]"
gpcheckcloud -t

gpcheckcloud -h

Options

-c  Connect to the specified S3 location with the configuration specified in the s3 protocol URL and return information about the files in the S3 location.
If the connection fails, the utility displays information about failures such as invalid credentials, prefix, or server address (DNS error), or server not available.

-d  Download data from the specified S3 location with the configuration specified in the s3 protocol URL and send the output to STDOUT.
If files are gzip compressed, the uncompressed data is sent to STDOUT.

-u  Upload a file to the S3 bucket specified in the s3 protocol URL using the specified configuration file if available. Use this option to test compression and chunksize and autocompress settings for your configuration.

-t  Sends a template configuration file to STDOUT. You can capture the output and create an s3 configuration file to connect to Amazon S3.

-h  Display gpcheckcloud help.

Examples

This example runs the utility without options to create a template s3 configuration file mytest_s3.config in the current directory.

gpcheckcloud -t > ./mytest_s3.config

This example attempts to upload a local file, test-data.csv to an S3 bucket location using the s3 configuration file s3.mytestconf:

gpcheckcloud -u ./test-data.csv "s3://s3-us-west-2.amazonaws.com/test1/abc config=s3.mytestconf"

A successful upload results in one or more files placed in the S3 bucket using the filename format abc<segment_id><random>.data[.gz]. See About S3 Data Files.

This example attempts to connect to an S3 bucket location with the s3 configuration file s3.mytestconf.

gpcheckcloud -c "s3://s3-us-west-2.amazonaws.com/test1/abc config=s3.mytestconf"

Download all files from the S3 bucket location and send the output to STDOUT.

gpcheckcloud -d "s3://s3-us-west-2.amazonaws.com/test1/abc config=s3.mytestconf"
Using a Custom Protocol
A custom protocol allows you to connect Greenplum Database to a data source that cannot be accessed with the file://, gpfdist://, or gphdfs:// (deprecated) protocols.

Creating a custom protocol requires that you implement a set of C functions with specified interfaces, declare the functions in Greenplum Database, and then use the `CREATE TRUSTED PROTOCOL` command to enable the protocol in the database.

See `Example Custom Data Access Protocol` for an example.

Handling Errors in External Table Data
By default, if external table data contains an error, the command fails and no data loads into the target database table.

Define the external table with single row error handling to enable loading correctly formatted rows and to isolate data errors in external table data. See `Handling Load Errors`.

The `gpfdist` file server uses the HTTP protocol. External table queries that use LIMIT end the connection after retrieving the rows, causing an HTTP socket error. If you use LIMIT in queries of external tables that use the gpfdist:// or http:// protocols, ignore these errors – data is returned to the database as expected.

Creating and Using External Web Tables
External web tables allow Greenplum Database to treat dynamic data sources like regular database tables. Because web table data can change as a query runs, the data is not rescannable.

`CREATE EXTERNAL WEB TABLE` creates a web table definition. You can define command-based or URL-based external web tables. The definition forms are distinct: you cannot mix command-based and URL-based definitions.

Command-based External Web Tables
The output of a shell command or script defines command-based web table data. Specify the command in the EXECUTE clause of `CREATE EXTERNAL WEB TABLE`. The data is current as of the time the command runs. The EXECUTE clause runs the shell command or script on the specified master, and/or segment host or hosts. The command or script must reside on the hosts corresponding to the host(s) defined in the EXECUTE clause.

By default, the command is run on segment hosts when active segments have output rows to process. For example, if each segment host runs four primary segment instances that have output rows to process, the command runs four times per segment host. You can optionally limit the number of segment instances that execute the web table command. All segments included in the web table definition in the ON clause run the command in parallel.

The command that you specify in the external table definition executes from the database and cannot access environment variables from .bashrc or .profile. Set environment variables in the EXECUTE clause. For example:

```bash
=# CREATE EXTERNAL WEB TABLE output (output text)
   EXECUTE 'PATH=/home/gpadmin/programs; export PATH; myprogram.sh'
   FORMAT 'TEXT';
```

Scripts must be executable by the gpadmin user and reside in the same location on the master or segment hosts.
The following command defines a web table that runs a script. The script runs on each segment host where a segment has output rows to process.

```
=# CREATE EXTERNAL WEB TABLE log_output
   (linenum int, message text)
EXECUTE '/var/load_scripts/get_log_data.sh' ON HOST
FORMAT 'TEXT' (DELIMITER '|');
```

**URL-based External Web Tables**

A URL-based web table accesses data from a web server using the HTTP protocol. Web table data is dynamic; the data is not rescannable.

Specify the `LOCATION` of files on a web server using `http://`. The web data file(s) must reside on a web server that Greenplum segment hosts can access. The number of URLs specified corresponds to the number of segment instances that work in parallel to access the web table. For example, if you specify two external files to a Greenplum Database system with eight primary segments, two of the eight segments access the web table in parallel at query runtime.

The following sample command defines a web table that gets data from several URLs.

```
=# CREATE EXTERNAL WEB TABLE ext_expenses (name text,
   date date, amount float4, category text, description text)
   LOCATION ('http://intranet.company.com/expenses/sales/file.csv',
   'http://intranet.company.com/expenses/exec/file.csv',
   'http://intranet.company.com/expenses/finance/file.csv',
   'http://intranet.company.com/expenses/ops/file.csv',
   'http://intranet.company.com/expenses/marketing/file.csv',
   'http://intranet.company.com/expenses/eng/file.csv')
   FORMAT 'CSV' ( HEADER );
```

**Examples for Creating External Tables**

These examples show how to define external data with different protocols. Each `CREATE EXTERNAL TABLE` command can contain only one protocol.

*Note:* When using IPv6, always enclose the numeric IP addresses in square brackets.

Start `gpfdist` before you create external tables with the `gpfdist` protocol. The following code starts the `gpfdist` file server program in the background on port `8081` serving files from directory `/var/data/staging`. The logs are saved in `/home/gpadmin/log`.

```
gpfdist -p 8081 -d /var/data/staging -l /home/gpadmin/log &
```

**Example 1—Single gpfdist instance on single-NIC machine**

Creates a readable external table, `ext_expenses`, using the `gpfdist` protocol. The files are formatted with a pipe (|) as the column delimiter.

```
=# CREATE EXTERNAL TABLE ext_expenses ( name text,
   date date, amount float4, category text, description text )
   LOCATION ('gpfdist://etlhost-1:8081/*')
   FORMAT 'TEXT' (DELIMITER '|');
```
Example 2—Multiple gpfdist instances

Creates a readable external table, `ext_expenses`, using the gpfdist protocol from all files with the `.txt` extension. The column delimiter is a pipe (`|`) and NULL (``) is a space.

```sql
=# CREATE EXTERNAL TABLE ext_expenses ( name text,
    date date, amount float4, category text, desc1 text )
 LOCATION ('gpfdist://etlhost-1:8081/*.txt',
    'gpfdist://etlhost-2:8081/*.txt')
 FORMAT 'TEXT' ( DELIMITER '|' NULL ' ') ;
```

Example 3—Multiple gpfdists instances

Creates a readable external table, `ext_expenses`, from all files with the `.txt` extension using the gpfdists protocol. The column delimiter is a pipe (`|`) and NULL (``) is a space. For information about the location of security certificates, see `gpfdists:// Protocol`.

1. Run `gpfdist` with the `--ssl` option.
2. Run the following command.

```sql
=# CREATE EXTERNAL TABLE ext_expenses ( name text,
    date date, amount float4, category text, desc1 text )
 LOCATION ('gpfdists://etlhost-1:8081/*.txt',
    'gpfdists://etlhost-2:8082/*.txt')
 FORMAT 'TEXT' ( DELIMITER '|' NULL ' ') ;
```

Example 4—Single gpfdist instance with error logging

Uses the gpfdist protocol to create a readable external table, `ext_expenses`, from all files with the `.txt` extension. The column delimiter is a pipe (`|`) and NULL (``) is a space.

Access to the external table is single row error isolation mode. Input data formatting errors are captured internally in Greenplum Database with a description of the error. See `Viewing Bad Rows in the Error Log` for information about investigating error rows. You can view the errors, fix the issues, and then reload the rejected data. If the error count on a segment is greater than five (the `SEGMENT REJECT LIMIT` value), the entire external table operation fails and no rows are processed.

```sql
=# CREATE EXTERNAL TABLE ext_expenses ( name text,
    date date, amount float4, category text, desc1 text )
 LOCATION ('gpfdist://etlhost-1:8081/*.txt',
    'gpfdist://etlhost-2:8082/*.txt')
 FORMAT 'TEXT' ( DELIMITER '|' NULL ' ')
 LOG ERRORS SEGMENT REJECT LIMIT 5;
```

To create the readable `ext_expenses` table from CSV-formatted text files:

```sql
=# CREATE EXTERNAL TABLE ext_expenses ( name text,
    date date, amount float4, category text, desc1 text )
 LOCATION ('gpfdist://etlhost-1:8081/*.txt',
    'gpfdist://etlhost-2:8082/*.txt')
 FORMAT 'CSV' ( DELIMITER ',' )
 LOG ERRORS SEGMENT REJECT LIMIT 5;
```

Example 5—TEXT Format on a Hadoop Distributed File Server

Note: The gphdfs external table protocol is deprecated and will be removed in the next major release of Greenplum Database.
Creates a readable external table, `ext_expenses`, using the `gphdfs` protocol. The column delimiter is a pipe (|).

```sql
=# CREATE EXTERNAL TABLE ext_expenses ( name text, 
    date date, amount float4, category text, desc1 text )
 LOCATION ('gphdfs://hdfshost-1:8081/data/filename.txt')
 FORMAT 'TEXT' (DELIMITER ' | ');
```

gphdfs requires only one data path.

For examples of reading and writing custom formatted data on a Hadoop Distributed File System, see [Reading and Writing Custom-Formatted HDFS Data with gphdfs (Deprecated)](#).

**Example 6—Multiple files in CSV format with header rows**

Creates a readable external table, `ext_expenses`, using the `file` protocol. The files are CSV format and have a header row.

```sql
=# CREATE EXTERNAL TABLE ext_expenses ( name text, 
    date date, amount float4, category text, desc1 text )
 LOCATION ('file://filehost/data/international/*',
    'file://filehost/data/regional/*',
    'file://filehost/data/supplement/*.csv')
 FORMAT 'CSV' (HEADER);
```

**Example 7—Readable External Web Table with Script**

Creates a readable external web table that executes a script once per segment host:

```sql
=# CREATE EXTERNAL WEB TABLE log_output (linenum int, 
    message text)
 EXECUTE '/var/load_scripts/get_log_data.sh' ON HOST
 FORMAT 'TEXT' (DELIMITER ' | ');
```

**Example 8—Writable External Table with gpfdist**

Creates a writable external table, `sales_out`, that uses `gpfdist` to write output data to the file `sales.out`. The column delimiter is a pipe (|) and NULL (') is a space. The file will be created in the directory specified when you started the gpfdist file server.

```sql
=# CREATE WRITABLE EXTERNAL TABLE sales_out (LIKE sales)
 LOCATION ('gpfdist://etl1:8081/sales.out')
 FORMAT 'TEXT' ( DELIMITER '|' NULL ' ')
 DISTRIBUTED BY (txn_id);
```

**Example 9—Writable External Web Table with Script**

Creates a writable external web table, `campaign_out`, that pipes output data received by the segments to an executable script, `to_adreport_etl.sh`:

```sql
=# CREATE WRITABLE EXTERNAL WEB TABLE campaign_out (LIKE campaign)
 EXECUTE '/var/unload_scripts/to_adreport_etl.sh'
 FORMAT 'TEXT' (DELIMITER '|');
```

**Example 10—Readable and Writable External Tables with XML Transformations**

Greenplum Database can read and write XML data to and from external tables with `gpfdist`. For information about setting up an XML transform, see [Transforming External Data with gpfdist and gpload](#).
Accessing External Data with PXF

Data managed by your organization may already reside in external sources. The Greenplum Platform Extension Framework (PXF) provides access to this external data via built-in connectors that map an external data source to a Greenplum Database table definition.

PXF is installed with Hadoop and Object Store connectors. These connectors enable you to read external data stored in text, Avro, JSON, RCFile, Parquet, SequenceFile, and ORC formats. You can use the JDBC connector to access an external SQL database.

**Note:** PXF supports filter pushdown in the Hive, HBase, and JDBC connectors.

The Greenplum Platform Extension Framework includes a protocol C library and a Java service. After you configure and initialize PXF, you start a single PXF JVM process on each Greenplum Database segment host. This long-running process concurrently serves multiple query requests.

For detailed information about the architecture of and using PXF, refer to the Greenplum Platform Extension Framework (PXF) documentation.

Accessing HDFS Data with gphdfs (Deprecated)

Greenplum Database leverages the parallel architecture of a Hadoop Distributed File System to read and write data files efficiently using the gphdfs protocol.

**Note:** The gphdfs external table protocol is deprecated and will be removed in the next major release of Greenplum Database. Consider using the Greenplum Platform Extension Framework (PXF) pxf external table protocol to access data stored in a Hadoop file system.

There are three steps to using the gphdfs protocol with HDFS:

- One-time gphdfs Protocol Installation (Deprecated)
- Grant Privileges for the gphdfs Protocol (Deprecated)
- Specify gphdfs Protocol in an External Table Definition (Deprecated)

For information about using Greenplum Database external tables with Amazon EMR when Greenplum Database is installed on Amazon Web Services (AWS), also see Using Amazon EMR with Greenplum Database installed on AWS (Deprecated).

One-time gphdfs Protocol Installation (Deprecated)

Install and configure Hadoop for use with gphdfs as follows:

1. Install Java 1.7 or later on all Greenplum Database hosts: master, segment, and standby master.
2. Install a compatible Hadoop distribution on all hosts. The distribution must be the same on all hosts. For Hadoop installation information, see the Hadoop distribution documentation.
   
   See the Greenplum Database Release Notes for information about compatible Hadoop distributions.
3. After installation, ensure that the Greenplum system user (gpadmin) has read and execute access to the Hadoop libraries or to the Greenplum MR client.
4. Set the following environment variables on all segments:
   
   - JAVA_HOME – the Java home directory
   - HADOOP_HOME – the Hadoop home directory

   For example, add lines such as the following to the gpadmin user .bashrc profile.

   ```bash
   export JAVA_HOME=/usr/java/default
   export HADOOP_HOME=/usr/lib/gphd
   ```

   The variables must be set in the ~gpadmin/.bashrc or the ~gpadmin/.bash_profile file so that the gpadmin user shell environment can locate the Java home and Hadoop home.
5. Set the following Greenplum Database server configuration parameters and restart Greenplum Database.

<table>
<thead>
<tr>
<th>Configuration Parameter</th>
<th>Description</th>
<th>Default Value</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>gp_hadoop_target_version</td>
<td>The Hadoop target. Choose one of the following:</td>
<td>hadoop</td>
<td>master session reload</td>
</tr>
<tr>
<td></td>
<td>cdh</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>hadoop</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>hdp</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>mpr</td>
<td></td>
<td></td>
</tr>
<tr>
<td>gp_hadoop_home</td>
<td>This parameter specifies the installation directory for Hadoop.</td>
<td>NULL</td>
<td>master session reload</td>
</tr>
</tbody>
</table>

For example, the following commands use the Greenplum Database utilities `gpconfig` and `gpstop` to set the server configuration parameters and restart Greenplum Database:

```
gpconfig -c gp_hadoop_target_version -v 'hdp'
gpstop -u
```

For information about the Greenplum Database utilities `gpconfig` and `gpstop`, see the *Greenplum Database Utility Guide*.

6. If needed, ensure that the `CLASSPATH` environment variable generated by the `$GPHOME/lib/hadoop/hadoop_env.sh` file on every Greenplum Database host contains the path to JAR files that contain Java classes that are required for `gphdfs`.

For example, if `gphdfs` returns a class not found exception, ensure the JAR file containing the class is on every Greenplum Database host and update the `$GPHOME/lib/hadoop/hadoop_env.sh` file so that the `CLASSPATH` environment variable created by file contains the JAR file.

**About gphdfs JVM Memory**

When Greenplum Database accesses external table data from an HDFS location with `gphdfs` protocol, each Greenplum Database segment on a host system starts a JVM for use by the protocol. The default JVM heapsize is 1GB and should be enough for most workloads.

If the `gphdfs` JVM runs out of memory, the issue might be related to the density of tuples inside the Hadoop HDFS block assigned to the `gphdfs` segment worker. A higher density of tuples per block requires more `gphdfs` memory. HDFS block size is usually 128MB, 256MB, or 512MB depending on the Hadoop cluster configuration.

You can increase the JVM heapsize by changing `GP_JAVA_OPT` variable in the file `$GPHOME/lib/hadoop/hadoop_env.sh`. In this example line, the option `-Xmx1000m` specifies that the JVM consumes 1GB of virtual memory.

```
export GP_JAVA_OPT='-Xmx1000m -XX:+DisplayVMOutputToStderr'
```

The `$GPHOME/lib/hadoop/hadoop_env.sh` must be updated for every segment instance in the Greenplum Database system.
Important: Before increasing the gphdfs JVM memory, ensure that you have sufficient memory on the host. For example, 8 primary segments consume 8GB of virtual memory for the gphdfs JVM when using default. Increasing the Java -Xmx value to 2GB results in 16GB allocated in that environment of 8 segments per host.

Grant Privileges for the gphdfs Protocol (Deprecated)

To enable privileges required to create external tables that access files on HDFS using gphdfs:

1. Grant the following privileges on gphdfs to the owner of the external table.
   - Grant SELECT privileges to enable creating readable external tables on HDFS.
   - Grant INSERT privileges to enable creating writable external tables on HDFS.

   Use the GRANT command to grant read privileges (SELECT) and, if needed, write privileges (INSERT) on HDFS to the Greenplum system user (gpadmin).

   ```
   GRANT INSERT ON PROTOCOL gphdfs TO gpadmin;
   ```

2. Greenplum Database uses OS credentials to connect to HDFS. Grant read privileges and, if needed, write privileges to HDFS to the Greenplum administrative user (gpadmin OS user).

Specify gphdfs Protocol in an External Table Definition (Deprecated)

The gphdfs LOCATION clause of the CREATE EXTERNAL TABLE command for HDFS files differs slightly for Hadoop HA (High Availability) clusters, Hadoop clusters without HA, and MapR clusters.

In a Hadoop HA cluster, the LOCATION clause references the logical nameservices id (the dfs.nameservices property in the hdfs-site.xml configuration file). The hdfs-site.xml file with the nameservices configuration must be installed on the Greenplum master and on each segment host.

For example, if dfs.nameservices is set to mycluster the LOCATION clause takes this format:

```
LOCATION ('gphdfs://mycluster/path/filename.txt')
```

A cluster without HA specifies the hostname and port of the name node in the LOCATION clause:

```
LOCATION ('gphdfs://hdfs_host[:port]/path/filename.txt')
```

If you are using MapR clusters, you specify a specific cluster and the file:

- To specify the default cluster, the first entry in the MapR configuration file /opt/mapr/conf/mapr-clusters.conf, specify the location of your table with this syntax:

  ```
  LOCATION ('gphdfs:///file_path')
  ```

  The file_path is the path to the file.

- To specify another MapR cluster listed in the configuration file, specify the file with this syntax:

  ```
  LOCATION ('gphdfs:///mapr/cluster_name/file_path')
  ```

  The cluster_name is the name of the cluster specified in the configuration file and file_path is the path to the file.

For information about MapR clusters, see the MapR documentation.

Restrictions for HDFS files are as follows.

- You can specify one path for a readable external table with gphdfs. Wildcard characters are allowed. If you specify a directory, the default is all files in the directory.

  You can specify only a directory for writable external tables.
• The URI of the LOCATION clause cannot contain any of these four characters: \, , , <, >. The CREATE EXTERNAL TABLE returns a an error if the URI contains any of the characters.

• Format restrictions are as follows.
  • Only the gphdfs_import formatter is allowed for readable external tables with a custom format.
  • Only the gphdfs_export formatter is allowed for writable external tables with a custom format.
  • You can set compression only for writable external tables. Compression settings are automatic for readable external tables.

**Setting Compression Options for Hadoop Writable External Tables**

Compression options for Hadoop Writable External Tables use the form of a URI query and begin with a question mark. Specify multiple compression options with an ampersand (&).

**Table 74: Compression Options**

<table>
<thead>
<tr>
<th>Compression Option</th>
<th>Values</th>
<th>Default Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>compress</td>
<td>true or false</td>
<td>false</td>
</tr>
<tr>
<td>compression_type</td>
<td>BLOCK or RECORD</td>
<td>RECORD</td>
</tr>
<tr>
<td></td>
<td></td>
<td>For AVRO format, compression_type must be block if compress is true.</td>
</tr>
<tr>
<td>codec</td>
<td>Codec class name</td>
<td>GzipCodec for text format and DefaultCodec for gphdfs_export format.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>For AVRO format, the value is either deflate (the default) or snappy</td>
</tr>
<tr>
<td>codec_level (for AVRO format and deflate codec only)</td>
<td>integer between 1 and 9</td>
<td>6</td>
</tr>
<tr>
<td></td>
<td></td>
<td>The level controls the trade-off between speed and compression. Valid values are 1 to 9, where 1 is the fastest and 9 is the most compressed.</td>
</tr>
</tbody>
</table>

Place compression options in the query portion of the URI.

**gphdfs Support for Avro Files (Deprecated)**

*Note:* The gphdfs external table protocol is deprecated and will be removed in the next major release of Greenplum Database. You can use the Greenplum Platform Extension Framework (PXF) to access Avro-format data.

You can use the Greenplum Database gphdfs protocol to access Avro files on a Hadoop file system (HDFS).

**About the Avro File Format**

An Avro file stores both the data definition (schema) and the data together in one file making it easy for programs to dynamically understand the information stored in an Avro file. The Avro schema is in JSON format, the data is in a binary format making it compact and efficient.

The following example Avro schema defines an Avro record with 3 fields:

- name
- favorite_number
- favorite_color

```json
{"namespace": "example.avro",}
"type": "record", "name": "User",
"fields": [
   {"name": "name", "type": "string"},
   {"name": "favorite_number", "type": ["int", "null"]},
   {"name": "favorite_color", "type": ["string", "null"]}
]
}

These are two rows of data based on the schema:

{ "name" : "miguno" , "favorite_number" : 6 , "favorite_color" : "red" }
{ "name" : "BlizzardCS" , "favorite_number" : 21 , "favorite_color" : "green" }

For information about the Avro file format, see http://avro.apache.org/docs/1.7.7/

**Required Avro Jar Files**

Support for the Avro file format requires these jar files:

- avro-1.7.7.jar
- avro-tools-1.7.7.jar
- avro-mapred-1.7.5-hadoop2.jar (available with Apache Pig)

**Note:** Hadoop 2 distributions include the Avro jar file $HADOOP_HOME/share/hadoop/common/lib/avro-1.7.4.jar. To avoid conflicts, you can rename the file to another file such as avro-1.7.4.jar.bak.

For the Cloudera 5.4.x Hadoop distribution, only the jar file avro-mapred-1.7.5-hadoop2.jar needs to be downloaded and installed. The distribution contains the other required jar files. The other files are included in the classpath used by the gphdfs protocol.

For information about downloading the Avro jar files, see https://avro.apache.org/releases.html.

On all the Greenplum Database hosts, ensure that the jar files are installed and are on the classpath used by the gphdfs protocol. The classpath is specified by the shell script $GPHOME/lib/hadoop/hadoop_env.sh.

As an example, if the directory $HADOOP_HOME/share/hadoop/common/lib does not exist, create it on all Greenplum Database hosts as the gpadmin user. Then, add the add the jar files to the directory on all hosts.

The hadoop_env.sh script file adds the jar files to classpath for the gphdfs protocol. This fragment in the script file adds the jar files to the classpath.

```bash
if [ -d "${HADOOP_HOME}/share/hadoop/common/lib" ]; then
   for f in ${HADOOP_HOME}/share/hadoop/common/lib/*.jar; do
      CLASSPATH=${CLASSPATH}:${f};
   done
```

**Avro File Format Support**

The Greenplum Database gphdfs protocol supports the Avro file type as an external table:

- Avro file format - GPDB certified with Avro version 1.7.7
- Reading and writing Avro files
- Support for overriding the Avro schema when reading an Avro file
- Compressing Avro files during writing
- Automatic Avro schema generation when writing an Avro file

Greenplum Database returns an error if the Avro file contains unsupported features or if the specified schema does not match the data.
Reading from and Writing to Avro Files

To read from or write to an Avro file, you create an external table and specify the location of the Avro file in the LOCATION clause and 'AVRO' in the FORMAT clause. For example, this is the syntax for a readable external table.

```
CREATE EXTERNAL TABLE tablename (column_spec) LOCATION ('gphdfs://location') FORMAT 'AVRO'
```

The location can be an individual Avro file or a directory containing a set of Avro files. If the location specifies multiple files (a directory name or a file name containing wildcard characters), Greenplum Database uses the schema in the first file of the directory as the schema of the whole directory. For the file name you can specify the wildcard character * to match any number of characters.

You can add parameters after the file specified in the location. You add parameters with the http query string syntax that starts with ? and & between field and value pairs. For readable external tables, the only valid parameter is schema. The gphdfs uses this schema instead of the Avro file schema when reading Avro files. See Avro Schema Overrides for Readable External Tables.

For writable external tables, you can specify schema, namespace, and parameters for compression.

Table 75: Avro External Table Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Value</th>
<th>Readable/Writable</th>
<th>Default Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>schema</td>
<td>URL_to_schema_file</td>
<td>Read and Write</td>
<td>None.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>For a readable external table</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>• The specified schema overrides the schema in the Avro file. See Avro Schema Overrides</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>• If not specified, Greenplum Database uses the Avro file schema.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>For a writable external table</td>
</tr>
</tbody>
</table>
|               |                              |                   | • Uses the specified schema when creating the Avro file.
<p>|               |                              |                   | • If not specified, Greenplum Database creates a schema according to the external table definition. |
| namespace     | avro_namespace               | Write only        | public.avro                                        |
|               |                              |                   | If specified, a valid Avro namespace.              |
| compress      | true or false                | Write only        | false                                             |
| compression_type | block                      | Write only        | Optional.                                          |
|               |                              |                   | For avro format, compression_type must be block if compress is true. |
| codec         | deflate or snappy            | Write only        | deflate                                            |</p>
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Value</th>
<th>Readable/Writable</th>
<th>Default Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>codec_level</td>
<td>integer between 1 and 9</td>
<td>Write only</td>
<td>6</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>The level controls the trade-off between speed and compression. Valid values</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>are 1 to 9, where 1 is the fastest and 9 is the most compressed.</td>
</tr>
</tbody>
</table>

This set of parameters specify *snappy* compression:

```sql
'compress=true&codec=snappy'
```

These two sets of parameters specify *deflate* compression and are equivalent:

```sql
'compress=true&codec=deflate&codec_level=1'
'compress=true&codec_level=1'
```

### Data Conversion When Reading Avro Files

When you create a readable external table to Avro file data, Greenplum Database converts Avro data types to Greenplum Database data types.

**Note:** When reading an Avro, Greenplum Database converts the Avro field data at the top level of the Avro schema to a Greenplum Database table column. This is how the `gphdfs` protocol converts the Avro data types.

- An Avro primitive data type, Greenplum Database converts the data to a Greenplum Database type.
- An Avro complex data type that is not `map` or `record`, Greenplum Database converts the data to a Greenplum Database type.
- An Avro `record` that is a sub-record (nested within the top level Avro schema record), Greenplum Database converts the data XML.

This table lists the Avro primitive data types and the Greenplum Database type it is converted to.

### Table 76: Avro Primitive Data Type Support for Readable External Tables

<table>
<thead>
<tr>
<th>Avro Data Type</th>
<th>Greenplum Database Data Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>null</td>
<td>Supported only in a Avro union data type. See <em>Data Conversion when Writing Avro Files.</em></td>
</tr>
<tr>
<td>boolean</td>
<td>boolean</td>
</tr>
<tr>
<td>int</td>
<td>int or smallint</td>
</tr>
<tr>
<td>long</td>
<td>bigint</td>
</tr>
<tr>
<td>float</td>
<td>real</td>
</tr>
<tr>
<td>double</td>
<td>double</td>
</tr>
<tr>
<td>bytes</td>
<td>bytea</td>
</tr>
<tr>
<td>string</td>
<td>text</td>
</tr>
</tbody>
</table>

**Note:** When reading the Avro `int` data type as Greenplum Database `smallint` data type, you must ensure that the Avro `int` values do not exceed the Greenplum Database maximum `smallint` value. If the Avro value is too large, the Greenplum Database value will be incorrect.
The gphdfs protocol converts performs this conversion for smallint:short result = (short)IntValue;.

This table lists the Avro complex data types and the and the Greenplum Database type it is converted to.

Table 77: Avro Complex Data Type Support for Readable External Tables

<table>
<thead>
<tr>
<th>Avro Data Type</th>
<th>Greenplum Database Data Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>enum</td>
<td>int</td>
</tr>
<tr>
<td></td>
<td>The integer represents the zero-based position of the symbol in the schema.</td>
</tr>
<tr>
<td>array</td>
<td>array</td>
</tr>
<tr>
<td></td>
<td>The Greenplum Database array dimensions match the Avro array dimensions. The element type is converted from the Avro data type to the Greenplum Database data type.</td>
</tr>
<tr>
<td>maps</td>
<td>Not supported</td>
</tr>
<tr>
<td>union</td>
<td>The first non-null data type.</td>
</tr>
<tr>
<td>fixed</td>
<td>bytea</td>
</tr>
<tr>
<td>record</td>
<td>XML data</td>
</tr>
</tbody>
</table>

Example Avro Schema

This is an example Avro schema. When reading the data from the Avro file the gphdfs protocol performs these conversions:

- name and color data are converted to Greenplum Database string.
- age data is converted to Greenplum Database int.
- clist records are converted to XML.

```json
{"namespace": "example.avro",
"type": "record",
"name": "User",
"fields": [
  {"name": "name", "type": "string"},
  {"name": "number", "type": ["int", "null"]},
  {"name": "color", "type": ["string", "null"]},
  {"name": "clist",
   "type": {
     "type": "record",
     "name": "clistRecord",
     "fields": [
       {"name": "class", "type": ["string", "null"]},
       {"name": "score", "type": ["double", "null"]},
       {"name": "grade",
        "type": {
         "type": "record",
         "name": "inner2",
         "fields": [
           {"name": "a", "type": ["double", "null"]},
           {"name": "b", "type": ["string", "null"]}
         ]
       },
       {"name": "grade2",
        "type": {
         "type": "record",
         "name": "inner",
         "fields": [
           {"name": "c", "type": ["string", "null"]}
         ]
       }
     ]
   }
  }
]}
```
This XML is an example of how the gpfdist protocol converts Avro data from the clist field to XML data based on the previous schema. For records nested in the Avro top-level record, gpfdist protocol converts the Avro element name to the XML element name and the name of the record is an attribute of the XML element. For example, the name of the top most element clist and the type attribute is the name of the Avro record element clistRecord.

```
<clist type="clistRecord">
  <class type="string">math</class>
  <score type="double">99.5</score>
  <grade type="inner2">
    <a type="double">88.8</a>
    <b type="string">subb0</b>
  </grade>
  <grade2 type="inner">
    <a type="double">77.7</a>
    <b type="string">subb20</b>
    <c type="inner3">
      <c1 type="string">subc</c1>
      <c2 type="int">0</c2>
    </c>
  </grade2>
</clist>
```

**Avro Schema Overrides for Readable External Tables**

When you specify schema for a readable external table that specifies an Avro file as a source, Greenplum Database uses the schema when reading data from the Avro file. The specified schema overrides the Avro file schema.

You can specify a file that contains an Avro schema as part of the location parameter `CREATE EXTERNAL TABLE` command, to override the Avro file schema. If a set of Avro files contain different, related schemas, you can specify an Avro schema to retrieve the data common to all the files.

Greenplum Database extracts the data from the Avro files based on the field name. If an Avro file contains a field with same name, Greenplum Database reads the data, otherwise a NULL is returned.

For example, if a set of Avro files contain one of the two different schemas. This is the original schema.

```
{  
  "type":"record",  
  "name":"tav2",  
  "namespace":"public.avro",  
  "doc":"",  
  "fields": [  
    {"name":"id", "type": ["null", "int"], "doc":""},  
```
This updated schema contains a comment field.

```json
{
  "type": "record",
  "name": "tav2",
  "namespace": "public.avro",
  "doc": "",
  "fields": [
    {"name": "id", "type": ["null", "int"], "doc": ""},
    {"name": "name", "type": ["null", "string"], "doc": ""},
    {"name": "birth", "type": ["null", "string"], "doc": ""},
    {"name": "age", "type": ["null", "long"], "doc": ""},
    {"name": "comment", "type": ["null", "string"], "doc": ""}
  ]
}
```

You can specify a file containing this Avro schema in a `CREATE EXTERNAL TABLE` command, to read the id, name, birth, and comment fields from the Avro files.

```json
{
  "type": "record",
  "name": "tav2",
  "namespace": "public.avro",
  "doc": "",
  "fields": [
    {"name": "id", "type": ["null", "int"], "doc": ""},
    {"name": "name", "type": ["null", "string"], "doc": ""},
    {"name": "birth", "type": ["null", "string"], "doc": ""},
    {"name": "age", "type": ["null", "long"], "doc": ""},
    {"name": "comment", "type": ["null", "string"], "doc": ""}
  ]
}
```

In this example command, the customer data is in the Avro files `tmp/cust*.avro`. Each file uses one of the schemas listed previously. The file `avro/cust.avsc` is a text file that contains the Avro schema used to override the schemas in the customer files.

```sql
CREATE WRITABLE EXTERNAL TABLE cust_avro(id int, name text, birth date)
  FORMAT 'avro';
```

When reading the Avro data, if Greenplum Database reads a file that does not contain a comment field, a NULL is returned for the comment data.

**Data Conversion when Writing Avro Files**

When you create a writable external table to write data to an Avro file, each table row is an Avro record and each table column is an Avro field. When writing an Avro file, the default compression algorithm is deflate.

For a writable external table, if the schema option is not specified, Greenplum Database creates an Avro schema for the Avro file based on the Greenplum Database external table definition. The name of the table column is the Avro field name. The data type is a union data type. See the following table:
Table 78: Avro Data Types Generated by Greenplum Database

<table>
<thead>
<tr>
<th>Greenplum Database Data Type</th>
<th>Avro Union Data Type Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>boolean</td>
<td>[&quot;boolean&quot;, &quot;null&quot;]</td>
</tr>
<tr>
<td>int</td>
<td>[&quot;int&quot;, &quot;null&quot;]</td>
</tr>
<tr>
<td>bigint</td>
<td>[&quot;long&quot;, &quot;null&quot;]</td>
</tr>
<tr>
<td>smallint</td>
<td>[&quot;int&quot;, &quot;null&quot;]</td>
</tr>
<tr>
<td>real</td>
<td>[&quot;float&quot;, &quot;null&quot;]</td>
</tr>
<tr>
<td>double</td>
<td>[&quot;double&quot;, &quot;null&quot;]</td>
</tr>
<tr>
<td>bytea</td>
<td>[&quot;bytes&quot;, &quot;null&quot;]</td>
</tr>
<tr>
<td>text</td>
<td>[&quot;string&quot;, &quot;null&quot;]</td>
</tr>
<tr>
<td>array</td>
<td>[{array}, &quot;null&quot;]</td>
</tr>
</tbody>
</table>

The Greenplum Database array is converted to an Avro array with same dimensions and same element type as the Greenplum Database array.

<table>
<thead>
<tr>
<th>other data types</th>
<th>[&quot;string&quot;, &quot;null&quot;]</th>
</tr>
</thead>
</table>

Data are formatted strings. The gphdfs protocol casts the data to Greenplum Database text and writes the text to the Avro file as an Avro string. For example, date and time data are formatted as date and time strings and converted to Avro string type.

You can specify a schema with the `schema` option. When you specify a schema, the file can be on the segment hosts or a file on the HDFS that is accessible to Greenplum Database. For a local file, the file must exist in all segment hosts in the same location. For a file on the HDFS, the file must exist in the same cluster as the data file.

This example `schema` option specifies a schema on an HDFS.

```
'schema=hdfs://mytest:8000/avro/array_simple.avsc'
```

This example `schema` option specifies a schema on the host file system.

```
'schema=file:///mydata/avro_schema/array_simple.avsc'
```

**gphdfs Limitations for Avro Files**

For a Greenplum Database writable external table definition, columns cannot specify the `NOT NULL` clause.

Greenplum Database supports only a single top-level schema in Avro files or specified with the `schema` parameter in the `CREATE EXTERNAL TABLE` command. An error is returned if Greenplum Database detects multiple top-level schemas.

Greenplum Database does not support the Avro `map` data type and returns an error when encountered.

When Greenplum Database reads an array from an Avro file, the array is converted to the literal text value. For example, the array `[1, 3]` is converted to `'(1, 3)'`.

User defined types (UDT), including array UDT, are supported. For a writable external table, the type is converted to string.
Examples

Simple CREATE EXTERNAL TABLE command that reads data from the two Avro fields id and ba.

```
CREATE EXTERNAL TABLE avrol (id int, ba bytea[])
    LOCATION ('gphdfs://my_hdfs:8020/avro/singleAvro/array2.avro')
    FORMAT 'avro';
```

CREATE WRITABLE EXTERNAL TABLE command specifies the Avro schema that is the gphdfs protocol uses to create the Avro file.

```
CREATE WRITABLE EXTERNAL TABLE at1w(id int, names text[], nums int[])
    LOCATION ('gphdfs://my_hdfs:8020/tmp/at1
?schema=hdfs://my_hdfs:8020/avro/array_simple.avsc')
    FORMAT 'avro';
```

CREATE WRITABLE EXTERNAL TABLE command that writes to an Avro file and specifies a namespace for the Avro schema.

```
CREATE WRITABLE EXTERNAL TABLE atudt1 (id int, info myt, birth date, salary numeric)
    LOCATION ('gphdfs://my_hdfs:8020/tmp/emp01.avro
?namespace=public.example.avro')
    FORMAT 'avro';
```

gphdfs Support for Parquet Files (Deprecated)

Note: The gphdfs external table protocol is deprecated and will be removed in the next major release of Greenplum Database. You can use the Greenplum Platform Extension Framework (PXF) to access Parquet-format data.

You can use the Greenplum Database gphdfs protocol to access Parquet files on a Hadoop file system (HDFS).

About the Parquet File Format

The Parquet file format is designed to take advantage of compressed, efficient columnar data representation available to projects in the Hadoop ecosystem. Parquet supports complex nested data structures and uses Dremel record shredding and assembly algorithms. Parquet supports very efficient compression and encoding schemes. Parquet allows compression schemes to be specified on a per-column level, and supports adding more encodings as they are invented and implemented.

For information about the Parquet file format, see the Parquet documentation [http://parquet.apache.org/documentation/latest/](http://parquet.apache.org/documentation/latest/).

Required Parquet Jar Files

The gphdfs protocol supports Parquet versions 1.7.0 and later. For each version, the required Parquet jar files are included in a bundled jar file parquet-hadoop-bundle-<version>.jar.

Earlier Parquet versions not use the Java class names org.apache.parquet and are not supported. The gphdfs protocol expects the Parquet Java class names to be org.apache.parquet.xxx.

Note: The Cloudera 5.4.x Hadoop distribution includes some Parquet jar files. However, the Java class names in the jar files are parquet.xxx. The jar files with the class name org.apache.parquet can be downloaded and installed on the Greenplum Database hosts.
For information about downloading the Parquet jar files, see https://mvnrepository.com/artifact/org.apache.parquet/parquet-hadoop-bundle

On all the Greenplum Database hosts, ensure that the jar files are installed and are on the classpath used by the gphdfs protocol. The classpath is specified by the shell script $GPHOME/lib/hadoop/hadoop_env.sh. As a Hadoop 2 example, you can install the jar files in $HADOOP_HOME/share/hadoop/common/lib. The hadoop_env.sh script file adds the jar files to the classpath.

As an example, if the directory $HADOOP_HOME/share/hadoop/common/lib does not exist, create it on all Greenplum Database hosts as the gpadmin user. Then, add the add the jar files to the directory on all hosts.

The hadoop_env.sh script file adds the jar files to classpath for the gphdfs protocol. This fragment in the script file adds the jar files to the classpath.

```bash
if [ -d "${HADOOP_HOME}/share/hadoop/common/lib" ]; then
  for f in ${HADOOP_HOME}/share/hadoop/common/lib/*.jar; do
    CLASSPATH=${CLASSPATH}:$f;
  done
done
```

**Parquet File Format Support**

The Greenplum Database gphdfs protocol supports the Parquet file format version 1 or 2. Parquet takes advantage of compressed, columnar data representation on HDFS. In a Parquet file, the metadata (Parquet schema definition) contains data structure information is written after the data to allow for single pass writing.

This is an example of the Parquet schema definition format:

```plaintext
message test {
  repeated byte_array binary_field;
  required int32 int32_field;
  optional int64 int64_field;
  required boolean boolean_field;
  required fixed_len_byte_array(3) flba_field;
  required byte_array someDay (utf8);
}
```

The definition for last field someDay specifies the binary data type with the utf8 annotation. The data type and annotation defines the data as a UTF-8 encoded character string.

**Reading from and Writing to Parquet Files**

To read from or write to a Parquet file, you create an external table and specify the location of the parquet file in the LOCATION clause and 'PARQUET' in the FORMAT clause. For example, this is the syntax for a readable external table.

```sql
CREATE EXTERNAL TABLE tablename (column_spec) LOCATION ( 'gphdfs://location') FORMAT 'PARQUET'
```

The location can be an Parquet file or a directory containing a set of Parquet files. For the file name you can specify the wildcard character * to match any number of characters. If the location specifies multiple files when reading Parquet files, Greenplum Database uses the schema in the first file that is read as the schema for the other files.

**Reading a Parquet File**

The following table identifies how Greenplum database converts the Parquet data type if the Parquet schema definition does not contain an annotation.
Table 79: Data Type Conversion when Reading a Parquet File

<table>
<thead>
<tr>
<th>Parquet Data Type</th>
<th>Greenplum Database Data Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>boolean</td>
<td>boolean</td>
</tr>
<tr>
<td>int32</td>
<td>int or smallint</td>
</tr>
<tr>
<td>int64</td>
<td>long</td>
</tr>
<tr>
<td>int96</td>
<td>bytea</td>
</tr>
<tr>
<td>float</td>
<td>real</td>
</tr>
<tr>
<td>double</td>
<td>double</td>
</tr>
<tr>
<td>byte_array</td>
<td>bytea</td>
</tr>
<tr>
<td>fixed_len_byte_array</td>
<td>bytea</td>
</tr>
</tbody>
</table>

**Note:** When reading the Parquet int data type as Greenplum Database smallint data type, you must ensure that the Parquet int values do not exceed the Greenplum Database maximum smallint value. If the value is too large, the Greenplum Database value will be incorrect.

The gphdfs protocol considers Parquet schema annotations for these cases. Otherwise, data conversion is based on the parquet schema primitive type:

Table 80: Data Type (with Annotation) Conversion when Reading Parquet File

<table>
<thead>
<tr>
<th>Parquet Schema Data Type and Annotation</th>
<th>Greenplum Database Data Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>binary with json or utf8 annotation</td>
<td>text</td>
</tr>
<tr>
<td>binary and the Greenplum Database column data type is text</td>
<td>text</td>
</tr>
<tr>
<td>int32 with int_16 annotation</td>
<td>smallint</td>
</tr>
<tr>
<td>int32, int64, fixed_len_byte_array, or binary with decimal annotation</td>
<td>decimal</td>
</tr>
<tr>
<td>repeated</td>
<td>array column - The data type is converted according to Table 79: Data Type Conversion when Reading a Parquet File</td>
</tr>
<tr>
<td>optional, required</td>
<td>Data type is converted according to Table 79: Data Type Conversion when Reading a Parquet File</td>
</tr>
</tbody>
</table>

**Note:** See Limitations and Notes and the Parquet documentation when specifying decimal, date, interval, or time* annotations.

The gphdfs protocol converts the field data to text if the Parquet field type is binary without any annotation, and the data type is defined as text for the corresponding Greenplum Database external table column.

When reading Parquet type group, the gphdfs protocol converts the group data into an XML document.

This schema contains a required group with the name inner.

```plaintext
message test {  
  required byte_array binary_field;  
  required int64 int64_field;  
  required group inner {  
    int32 age;  
  }  
}```
This how a single row of the group data would be converted to XML.

```xml
<inner type="group">
    <age type="int">50</age>
    <test type="boolean">true</test>
    <name type="string">fred</name>
</inner>
```

This example schema contains a repeated group with the name `inner`.

```protobuf
text {
    required byte_array binary_field;
    required int64 int64_field;
    repeated group inner {
        int32 age;
        required boolean test;
        required byte_array name (UTF8);
    }
}
```

For a repeated group, the Parquet file can contain multiple sets of the group data in a single row. For the example schema, the data for the `inner` group is converted into XML data.

This is sample output if the data in the Parquet file contained two sets of data for the `inner` group.

```xml
<inner type="repeated">
    <inner type="group">
        <age type="int">50</age>
        <test type="boolean">true</test>
        <name type="string">fred</name>
    </inner>
    <inner>
        <age type="int">23</age>
        <test type="boolean">false</test>
        <name type="string">sam</name>
    </inner>
</inner>
```

### Reading a Hive Generated Parquet File

The Apache Hive data warehouse software can manage and query large datasets that reside in distributed storage. Apache Hive 0.13.0 and later can store data in Parquet format files. For information about Parquet used by Apache Hive, see [https://cwiki.apache.org/confluence/display/Hive/Parquet](https://cwiki.apache.org/confluence/display/Hive/Parquet).

For Hive 1.1 data stored in Parquet files, this table lists how Greenplum database converts the data. The conversion is based on the Parquet schema that is generated by Hive. For information about the Parquet schema generated by Hive, see [Notes on the Hive Generated Parquet Schema](#).

<table>
<thead>
<tr>
<th>Hive Data Type</th>
<th>Greenplum Database Data Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>tinyint</td>
<td>int</td>
</tr>
<tr>
<td>smallint</td>
<td>int</td>
</tr>
</tbody>
</table>

### Table 81: Data Type Conversion when Reading a Hive Generated Parquet File
### Notes on the Hive Generated Parquet Schema

- When writing data to Parquet files, Hive treats all integer data types `tinyint`, `smallint`, `int` as `int32`. When you create an external table in Greenplum Database for a Hive generated Parquet file, specify the column data type as `int`. For example, this Hive `CREATE TABLE` command stores data in Parquet files.

```sql
CREATE TABLE hpSimple(c1 tinyint, c2 smallint, c3 int, c4 bigint, c5 float, c6 double, c7 boolean, c8 string) STORED AS PARQUET;
```

This is the Hive generated Parquet schema for the `hpSimple` table data.

```java
message hive_schema {
  optional int32 c1;
  optional int32 c2;
  optional int32 c3;
  optional int64 c4;
  optional float c5;
  optional double c6;
  optional boolean c7;
  optional binary c8 (UTF8);
}
```

The `gphdfs` protocol converts the Parquet integer data types to the Greenplum Database data type `int`.

- For the Hive `char` data type, the Greenplum Database column data types can be either `text` or `char`. For the Hive `varchar` data type, the Greenplum Database column data type can be either `text` or `varchar`.

- Based on the Hive generated Parquet schema, some Hive data is converted to Greenplum Database XML data. For example, Hive array column data that is stored in a Parquet file is converted to XML.
data. As an example, this is the Hive generated Parquet schema for a Hive column `col1` of data type `array[int]`:

```plaintext
optional group col1 (LIST) {
  repeated group bag {
    optional int32 array_element;
  }
}
```

The `gphdfs` protocol converts the Parquet group data to the Greenplum Database data type `XML`.

- For the Hive `timestamp` data type, the Hive generated Parquet schema for the data type specifies that the data is stored as data type `int96`. The `gphdfs` protocol converts the `int96` data type to the Greenplum Database `bytea` data type.

### Writing a Parquet File

For writable external tables, you can add parameters after the file specified in the `location`. You add parameters with the HTTP query string syntax that starts with `?` and `&` between field and value pairs.

#### Table 82: Parquet Format External Table location Parameters

<table>
<thead>
<tr>
<th>Option</th>
<th>Values</th>
<th>Readable/Writable</th>
<th>Default Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>schema</td>
<td><code>URL_to_schema</code></td>
<td>Write only</td>
<td>None. If not specified, the <code>gphdfs</code> protocol creates a schema according to the external table definition.</td>
</tr>
<tr>
<td>pagesize</td>
<td>&gt; 1024 Bytes</td>
<td>Write only</td>
<td>1 MB</td>
</tr>
<tr>
<td>rowgroupsize</td>
<td>&gt; 1024 Bytes</td>
<td>Write only</td>
<td>8 MB</td>
</tr>
<tr>
<td>parquetversion or pqversion</td>
<td>v1, v2</td>
<td>Write only</td>
<td>v1</td>
</tr>
<tr>
<td>codec</td>
<td>UNCOMPRESSED, GZIP, LZO, snappy</td>
<td>Write only</td>
<td>UNCOMPRESSED</td>
</tr>
<tr>
<td>dictionaryenable</td>
<td>true, false</td>
<td>Write only</td>
<td>false</td>
</tr>
<tr>
<td>dictionarypagesize</td>
<td>&gt; 1024 Bytes</td>
<td>Write only</td>
<td>512 KB</td>
</tr>
</tbody>
</table>

**Note:**

1. Creates an internal dictionary. Enabling a dictionary can improve Parquet file compression if text columns contain similar or duplicate data.

When writing a Parquet file, the `gphdfs` protocol can generate a Parquet schema based on the table definition.

- The table name is used as the Parquet `message` name.
- The column name is used as the Parquet `field` name.

When creating the Parquet schema from a Greenplum Database table definition, the schema is generated based on the column data type.
Table 83: Schema Data Type Conversion when Writing a Parquet File

<table>
<thead>
<tr>
<th>Greenplum Database Data Type</th>
<th>Parquet Schema Data Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>boolean</td>
<td>optional boolean</td>
</tr>
<tr>
<td>smallint</td>
<td>optional int32 with annotation \texttt{int}_16</td>
</tr>
<tr>
<td>int</td>
<td>optional int32</td>
</tr>
<tr>
<td>bigint</td>
<td>optional int64</td>
</tr>
<tr>
<td>real</td>
<td>optional float</td>
</tr>
<tr>
<td>double</td>
<td>optional double</td>
</tr>
<tr>
<td>numeric or decimal</td>
<td>binary with annotation \texttt{decimal}</td>
</tr>
<tr>
<td>bytea</td>
<td>optional binary</td>
</tr>
<tr>
<td>array column</td>
<td>repeated field - The data type is the same data type as the Greenplum Database the array. For example, \texttt{array[int]} is converted to \texttt{repeated int}</td>
</tr>
<tr>
<td>Others</td>
<td>binary with annotation \texttt{utf8}</td>
</tr>
</tbody>
</table>

**Note:** To support \texttt{Null} data, \texttt{gphdfs} protocol specifies the Parquet \texttt{optional} schema annotation when creating a Parquet schema.

A simple example of a Greenplum Database table definition and the Parquet schema generated by the \texttt{gphdfs} protocol.

An example external table definition for a Parquet file.

```sql
CREATE WRITABLE EXTERNAL TABLE films (  
    code char(5),  
    title varchar(40),  
    id integer,  
    date_prod date,  
    subtitle boolean
) LOCATION ( 'gphdfs://my-films') FORMAT 'PARQUET';
```

This is the Parquet schema for the Parquet file \texttt{my-films} generated by the \texttt{gphdfs} protocol.

```plaintext
message films {  
    optional byte_array code;  
    optional byte_array title (utf8);  
    optional int32 id;  
    optional binary date_prod (utf8);  
    optional boolean subtitle;  
};
```

**Limitations and Notes**

- For writable external tables, column definitions in Greenplum Database external table cannot specify \texttt{NOT NULL} to support automatically generating a Parquet schema. When the \texttt{gphdfs} protocol automatically generates a Parquet schema, the \texttt{gphdfs} protocol specifies the field attribute \texttt{optional} to support \texttt{null} in the Parquet schema. Repeated fields can be \texttt{null} in Parquet.
- The \texttt{gphdfs} protocol supports Parquet nested \texttt{group} structures only for readable external files. The nested structures are converted to an XML document.
• Greenplum Database does not have an unsigned int data type. Greenplum Database converts the Parquet unsigned int data type to the next largest Greenplum Database int type. For example, Parquet uint_8 is converted to Greenplum Database int (32 bit).
• Greenplum Database supports any UDT data type or UDT array data type. Greenplum Database attempts to convert the UDT to a sting. If the UDT cannot be converted to a sting, Greenplum Database returns an error.
• The definition of the Interval data type in Parquet is significantly different than the Interval definition in Greenplum Database and cannot be converted. The Parquet Interval data is formatted as bytea.
• The Date data type in Parquet is starts from 1970.1.1, while Date in Greenplum Database starts from 4173 BC, Greenplum Database cannot convert date data types because largest values are different. A similar situation occurs between Timestamp_millis in Parquet and Timestamp in Greenplum Database.

HDFS Readable and Writable External Table Examples (Deprecated)

Note: The gphdfs external table protocol is deprecated and will be removed in the next major release of Greenplum Database.

The following code defines a readable external table for an HDFS file named filename.txt on port 8081.

```sql
=# CREATE EXTERNAL TABLE ext_expenses (
    name text,
    date date,
    amount float4,
    category text,
    desc1 text )
LOCATION ('gphdfs://hdfshost-1:8081/data/filename.txt')
FORMAT 'TEXT' (DELIMITER ',');
```

The following code defines a set of readable external tables that have a custom format located in the same HDFS directory on port 8081.

```sql
=# CREATE EXTERNAL TABLE ext_expenses (
    name text,
    date date,
    amount float4,
    category text,
    desc1 text )
LOCATION ('gphdfs://hdfshost-1:8081/data/custdat*.dat')
FORMAT 'custom' (formatter='gphdfs_import');
```

The following code defines an HDFS directory for a writable external table on port 8081 with all compression options specified.

```sql
=# CREATE WRITABLE EXTERNAL TABLE ext_expenses (
    name text,
    date date,
    amount float4,
    category text,
    desc1 text )
LOCATION ('gphdfs://hdfshost-1:8081/data/?
compress=true&compression_type=RECORD
&codec=org.apache.hadoop.io.compress.DefaultCodec')
FORMAT 'custom' (formatter='gphdfs_export');
```
Because the previous code uses the default compression options for `compression_type` and `codec`, the following command is equivalent.

```sql
=# CREATE WRITABLE EXTERNAL TABLE ext_expenses (  
    name text,  
    date date,  
    amount float4,  
    category text,  
    desc1 text )  
LOCATION ('gphdfs://hdfshost-1:8081/data?compress=true')  
FORMAT 'custom' (formatter='gphdfs_export');
```

**Reading and Writing Custom-Formatted HDFS Data with gphdfs (Deprecated)**

**Note:** The gphdfs external table protocol is deprecated and will be removed in the next major release of Greenplum Database.

Use MapReduce and the `CREATE EXTERNAL TABLE` command to read and write data with custom formats on HDFS.

To read custom-formatted data:

1. Author and run a MapReduce job that creates a copy of the data in a format accessible to Greenplum Database.
2. Use `CREATE EXTERNAL TABLE` to read the data into Greenplum Database.

See **Example 1 - Read Custom-Formatted Data from HDFS**.

To write custom-formatted data:

1. Write the data.
2. Author and run a MapReduce program to convert the data to the custom format and place it on the Hadoop Distributed File System.

See **Example 2 - Write Custom-Formatted Data from Greenplum Database to HDFS**.

MapReduce code is written in Java. Greenplum provides Java APIs for use in the MapReduce code. The Javadoc is available in the `$GPHOME/docs` directory. To view the Javadoc, expand the file `gnet-1.2-javadoc.tar` and open `index.html`. The Javadoc documents the following packages:

```java
com.emc.greenplum.gpdb.hadoop.io
com.emc.greenplum.gpdb.hadoop.mapred
com.emc.greenplum.gpdb.hadoop.mapreduce.lib.input
com.emc.greenplum.gpdb.hadoop.mapreduce.lib.output
```

The HDFS cross-connect packages contain the Java library, which contains the packages `GPDBWritable`, `GPDBInputFormat`, and `GPDBOutputFormat`. The Java packages are available in `$GPHOME/lib/hadoop`. Compile and run the MapReduce job with the cross-connect package. For example, compile and run the MapReduce job with `hdp-gnet-1.2.0.0.jar` if you use the HDP distribution of Hadoop.

To make the Java library available to all Hadoop users, the Hadoop cluster administrator should place the corresponding `gphdfs` connector jar in the `$HADOOP_HOME/lib` directory and restart the job tracker. If this is not done, a Hadoop user can still use the `gphdfs` connector jar; but with the `distributed cache` technique.

**Example 1 - Read Custom-Formatted Data from HDFS**

The sample code makes the following assumptions.
- The data is contained in HDFS directory `/demo/data/temp` and the name node is running on port 8081.
- This code writes the data in Greenplum Database format to `/demo/data/MRTest1` on HDFS.
- The data contains the following columns, in order.
  1. A long integer
  2. A Boolean
  3. A text string

**Sample MapReduce Code**

```java
import com.emc.greenplum.gpdb.hadoop.io.GPDBWritable;
import com.emc.greenplum.gpdb.hadoop.mapreduce.lib.input.GPDBInputFormat;
import com.emc.greenplum.gpdb.hadoop.mapreduce.lib.output.GPDBOutputFormat;
import java.io.*;
import java.util.*;
import org.apache.hadoop.fs.Path;
import org.apache.hadoop.conf.*;
import org.apache.hadoop.io.*;
import org.apache.hadoop.mapreduce.*;
import org.apache.hadoop.mapreduce.lib.output.*;
import org.apache.hadoop.mapreduce.lib.input.*;
import org.apache.hadoop.util.*;

public class demoMR {

    /*
     * Helper routine to create our generic record. This section shows the
     * format of the data. Modify as necessary.
     */
    public static GPDBWritable generateGenericRecord() throws IOException {
        int[] colType = new int[3];
        colType[0] = GPDBWritable.BIGINT;
        colType[1] = GPDBWritable.BOOLEAN;
        colType[2] = GPDBWritable.VARCHAR;

        /*
         * This section passes the values of the data. Modify as necessary.
         */
        GPDBWritable gw = new GPDBWritable(colType);
        gw.setLong (0, (long)12345);
        gw.setBoolean(1, true);
        gw.setString (2, "abcdef");
        return gw;
    }

    /*
     * DEMO Map/Reduce class test1
     * -- Regardless of the input, this section dumps the generic record
     * into GPDBFormat/
     */
    public static class Map_test1
        extends Mapper<LongWritable, Text, LongWritable, GPDBWritable> {
        private LongWritable word = new LongWritable(1);

        public void map(LongWritable key, Text value, Context context) throws
        IOException {
            try {
                GPDBWritable gw = generateGenericRecord();
                context.write(word, gw);
            } catch (Exception e) {
                e.printStackTrace();
            }
        }
    }
}
```
```java
try {
    context.write(new Text(value.toString()), NullWritable.get());
} catch (Exception e) { throw new IOException (e.getMessage()); }
}

Configuration conf = new Configuration(true);
Job job = new Job(conf, "test1");
job.setJarByClass(demoMR.class);
job.setInputFormatClass(TextInputFormat.class);
job.setOutputKeyClass (LongWritable.class);
job.setOutputValueClass (GPDBWritable.class);
job.setOutputFormatClass(GPDBOutputFormat.class);
job.setMapperClass(Map_test1.class);
FileInputFormat.setInputPaths (job, new Path("/demo/data/tmp"));
GPDBOutputFormat.setOutputPath(job, new Path("/demo/data/MRTest1"));
job.waitForCompletion(true);
}
```

**Run CREATE EXTERNAL TABLE**

The Hadoop location corresponds to the output path in the MapReduce job.

```sql
=# CREATE EXTERNAL TABLE demodata
   LOCATION ('gphdfs://hdfshost-1:8081/demo/data/MRTest1')
   FORMAT 'custom' (formatter='gphdfs_import');
```

**Example 2 - Write Custom-Formatted Data from Greenplum Database to HDFS**

The sample code makes the following assumptions.

- The data in Greenplum Database format is located on the Hadoop Distributed File System on /demo/data/writeFromGPDB_42 on port 8081.
- This code writes the data to /demo/data/MRTest2 on port 8081.

1. Run a SQL command to create the writable table.

```sql
=# CREATE WRITABLE EXTERNAL TABLE demodata
   LOCATION ('gphdfs://hdfshost-1:8081/demo/data/MRTest2')
   FORMAT 'custom' (formatter='gphdfs_export');
```

2. Author and run code for a MapReduce job. Use the same import statements shown in Example 1 - Read Custom-Formatted Data from HDFS.

**Sample MapReduce Code**

```java
/*
 * DEMO Map/Reduce class test2
 * -- Convert GPDBFormat back to TEXT
 */
public static class Map_test2 extends Mapper<LongWritable, GPDBWritable, Text, NullWritable> { 
    public void map(LongWritable key, GPDBWritable value, Context context) 
        throws IOException {
    try {
        context.write(new Text(value.toString()), NullWritable.get());
    } catch (Exception e) { throw new IOException (e.getMessage()); }
} 
```
public static void runTest2() throws Exception{
  Configuration conf = new Configuration(true);
  Job job = new Job(conf, "test2");
  job.setJarByClass(demoMR.class);
  job.setInputFormatClass(GPDBInputFormat.class);
  job.setOutputKeyLClass (Text.class);
  job.setOutputValueClass(NullWritable.class);
  job.setOutputFormatClass(TextOutputFormat.class);
  job.setMapperClass(Map_test2.class);
  GPDBInputFormat.setInputPaths (job,
    new Path("/demo/data/writeFromGPDB_42"));
  GPDBOutputFormat.setOutputPath(job, new Path("/demo/data/MRTest2"));
  job.waitForCompletion(true);
}

Using Amazon EMR with Greenplum Database installed on AWS (Deprecated)

Note: The gphdfs external table protocol is deprecated and will be removed in the next major release of Greenplum Database.

Amazon Elastic MapReduce (EMR) is a managed cluster platform that can run big data frameworks, such as Apache Hadoop and Apache Spark, on Amazon Web Services (AWS) to process and analyze data. For a Greenplum Database system that is installed on Amazon Web Services (AWS), you can define Greenplum Database external tables that use the gphdfs protocol to access files on an Amazon EMR instance HDFS.

In addition to the steps described in One-time gphdfs Protocol Installation (Deprecated), you must also ensure Greenplum Database can access the EMR instance. If your Greenplum Database system is running on an Amazon Elastic Compute Cloud (EC2) instance, you configure the Greenplum Database system and the EMR security group.

For information about Amazon EMR, see https://aws.amazon.com/emr/. For information about Amazon EC2, see https://aws.amazon.com/ec2/

Configuring Greenplum Database and Amazon EMR

These steps describe how to set up Greenplum Database system and an Amazon EMR instance to support Greenplum Database external tables:

1. Ensure that the appropriate Java (including JDK) and Hadoop environments are correctly installed on all Greenplum Database segment hosts.
   
   For example, Amazon EMR Release 4.0.0 includes Apache Hadoop 2.6.0. This Amazon page describes Amazon EMR Release 4.0.0.
   
   For information about Hadoop versions used by EMR and Greenplum Database, see Table 84: EMR Hadoop Configuration Information.

2. Ensure the environment variables and Greenplum Database server configuration parameters are set:
   
   - System environment variables:
     - HADOOP_HOME
     - JAVA_HOME
   - Greenplum Database server configuration parameters:
     - gp_hadoop_target_version
     - gp_hadoop_home

3. Configure communication between Greenplum Database and the EMR instance Hadoop master.
   
   For example, open port 8020 in the AWS security group.
4. Configure for communication between Greenplum Database and EMR instance Hadoop data nodes. Open a TCP/IP port for so that Greenplum Database segments hosts can communicate with EMR instance Hadoop data nodes.

For example, open port 50010 in the AWS security manager.

This table lists EMR and Hadoop version information that can be used to configure Greenplum Database.

### Table 84: EMR Hadoop Configuration Information

<table>
<thead>
<tr>
<th>EMR Version</th>
<th>EMR Apache Hadoop Version</th>
<th>EMR Hadoop Master Port</th>
<th>gp_hadoop_target_version</th>
<th>Hadoop Version on Greenplum Database Segment Hosts</th>
</tr>

</table>

### Using the Greenplum Parallel File Server (gpfdist)

The gpfdist protocol is used in a `CREATE EXTERNAL TABLE` SQL command to access external data served by the Greenplum Database gpfdist file server utility. When external data is served by gpfdist, all segments in the Greenplum Database system can read or write external table data in parallel.

This topic describes the setup and management tasks for using gpfdist with external tables.

- About gpfdist and External Tables
- About gpfdist Setup and Performance
- Controlling Segment Parallelism
- Installing gpfdist
- Starting and Stopping gpfdist
- Troubleshooting gpfdist

### About gpfdist and External Tables

The gpfdist file server utility is located in the `$GPHOME/bin` directory on your Greenplum Database master host and on each segment host. When you start a gpfdist instance you specify a listen port and the path to a directory containing files to read or where files are to be written. For example, this command runs gpfdist in the background, listening on port 8801, and serving files in the `/home/gpadmin/external_files` directory:

```
$ gpfdist -p 8801 -d /home/gpadmin/external_files &
```

The `CREATE EXTERNAL TABLE` command LOCATION clause connects an external table definition to one or more gpfdist instances. If the external table is readable, the gpfdist server reads data records from files from in specified directory, packs them into a block, and sends the block in a response to a Greenplum Database segment's request. The segments unpack rows they receive and distribute them according to the external table's distribution policy. If the external table is a writable table, segments send blocks of rows in a request to gpfdist and gpfdist writes them to the external file.

External data files can contain rows in CSV format or any delimited text format supported by the FORMAT clause of the `CREATE EXTERNAL TABLE` command. In addition, gpfdist can be configured with a YAML-formatted file to transform external data files between a supported text format and another format, for example XML or JSON. See <ref> for an example that shows how to use gpfdist to read external XML files into a Greenplum Database readable external table.
For readable external tables, `gpfdist` uncompresses `gzip (.gz)` and `bzip2 (.bz2)` files automatically. You can use the wildcard character (*) or other C-style pattern matching to denote multiple files to read. External files are assumed to be relative to the directory specified when you started the `gpfdist` instance.

**About gpfdist Setup and Performance**

You can run `gpfdist` instances on multiple hosts and you can run multiple `gpfdist` instances on each host. This allows you to deploy `gpfdist` servers strategically so that you can attain fast data load and unload rates by utilizing all of the available network bandwidth and Greenplum Database’s parallelism.

- Allow network traffic to use all ETL host network interfaces simultaneously. Run one instance of `gpfdist` for each interface on the ETL host, then declare the host name of each NIC in the `LOCATION` clause of your external table definition (see Examples for Creating External Tables).

![Figure 28: External Table Using Single gpfdist Instance with Multiple NICs](image)

- Divide external table data equally among multiple `gpfdist` instances on the ETL host. For example, on an ETL system with two NICs, run two `gpfdist` instances (one on each NIC) to optimize data load performance and divide the external table data files evenly between the two `gpfdist` servers.
Controlling Segment Parallelism

The `gp_external_max_segs` server configuration parameter controls the number of segment instances that can access a single `gpfdist` instance simultaneously. 64 is the default. You can set the number of segments such that some segments process external data files and some perform other database processing. Set this parameter in the `postgresql.conf` file of your master instance.

Installing `gpfdist`

`gpfdist` is installed in `$GPHOME/bin` of your Greenplum Database master host installation. Run `gpfdist` on a machine other than the Greenplum Database master or standby master, such as on a machine devoted to ETL processing. Running `gpfdist` on the master or standby master can have a performance impact on query execution. To install `gpfdist` on your ETL server, get it from the Greenplum Load Tools package and follow its installation instructions.

Starting and Stopping `gpfdist`

You can start `gpfdist` in your current directory location or in any directory that you specify. The default port is 8080.

From your current directory, type:

```
gpfdist &
```

From a different directory, specify the directory from which to serve files, and optionally, the HTTP port to run on.
To start *gpfdist* in the background and log output messages and errors to a log file:

```
$ gpfdist -d /var/load_files -p 8081 -l /home/gpadmin/log &
```

For multiple *gpfdist* instances on the same ETL host (see Figure 28: External Table Using Single *gpfdist* Instance with Multiple NICs), use a different base directory and port for each instance. For example:

```
$ gpfdist -d /var/load_files1 -p 8081 -l /home/gpadmin/log1 &
$ gpfdist -d /var/load_files2 -p 8082 -l /home/gpadmin/log2 &
```

To stop *gpfdist* when it is running in the background:

First find its process id:

```
$ ps -ef | grep gpfdist
```

Then kill the process, for example (where 3456 is the process ID in this example):

```
$ kill 3456
```

**Troubleshooting gpfdist**

The segments access *gpfdist* at runtime. Ensure that the Greenplum segment hosts have network access to *gpfdist*. *gpfdist* is a web server: test connectivity by running the following command from each host in the Greenplum array (segments and master):

```
$ wget http://gpfdist_hostname:port/filename
```

The **CREATE EXTERNAL TABLE** definition must have the correct host name, port, and file names for *gpfdist*. Specify file names and paths relative to the directory from which *gpfdist* serves files (the directory path specified when *gpfdist* started). See Examples for Creating External Tables.

If you start *gpfdist* on your system and IPv6 networking is disabled, *gpfdist* displays this warning message when testing for an IPv6 port.

```
[WRN gpfdist.c:2050] Creating the socket failed
```

If the corresponding IPv4 port is available, *gpfdist* uses that port and the warning for IPv6 port can be ignored. To see information about the ports that *gpfdist* tests, use the `-V` option.

For information about IPv6 and IPv4 networking, see your operating system documentation.

When reading or writing data with the *gpfdist* or *gfdists* protocol, the *gpfdist* utility rejects HTTP requests that do not include `X-GP-PROTO` in the request header. If `X-GP-PROTO` is not detected in the header request *gpfist* returns a 400 error in the status line of the HTTP response header: `400 invalid request (no gp-proto)`.

Greenplum Database includes `X-GP-PROTO` in the HTTP request header to indicate that the request is from Greenplum Database.

If the *gpfdist* utility hangs with no read or write activity occurring, you can generate a core dump the next time a hang occurs to help debug the issue. Set the environment variable `GPFDIST_WATCHDOG_TIMER` to the number of seconds of no activity to wait before *gpfdist* is forced to exit. When the environment variable is set and *gpfdist* hangs, the utility aborts after the specified number of seconds, creates a core dump, and sends abort information to the log file.
This example sets the environment variable on a Linux system so that `gpfidst` exits after 300 seconds (5 minutes) of no activity.

```bash
export GPFDIST_WATCHDOG_TIMER=300
```
Loading and Unloading Data

The topics in this section describe methods for loading and writing data into and out of a Greenplum Database, and how to format data files.

Greenplum Database supports high-performance parallel data loading and unloading, and for smaller amounts of data, single file, non-parallel data import and export.

Greenplum Database can read from and write to several types of external data sources, including text files, Hadoop file systems, Amazon S3, and web servers.

- The **COPY** SQL command transfers data between an external text file on the master host, or multiple text files on segment hosts, and a Greenplum Database table.
- Readable external tables allow you to query data outside of the database directly and in parallel using SQL commands such as **SELECT**, **JOIN**, or **SORT EXTERNAL TABLE DATA**, and you can create views for external tables. External tables are often used to load external data into a regular database table using a command such as **CREATE TABLE table AS SELECT * FROM ext_table**.
- External web tables provide access to dynamic data. They can be backed with data from URLs accessed using the HTTP protocol or by the output of an OS script running on one or more segments.
- The **gpfdist** utility is the Greenplum Database parallel file distribution program. It is an HTTP server that is used with external tables to allow Greenplum Database segments to load external data in parallel, from multiple file systems. You can run multiple instances of **gpfdist** on different hosts and network interfaces and access them in parallel.
- The **gpload** utility automates the steps of a load task using **gpfdist** and a YAML-formatted control file.
- You can create readable and writable external tables with the Greenplum Platform Extension Framework (PXF), and use these tables to load data into, or offload data from, Greenplum Database. For information about using PXF, refer to [Accessing External Data with PXF](#).
- The Greenplum-Kafka Integration provides high-speed, parallel data transfer from Kafka to Greenplum Database. For information about using these tools, refer to the documentation at [Pivotal Greenplum-Kafka Integration](#).
- The GemFire-Greenplum Connector allows the transfer of data between a Pivotal GemFire region and a Greenplum Database table. Pivotal GemFire is an in-memory data management system that provides reliable asynchronous event notifications and guaranteed message delivery. For information about using GemFire-Greenplum Connector, see [http://ggc.docs.pivotal.io/](http://ggc.docs.pivotal.io/). For information about Pivotal GemFire, see [http://gemfire.docs.pivotal.io/](http://gemfire.docs.pivotal.io/).
- The Greenplum-Spark Connector provides high speed, parallel data transfer between Pivotal Greenplum Database and Apache Spark. For information about using the Greenplum-Spark Connector, refer to the documentation at [https://greenplum-spark.docs.pivotal.io/](https://greenplum-spark.docs.pivotal.io/).
- The Greenplum-Informatica Connector provides high speed data transfer from an Informatica PowerCenter cluster to a Pivotal Greenplum Database cluster for batch and streaming ETL operations. For information about using the Greenplum-Informatica Connector, refer to the documentation at [https://greenplum-informatica.docs.pivotal.io/](https://greenplum-informatica.docs.pivotal.io/).

The method you choose to load data depends on the characteristics of the source data—its location, size, format, and any transformations required.

In the simplest case, the **COPY** SQL command loads data into a table from a text file that is accessible to the Greenplum Database master instance. This requires no setup and provides good performance for smaller amounts of data. With the **COPY** command, the data copied into or out of the database passes between a single file on the master host and the database. This limits the total size of the dataset to the capacity of the file system where the external file resides and limits the data transfer to a single file write stream.

More efficient data loading options for large datasets take advantage of the Greenplum Database MPP architecture, using the Greenplum Database segments to load data in parallel. These methods allow data
to load simultaneously from multiple file systems, through multiple NICs, on multiple hosts, achieving
very high data transfer rates. External tables allow you to access external files from within the database
as if they are regular database tables. When used with gpfdist, the Greenplum Database parallel file
distribution program, external tables provide full parallelism by using the resources of all Greenplum
Database segments to load or unload data.

Greenplum Database leverages the parallel architecture of the Hadoop Distributed File System to access
files on that system.

### Loading Data Using an External Table

Use SQL commands such as `INSERT` and `SELECT` to query a readable external table, the same way
that you query a regular database table. For example, to load travel expense data from an external table,
extExpenses, into a database table, expenses_travel:

```
=# INSERT INTO expenses_travel
   SELECT * FROM ext_expenses WHERE category='travel';
```

To load all data into a new database table:

```
=# CREATE TABLE expenses AS SELECT * FROM ext_expenses;
```

### Loading and Writing Non-HDFS Custom Data

Greenplum Database supports **TEXT** and **CSV** formats for importing and exporting data through external
tables. You can load and save data in other formats by defining a custom format or custom protocol or by
setting up a transformation with the gpfdist parallel file server.

For information about importing custom data from HDFS, see [Reading and Writing Custom-Formatted
HDFS Data with gphdfs (Deprecated)](#).

### Using a Custom Format

You specify a custom data format in the `FORMAT` clause of `CREATE EXTERNAL TABLE`.

```
FORMAT 'CUSTOM' (formatter=format_function, key1=val1,...keyn=valn)
```

Where the `CUSTOM` keyword indicates that the data has a custom format and `formatter` specifies the
function to use to format the data, followed by comma-separated parameters to the formatter function.

Greenplum Database provides functions for formatting fixed-width data, but you must author the formatter
functions for variable-width data. The steps are as follows.

1. Author and compile input and output functions as a shared library.
2. Specify the shared library function with `CREATE FUNCTION` in Greenplum Database.
3. Use the `formatter` parameter of `CREATE EXTERNAL TABLE`’s `FORMAT` clause to call the function.

### Importing and Exporting Fixed Width Data

Specify custom formats for fixed-width data with the Greenplum Database functions `fixedwidth_in` and
`fixedwidth_out`. These functions already exist in the file `SGHOME/share/postgresql/cdb_external_extensions.sql`. The following example declares a custom format, then calls the
`fixedwidth_in` function to format the data.

```
CREATE READABLE EXTERNAL TABLE students (
   name varchar(20), address varchar(30), age int)
LOCATION ('file://<host>/file/path/')
FORMAT 'CUSTOM' (formatter=fixedwidth_in,
```
The following options specify how to import fixed width data.

- **Read all the data.**

  To load all the fields on a line of fixed with data, you must load them in their physical order. You must specify the field length, but cannot specify a starting and ending position. The fields names in the fixed width arguments must match the order in the field list at the beginning of the `CREATE TABLE` command.

- **Set options for blank and null characters.**

  Trailing blanks are trimmed by default. To keep trailing blanks, use the `preserve_blanks=on` option. You can reset the trailing blanks option to the default with the `preserve_blanks=off` option.

  Use the `null='null_string_value'` option to specify a value for null characters.

  - If you specify `preserve_blanks=on`, you must also define a value for null characters.
  - If you specify `preserve_blanks=off`, null is not defined, and the field contains only blanks, Greenplum writes a null to the table. If null is defined, Greenplum writes an empty string to the table.

  Use the `line_delim='line_ending'` parameter to specify the line ending character. The following examples cover most cases. The `\E` specifies an escape string constant.

  ```
  line_delim=E'\n'
  line_delim=E'\r'
  line_delim=E'\r\n'
  line_delim='abc'
  ```

**Examples: Read Fixed-Width Data**

The following examples show how to read fixed-width data.

**Example 1 – Loading a table with all fields defined**

```sql
CREATE READABLE EXTERNAL TABLE students (    name varchar(20), address varchar(30), age int) LOCATION ('file://<host>/file/path/') FORMAT 'CUSTOM' (formatter=fixedwidth_in, name=20, address=30, age=4);
```

**Example 2 – Loading a table with PRESERVED_BLANKS on**

```sql
CREATE READABLE EXTERNAL TABLE students (    name varchar(20), address varchar(30), age int) LOCATION ('gpfdist://<host>:<portNum>/file/path/') FORMAT 'CUSTOM' (formatter=fixedwidth_in, name=20, address=30, age=4, preserve_blanks='on',null='NULL');
```

**Example 3 – Loading data with no line delimiter**

```sql
CREATE READABLE EXTERNAL TABLE students (    name varchar(20), address varchar(30), age int) LOCATION ('file://<host>/file/path/') FORMAT 'CUSTOM' (formatter=fixedwidth_in, name='20', address='30', age='4', line_delim='?@')
```
Example 4 – Create a writable external table with a \n line delimiter

```
CREATE WRITABLE EXTERNAL TABLE students_out (
  name varchar(20), address varchar(30), age int)
LOCATION ('gpfdist://<host>:<portNum>/file/path/students_out.txt')
FORMAT 'CUSTOM' (formatter=fixedwidth_out,
  name=20, address=30, age=4, line_delim=E'\r\n');
```

Using a Custom Protocol

Greenplum Database provides protocols such as gpfdist, http, and file for accessing data over a network, or you can author a custom protocol. You can use the standard data formats, TEXT and CSV, or a custom data format with custom protocols.

You can create a custom protocol whenever the available built-in protocols do not suffice for a particular need. For example, you could connect Greenplum Database in parallel to another system directly, and stream data from one to the other without the need to materialize the data on disk or use an intermediate process such as gpfdist.

1. Author the send, receive, and (optionally) validator functions in C, with a predefined API. These functions are compiled and registered with the Greenplum Database. For an example custom protocol, see Example Custom Data Access Protocol.

2. After writing and compiling the read and write functions into a shared object (.so), declare a database function that points to the .so file and function names.

   The following examples use the compiled import and export code.

   ```
   CREATE FUNCTION myread() RETURNS integer
   as '$libdir/gpextprotocol.so', 'myprot_import'
   LANGUAGE C STABLE;
   CREATE FUNCTION mywrite() RETURNS integer
   as '$libdir/gpextprotocol.so', 'myprot_export'
   LANGUAGE C STABLE;
   ```

   The format of the optional validator function is:

   ```
   CREATE OR REPLACE FUNCTION myvalidate() RETURNS void
   AS '$libdir/gpextprotocol.so', 'myprot_validate'
   LANGUAGE C STABLE;
   ```

3. Create a protocol that accesses these functions. Validatorfunc is optional.

   ```
   CREATE TRUSTED PROTOCOL myprot(
     writefunc='mywrite',
     readfunc='myread',
     validatorfunc='myvalidate');
   ```

4. Grant access to any other users, as necessary.

   ```
   GRANT ALL ON PROTOCOL myprot TO otheruser;
   ```

5. Use the protocol in readable or writable external tables.

   ```
   CREATE WRITABLE EXTERNAL TABLE ext_sales(LIKE sales)
   LOCATION ('myprot://<meta>/<meta>/...')
   FORMAT 'TEXT';
   CREATE READABLE EXTERNAL TABLE ext_sales(LIKE sales)
   LOCATION('myprot://<meta>/<meta>/...')
   FORMAT 'TEXT';
   ```
Declare custom protocols with the SQL command `CREATE TRUSTED PROTOCOL`, then use the `GRANT` command to grant access to your users. For example:

- Allow a user to create a readable external table with a trusted protocol

  ```sql
  GRANT SELECT ON PROTOCOL <protocol name> TO <user name>;
  ```

- Allow a user to create a writable external table with a trusted protocol

  ```sql
  GRANT INSERT ON PROTOCOL <protocol name> TO <user name>;
  ```

- Allow a user to create readable and writable external tables with a trusted protocol

  ```sql
  GRANT ALL ON PROTOCOL <protocol name> TO <user name>;
  ```

### Handling Load Errors

Readable external tables are most commonly used to select data to load into regular database tables. You use the `CREATE TABLE AS SELECT` or `INSERT INTO` commands to query the external table data. By default, if the data contains an error, the entire command fails and the data is not loaded into the target database table.

The `SEGMENT REJECT LIMIT` clause allows you to isolate format errors in external table data and to continue loading correctly formatted rows. Use `SEGMENT REJECT LIMIT` to set an error threshold, specifying the reject limit count as number of rows (the default) or as a percent of total rows (1-100).

The entire external table operation is aborted, and no rows are processed, if the number of error rows reaches the `SEGMENT REJECT LIMIT`. The limit of error rows is per-segment, not per entire operation. The operation processes all good rows, and it discards and optionally logs formatting errors for erroneous rows, if the number of error rows does not reach the `SEGMENT REJECT LIMIT`.

The `LOG ERRORS` clause allows you to keep error rows for further examination. For information about the `LOG ERRORS` clause, see the `CREATE EXTERNAL TABLE` command in the *Greenplum Database Reference Guide*.

When you set `SEGMENT REJECT LIMIT`, Greenplum scans the external data in single row error isolation mode. Single row error isolation mode applies to external data rows with format errors such as extra or missing attributes, attributes of a wrong data type, or invalid client encoding sequences. Greenplum does not check constraint errors, but you can filter constraint errors by limiting the `SELECT` from an external table at runtime. For example, to eliminate duplicate key errors:

```sql
=# INSERT INTO table_with_pkeys
SELECT DISTINCT * FROM external_table;
```

**Note:** When loading data with the `COPY` command or an external table, the value of the server configuration parameter `gp_initial_bad_row_limit` limits the initial number of rows that are processed that are not formatted properly. The default is to stop processing if the first 1000 rows contain formatting errors. See the *Greenplum Database Reference Guide* for information about the parameter.

### Define an External Table with Single Row Error Isolation

The following example logs errors internally in Greenplum Database and sets an error threshold of 10 errors.

```sql
=# CREATE EXTERNAL TABLE ext_expenses ( name text, date date, amount float4, category text, desc1 text )
LOCATION ('gpfdist://etlhost-1:8081/**',
'gpfdist://etlhost-2:8082/**')
FORMAT 'TEXT' (DELIMITER '|')
```
LOG ERRORS SEGMENT REJECT LIMIT 10 ROWS;

Use the built-in SQL function `gp_read_error_log('external_table')` to read the error log data. This example command displays the log errors for `ext_expenses`:

```
SELECT gp_read_error_log('ext_expenses');
```

For information about the format of the error log, see Viewing Bad Rows in the Error Log.

The built-in SQL function `gp_truncate_error_log('external_table')` deletes the error data. This example deletes the error log data created from the previous external table example:

```
SELECT gp_truncate_error_log('ext_expenses');
```

Capture Row Formatting Errors and Declare a Reject Limit

The following SQL fragment captures formatting errors internally in Greenplum Database and declares a reject limit of 10 rows.

```
LOG ERRORS SEGMENT REJECT LIMIT 10 ROWS
```

Use the built-in SQL function `gp_read_error_log()` to read the error log data. For information about viewing log errors, see Viewing Bad Rows in the Error Log.

Viewing Bad Rows in the Error Log

If you use single row error isolation (see Define an External Table with Single Row Error Isolation or Running COPY in Single Row Error Isolation Mode), any rows with formatting errors are logged internally by Greenplum Database.

Greenplum Database captures the following error information in a table format:

**Table 85: Error Log Format**

<table>
<thead>
<tr>
<th>column</th>
<th>type</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>
<td>cmdtime</td>
<td>timestamptz</td>
<td>Timestamp when the error occurred.</td>
</tr>
<tr>
<td>relname</td>
<td>text</td>
<td>The name of the external table or the target table of a COPY command.</td>
</tr>
<tr>
<td>filename</td>
<td>text</td>
<td>The name of the load file that contains the error.</td>
</tr>
<tr>
<td>linenum</td>
<td>int</td>
<td>If COPY was used, the line number in the load file where the error occurred. For external tables using file:// protocol or gpfdist:// protocol and CSV format, the file name and line number is logged.</td>
</tr>
<tr>
<td>bytenum</td>
<td>int</td>
<td>For external tables with the gpfdist:// protocol and data in TEXT format: the byte offset in the load file where the error occurred. gpfdist parses TEXT files in blocks, so logging a line number is not possible. CSV files are parsed a line at a time so line number tracking is possible for CSV files.</td>
</tr>
<tr>
<td>errmsg</td>
<td>text</td>
<td>The error message text.</td>
</tr>
<tr>
<td>rawdata</td>
<td>text</td>
<td>The raw data of the rejected row.</td>
</tr>
</tbody>
</table>
You can use the Greenplum Database built-in SQL function `gp_read_error_log()` to display formatting errors that are logged internally. For example, this command displays the error log information for the table `ext_expenses`:

```sql
SELECT gp_read_error_log('ext_expenses');
```

For information about managing formatting errors that are logged internally, see the command `COPY` or `CREATE EXTERNAL TABLE` in the Greenplum Database Reference Guide.

### Identifying Invalid CSV Files in Error Table Data

If a CSV file contains invalid formatting, the `rawdata` field in the error table can contain several combined rows. For example, if a closing quote for a specific field is missing, all the following newlines are treated as embedded newlines. When this happens, Greenplum stops parsing a row when it reaches 64K, puts that 64K of data into the error table as a single row, resets the quote flag, and continues. If this happens three times during load processing, the load file is considered invalid and the entire load fails with the message "rejected N or more rows". See Escaping in CSV Formatted Files for more information on the correct use of quotes in CSV files.

### Moving Data between Tables

You can use `CREATE TABLE AS` or `INSERT...SELECT` to load external and external web table data into another (non-external) database table, and the data will be loaded in parallel according to the external or external web table definition.

If an external table file or external web table data source has an error, one of the following will happen, depending on the isolation mode used:

- **Tables without error isolation mode**: any operation that reads from that table fails. Loading from external and external web tables without error isolation mode is an all or nothing operation.
- **Tables with error isolation mode**: the entire file will be loaded, except for the problematic rows (subject to the configured REJECT_LIMIT)

### Loading Data with `gpload`

The Greenplum `gpload` utility loads data using readable external tables and the Greenplum parallel file server (`gpfdist` or `gpfdists`). It handles parallel file-based external table setup and allows users to configure their data format, external table definition, and `gpfdist` or `gpfdists` setup in a single configuration file.

**Note**: `gpfdist` and `gpload` are compatible only with the Greenplum Database major version in which they are shipped. For example, a `gpfdist` utility that is installed with Greenplum Database 4.x cannot be used with Greenplum Database 5.x or 6.x.

**Note**: `MERGE` and `UPDATE` operations are not supported if the target table column name is a reserved keyword, has capital letters, or includes any character that requires quotes (" ") to identify the column.
To use gpload

1. Ensure that your environment is set up to run gpload. Some dependent files from your Greenplum Database installation are required, such as gpdist and Python, as well as network access to the Greenplum segment hosts.

   See the Greenplum Database Reference Guide for details.

2. Create your load control file. This is a YAML-formatted file that specifies the Greenplum Database connection information, gpfdist configuration information, external table options, and data format.

   See the Greenplum Database Reference Guide for details.

   For example:

   ```yaml
   ---
   VERSION: 1.0.0.1
   DATABASE: ops
   USER: gpadmin
   HOST: mdw-1
   PORT: 5432
   GPLOAD:
      INPUT:
         - SOURCE:
           LOCAL_HOSTNAME:
              - etl1-1
              - etl1-2
              - etl1-3
              - etl1-4
           PORT: 8081
           FILE:
              - /var/load/data/*
         - COLUMNS:
           - name: text
           - amount: float4
           - category: text
           - desc: text
           - date: date
         - FORMAT: text
         - DELIMITER: '|'
         - ERROR_LIMIT: 25
         - LOG_ERRORS: true
      OUTPUT:
         - TABLE: payables.expenses
         - MODE: INSERT
         - REUSE_TABLES: true
      SQL:
         - BEFORE: "INSERT INTO audit VALUES('start', current_timestamp)"
         - AFTER: "INSERT INTO audit VALUES('end', current_timestamp)"
   ```

3. Run gpload, passing in the load control file. For example:

   `gpload -f my_load.yml`

Accessing External Data with PXF

Data managed by your organization may already reside in external sources. The Greenplum Platform Extension Framework (PXF) provides access to this external data via built-in connectors that map an external data source to a Greenplum Database table definition.

PXF is installed with Hadoop and Object Store connectors. These connectors enable you to read external data stored in text, Avro, JSON, RCFile, Parquet, SequenceFile, and ORC formats. You can use the JDBC connector to access an external SQL database.
Note: PXF supports filter pushdown in the Hive, HBase, and JDBC connectors.

The Greenplum Platform Extension Framework includes a protocol C library and a Java service. After you configure and initialize PXF, you start a single PXF JVM process on each Greenplum Database segment host. This long-running process concurrently serves multiple query requests.

For detailed information about the architecture of and using PXF, refer to the Greenplum Platform Extension Framework (PXF) documentation.

Transforming External Data with gpfdist and gpload

The gpfdist parallel file server allows you to set up transformations that enable Greenplum Database external tables to read and write files in formats that are not supported with the CREATE EXTERNAL TABLE command's FORMAT clause. An input transformation reads a file in the foreign data format and outputs rows to gpfdist in the CSV or other text format specified in the external table's FORMAT clause. An output transformation receives rows from gpfdist in text format and converts them to the foreign data format.

Note: gpfdist and gpload are compatible only with the Greenplum Database major version in which they are shipped. For example, a gpfdist utility that is installed with Greenplum Database 4.x cannot be used with Greenplum Database 5.x or 6.x.

This topic describes the tasks to set up data transformations that work with gpfdist to read or write external data files with formats that Greenplum Database does not support.

- About gpfdist Transformations
- Determine the Transformation Schema
- Write a Transformation
- Write the gpfdist Configuration File
- Transfer the Data
- Configuration File Format
- XML Transformation Examples

About gpfdist Transformations

To set up a transformation for a data format, you provide an executable command that gpfdist can call with the name of the file containing data. For example, you could write a shell script that runs an XSLT transformation on an XML file to output rows with columns delimited with a vertical bar (|) character and rows delimited with linefeeds.

Transformations are configured in a YAML-formatted configuration file passed to gpfdist on the command line.

If you want to load the external data into a table in the Greenplum database, you can use the gpload utility to automate the tasks to create an external table, run gpfdist, and load the transformed data into the database table.

Accessing data in external XML files from within the database is a common example requiring transformation. The following diagram shows gpfdist performing a transformation on XML files on an ETL server.
Figure 30: External Tables using XML Transformations

Following are the high-level steps to set up a *gpfdist* transformation for external data files. The process is illustrated with an XML example.

1. **Determine the transformation schema.**
2. **Write a transformation.**
3. **Write the gpfdist configuration file.**
4. **Transfer the data.**

**Determine the Transformation Schema**

To prepare for the transformation project:

1. Determine the goal of the project, such as indexing data, analyzing data, combining data, and so on.
2. Examine the source files and note the file structure and element names.
3. Choose the elements to import and decide if any other limits are appropriate.

For example, the following XML file, *prices.xml*, is a simple XML file that contains price records. Each price record contains two fields: an item number and a price.

```xml
<?xml version="1.0" encoding="ISO-8859-1" ?>
<prices>
  <pricerecord>
    <itemnumber>708421</itemnumber>
    <price>19.99</price>
  </pricerecord>
  <pricerecord>
    <itemnumber>708466</itemnumber>
    <price>59.25</price>
  </pricerecord>
  <pricerecord>
    <itemnumber>711121</itemnumber>
    <price>24.99</price>
  </pricerecord>
</prices>
```
The goal of this transformation is to import all the data into a Greenplum Database readable external table with an integer `itemnumber` column and a decimal `price` column.

### Write a Transformation

The transformation specifies what to extract from the data. You can use any authoring environment and language appropriate for your project. For XML transformations choose from technologies such as XSLT, Joost (STX), Java, Python, or Perl, based on the goals and scope of the project.

In the price example, the next step is to transform the XML data into a two-column delimited text format.

<table>
<thead>
<tr>
<th>Item Number</th>
<th>Price</th>
</tr>
</thead>
<tbody>
<tr>
<td>708421</td>
<td>19.99</td>
</tr>
<tr>
<td>708466</td>
<td>59.25</td>
</tr>
<tr>
<td>711121</td>
<td>24.99</td>
</tr>
</tbody>
</table>

The following STX transform, called `input_transform.stx`, performs the data transformation.

```xml
<?xml version="1.0"?>
<stx:transform version="1.0" xmlns:stx="http://stx.sourceforge.net/2002/ns" pass-through="none">
<!-- declare variables -->
<stx:variable name="itemnumber"/>
<stx:variable name="price"/>
<!-- match and output prices as columns delimited by | -->
<stx:template match="/prices/pricerecord">
  <stx:process-children/>
  <stx:value-of select="$itemnumber"/>
  <stx:text>|</stx:text>
  <stx:value-of select="$price" />
</stx:template>
</stx:transform>
```

This STX transform declares two temporary variables, `itemnumber` and `price`, and the following rules.

1. When an element that satisfies the XPath expression `/prices/pricerecord` is found, examine the child elements and generate output that contains the value of the `itemnumber` variable, a `|` character, the value of the `price` variable, and a newline.
2. When an `<itemnumber>` element is found, store the content of that element in the variable `itemnumber`.
3. When a `<price>` element is found, store the content of that element in the variable `price`.

### Write the gpfdist Configuration File

The `gpfdist` configuration is specified as a YAML 1.1 document. It contains rules that `gpfdist` uses to select a transformation to apply when loading or extracting data.

This example `gpfdist` configuration contains the following items that are required for the `prices.xml` transformation scenario:

- the `config.yaml` file defining `TRANSFORMATIONS`
- the `input_transform.sh` wrapper script, referenced in the `config.yaml` file
- the `input_transform.stx` joost transformation, called from `input_transform.sh`
Aside from the ordinary YAML rules, such as starting the document with three dashes (---), a gpfdist configuration must conform to the following restrictions:

1. A VERSION setting must be present with the value 1.0.0.1.
2. A TRANSFORMATIONS setting must be present and contain one or more mappings.
3. Each mapping in the TRANSFORMATION must contain:
   - a TYPE with the value 'input' or 'output'
   - a COMMAND indicating how the transformation is run.
4. Each mapping in the TRANSFORMATION can contain optional CONTENT, SAFE, and STDERR settings.

The following gpfdist configuration, called config.yaml, applies to the prices example. The initial indentation on each line is significant and reflects the hierarchical nature of the specification. The transformation name prices_input in the following example will be referenced later when creating the table in SQL.

```yaml
---
VERSION: 1.0.0.1
TRANSFORMATIONS:
  prices_input:
    TYPE:     input
    COMMAND:  /bin/bash input_transform.sh %filename%
```

The COMMAND setting uses a wrapper script called input_transform.sh with a %filename% placeholder. When gpfdist runs the prices_input transform, it invokes input_transform.sh with /bin/bash and replaces the %filename% placeholder with the path to the input file to transform. The wrapper script called input_transform.sh contains the logic to invoke the STX transformation and return the output.

If Joost is used, the Joost STX engine must be installed.

```bash
#!/bin/bash
# input_transform.sh - sample input transformation,
# demonstrating use of Java and Joost STX to convert XML into
# text to load into Greenplum Database.
# java arguments:
#   -jar joost.jar     joost STX engine
#   -nodecl            don't generate a <?xml?> declaration
#   $1                  filename to process
#   input_transform.stx the STX transformation
#
# the AWK step eliminates a blank line joost emits at the end
java -jar joost.jar -nodecl $1 input_transform.stx \
| awk 'NF>0'
```

The input_transform.sh file uses the Joost STX engine with the AWK interpreter. The following diagram shows the process flow as gpfdist runs the transformation.
Transfer the Data

Create the target database tables with SQL statements based on the appropriate schema.

There are no special requirements for Greenplum Database tables that hold loaded data. In the prices example, the following command creates the `prices` table, where the data is to be loaded.

```sql
CREATE TABLE prices (
    itemnumber integer,
    price       decimal
) DISTRIBUTED BY (itemnumber);
```

Next, use one of the following approaches to transform the data with `gpfdist`.

- `gpload` supports only input transformations, but in many cases is easier to implement.
- `gpfdist` with `INSERT INTO SELECT FROM` supports both input and output transformations, but exposes details that `gpload` automates for you.

### Transforming with gpload

The Greenplum Database `gpload` utility orchestrates a data load operation using the `gpfdist` parallel file server and a YAML-formatted configuration file. `gpload` automates these tasks:

- Creates a readable external table in the database.
- Starts `gpfdist` instances with the configuration file that contains the transformation.
- Runs `INSERT INTO table_name SELECT FROM external_table` to load the data.
- Removes the external table definition.

Transforming data with `gpload` requires that the settings `TRANSFORM` and `TRANSFORM_CONFIG` appear in the `INPUT` section of the `gpload` control file.

For more information about the syntax and placement of these settings in the `gpload` control file, see the Greenplum Database Reference Guide.

- `TRANSFORM_CONFIG` specifies the name of the `gpfdist` configuration file.
- The `TRANSFORM` setting indicates the name of the transformation that is described in the file named in `TRANSFORM_CONFIG`. 
USER: gpadmin
GPLOAD:
  INPUT:
    - TRANSFORM_CONFIG: config.yaml
    - TRANSFORM: prices_input
    - SOURCE:
      FILE: prices.xml

The transformation name must appear in two places: in the TRANSFORM setting of the gpfdist configuration file and in the TRANSFORMATIONS section of the file named in the TRANSFORM_CONFIG section.

In the gpload control file, the optional parameter MAX_LINE_LENGTH specifies the maximum length of a line in the XML transformation data that is passed to gpload.

The following diagram shows the relationships between the gpload control file, the gpfdist configuration file, and the XML data file.

---

Transforming with gpfdist and INSERT INTO SELECT FROM

With this load method, you perform each of the tasks that gpload automates. You start gpfdist, create an external table, load the data, and clean up by dropping the table and stopping gpfdist.

Specify the transformation in the CREATE EXTERNAL TABLE definition's LOCATION clause. For example, the transform is shown in bold in the following command. (Run gpfdist first, using the command gpfdist -c config.yaml).

```
CREATE READABLE EXTERNAL TABLE prices_readable (LIKE prices)
    LOCATION ('gpfdist://hostname:8080/prices.xml#transform=prices_input')
    FORMAT 'TEXT' (DELIMITER '|')
    LOG ERRORS SEGMENT REJECT LIMIT 10;
```

In the command above, change hostname to your hostname. prices_input comes from the gpfdist configuration file.
The following query then loads the data into the **prices** table.

```
INSERT INTO prices SELECT * FROM prices_readable;
```

**Configuration File Format**

The **gpfdist** configuration file uses the YAML 1.1 document format and implements a schema for defining the transformation parameters. The configuration file must be a valid YAML document.

The **gpfdist** program processes the document in order and uses indentation (spaces) to determine the document hierarchy and relationships of the sections to one another. The use of white space is significant. Do not use white space for formatting and do not use tabs.

The following is the basic structure of a configuration file.

```yaml
---
VERSION:   1.0.0.1
TRANSFORMATIONS:
  transformation_name1:
    TYPE:      input | output
    COMMAND:   command
    CONTENT:   data | paths
    SAFE:      posix-regex
    STDERR:    server | console
  transformation_name2:
    TYPE:      input | output
    COMMAND:   command
...```

**VERSION**

Required. The version of the **gpfdist** configuration file schema. The current version is 1.0.0.1.

**TRANSFORMATIONS**

Required. Begins the transformation specification section. A configuration file must have at least one transformation. When **gpfdist** receives a transformation request, it looks in this section for an entry with the matching transformation name.

**TYPE**

Required. Specifies the direction of transformation. Values are **input** or **output**.

- **input**: **gpfdist** treats the standard output of the transformation process as a stream of records to load into Greenplum Database.
- **output**: **gpfdist** treats the standard input of the transformation process as a stream of records from Greenplum Database to transform and write to the appropriate output.

**COMMAND**

Required. Specifies the command **gpfdist** will execute to perform the transformation.

For input transformations, **gpfdist** invokes the command specified in the **CONTENT** setting. The command is expected to open the underlying file(s) as appropriate and produce one line of **TEXT** for each row to load into Greenplum Database. The input transform determines whether the entire content should be converted to one row or to multiple rows.

For output transformations, **gpfdist** invokes this command as specified in the **CONTENT** setting. The output command is expected to open and write to the underlying file(s) as appropriate. The output transformation determines the final placement of the converted output.

**CONTENT**
Optional. The values are data and paths. The default value is data.

- When CONTENT specifies data, the text %filename% in the COMMAND section is replaced by the path to the file to read or write.
- When CONTENT specifies paths, the text %filename% in the COMMAND section is replaced by the path to the temporary file that contains the list of files to read or write.

The following is an example of a COMMAND section showing the text %filename% that is replaced.

```
COMMAND: /bin/bash input_transform.sh %filename%
```

**SAFE**

Optional. A POSIX regular expression that the paths must match to be passed to the transformation. Specify SAFE when there is a concern about injection or improper interpretation of paths passed to the command. The default is no restriction on paths.

**STDERR**

Optional. The values are server and console.

This setting specifies how to handle standard error output from the transformation. The default, server, specifies that gpfdist will capture the standard error output from the transformation in a temporary file and send the first 8k of that file to Greenplum Database as an error message. The error message will appear as an SQL error. Console specifies that gpfdist does not redirect or transmit the standard error output from the transformation.

**XML Transformation Examples**

The following examples demonstrate the complete process for different types of XML data and STX transformations. Files and detailed instructions associated with these examples are in the GitHub repo github.com://greenplum-db/gpdb in the gpMgmt/demo/gpfdist_transform directory. Read the README file in the Before You Begin section before you run the examples. The README file explains how to download the example data file used in the examples.

**Command-based External Web Tables**

The output of a shell command or script defines command-based web table data. Specify the command in the EXECUTE clause of CREATE EXTERNAL WEB TABLE. The data is current as of the time the command runs. The EXECUTE clause runs the shell command or script on the specified master, and/or segment host or hosts. The command or script must reside on the hosts corresponding to the host(s) defined in the EXECUTE clause.

By default, the command is run on segment hosts when active segments have output rows to process. For example, if each segment host runs four primary segment instances that have output rows to process, the command runs four times per segment host. You can optionally limit the number of segment instances that execute the web table command. All segments included in the web table definition in the ON clause run the command in parallel.

The command that you specify in the external table definition executes from the database and cannot access environment variables from .bashrc or .profile. Set environment variables in the EXECUTE clause. For example:

```
=# CREATE EXTERNAL WEB TABLE output (output text)
  EXECUTE 'PATH=/home/gpadmin/programs; export PATH; myprogram.sh'
  FORMAT 'TEXT';
```

Scripts must be executable by the gpadmin user and reside in the same location on the master or segment hosts.
The following command defines a web table that runs a script. The script runs on each segment host where a segment has output rows to process.

```sql
# CREATE EXTERNAL WEB TABLE log_output
  (linenum int, message text)
EXECUTE '/var/load_scripts/get_log_data.sh' ON HOST
FORMAT 'TEXT' (DELIMITER '|');
```

**IRS MeF XML Files (In demo Directory)**

This example demonstrates loading a sample IRS Modernized eFile tax return using a Joost STX transformation. The data is in the form of a complex XML file.

The U.S. Internal Revenue Service (IRS) made a significant commitment to XML and specifies its use in its Modernized e-File (MeF) system. In MeF, each tax return is an XML document with a deep hierarchical structure that closely reflects the particular form of the underlying tax code.

XML, XML Schema and stylesheets play a role in their data representation and business workflow. The actual XML data is extracted from a ZIP file attached to a MIME "transmission file" message. For more information about MeF, see [Modernized e-File (Overview)] on the IRS web site.

The sample XML document, `RET990EZ_2006.xml`, is about 350KB in size with two elements:

- ReturnHeader
- ReturnData

The `<ReturnHeader>` element contains general details about the tax return such as the taxpayer's name, the tax year of the return, and the preparer. The `<ReturnData>` element contains multiple sections with specific details about the tax return and associated schedules.

The following is an abridged sample of the XML file.

```xml
<?xml version="1.0" encoding="UTF-8"?>
<Return returnVersion="2006v2.0"
  xmlns="https://www.irs.gov/efile"
  xmlns:efile="https://www.irs.gov/efile"
  xsi:schemaLocation="https://www.irs.gov/efile"
  xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance">
  <ReturnHeader binaryAttachmentCount="1">
    <ReturnId>AAAAAAAAAAAAAAAAAAAA</ReturnId>
    <Timestamp>1999-05-30T12:01:01+05:01</Timestamp>
    <ReturnType>990EZ</ReturnType>
    <TaxPeriodBeginDate>2005-01-01</TaxPeriodBeginDate>
    <TaxPeriodEndDate>2005-12-31</TaxPeriodEndDate>
    <Filer>
      <EIN>011248772</EIN>
      ... more data ...
    </Filer>
    <Preparer>
      <Name>Percy Polar</Name>
      ... more data ...
    </Preparer>
    <TaxYear>2005</TaxYear>
  </ReturnHeader>
  ... more data ...
</Return>
```

The goal is to import all the data into a Greenplum database. First, convert the XML document into text with newlines "escaped", with two columns: `ReturnId` and a single column on the end for the entire MeF tax return. For example:

```
AAAAAAAAAAAAAAAAAAAAAAA|<Return returnVersion="2006v2.0"...
```
Load the data into Greenplum Database.

**WITSML™ Files (In demo Directory)**

This example demonstrates loading sample data describing an oil rig using a Joost STX transformation. The data is in the form of a complex XML file downloaded from energistics.org.

The Wellsite Information Transfer Standard Markup Language (WITSML™) is an oil industry initiative to provide open, non-proprietary, standard interfaces for technology and software to share information among oil companies, service companies, drilling contractors, application vendors, and regulatory agencies. For more information about WITSML™, see [http://www.energistics.org/](http://www.energistics.org/).

The oil rig information consists of a top level `<rigs>` element with multiple child elements such as `<documentInfo>`, `<rig>`, and so on. The following excerpt from the file shows the type of information in the `<rig>` tag.

```xml
<?xml version="1.0" encoding="UTF-8"?>
<?xml-stylesheet href="../stylesheets/rig.xsl" type="text/xsl" media="screen"?>
<rigs
   xmlns="http://www.energistics.org/schemas/131"
   xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
   xsi:schemaLocation="http://www.energistics.org/schemas/131 ../obj_rig.xsd"
   version="1.3.1.1">
   <documentInfo>
   ... misc data ...
</documentInfo>
<rigs
   uidWell="W-12" uidWellbore="B-01" uid="xr31">
   <nameWell>6507/7-A-42</nameWell>
   <nameWellbore>A-42</nameWellbore>
   <name>Deep Drill #5</name>
   <owner>Deep Drilling Co.</owner>
   <typeRig>floater</typeRig>
   <manufacturer>Fitsui Engineering</manufacturer>
   <yearEntService>1980</yearEntService>
   <classRig>ABS Class A1 M CSDU AMS ACCU</classRig>
   <approvals>DNV</approvals>
   ... more data ...
</rigs>
```

The goal is to import the information for this rig into Greenplum Database.

The sample document, `rig.xml`, is about 11KB in size. The input does not contain tabs so the relevant information can be converted into records delimited with a pipe (|).

W-12|6507/7-A-42|xr31|Deep Drill #5|Deep Drilling Co.|John Doe|John.Doe@example.com|

With the columns:

- well_uid text, -- e.g. W-12
- well_name text, -- e.g. 6507/7-A-42
- rig_uid text, -- e.g. xr31
- rig_name text, -- e.g. Deep Drill #5
- rig_owner text, -- e.g. Deep Drilling Co.
- rig_contact text, -- e.g. John Doe
- rig_email text, -- e.g. John.Doe@example.com
- doc xml

Then, load the data into Greenplum Database.
Loading Data with COPY

COPY FROM copies data from a file or standard input into a table and appends the data to the table contents. COPY is non-parallel: data is loaded in a single process using the Greenplum master instance. Using COPY is only recommended for very small data files.

The COPY source file must be accessible to the master host. Specify the COPY source file name relative to the master host location.

Greenplum copies data from STDIN or STDOUT using the connection between the client and the master server.

Running COPY in Single Row Error Isolation Mode

By default, COPY stops an operation at the first error: if the data contains an error, the operation fails and no data loads. If you run COPY FROM in single row error isolation mode, Greenplum skips rows that contain format errors and loads properly formatted rows. Single row error isolation mode applies only to rows in the input file that contain format errors. If the data contains a constraint error such as violation of a NOT NULL, CHECK, or UNIQUE constraint, the operation fails and no data loads.

Specifying SEGMENT REJECT LIMIT runs the COPY operation in single row error isolation mode. Specify the acceptable number of error rows on each segment, after which the entire COPY FROM operation fails and no rows load. The error row count is for each Greenplum Database segment, not for the entire load operation.

If the COPY operation does not reach the error limit, Greenplum loads all correctly-formatted rows and discards the error rows. Use the LOG ERRORS clause to capture data formatting errors internally in Greenplum Database. For example:

```sql
=> COPY country FROM '/data/gpdb/country_data' 
   WITH DELIMITER '|' LOG ERRORS 
   SEGMENT REJECT LIMIT 10 ROWS;
```

See Viewing Bad Rows in the Error Log for information about investigating error rows.

Optimizing Data Load and Query Performance

Use the following tips to help optimize your data load and subsequent query performance.

- Drop indexes before loading data into existing tables.
  Creating an index on pre-existing data is faster than updating it incrementally as each row is loaded. You can temporarily increase the maintenance_work_mem server configuration parameter to help speed up CREATE INDEX commands, though load performance is affected. Drop and recreate indexes only when there are no active users on the system.

- Create indexes last when loading data into new tables. Create the table, load the data, and create any required indexes.

- Run ANALYZE after loading data. If you significantly altered the data in a table, run ANALYZE or VACUUM ANALYZE to update table statistics for the query optimizer. Current statistics ensure that the optimizer makes the best decisions during query planning and avoids poor performance due to inaccurate or nonexistent statistics.

- Run VACUUM after load errors. If the load operation does not run in single row error isolation mode, the operation stops at the first error. The target table contains the rows loaded before the error occurred. You cannot access these rows, but they occupy disk space. Use the VACUUM command to recover the wasted space.
Unloading Data from Greenplum Database

A writable external table allows you to select rows from other database tables and output the rows to files, named pipes, to applications, or as output targets for Greenplum parallel MapReduce calculations. You can define file-based and web-based writable external tables.

This topic describes how to unload data from Greenplum Database using parallel unload (writable external tables) and non-parallel unload (COPY).

Defining a File-Based Writable External Table

Writable external tables that output data to files use the Greenplum parallel file server program, gpfdist, or the Hadoop Distributed File System interface, gphdfs (deprecated).

Use the CREATE WRITABLE EXTERNAL TABLE command to define the external table and specify the location and format of the output files. See Using the Greenplum Parallel File Server (gpfdist) for instructions on setting up gpfdist for use with an external table and Accessing HDFS Data with gphdfs (Deprecated) for instructions on setting up gphdfs for use with an external table.

• With a writable external table using the gpfdist protocol, the Greenplum segments send their data to gpfdist, which writes the data to the named file. gpfdist must run on a host that the Greenplum segments can access over the network. gpfdist points to a file location on the output host and writes data received from the Greenplum segments to the file. To divide the output data among multiple files, list multiple gpfdist URIs in your writable external table definition.

• A writable external web table sends data to an application as a stream of data. For example, unload data from Greenplum Database and send it to an application that connects to another database or ETL tool to load the data elsewhere. Writable external web tables use the EXECUTE clause to specify a shell command, script, or application to run on the segment hosts and accept an input stream of data. See Defining a Command-Based Writable External Web Table for more information about using EXECUTE commands in a writable external table definition.

You can optionally declare a distribution policy for your writable external tables. By default, writable external tables use a random distribution policy. If the source table you are exporting data from has a hash distribution policy, defining the same distribution key column(s) for the writable external table improves unload performance by eliminating the requirement to move rows over the interconnect. If you unload data from a particular table, you can use the LIKE clause to copy the column definitions and distribution policy from the source table.

Example 1—Greenplum file server (gpfdist)

```sql
=# CREATE WRITABLE EXTERNAL TABLE unload_expenses  
   ( LIKE expenses )  
   LOCATION ('gpfdist://etlhost-1:8081/expenses1.out', 
              'gpfdist://etlhost-2:8081/expenses2.out')  
   FORMAT 'TEXT' (DELIMITER ',')  
   DISTRIBUTED BY (exp_id);
```

Example 2—Hadoop file server (gphdfs (Deprecated))

```sql
=# CREATE WRITABLE EXTERNAL TABLE unload_expenses  
   ( LIKE expenses )  
   LOCATION ('gphdfs://hdfs1host-1:8081/path')  
   FORMAT 'TEXT' (DELIMITER ',')  
   DISTRIBUTED BY (exp_id);
```

You can only specify a directory for a writable external table with the gphdfs protocol. (You can only specify one file for a readable external table with the gphdfs protocol)
Note: The default port number is 9000.

Defining a Command-Based Writable External Web Table

You can define writable external web tables to send output rows to an application or script. The application must accept an input stream, reside in the same location on all of the Greenplum segment hosts, and be executable by the gpadmin user. All segments in the Greenplum system run the application or script, whether or not a segment has output rows to process.

Use `CREATE WRITABLE EXTERNAL WEB TABLE` to define the external table and specify the application or script to run on the segment hosts. Commands execute from within the database and cannot access environment variables (such as `$PATH`). Set environment variables in the `EXECUTE` clause of your writable external table definition. For example:

```sql
=# CREATE WRITABLE EXTERNAL WEB TABLE output (output text)
   EXECUTE 'export PATH=SPATH:/home/gpadmin
           /programs;
           myprogram.sh'
   FORMAT 'TEXT'
   DISTRIBUTED RANDOMLY;
```

The following Greenplum Database variables are available for use in OS commands executed by a web or writable external table. Set these variables as environment variables in the shell that executes the command(s). They can be used to identify a set of requests made by an external table statement across the Greenplum Database array of hosts and segment instances.

Table 86: External Table EXECUTE Variables

<table>
<thead>
<tr>
<th>Variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>$GP_CID</td>
<td>Command count of the transaction executing the external table statement.</td>
</tr>
<tr>
<td>$GP_DATABASE</td>
<td>The database in which the external table definition resides.</td>
</tr>
<tr>
<td>$GP_DATE</td>
<td>The date on which the external table command ran.</td>
</tr>
<tr>
<td>$GP_MASTER_HOST</td>
<td>The host name of the Greenplum master host from which the external table</td>
</tr>
<tr>
<td></td>
<td>statement was dispatched.</td>
</tr>
<tr>
<td>$GP_MASTER_PORT</td>
<td>The port number of the Greenplum master instance from which the external</td>
</tr>
<tr>
<td></td>
<td>table statement was dispatched.</td>
</tr>
<tr>
<td>$GP_QUERY_STRING</td>
<td>The SQL command (DML or SQL query) executed by Greenplum Database.</td>
</tr>
<tr>
<td>$GP_SEG_DATADIR</td>
<td>The location of the data directory of the segment instance executing the</td>
</tr>
<tr>
<td></td>
<td>external table command.</td>
</tr>
<tr>
<td>$GP_SEG_PG_CONF</td>
<td>The location of the <code>postgresql.conf</code> file of the segment instance executing</td>
</tr>
<tr>
<td></td>
<td>the external table command.</td>
</tr>
<tr>
<td>$GP_SEG_PORT</td>
<td>The port number of the segment instance executing the external table command.</td>
</tr>
<tr>
<td>$GP_SEGMENT_COUNT</td>
<td>The total number of primary segment instances in the Greenplum Database</td>
</tr>
<tr>
<td>$GP_SEGMENT_ID</td>
<td>The ID number of the segment instance executing the external table command</td>
</tr>
<tr>
<td></td>
<td>(same as <code>dbid</code> in <code>gp_segment_configuration</code>).</td>
</tr>
<tr>
<td>Variable</td>
<td>Description</td>
</tr>
<tr>
<td>---------------</td>
<td>----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>$GP_SESSION_ID</td>
<td>The database session identifier number associated with the external table statement.</td>
</tr>
<tr>
<td>$GP_SN</td>
<td>Serial number of the external table scan node in the query plan of the external table statement.</td>
</tr>
<tr>
<td>$GP_TIME</td>
<td>The time the external table command was executed.</td>
</tr>
<tr>
<td>$GP_USER</td>
<td>The database user executing the external table statement.</td>
</tr>
<tr>
<td>$GP_XID</td>
<td>The transaction ID of the external table statement.</td>
</tr>
</tbody>
</table>

**Disabling EXECUTE for Web or Writable External Tables**

There is a security risk associated with allowing external tables to execute OS commands or scripts. To disable the use of `EXECUTE` in web and writable external table definitions, set the `gp_external_enable_exec` server configuration parameter to `off` in your master `postgresql.conf` file:

```
gp_external_enable_exec = off
```

**Unloading Data Using a Writable External Table**

Writable external tables allow only `INSERT` operations. You must grant `INSERT` permission on a table to enable access to users who are not the table owner or a superuser. For example:

```
GRANT INSERT ON writable_ext_table TO admin;
```

To unload data using a writable external table, select the data from the source table(s) and insert it into the writable external table. The resulting rows are output to the writable external table. For example:

```
INSERT INTO writable_ext_table SELECT * FROM regular_table;
```

**Unloading Data Using COPY**

`COPY TO` copies data from a table to a file (or standard input) on the Greenplum master host using a single process on the Greenplum master instance. Use `COPY` to output a table's entire contents, or filter the output using a `SELECT` statement. For example:

```
COPY (SELECT * FROM country WHERE country_name LIKE 'A%')
TO '/home/gpadmin/a_list_countries.out';
```

**Formatting Data Files**

When you use the Greenplum tools for loading and unloading data, you must specify how your data is formatted. `COPY`, `CREATE EXTERNAL TABLE`, and `gpload` have clauses that allow you to specify how your data is formatted. Data can be delimited text (`TEXT`) or comma separated values (`CSV`) format. External data must be formatted correctly to be read by Greenplum Database. This topic explains the format of data files expected by Greenplum Database.

**Formatting Rows**

Greenplum Database expects rows of data to be separated by the `LF` character (Line feed, 0x0A), `CR` (Carriage return, 0x0D), or `CR` followed by `LF` (`CR+LF`, 0x0D 0x0A). LF is the standard newline representation on UNIX or UNIX-like operating systems. Operating systems such as Windows or Mac OS
X use CR or CR+LF. All of these representations of a newline are supported by Greenplum Database as a row delimiter. For more information, see *Importing and Exporting Fixed Width Data*.

### Formatting Columns

The default column or field delimiter is the horizontal TAB character (0x09) for text files and the comma character (0x2C) for CSV files. You can declare a single character delimiter using the `DELIMITER` clause of `COPY`, `CREATE EXTERNAL TABLE` or `gpload` when you define your data format. The delimiter character must appear between any two data value fields. Do not place a delimiter at the beginning or end of a row. For example, if the pipe character ( | ) is your delimiter:

```
data value 1|data value 2|data value 3
```

The following command shows the use of the pipe character as a column delimiter:

```
=# CREATE EXTERNAL TABLE ext_table (name text, date date)
LOCATION ('gpfdist://<hostname>/filename.txt')
FORMAT 'TEXT' (DELIMITER '|');
```

### Representing NULL Values

`NULL` represents an unknown piece of data in a column or field. Within your data files you can designate a string to represent null values. The default string is `\N` (backslash-N) in TEXT mode, or an empty value with no quotations in CSV mode. You can also declare a different string using the `NULL` clause of `COPY`, `CREATE EXTERNAL TABLE` or `gpload` when defining your data format. For example, you can use an empty string if you do not want to distinguish nulls from empty strings. When using the Greenplum Database loading tools, any data item that matches the designated null string is considered a null value.

### Escaping

There are two reserved characters that have special meaning to Greenplum Database:

- The designated delimiter character separates columns or fields in the data file.
- The newline character designates a new row in the data file.

If your data contains either of these characters, you must escape the character so that Greenplum treats it as data and not as a field separator or new row. By default, the escape character is a \ (backslash) for text-formatted files and a double quote (") for csv-formatted files.

#### Escaping in Text Formatted Files

By default, the escape character is a \ (backslash) for text-formatted files. You can declare a different escape character in the `ESCAPE` clause of `COPY`, `CREATE EXTERNAL TABLE` or `gpload`. If your escape character appears in your data, use it to escape itself.

For example, suppose you have a table with three columns and you want to load the following three fields:

- `backslash = \`
- `vertical bar = |`
- `exclamation point = !`

Your designated delimiter character is | (pipe character), and your designated escape character is \ (backslash). The formatted row in your data file looks like this:

```
backslash = \\ | vertical bar = || | exclamation point = !
```

Notice how the backslash character that is part of the data is escaped with another backslash character, and the pipe character that is part of the data is escaped with a backslash character.
You can use the escape character to escape octal and hexadecimal sequences. The escaped value is converted to the equivalent character when loaded into Greenplum Database. For example, to load the ampersand character (&), use the escape character to escape its equivalent hexadecimal (\x26) or octal (\046) representation.

You can disable escaping in TEXT-formatted files using the ESCAPE clause of COPY, CREATE EXTERNAL TABLE or gpload as follows:

```
ESCAPE 'OFF'
```

This is useful for input data that contains many backslash characters, such as web log data.

**Escaping in CSV Formatted Files**

By default, the escape character is a " (double quote) for CSV-formatted files. If you want to use a different escape character, use the ESCAPE clause of COPY, CREATE EXTERNAL TABLE or gpload to declare a different escape character. In cases where your selected escape character is present in your data, you can use it to escape itself.

For example, suppose you have a table with three columns and you want to load the following three fields:

- Free trip to A,B
- 5.89
- Special rate "1.79"

Your designated delimiter character is , (comma), and your designated escape character is " (double quote). The formatted row in your data file looks like this:

```
"Free trip to A,B","5.89","Special rate "1.79"
```

The data value with a comma character that is part of the data is enclosed in double quotes. The double quotes that are part of the data are escaped with a double quote even though the field value is enclosed in double quotes.

Embedding the entire field inside a set of double quotes guarantees preservation of leading and trailing whitespace characters:

```
"Free trip to A,B","5.89","Special rate "1.79"
```

**Note:** In CSV mode, all characters are significant. A quoted value surrounded by white space, or any characters other than DELIMITER, includes those characters. This can cause errors if you import data from a system that pads CSV lines with white space to some fixed width. In this case, preprocess the CSV file to remove the trailing white space before importing the data into Greenplum Database.

**Character Encoding**

Character encoding systems consist of a code that pairs each character from a character set with something else, such as a sequence of numbers or octets, to facilitate data transmission and storage. Greenplum Database supports a variety of character sets, including single-byte character sets such as the ISO 8859 series and multiple-byte character sets such as EUC (Extended UNIX Code), UTF-8, and Mule internal code. The server-side character set is defined during database initialization, UTF-8 is the default and can be changed. Clients can use all supported character sets transparently, but a few are not supported for use within the server as a server-side encoding. When loading or inserting data into Greenplum Database, Greenplum transparently converts the data from the specified client encoding into the server encoding. When sending data back to the client, Greenplum converts the data from the server character encoding into the specified client encoding.
Data files must be in a character encoding recognized by Greenplum Database. See the Greenplum Database Reference Guide for the supported character sets. Data files that contain invalid or unsupported encoding sequences encounter errors when loading into Greenplum Database.

**Note:** On data files generated on a Microsoft Windows operating system, run the `dos2unix` system command to remove any Windows-only characters before loading into Greenplum Database.

**Note:** If you change the ENCODING value in an existing gpload control file, you must manually drop any external tables that were creating using the previous ENCODING configuration. gpload does not drop and recreate external tables to use the new ENCODING if REUSE_TABLES is set to true.

### Changing the Client-Side Character Encoding

The client-side character encoding can be changed for a session by setting the server configuration parameter `client_encoding`

```
SET client_encoding TO 'latin1';
```

Change the client-side character encoding back to the default value:

```
RESET client_encoding;
```

Show the current client-side character encoding setting:

```
SHOW client_encoding;
```

### Example Custom Data Access Protocol

The following is the API for the Greenplum Database custom data access protocol. The example protocol implementation `gpextprotocol.c` is written in C and shows how the API can be used. For information about accessing a custom data access protocol, see *Using a Custom Protocol*.

```c
/* ---- Read/Write function API ------*/
CALLED_AS_EXTPROTOCOL(fcinfo)
EXTPROTOCOL_GET_URL(fcinfo)(fcinfo)
EXTPROTOCOL_GET_DATABUF(fcinfo)
EXTPROTOCOL_GET_DATALEN(fcinfo)
EXTPROTOCOL_GET_SCANQUALS(fcinfo)
EXTPROTOCOL_GET_USER_CTX(fcinfo)
EXTPROTOCOL_IS_LAST_CALL(fcinfo)
EXTPROTOCOL_SET_LAST_CALL(fcinfo)
EXTPROTOCOL_SET_USER_CTX(fcinfo, p)

/* ------ Validator function API ------*/
CALLED_AS_EXTPROTOCOL_VALIDATOR(fcinfo)
EXTPROTOCOL_VALIDATOR_GET_URL_LIST(fcinfo)
EXTPROTOCOL_VALIDATOR_GET_NUM_URLS(fcinfo)
EXTPROTOCOL_VALIDATOR_GET_NTH_URL(fcinfo, n)
EXTPROTOCOL_VALIDATOR_GET_DIRECTION(fcinfo)
```

**Notes**

The protocol corresponds to the example described in *Using a Custom Protocol*. The source code file name and shared object are `gpextprotocol.c` and `gpextprotocol.so`.

The protocol has the following properties:

- The name defined for the protocol is `myprot`. 
• The protocol has the following simple form: the protocol name and a path, separated by ://.
  myprot:// path
• Three functions are implemented:
  • myprot_import() a read function
  • myprot_export() a write function
  • myprot_validate_urls() a validation function

  These functions are referenced in the CREATE PROTOCOL statement when the protocol is created and
declared in the database.

The example implementation gpextprotocol.c uses fopen() and fread() to simulate a simple protocol
that reads local files. In practice, however, the protocol would implement functionality such as a remote
connection to some process over the network.

Installing the External Table Protocol

To use the example external table protocol, you use the C compiler cc to compile and link the source code
to create a shared object that can be dynamically loaded by Greenplum Database. The commands to
compile and link the source code on a Linux system are similar to this:

cc -fpic -c gpextprotocol.c cc -shared -o gpextprotocol.so gpextprotocol.o

The option -fpic specifies creating position-independent code (PIC) and the -c option compiles the
source code without linking and creates an object file. The object file needs to be created as position-
independent code (PIC) so that it can be loaded at any arbitrary location in memory by Greenplum
Database.

The flag -shared specifies creating a shared object (shared library) and the -o option specifies the
shared object file name gpextprotocol.so. Refer to the GCC manual for more information on the cc
options.

The header files that are declared as include files in gpextprotocol.c are located in subdirectories of
$GPHOME/include/postgresql/.

For more information on compiling and linking dynamically-loaded functions and examples of compiling
C source code to create a shared library on other operating systems, see the Postgres documentation at
https://www.postgresql.org/docs/8.4/static/xfunc-c.html#DFUNC.

The manual pages for the C compiler cc and the link editor ld for your operating system also contain
information on compiling and linking source code on your system.

The compiled code (shared object file) for the custom protocol must be placed in the same location on
every host in your Greenplum Database array (master and all segments). This location must also be in the
LD_LIBRARY_PATH so that the server can locate the files. It is recommended to locate shared libraries
either relative to $libdir (which is located at $GPHOME/lib) or through the dynamic library path (set
by the dynamic_library_path server configuration parameter) on all master segment instances in the
Greenplum Database array. You can use the Greenplum Database utilities gpssh and gpscp to update
segments.

Managing Performance

The topics in this section cover Greenplum Database performance management, including how to monitor performance and how to configure workloads to prioritize resource utilization.

This section contains the following topics:

- Defining Database Performance
- Common Causes of Performance Issues
- Using Resource Queues
- Investigating a Performance Problem

Defining Database Performance

Managing system performance includes measuring performance, identifying the causes of performance problems, and applying the tools and techniques available to you to remedy the problems.

Greenplum measures database performance based on the rate at which the database management system (DBMS) supplies information to requesters.

Understanding the Performance Factors

Several key performance factors influence database performance. Understanding these factors helps identify performance opportunities and avoid problems:

- System Resources
- Workload
- Throughput
- Contention
- Optimization

System Resources

Database performance relies heavily on disk I/O and memory usage. To accurately set performance expectations, you need to know the baseline performance of the hardware on which your DBMS is deployed. Performance of hardware components such as CPUs, hard disks, disk controllers, RAM, and network interfaces will significantly affect how fast your database performs.

Workload

The workload equals the total demand from the DBMS, and it varies over time. The total workload is a combination of user queries, applications, batch jobs, transactions, and system commands directed through the DBMS at any given time. For example, it can increase when month-end reports are run or decrease on weekends when most users are out of the office. Workload strongly influences database performance. Knowing your workload and peak demand times helps you plan for the most efficient use of your system resources and enables processing the largest possible workload.

Throughput

A system’s throughput defines its overall capability to process data. DBMS throughput is measured in queries per second, transactions per second, or average response times. DBMS throughput is closely related to the processing capacity of the underlying systems (disk I/O, CPU speed, memory bandwidth, and so on), so it is important to know the throughput capacity of your hardware when setting DBMS throughput goals.
**Contention**

Contention is the condition in which two or more components of the workload attempt to use the system in a conflicting way — for example, multiple queries that try to update the same piece of data at the same time or multiple large workloads that compete for system resources. As contention increases, throughput decreases.

**Optimization**

DBMS optimizations can affect the overall system performance. SQL formulation, database configuration parameters, table design, data distribution, and so on enable the database query optimizer to create the most efficient access plans.

**Determining Acceptable Performance**

When approaching a performance tuning initiative, you should know your system’s expected level of performance and define measurable performance requirements so you can accurately evaluate your system’s performance. Consider the following when setting performance goals:

- *Baseline Hardware Performance*
- *Performance Benchmarks*

**Baseline Hardware Performance**

Most database performance problems are caused not by the database, but by the underlying systems on which the database runs. I/O bottlenecks, memory problems, and network issues can notably degrade database performance. Knowing the baseline capabilities of your hardware and operating system (OS) will help you identify and troubleshoot hardware-related problems before you explore database-level or query-level tuning initiatives.

See the *Greenplum Database Reference Guide* for information about running the `gpcheckperf` utility to validate hardware and network performance.

**Performance Benchmarks**

To maintain good performance or fix performance issues, you should know the capabilities of your DBMS on a defined workload. A benchmark is a predefined workload that produces a known result set. Periodically run the same benchmark tests to help identify system-related performance degradation over time. Use benchmarks to compare workloads and identify queries or applications that need optimization.

Many third-party organizations, such as the Transaction Processing Performance Council (TPC), provide benchmark tools for the database industry. TPC provides TPC-H, a decision support system that examines large volumes of data, executes queries with a high degree of complexity, and gives answers to critical business questions. For more information about TPC-H, go to:

[http://www.tpc.org/tpch](http://www.tpc.org/tpch)

**Common Causes of Performance Issues**

This section explains the troubleshooting processes for common performance issues and potential solutions to these issues.

**Identifying Hardware and Segment Failures**

The performance of Greenplum Database depends on the hardware and IT infrastructure on which it runs. Greenplum Database is comprised of several servers (hosts) acting together as one cohesive system (array); as a first step in diagnosing performance problems, ensure that all Greenplum Database segments are online. Greenplum Database’s performance will be as fast as the slowest host in the array. Problems
with CPU utilization, memory management, I/O processing, or network load affect performance. Common
hardware-related issues are:

- **Disk Failure** – Although a single disk failure should not dramatically affect database performance if
  you are using RAID, disk resynchronization does consume resources on the host with failed disks. The
  `gpcheckperf` utility can help identify segment hosts that have disk I/O issues.

- **Host Failure** – When a host is offline, the segments on that host are nonoperational. This means
  other hosts in the array must perform twice their usual workload because they are running the primary
  segments and multiple mirrors. If mirrors are not enabled, service is interrupted. Service is temporarily
  interrupted to recover failed segments. The `gpstate` utility helps identify failed segments.

- **Network Failure** – Failure of a network interface card, a switch, or DNS server can bring down
  segments. If host names or IP addresses cannot be resolved within your Greenplum array, these
  manifest themselves as interconnect errors in Greenplum Database. The `gpcheckperf` utility helps
  identify segment hosts that have network issues.

- **Disk Capacity** – Disk capacity on your segment hosts should never exceed 70 percent full. Greenplum
  Database needs some free space for runtime processing. To reclaim disk space that deleted rows
  occupy, run `VACUUM` after loads or updates. The `gp_toolkit` administrative schema has many views for
  checking the size of distributed database objects.

  See the *Greenplum Database Reference Guide* for information about checking database object sizes
  and disk space.

**Managing Workload**

A database system has a limited CPU capacity, memory, and disk I/O resources. When multiple workloads
compete for access to these resources, database performance suffers. Resource management maximizes
system throughput while meeting varied business requirements. Greenplum Database provides resource
queues and resource groups to help you manage these system resources.

Resource queues and resource groups limit resource usage and the total number of concurrent queries
executing in the particular queue or group. By assigning database roles to the appropriate queue or
group, administrators can control concurrent user queries and prevent system overload. For more
information about resource queues and resource groups, including selecting the appropriate scheme for
your Greenplum Database environment, see *Managing Resources*.

Greenplum Database administrators should run maintenance workloads such as data loads and `VACUUM`
`ANALYZE` operations after business hours. Do not compete with database users for system resources;
perform administrative tasks at low-usage times.

**Avoiding Contention**

Contention arises when multiple users or workloads try to use the system in a conflicting way; for example,
contention occurs when two transactions try to update a table simultaneously. A transaction that seeks a
table-level or row-level lock will wait indefinitely for conflicting locks to be released. Applications should not
hold transactions open for long periods of time, for example, while waiting for user input.

**Maintaining Database Statistics**

Greenplum Database uses a cost-based query optimizer that relies on database statistics. Accurate
statistics allow the query optimizer to better estimate the number of rows retrieved by a query to choose
the most efficient query plan. Without database statistics, the query optimizer cannot estimate how many
records will be returned. The optimizer does not assume it has sufficient memory to perform certain
operations such as aggregations, so it takes the most conservative action and does these operations by
reading and writing from disk. This is significantly slower than doing them in memory. `ANALYZE` collects
statistics about the database that the query optimizer needs.

**Note:** When executing an SQL command with GPOCA, Greenplum Database issues a warning if
the command performance could be improved by collecting statistics on a column or set of columns
referenced by the command. The warning is issued on the command line and information is added to the Greenplum Database log file. For information about collecting statistics on table columns, see the ANALYZE command in the Greenplum Database Reference Guide

**Identifying Statistics Problems in Query Plans**

Before you interpret a query plan for a query using EXPLAIN or EXPLAIN ANALYZE, familiarize yourself with the data to help identify possible statistics problems. Check the plan for the following indicators of inaccurate statistics:

- **Are the optimizer's estimates close to reality?** Run EXPLAIN ANALYZE and see if the number of rows the optimizer estimated is close to the number of rows the query operation returned.
- **Are selective predicates applied early in the plan?** The most selective filters should be applied early in the plan so fewer rows move up the plan tree.
- **Is the optimizer choosing the best join order?** When you have a query that joins multiple tables, make sure the optimizer chooses the most selective join order. Joins that eliminate the largest number of rows should be done earlier in the plan so fewer rows move up the plan tree.

See Query Profiling for more information about reading query plans.

**Tuning Statistics Collection**

The following configuration parameters control the amount of data sampled for statistics collection:

- `default_statistics_target`
- `gp_analyze_relative_error`

These parameters control statistics sampling at the system level. It is better to sample only increased statistics for columns used most frequently in query predicates. You can adjust statistics for a particular column using the command:

```
ALTER TABLE...SET STATISTICS
```

For example:

```
ALTER TABLE sales ALTER COLUMN region SET STATISTICS 50;
```

This is equivalent to changing `default_statistics_target` for a particular column. Subsequent ANALYZE operations will then gather more statistics data for that column and produce better query plans as a result.

**Optimizing Data Distribution**

When you create a table in Greenplum Database, you must declare a distribution key that allows for even data distribution across all segments in the system. Because the segments work on a query in parallel, Greenplum Database will always be as fast as the slowest segment. If the data is unbalanced, the segments that have more data will return their results slower and therefore slow down the entire system.

**Optimizing Your Database Design**

Many performance issues can be improved by database design. Examine your database design and consider the following:

- Does the schema reflect the way the data is accessed?
- Can larger tables be broken down into partitions?
- Are you using the smallest data type possible to store column values?
- Are columns used to join tables of the same datatype?
- Are your indexes being used?
**Greenplum Database Maximum Limits**

To help optimize database design, review the maximum limits that Greenplum Database supports:

Table 87: Maximum Limits of Greenplum Database

<table>
<thead>
<tr>
<th>Dimension</th>
<th>Limit</th>
</tr>
</thead>
<tbody>
<tr>
<td>Database Size</td>
<td>Unlimited</td>
</tr>
<tr>
<td>Table Size</td>
<td>Unlimited, 128 TB per partition per segment</td>
</tr>
<tr>
<td>Row Size</td>
<td>1.6 TB (1600 columns * 1 GB)</td>
</tr>
<tr>
<td>Field Size</td>
<td>1 GB</td>
</tr>
<tr>
<td>Rows per Table</td>
<td>281474976710656 (2^48)</td>
</tr>
<tr>
<td>Columns per Table/View</td>
<td>1600</td>
</tr>
<tr>
<td>Indexes per Table</td>
<td>Unlimited</td>
</tr>
<tr>
<td>Columns per Index</td>
<td>32</td>
</tr>
<tr>
<td>Table-level Constraints per Table</td>
<td>Unlimited</td>
</tr>
<tr>
<td>Table Name Length</td>
<td>63 Bytes (Limited by name data type)</td>
</tr>
</tbody>
</table>

Dimensions listed as unlimited are not intrinsically limited by Greenplum Database. However, they are limited in practice to available disk space and memory/swap space. Performance may suffer when these values are unusually large.

**Note:**

There is a maximum limit on the number of objects (tables, indexes, and views, but not rows) that may exist at one time. This limit is 4294967296 (2^32).

**Greenplum Database Memory Overview**

Memory is a key resource for a Greenplum Database system and, when used efficiently, can ensure high performance and throughput. This topic describes how segment host memory is allocated between segments and the options available to administrators to configure memory.

A Greenplum Database segment host runs multiple PostgreSQL instances, all sharing the host's memory. The segments have an identical configuration and they consume similar amounts of memory, CPU, and disk IO simultaneously, while working on queries in parallel.

For best query throughput, the memory configuration should be managed carefully. There are memory configuration options at every level in Greenplum Database, from operating system parameters, to managing resources with resource queues and resource groups, to setting the amount of memory allocated to an individual query.

**Segment Host Memory**

On a Greenplum Database segment host, the available host memory is shared among all the processes executing on the computer, including the operating system, Greenplum Database segment instances, and other application processes. Administrators must determine what Greenplum Database and non-Greenplum Database processes share the hosts' memory and configure the system to use the memory efficiently. It is equally important to monitor memory usage regularly to detect any changes in the way host memory is consumed by Greenplum Database or other processes.
The following figure illustrates how memory is consumed on a Greenplum Database segment host when resource queue-based resource management is active.

![Figure 31: Greenplum Database Segment Host Memory](image)

Beginning at the bottom of the illustration, the line labeled \( A \) represents the total host memory. The line directly above line \( A \) shows that the total host memory comprises both physical RAM and swap space.

The line labelled \( B \) shows that the total memory available must be shared by Greenplum Database and all other processes on the host. Non-Greenplum Database processes include the operating system and any other applications, for example system monitoring agents. Some applications may use a significant portion of memory and, as a result, you may have to adjust the number of segments per Greenplum Database host or the amount of memory per segment.

The segments (C) each get an equal share of the Greenplum Database Memory (B).

Within a segment, the currently active resource management scheme, Resource Queues or Resource Groups, governs how memory is allocated to execute a SQL statement. These constructs allow you to translate business requirements into execution policies in your Greenplum Database system and to guard against queries that could degrade performance. For an overview of resource groups and resource queues, refer to Managing Resources.

**Options for Configuring Segment Host Memory**

Host memory is the total memory shared by all applications on the segment host. You can configure the amount of host memory using any of the following methods:

- Add more RAM to the nodes to increase the physical memory.
- Allocate swap space to increase the size of virtual memory.
- Set the kernel parameters `vm.overcommit_memory` and `vm.overcommit_ratio` to configure how the operating system handles large memory allocation requests.

The physical RAM and OS configuration are usually managed by the platform team and system administrators. See the Greenplum Database Installation Guide for the recommended kernel parameter settings.

The amount of memory to reserve for the operating system and other processes is workload dependent. The minimum recommendation for operating system memory is 32GB, but if there is much concurrency in Greenplum Database, increasing to 64GB of reserved memory may be required. The largest user of
operating system memory is SLAB, which increases as Greenplum Database concurrency and the number of sockets used increases.

The `vm.overcommit_memory` kernel parameter should always be set to 2, the only safe value for Greenplum Database.

The `vm.overcommit_ratio` kernel parameter sets the percentage of RAM that is used for application processes, the remainder reserved for the operating system. The default for Red Hat is 50 (50%). Setting this parameter too high may result in insufficient memory reserved for the operating system, which can cause segment host failure or database failure. Leaving the setting at the default of 50 is generally safe, but conservative. Setting the value too low reduces the amount of concurrency and the complexity of queries you can run at the same time by reducing the amount of memory available to Greenplum Database. When increasing `vm.overcommit_ratio`, it is important to remember to always reserve some memory for operating system activities.

**Configuring `vm.overcommit_ratio` when Resource Group-Based Resource Management is Active**

When resource group-based resource management is active, tune the operating system `vm.overcommit_ratio` as necessary. If your memory utilization is too low, increase the value; if your memory or swap usage is too high, decrease the setting.

**Configuring `vm.overcommit_ratio` when Resource Queue-Based Resource Management is Active**

To calculate a safe value for `vm.overcommit_ratio` when resource queue-based resource management is active, first determine the total memory available to Greenplum Database processes, `gp_vmem_rq`, with this formula:

\[
gp_vmem_rq = ((SWAP + RAM) - (7.5GB + 0.05 * RAM)) / 1.7
\]

where `SWAP` is the swap space on the host in GB, and `RAM` is the number of GB of RAM installed on the host. When resource queue-based resource management is active, use `gp_vmem_rq` to calculate the `vm.overcommit_ratio` value with this formula:

\[
vm.overcommit_ratio = (RAM - 0.026 * gp_vmem_rq) / RAM
\]

**Configuring Greenplum Database Memory**

Greenplum Database Memory is the amount of memory available to all Greenplum Database segment instances.

When you set up the Greenplum Database cluster, you determine the number of primary segments to run per host and the amount of memory to allocate for each segment. Depending on the CPU cores, amount of physical RAM, and workload characteristics, the number of segments is usually a value between 4 and 8. With segment mirroring enabled, it is important to allocate memory for the maximum number of primary segments executing on a host during a failure. For example, if you use the default grouping mirror configuration, a segment host failure doubles the number of acting primaries on the host that has the failed host's mirrors. Mirror configurations that spread each host's mirrors over multiple other hosts can lower the maximum, allowing more memory to be allocated for each segment. For example, if you use a block mirroring configuration with 4 hosts per block and 8 primary segments per host, a single host failure would cause other hosts in the block to have a maximum of 11 active primaries, compared to 16 for the default grouping mirror configuration.

**Configuring Segment Memory when Resource Group-Based Resource Management is Active**

When resource group-based resource management is active, the amount of memory allocated to each segment on a segment host is the memory available to Greenplum Database multiplied by the `gp_resource_group_memory_limit` server configuration parameter and divided by the number of active primary segments on the host. Use the following formula to calculate segment memory when using resource groups for resource management.
Resource groups expose additional configuration parameters that enable you to further control and refine the amount of memory allocated for queries.

### Configuring Segment Memory when Resource Queue-Based Resource Management is Active

When resource queue-based resource management is active, the `gp_vmem_protect_limit` server configuration parameter value identifies the amount of memory to allocate to each segment. This value is estimated by calculating the memory available for all Greenplum Database processes and dividing by the maximum number of primary segments during a failure. If `gp_vmem_protect_limit` is set too high, queries can fail. Use the following formula to calculate a safe value for `gp_vmem_protect_limit`; provide the `gp_vmem_rq` value that you calculated earlier.

\[
gp_vmem_protect_limit = \frac{gp_vmem_rq}{max_acting_primary_segments}
\]

where `max_acting_primary_segments` is the maximum number of primary segments that could be running on a host when mirror segments are activated due to a host or segment failure.

`gp_vmem_protect_limit` does not affect segment memory when using resource groups for Greenplum Database resource management.

Resource queues expose additional configuration parameters that enable you to further control and refine the amount of memory allocated for queries.

### Example Memory Configuration Calculations

This section provides example memory calculations for resource queues and resource groups for a Greenplum Database system with the following specifications:

- Total RAM = 256GB
- Swap = 64GB
- 8 primary segments and 8 mirror segments per host, in blocks of 4 hosts
- Maximum number of primaries per host during failure is 11

#### Resource Group Example

When resource group-based resource management is active in Greenplum Database, the usable memory available on a host is a function of the amount of RAM and swap space configured for the system, as well as the `vm.overcommit_ratio` system parameter setting:

\[
total_node_usable_memory = \text{RAM} \times \left(\frac{\text{vm.overcommit_ratio}}{100}\right) + \text{Swap} = 256\text{GB} \times \left(\frac{50}{100}\right) + 64\text{GB} = 192\text{GB}
\]

Assuming the default `gp_resource_group_memory_limit` value (.7), the memory allocated to a Greenplum Database host with the example configuration is:

\[
total_{gp\_memory} = total_{node\_usable\_memory} \times gp_resource_group_memory_limit = 192\text{GB} \times .7 = 134.4\text{GB}
\]

The memory available to a Greenplum Database segment on a segment host is a function of the memory reserved for Greenplum on the host and the number of active primary segments on the host. On cluster startup:
\[
gp\_seg\_memory = \frac{\text{total}\_gp\_memory}{\text{number}\_of\_active\_primary\_segments}
\]
\[
= \frac{134.4\text{GB}}{8}
\]
\[
= 16.8\text{GB}
\]

Note that when 3 mirror segments switch to primary segments, the per-segment memory is still 16.8GB. Total memory usage on the segment host may approach:

\[
\text{total}\_gp\_memory\_with\_primaries = 16.8\text{GB} \times 11 = 184.8\text{GB}
\]

**Resource Queue Example**

The `vm.overcommit_ratio` calculation for the example system when resource queue-based resource management is active in Greenplum Database follows:

\[
gp\_vmem\_rq = \frac{\left((\text{SWAP} + \text{RAM}) - (7.5\text{GB} + 0.05 \times \text{RAM})\right)}{1.7}
\]
\[
= \frac{\left((64 + 256) - (7.5 + 0.05 \times 256)\right)}{1.7}
\]
\[
= 176
\]

\[
\text{vm.overcommit}\_ratio = \frac{\left(\text{RAM} - (0.026 \times \text{gp\_vmem\_rq})\right)}{\text{RAM}}
\]
\[
= \frac{(256 - (0.026 \times 176))}{256}
\]
\[
= .982
\]

You would set `vm.overcommit_ratio` of the example system to 98.

The `gp\_vmem\_protect\_limit` calculation when resource queue-based resource management is active in Greenplum Database:

\[
gp\_vmem\_protect\_limit = \frac{\text{gp\_vmem\_rq}}{\text{maximum}\_acting\_primary\_segments}
\]
\[
= \frac{176}{11}
\]
\[
= 16\text{GB}
\]
\[
= 16384\text{MB}
\]

You would set the `gp\_vmem\_protect\_limit` server configuration parameter on the example system to 16384.

**Managing Resources**

Greenplum Database provides features to help you prioritize and allocate resources to queries according to business requirements and to prevent queries from starting when resources are unavailable.

You can use resource management features to limit the number of concurrent queries, the amount of memory used to execute a query, and the relative amount of CPU devoted to processing a query. Greenplum Database provides two schemes to manage resources - Resource Queues and Resource Groups.

**Important:** Significant Greenplum Database performance degradation has been observed when enabling resource group-based workload management on RedHat 6.x, CentOS 6.x, and SuSE 11 systems. This issue is caused by a Linux cgroup kernel bug. This kernel bug has been fixed in CentOS 7.x and Red Hat 7.x systems, and on SuSE 12 SP2/SP3 systems with kernel version 4.4.73-5.1 or newer.

If you use RedHat 6 and the performance with resource groups is acceptable for your use case, upgrade your kernel to version 2.6.32-696 or higher to benefit from other fixes to the cgroups implementation.

SuSE 11 does not have a kernel version that resolves this issue; resource groups are still considered to be a Beta feature on this platform. Resource groups are not supported on SuSE 11 for production use.
Either the resource queue or the resource group management scheme can be active in Greenplum Database; both schemes cannot be active at the same time.

Resource queues are enabled by default when you install your Greenplum Database cluster. While you can create and assign resource groups when resource queues are active, you must explicitly enable resource groups to start using that management scheme.

The following table summarizes some of the differences between Resource Queues and Resource Groups.

<table>
<thead>
<tr>
<th>Metric</th>
<th>Resource Queues</th>
<th>Resource Groups</th>
</tr>
</thead>
<tbody>
<tr>
<td>Concurrency</td>
<td>Managed at the query level</td>
<td>Managed at the transaction level</td>
</tr>
<tr>
<td>CPU</td>
<td>Specify query priority</td>
<td>Specify percentage of CPU resources; uses Linux Control Groups</td>
</tr>
<tr>
<td>Memory</td>
<td>Managed at the queue and operator level; users can over-subscribe</td>
<td>Managed at the transaction level, with enhanced allocation and tracking; users cannot over-subscribe</td>
</tr>
<tr>
<td>Memory Isolation</td>
<td>None</td>
<td>Memory is isolated between resource groups and between transactions within the same resource group</td>
</tr>
<tr>
<td>Users</td>
<td>Limits are applied only to non-admin users</td>
<td>Limits are applied to SUPERUSER and non-admin users alike</td>
</tr>
<tr>
<td>Queueing</td>
<td>Queue only when no slot available</td>
<td>Queue when no slot is available or not enough available memory</td>
</tr>
<tr>
<td>Query Failure</td>
<td>Query may fail immediately if not enough memory</td>
<td>Query may fail after reaching transaction fixed memory limit when no shared resource group memory exists and the transaction requests more memory</td>
</tr>
<tr>
<td>Limit Bypass</td>
<td>Limits are not enforced for SUPERUSER roles and certain operators and functions</td>
<td>Limits are not enforced on SET, RESET, and SHOW commands</td>
</tr>
<tr>
<td>External Components</td>
<td>None</td>
<td>Manage PL/Container CPU and memory resources</td>
</tr>
</tbody>
</table>

**Using Resource Groups**

You use resource groups to set and enforce CPU, memory, and concurrent transaction limits in Greenplum Database. After you define a resource group, you can then assign the group to one or more Greenplum Database roles, or to an external component such as PL/Container, in order to control the resources used by those roles or components.

When you assign a resource group to a role (a role-based resource group), the resource limits that you define for the group apply to all of the roles to which you assign the group. For example, the memory limit for a resource group identifies the maximum memory usage for all running transactions submitted by Greenplum Database users in all roles to which you assign the group.

Similarly, when you assign a resource group to an external component, the group limits apply to all running instances of the component. For example, if you create a resource group for a PL/Container external
component, the memory limit that you define for the group specifies the maximum memory usage for all running instances of each PL/Container runtime to which you assign the group.

This topic includes the following subtopics:

- Understanding Role and Component Resource Groups
- Resource Group Attributes and Limits
  - Memory Auditor
  - Transaction Concurrency Limit
  - CPU Limits
  - Memory Limits
- Using Greenplum Command Center to Manage Resource Groups
- Using Resource Groups
  - Enabling Resource Groups
  - Creating Resource Groups
  - Assigning a Resource Group to a Role
  - Monitoring Resource Group Status
- Resource Group Frequently Asked Questions

**Understanding Role and Component Resource Groups**

Greenplum Database supports two types of resource groups: groups that manage resources for roles, and groups that manage resources for external components such as PL/Container.

The most common application for resource groups is to manage the number of active queries that different roles may execute concurrently in your Greenplum Database cluster. You can also manage the amount of CPU and memory resources that Greenplum allocates to each query.

Resource groups for roles use Linux control groups (cgroups) for CPU resource management. Greenplum Database tracks virtual memory internally for these resource groups using a memory auditor referred to as `vmtracker`.

When the user executes a query, Greenplum Database evaluates the query against a set of limits defined for the resource group. Greenplum Database executes the query immediately if the group's resource limits have not yet been reached and the query does not cause the group to exceed the concurrent transaction limit. If these conditions are not met, Greenplum Database queues the query. For example, if the maximum number of concurrent transactions for the resource group has already been reached, a subsequent query is queued and must wait until other queries complete before it runs. Greenplum Database may also execute a pending query when the resource group's concurrency and memory limits are altered to large enough values.

Within a resource group for roles, transactions are evaluated on a first in, first out basis. Greenplum Database periodically assesses the active workload of the system, reallocating resources and starting/queuing jobs as necessary.

You can also use resource groups to manage the CPU and memory resources of external components such as PL/Container. Resource groups for external components use Linux cgroups to manage both the total CPU and total memory resources for the component.

**Note:** Containerized deployments of Greenplum Database, such as Greenplum for Kubernetes, might create a hierarchical set of nested cgroups to manage host system resources. The nesting of cgroups affects the Greenplum Database resource group limits for CPU percentage, CPU cores, and memory (except for Greenplum Database external components). The Greenplum Database resource group system resource limit is based on the quota for the parent group.

For example, Greenplum Database is running in a cgroup demo, and the Greenplum Database cgroup is nested in the cgroup demo. If the cgroup demo is configured with a CPU limit of 60% of system CPU resources and the Greenplum Database resource group CPU limit is set 90%, the Greenplum Database limit of host system CPU resources is 54% (0.6 x 0.9).
Nested cgroups do not affect memory limits for Greenplum Database external components such as PL/Container. Memory limits for external components can only be managed if the cgroup that is used to manage Greenplum Database resources is not nested, the cgroup is configured as a top-level cgroup.

For information about configuring cgroups for use by resource groups, see Using Resource Groups.

Resource Group Attributes and Limits

When you create a resource group, you:

- Specify the type of resource group by identifying how memory for the group is audited.
- Provide a set of limits that determine the amount of CPU and memory resources available to the group.

Resource group attributes and limits:

<table>
<thead>
<tr>
<th>Limit Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>MEMORY_AUDITOR</td>
<td>The memory auditor in use for the resource group. <strong>vmtracker</strong> (the default) is required if you want to assign the resource group to roles. Specify <strong>cgroup</strong> to assign the resource group to an external component.</td>
</tr>
<tr>
<td>CONCURRENCY</td>
<td>The maximum number of concurrent transactions, including active and idle transactions, that are permitted in the resource group.</td>
</tr>
<tr>
<td>CPU_RATE_LIMIT</td>
<td>The percentage of CPU resources available to this resource group.</td>
</tr>
<tr>
<td>CPUSET</td>
<td>The CPU cores to reserve for this resource group.</td>
</tr>
<tr>
<td>MEMORY_LIMIT</td>
<td>The percentage of reserved memory resources available to this resource group.</td>
</tr>
<tr>
<td>MEMORY_SHARED_QUOTA</td>
<td>The percentage of reserved memory to share across transactions submitted in this resource group.</td>
</tr>
<tr>
<td>MEMORY_SPILL_RATIO</td>
<td>The memory usage threshold for memory-intensive transactions. When a transaction reaches this threshold, it spills to disk.</td>
</tr>
</tbody>
</table>

Note: Resource limits are not enforced on SET, RESET, and SHOW commands.

Memory Auditor

The MEMORY_AUDITOR attribute specifies the type of resource group by identifying the memory auditor for the group. A resource group that specifies the **vmtracker** MEMORY_AUDITOR identifies a resource group for roles. A resource group specifying the **cgroup** MEMORY_AUDITOR identifies a resource group for external components.

The default MEMORY_AUDITOR is **vmtracker**.

The MEMORY_AUDITOR that you specify for a resource group determines if and how Greenplum Database uses the limit attributes to manage CPU and memory resources:

<table>
<thead>
<tr>
<th>Limit Type</th>
<th>Resource Group for Roles</th>
<th>Resource Group for External Components</th>
</tr>
</thead>
<tbody>
<tr>
<td>CONCURRENCY</td>
<td>Yes</td>
<td>No; must be zero (0)</td>
</tr>
</tbody>
</table>
### Limit Type

<table>
<thead>
<tr>
<th>Limit Type</th>
<th>Resource Group for Roles</th>
<th>Resource Group for External Components</th>
</tr>
</thead>
<tbody>
<tr>
<td>CPU_RATE_LIMIT</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>CPUSET</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>MEMORY_LIMIT</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>MEMORY_SHARED_QUOTA</td>
<td>Yes</td>
<td>Component-specific</td>
</tr>
<tr>
<td>MEMORY_SPILL_RATIO</td>
<td>Yes</td>
<td>Component-specific</td>
</tr>
</tbody>
</table>

#### Transaction Concurrency Limit

The **CONCURRENCY** limit controls the maximum number of concurrent transactions permitted for a resource group for roles.

**Note:** The **CONCURRENCY** limit is not applicable to resource groups for external components and must be set to zero (0) for such groups.

Each resource group for roles is logically divided into a fixed number of slots equal to the **CONCURRENCY** limit. Greenplum Database allocates these slots an equal, fixed percentage of memory resources.

The default **CONCURRENCY** limit value for a resource group for roles is 20.

Greenplum Database queues any transactions submitted after the resource group reaches its **CONCURRENCY** limit. When a running transaction completes, Greenplum Database un-queues and executes the earliest queued transaction if sufficient memory resources exist.

You can set the server configuration parameter `gp_resource_group_bypass` to bypass a resource group concurrency limit.

#### CPU Limits

You configure the share of CPU resources to reserve for a resource group on a segment host by assigning specific CPU core(s) to the group, or by identifying the percentage of segment CPU resources to allocate to the group. Greenplum Database uses the **CPUSET** and **CPU_RATE_LIMIT** resource group limits to identify the CPU resource allocation mode. You must specify only one of these limits when you configure a resource group.

You may employ both modes of CPU resource allocation simultaneously in your Greenplum Database cluster. You may also change the CPU resource allocation mode for a resource group at runtime.

The `gp_resource_group_cpu_limit` server configuration parameter identifies the maximum percentage of system CPU resources to allocate to resource groups on each Greenplum Database segment host. This limit governs the maximum CPU usage of all resource groups on a segment host regardless of the CPU allocation mode configured for the group. The remaining unreserved CPU resources are used for the OS kernel and the Greenplum Database auxiliary daemon processes. The default `gp_resource_group_cpu_limit` value is .9 (90%).

**Note:** The default `gp_resource_group_cpu_limit` value may not leave sufficient CPU resources if you are running other workloads on your Greenplum Database cluster nodes, so be sure to adjust this server configuration parameter accordingly.

**Warning:** Avoid setting `gp_resource_group_cpu_limit` to a value higher than .9. Doing so may result in high workload queries taking near all CPU resources, potentially starving Greenplum Database auxiliary processes.

#### Assigning CPU Resources by Core

You identify the CPU cores that you want to reserve for a resource group with the **CPUSET** property. The CPU cores that you specify must be available in the system and cannot overlap with any CPU cores that
you reserved for other resource groups. (Although Greenplum Database uses the cores that you assign to a resource group exclusively for that group, note that those CPU cores may also be used by non-Greenplum processes in the system.)

Specify a comma-separated list of single core numbers or number intervals when you configure CPuset. You must enclose the core numbers/intervals in single quotes, for example, ‘1,3-4’.

When you assign CPU cores to CPuset groups, consider the following:

- A resource group that you create with CPuset uses the specified cores exclusively. If there are no running queries in the group, the reserved cores are idle and cannot be used by queries in other resource groups. Consider minimizing the number of CPuset groups to avoid wasting system CPU resources.
- Consider keeping CPU core 0 unassigned. CPU core 0 is used as a fallback mechanism in the following cases:
  - admin_group and default_group require at least one CPU core. When all CPU cores are reserved, Greenplum Database assigns CPU core 0 to these default groups. In this situation, the resource group to which you assigned CPU core 0 shares the core with admin_group and default_group.
  - If you restart your Greenplum Database cluster with one node replacement and the node does not have enough cores to service all CPuset resource groups, the groups are automatically assigned CPU core 0 to avoid system start failure.
  - Use the lowest possible core numbers when you assign cores to resource groups. If you replace a Greenplum Database node and the new node has fewer CPU cores than the original, or if you back up the database and want to restore it on a cluster with nodes with fewer CPU cores, the operation may fail. For example, if your Greenplum Database cluster has 16 cores, assigning cores 1-7 is optimal. If you create a resource group and assign CPU core 9 to this group, database restore to an 8 core node will fail.

Resource groups that you configure with CPuset have a higher priority on CPU resources. The maximum CPU resource usage percentage for all resource groups configured with CPuset on a segment host is the number of CPU cores reserved divided by the number of all CPU cores, multiplied by 100.

When you configure CPuset for a resource group, Greenplum Database disables CPU_RATE_LIMIT for the group and sets the value to -1.

**Note:** You must configure CPuset for a resource group **after** you have enabled resource group-based resource management for your Greenplum Database cluster.

**Assigning CPU Resources by Percentage**

The Greenplum Database node CPU percentage is divided equally among each segment on the Greenplum node. Each resource group that you configure with a CPU_RATE_LIMIT reserves the specified percentage of the segment CPU for resource management.

The minimum CPU_RATE_LIMIT percentage you can specify for a resource group is 1, the maximum is 100.

The sum of CPU_RATE_LIMITS specified for all resource groups that you define in your Greenplum Database cluster must not exceed 100.

The maximum CPU resource usage for all resource groups configured with a CPU_RATE_LIMIT on a segment host is the minimum of:

- The number of non-reserved CPU cores divided by the number of all CPU cores, multiplied by 100, and
- The gp_resource_group_cpu_limit value.

CPU resource assignment for resource groups configured with a CPU_RATE_LIMIT is elastic in that Greenplum Database may allocate the CPU resources of an idle resource group to a busier one(s). In such situations, CPU resources are re-allocated to the previously idle resource group when that resource group next becomes active. If multiple resource groups are busy, they are allocated the CPU resources of
any idle resource groups based on the ratio of their CPU_RATE_LIMITs. For example, a resource group created with a CPU_RATE_LIMIT of 40 will be allocated twice as much extra CPU resource as a resource group that you create with a CPU_RATE_LIMIT of 20.

When you configure CPU_RATE_LIMIT for a resource group, Greenplum Database disables CPUSet for the group and sets the value to -1.

**Memory Limits**

When resource groups are enabled, memory usage is managed at the Greenplum Database node, segment, and resource group levels. You can also manage memory at the transaction level with a resource group for roles.

The gp_resource_group_memory_limit server configuration parameter identifies the maximum percentage of system memory resources to allocate to resource groups on each Greenplum Database segment host. The default gp_resource_group_memory_limit value is .7 (70%).

The memory resource available on a Greenplum Database node is further divided equally among each segment on the node. When resource group-based resource management is active, the amount of memory allocated to each segment on a segment host is the memory available to Greenplum Database multiplied by the gp_resource_group_memory_limit server configuration parameter and divided by the number of active primary segments on the host:

\[
rg\_perseg\_mem = ((RAM \times (vm.overcommit\_ratio / 100) + SWAP) \times \text{gp\_resource\_group\_memory\_limit}) / \text{num\_active\_primary\_segments}
\]

Each resource group may reserve a percentage of the segment memory for resource management. You identify this percentage via the MEMORY_LIMIT value that you specify when you create the resource group. The minimum MEMORY_LIMIT percentage you can specify for a resource group is 0, the maximum is 100. When MEMORY_LIMIT is 0, Greenplum Database reserves no memory for the resource group, but uses resource group global shared memory to fulfill all memory requests in the group. Refer to [Global Shared Memory](#) for more information about resource group global shared memory.

The sum of MEMORY_LIMITs specified for all resource groups that you define in your Greenplum Database cluster must not exceed 100.

**Additional Memory Limits for Role-based Resource Groups**

If resource group memory is reserved for roles (non-zero MEMORY_LIMIT), the memory is further divided into fixed and shared components. The MEMORY_SHARED_QUOTA value that you specify when you create the resource group identifies the percentage of reserved resource group memory that may be shared among the currently running transactions. This memory is allotted on a first-come, first-served basis. A running transaction may use none, some, or all of the MEMORY_SHARED_QUOTA.

The minimum MEMORY_SHARED_QUOTA that you can specify is 0, the maximum is 100. The default MEMORY_SHARED_QUOTA is 20.

As mentioned previously, CONCURRENCY identifies the maximum number of concurrently running transactions permitted in a resource group for roles. If fixed memory is reserved by a resource group (non-zero MEMORY_LIMIT), it is divided into CONCURRENCY number of transaction slots. Each slot is allocated a fixed, equal amount of the resource group memory. Greenplum Database guarantees this fixed memory to each transaction.
Figure 32: Resource Group Memory Allotments

When a query's memory usage exceeds the fixed per-transaction memory usage amount, Greenplum Database allocates available resource group shared memory to the query. The maximum amount of resource group memory available to a specific transaction slot is the sum of the transaction's fixed memory and the full resource group shared memory allotment.

Global Shared Memory

The sum of the MEMORY_LIMITs configured for all resource groups (including the default admin_group and default_group groups) identifies the percentage of reserved resource group memory. If this sum is less than 100, Greenplum Database allocates any unreserved memory to a resource group global shared memory pool.

Resource group global shared memory is available only to resource groups that you configure with the vmtracker memory auditor.

When available, Greenplum Database allocates global shared memory to a transaction after first allocating slot and resource group shared memory (if applicable). Greenplum Database allocates resource group global shared memory to transactions on a first-come first-served basis.
Note: Greenplum Database tracks, but does not actively monitor, transaction memory usage in resource groups. If the memory usage for a resource group exceeds its fixed memory allotment, a transaction in the resource group fails when all of these conditions are met:

- No available resource group shared memory exists.
- No available global shared memory exists.
- The transaction requests additional memory.

Greenplum Database uses resource group memory more efficiently when you leave some memory (for example, 10-20%) unallocated for the global shared memory pool. The availability of global shared memory also helps to mitigate the failure of memory-consuming or unpredicted queries.

Query Operator Memory

Most query operators are non-memory-intensive; that is, during processing, Greenplum Database can hold their data in allocated memory. When memory-intensive query operators such as join and sort process more data than can be held in memory, data is spilled to disk.

The `gp_resgroup_memory_policy` server configuration parameter governs the memory allocation and distribution algorithm for all query operators. Greenplum Database supports eager-free (the default) and auto memory policies for resource groups. When you specify the auto policy, Greenplum Database uses resource group memory limits to distribute memory across query operators, allocating a fixed size of memory to non-memory-intensive operators and the rest to memory-intensive operators. When the eager_free policy is in place, Greenplum Database distributes memory among operators more optimally by re-allocating memory released by operators that have completed their processing to operators in a later query stage.

`MEMORY_SPILL_RATIO` identifies the memory usage threshold for memory-intensive operators in a transaction. When this threshold is reached, a transaction spills to disk. Greenplum Database uses the `MEMORY_SPILL_RATIO` to determine the initial memory to allocate to a transaction.

You can specify an integer percentage value from 0 to 100 inclusive for `MEMORY_SPILL_RATIO`. The default `MEMORY_SPILL_RATIO` is 20.

When `MEMORY_SPILL_RATIO` is 0, Greenplum Database uses the `statement_mem` server configuration parameter value to control initial query operator memory.

Note: When you set `MEMORY_LIMIT` to 0, `MEMORY_SPILL_RATIO` must also be set to 0.

You can selectively set the `MEMORY_SPILL_RATIO` on a per-query basis at the session level with the `memory_spill_ratio` server configuration parameter.

memory_spill_ratio and Low Memory Queries

A low `statement_mem` setting (for example, in the 10MB range) has been shown to increase the performance of queries with low memory requirements. Use the `memory_spill_ratio` and `statement_mem` server configuration parameters to override the setting on a per-query basis. For example:

```sql
SET memory_spill_ratio=0;
SET statement_mem='10 MB';
```

About Using Reserved Resource Group Memory vs. Using Resource Group Global Shared Memory

When you do not reserve memory for a resource group (`MEMORY_LIMIT` and `MEMORY_SPILL_RATIO` are set to 0):

- It increases the size of the resource group global shared memory pool.
- The resource group functions similarly to a resource queue, using the `statement_mem` server configuration parameter value to control initial query operator memory.
• Any query submitted in the resource group competes for resource group global shared memory on a first-come, first-served basis with queries running in other groups.
• There is no guarantee that Greenplum Database will be able to allocate memory for a query running in the resource group. The risk of a query in the group encountering an out of memory (OOM) condition increases when there are many concurrent queries consuming memory from the resource group global shared memory pool at the same time.

To reduce the risk of OOM for a query running in an important resource group, consider reserving some fixed memory for the group. While reserving fixed memory for a group reduces the size of the resource group global shared memory pool, this may be a fair tradeoff to reduce the risk of encountering an OOM condition in a query running in a critical resource group.

Other Memory Considerations

Resource groups for roles track all Greenplum Database memory allocated via the `palloc()` function. Memory that you allocate using the Linux `malloc()` function is not managed by these resource groups. To ensure that resource groups for roles are accurately tracking memory usage, avoid using `malloc()` to allocate large amounts of memory in custom Greenplum Database user-defined functions.

Using Greenplum Command Center to Manage Resource Groups

Using Pivotal Greenplum Command Center, an administrator can create and manage resource groups, change roles' resource groups, and create workload management rules.

Workload management rules are defined in Command Center and stored in Greenplum Database. When a transaction is submitted, Greenplum Database calls the workload management database extension to evaluate and apply the rules.

Workload management assignment rules assign transactions to different resource groups based on user-defined criteria. If no assignment rule is matched, Greenplum Database assigns the transaction to the role's default resource group. Workload management idle session kill rules set the maximum number of seconds that sessions managed by a resource group can remain idle before they are terminated.

Refer to the Greenplum Command Center documentation for more information about creating and managing resource groups and workload management rules.

Using Resource Groups

Important: Significant Greenplum Database performance degradation has been observed when enabling resource group-based workload management on RedHat 6.x, CentOS 6.x, and SuSE 11 systems. This issue is caused by a Linux cgroup kernel bug. This kernel bug has been fixed in CentOS 7.x and Red Hat 7.x systems, and on SuSE 12 SP2/SP3 systems with kernel version 4.4.73-5.1 or newer.

If you use RedHat 6 and the performance with resource groups is acceptable for your use case, upgrade your kernel to version 2.6.32-696 or higher to benefit from other fixes to the cgroups implementation.

SuSE 11 does not have a kernel version that resolves this issue; resource groups are still considered to be a Beta feature on this platform. Resource groups are not supported on SuSE 11 for production use.

Prerequisite

Greenplum Database resource groups use Linux Control Groups (cgroups) to manage CPU resources. Greenplum Database also uses cgroups to manage memory for resource groups for external components. With cgroups, Greenplum isolates the CPU and external component memory usage of your Greenplum processes from other processes on the node. This allows Greenplum to support CPU and external component memory usage restrictions on a per-resource-group basis.
For detailed information about cgroups, refer to the Control Groups documentation for your Linux distribution.

Complete the following tasks on each node in your Greenplum Database cluster to set up cgroups for use with resource groups:

1. If you are running the SuSE 11+ operating system on your Greenplum Database cluster nodes, you must enable swap accounting on each node and restart your Greenplum Database cluster. The `swapaccount` kernel boot parameter governs the swap accounting setting on SuSE 11+ systems. After setting this boot parameter, you must reboot your systems. For details, refer to the Cgroup Swap Control discussion in the SuSE 11 release notes. You must be the superuser or have `sudo` access to configure kernel boot parameters and reboot systems.

2. Create the Greenplum Database cgroups configuration file `/etc/cgconfig.d/gpdb.conf`. You must be the superuser or have `sudo` access to create this file:

   ```bash
   sudo vi /etc/cgconfig.d/gpdb.conf
   ```

3. Add the following configuration information to `/etc/cgconfig.d/gpdb.conf`:

   ```bash
group gpdb {
    perm {
     task {
      uid = gpadmin;
      gid = gpadmin;
     }
     admin {
      uid = gpadmin;
      gid = gpadmin;
     }
    }
    cpu {
    }
    cpuacct {
    }
}
```  

   This content configures CPU and CPU accounting control groups managed by the `gpadmin` user.

4. If you plan to use resource groups to manage PL/Container instances, you must add a memory block to the `gpdb.conf` file. Be sure to add the block before the closing curly-brace (`{`):

   ```bash
cpuacct {
}
memory {
}
```  

5. If you plan to assign specific CPU cores to resource groups, you must add a cpuset block to the `gpdb.conf` file. Be sure to add the block before the closing curly-brace (`{`):

   ```bash
cpuacct {
}
cpuset {
}
```  

6. If not already installed and running, install the Control Groups operating system package and start the cgroups service on each Greenplum Database node. The commands that you run to perform these tasks will differ based on the operating system installed on the node. You must be the superuser or have `sudo` access to run these commands:
Redhat/CentOS 7.x systems:

```bash
sudo yum install libcgroup-tools
sudo cgconfigparser -l /etc/cgconfig.d/gpdb.conf
```

Redhat/CentOS 6.x systems:

```bash
sudo yum install libcgroup
sudo service cgconfig start
```

SuSE 11+ systems:

```bash
sudo zypper install libcgroup-tools
sudo cgconfigparser -l /etc/cgconfig.d/gpdb.conf
```

7. Identify the cgroup directory mount point for the node:

```
grep cgroup /proc/mounts
```

The first line of output identifies the cgroup mount point.

8. Verify that you set up the Greenplum Database cgroups configuration correctly by running the following commands. Replace `<cgroup_mount_point>` with the mount point that you identified in the previous step:

```
ls -l <cgroup_mount_point>/cpu/gpdb
ls -l <cgroup_mount_point>/cpuacct/gpdb
ls -l <cgroup_mount_point>/cpuset/gpdb
ls -l <cgroup_mount_point>/memory/gpdb
```

If these directories exist and are owned by `gpadmin:gpadmin`, you have successfully configured cgroups for Greenplum Database CPU resource management.

9. To automatically recreate Greenplum Database required cgroup hierarchies and parameters when your system is restarted, configure your system to enable the Linux cgroup service daemon `cgconfig.service` (Redhat/CentOS 7.x and SuSE 11+) or `cgconfig` (Redhat/CentOS 6.x) at node start-up. For example, configure one of the following cgroup service commands in your preferred service auto-start tool:

   - Redhat/CentOS 7.x and SuSE11+ systems:
     ```bash
     sudo systemctl enable cgconfig.service
     To start the service immediately (without having to reboot) enter:
     sudo systemctl start cgconfig.service
     ```

   - Redhat/CentOS 6.x systems:
     ```bash
     sudo chkconfig cgconfig on
     ```

You may choose a different method to recreate the Greenplum Database resource group cgroup hierarchies.

**Procedure**

To use resource groups in your Greenplum Database cluster, you:

1. *Enable resource groups for your Greenplum Database cluster.*
2. *Create resource groups.*
3. *Assign the resource groups to one or more roles.*
4. Use resource management system views to monitor and manage the resource groups.

**Enabling Resource Groups**

When you install Greenplum Database, resource queues are enabled by default. To use resource groups instead of resource queues, you must set the `gp_resource_manager` server configuration parameter.

1. Set the `gp_resource_manager` server configuration parameter to the value "group":

   ```
gpconfig -s gp_resource_manager
   gpconfig -c gp_resource_manager -v "group"
   ```

2. Restart Greenplum Database:

   ```
gpstop
gpstart
   ```

Once enabled, any transaction submitted by a role is directed to the resource group assigned to the role, and is governed by that resource group's concurrency, memory, and CPU limits. Similarly, CPU and memory usage by an external component is governed by the CPU and memory limits configured for the resource group assigned to the component.

Greenplum Database creates two default resource groups for roles named `admin_group` and `default_group`. When you enable resources groups, any role that was not explicitly assigned a resource group is assigned the default group for the role's capability. **SUPERUSER** roles are assigned the `admin_group`, non-admin roles are assigned the group named `default_group`.

The default resource groups `admin_group` and `default_group` are created with the following resource limits:

<table>
<thead>
<tr>
<th>Limit Type</th>
<th><code>admin_group</code></th>
<th><code>default_group</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>CONCURRENCY</td>
<td>10</td>
<td>20</td>
</tr>
<tr>
<td>CPU_RATE_LIMIT</td>
<td>10</td>
<td>30</td>
</tr>
<tr>
<td>CPUSERET</td>
<td>30</td>
<td>50</td>
</tr>
<tr>
<td>MEMORY_LIMIT</td>
<td>10</td>
<td>30</td>
</tr>
<tr>
<td>MEMORY_SHARED_QUOTA</td>
<td>50</td>
<td>50</td>
</tr>
<tr>
<td>MEMORY_SPILL_RATIO</td>
<td>20</td>
<td>20</td>
</tr>
<tr>
<td>MEMORY_AUDITOR</td>
<td>vmtracker</td>
<td>vmtracker</td>
</tr>
</tbody>
</table>

Keep in mind that the CPU_RATE_LIMIT and MEMORY_LIMIT values for the default resource groups `admin_group` and `default_group` contribute to the total percentages on a segment host. You may find that you need to adjust these limits for `admin_group` and/or `default_group` as you create and add new resource groups to your Greenplum Database deployment.

**Creating Resource Groups**

When you create a resource group for a role, you provide a name, a CPU resource allocation mode, and a memory limit. You can optionally provide a concurrent transaction limit and memory shared quota and spill ratio. Use the `CREATE RESOURCE GROUP` command to create a new resource group.

When you create a resource group for a role, you must provide CPU_RATE_LIMIT or CPUSERET and MEMORY_LIMIT limit values. These limits identify the percentage of Greenplum Database resources to allocate to this resource group. You specify a MEMORY_LIMIT to reserve a fixed amount of memory for the resource group. If you specify a MEMORY_LIMIT of 0, Greenplum Database uses global shared memory to fulfill all memory requirements for the resource group.
For example, to create a resource group named `rgroup1` with a CPU limit of 20 and a memory limit of 25:

```sql
CREATE RESOURCE GROUP rgroup1 WITH (CPU_RATE_LIMIT=20, MEMORY_LIMIT=25);
```

The CPU limit of 20 is shared by every role to which `rgroup1` is assigned. Similarly, the memory limit of 25 is shared by every role to which `rgroup1` is assigned. `rgroup1` utilizes the default MEMORY_AUDITOR `vmtracker` and the default CONCURRENCY setting of 20.

When you create a resource group for an external component, you must provide CPU_RATE_LIMIT or CPUSET and MEMORY_LIMIT limit values. You must also provide the MEMORY_AUDITOR and explicitly set CONCURRENCY to zero (0). For example, to create a resource group named `rgroup_extcomp` for which you reserve CPU core 1 and assign a memory limit of 15:

```sql
CREATE RESOURCE GROUP rgroup_extcomp WITH (MEMORY_AUDITOR=cgroup,
CONCURRENCY=0,
CPUSET='1', MEMORY_LIMIT=15);
```

The `ALTER RESOURCE GROUP` command updates the limits of a resource group. To change the limits of a resource group, specify the new values that you want for the group. For example:

```sql
ALTER RESOURCE GROUP rg_role_light SET CONCURRENCY 7;
ALTER RESOURCE GROUP exec SET MEMORY_LIMIT 25;
ALTER RESOURCE GROUP rgroup1 SET CPUSET '2,4';
```

**Note:** You cannot set or alter the CONCURRENCY value for the admin_group to zero (0).

The `DROP RESOURCE GROUP` command drops a resource group. To drop a resource group for a role, the group cannot be assigned to any role, nor can there be any transactions active or waiting in the resource group. Dropping a resource group for an external component in which there are running instances kills the running instances.

To drop a resource group:

```sql
DROP RESOURCE GROUP exec;
```

**Assigning a Resource Group to a Role**

When you create a resource group with the default MEMORY_AUDITOR `vmtracker`, the group is available for assignment to one or more roles (users). You assign a resource group to a database role using the RESOURCE_GROUP clause of the CREATE ROLE or ALTER ROLE commands. If you do not specify a resource group for a role, the role is assigned the default group for the role's capability. SUPERUSER roles are assigned the admin_group, non-admin roles are assigned the group named default_group.

Use the `ALTER ROLE` or `CREATE ROLE` commands to assign a resource group to a role. For example:

```sql
ALTER ROLE bill RESOURCE GROUP rg_light;
CREATE ROLE mary RESOURCE GROUP exec;
```

You can assign a resource group to one or more roles. If you have defined a role hierarchy, assigning a resource group to a parent role does not propagate down to the members of that role group.

**Note:** You cannot assign a resource group that you create for an external component to a role.

If you wish to remove a resource group assignment from a role and assign the role the default group, change the role's group name assignment to NONE. For example:

```sql
ALTER ROLE mary RESOURCE GROUP NONE;
```
Monitoring Resource Group Status

Monitoring the status of your resource groups and queries may involve the following tasks:

- Viewing Resource Group Limits
- Viewing Resource Group Query Status and CPU/Memory Usage
- Viewing the Resource Group Assigned to a Role
- Viewing a Resource Group’s Running and Pending Queries
- Cancelling a Running or Queued Transaction in a Resource Group

Viewing Resource Group Limits

The `gp_resgroup_config` `gp_toolkit` system view displays the current and proposed limits for a resource group. The proposed limit differs from the current limit when you alter the limit but the new value cannot be immediately applied. To view the limits of all resource groups:

```
=# SELECT * FROM gp_toolkit.gp_resgroup_config;
```

The `gp_toolkit.gp_resgroup_config` view does not display the resource group memory auditor or CPU core assignment attributes. To view these attributes along with the other resource group limits, run the following query:

```
=# SELECT g.oid AS groupid, g.rsgname AS groupname,
    t1.value AS concurrency, t1.proposed AS proposed_concurrency,
    t2.value AS cpu_rate_limit, t3.value AS memory_limit,
    t3.proposed AS proposed_memory_limit,
    t4.value AS memory_shared_quota,
    t4.proposed AS proposed_memory_shared_quota,
    t5.value AS memory_spill_ratio,
    t5.proposed AS proposed_memory_spill_ratio,
    CASE
        WHEN t6.value IS NULL THEN 'vmtracker'::text
        WHEN t6.value = '0'::text THEN 'vmtracker'::text
        WHEN t6.value = '1'::text THEN 'cgroup'::text
        ELSE 'unknown'::text
    END AS memory_auditor,
    t7.value AS cpuset
FROM pg_resgroup g
    JOIN pg_resgroupcapability t1 ON g.oid = t1.resgroupid AND t1.reslimittype = 1
    JOIN pg_resgroupcapability t2 ON g.oid = t2.resgroupid AND t2.reslimittype = 2
    JOIN pg_resgroupcapability t3 ON g.oid = t3.resgroupid AND t3.reslimittype = 3
    JOIN pg_resgroupcapability t4 ON g.oid = t4.resgroupid AND t4.reslimittype = 4
    JOIN pg_resgroupcapability t5 ON g.oid = t5.resgroupid AND t5.reslimittype = 5
    LEFT JOIN pg_resgroupcapability t6 ON g.oid = t6.resgroupid AND t6.reslimittype = 6
    LEFT JOIN pg_resgroupcapability t7 ON g.oid = t7.resgroupid AND t7.reslimittype = 7;
```
**Viewing Resource Group Query Status and CPU/Memory Usage**

The `gp_resgroup_status` `gp_toolkit` system view enables you to view the status and activity of a resource group. The view displays the number of running and queued transactions. It also displays the real-time CPU and memory usage of the resource group. To view this information:

```sql
=# SELECT * FROM gp_toolkit.gp_resgroup_status;
```

**Viewing the Resource Group Assigned to a Role**

To view the resource group-to-role assignments, perform the following query on the `pg_roles` and `pg_resgroup` system catalog tables:

```sql
=# SELECT rolname, rsgname FROM pg_roles, pg_resgroup
    WHERE pg_roles.rolresgroup=pg_resgroup.oid;
```

**Viewing a Resource Group's Running and Pending Queries**

To view a resource group's running queries, pending queries, and how long the pending queries have been queued, examine the `pg_stat_activity` system catalog table:

```sql
=# SELECT current_query, waiting, rsgname, rsgqueueduration
    FROM pg_stat_activity;
```

`pg_stat_activity` displays information about the user/role that initiated a query. A query that uses an external component such as PL/Container is composed of two parts: the query operator that runs in Greenplum Database and the UDF that runs in a PL/Container instance. Greenplum Database processes the query operators under the resource group assigned to the role that initiated the query. A UDF running in a PL/Container instance runs under the resource group assigned to the PL/Container runtime. The latter is not represented in the `pg_stat_activity` view; Greenplum Database does not have any insight into how external components such as PL/Container manage memory in running instances.

**Cancelling a Running or Queued Transaction in a Resource Group**

There may be cases when you want to cancel a running or queued transaction in a resource group. For example, you may want to remove a query that is waiting in the resource group queue but has not yet been executed. Or, you may want to stop a running query that is taking too long to execute, or one that is sitting idle in a transaction and taking up resource group transaction slots that are needed by other users.

To cancel a running or queued transaction, you must first determine the process id (pid) associated with the transaction. Once you have obtained the process id, you can invoke `pg_cancel_backend()` to end that process, as shown below.

For example, to view the process information associated with all statements currently active or waiting in all resource groups, run the following query. If the query returns no results, then there are no running or queued transactions in any resource group.

```sql
=# SELECT rolname, g.rsgname, procpid, waiting, current_query, datname
    FROM pg_roles, gp_toolkit.gp_resgroup_status g, pg_stat_activity
    WHERE pg_roles.rolresgroup=g.groupid
    AND pg_stat_activity.usename=pg_roles.rolname;
```

Sample partial query output:

<table>
<thead>
<tr>
<th>rolname</th>
<th>rsgname</th>
<th>procpid</th>
<th>waiting</th>
<th>current_query</th>
<th>datname</th>
</tr>
</thead>
<tbody>
<tr>
<td>sammy</td>
<td>rg_light</td>
<td>31861</td>
<td>f</td>
<td>&lt;IDLE&gt; in transaction</td>
<td>testdb</td>
</tr>
<tr>
<td>billy</td>
<td>rg_light</td>
<td>31905</td>
<td>t</td>
<td>SELECT * FROM topten;</td>
<td>testdb</td>
</tr>
</tbody>
</table>
Use this output to identify the process id (**procpid**) of the transaction you want to cancel, and then cancel the process. For example, to cancel the pending query identified in the sample output above:

```
=# SELECT pg_cancel_backend(31905);
```

You can provide an optional message in a second argument to **pg_cancel_backend()** to indicate to the user why the process was cancelled.

**Note:**

Do not use an operating system **KILL** command to cancel any Greenplum Database process.

**Resource Group Frequently Asked Questions**

**CPU**

- **Why is CPU usage lower than the **CPU_RATE_LIMIT** configured for the resource group?**
  
  You may run into this situation when a low number of queries and slices are running in the resource group, and these processes are not utilizing all of the cores on the system.

- **Why is CPU usage for the resource group higher than the configured **CPU_RATE_LIMIT**?**
  
  This situation can occur in the following circumstances:
  
  - A resource group may utilize more CPU than its **CPU_RATE_LIMIT** when other resource groups are idle. In this situation, Greenplum Database allocates the CPU resource of an idle resource group to a busier one. This resource group feature is called CPU burst.
  
  - The operating system CPU scheduler may cause CPU usage to spike, then drop down. If you believe this might be occurring, calculate the average CPU usage within a given period of time (for example, 5 seconds) and use that average to determine if CPU usage is higher than the configured limit.

**Memory**

- **Why did my query return an "out of memory" error?**
  
  A transaction submitted in a resource group fails and exits when memory usage exceeds its fixed memory allotment, no available resource group shared memory exists, and the transaction requests more memory.

- **Why did my query return a "memory limit reached" error?**
  
  Greenplum Database automatically adjusts transaction and group memory to the new settings when you use **ALTER RESOURCE GROUP** to change a resource group’s memory and/or concurrency limits. An "out of memory" error may occur if you recently altered resource group attributes and there is no longer a sufficient amount of memory available for a currently running query.

- **Why does the actual memory usage of my resource group exceed the amount configured for the group?**
  
  The actual memory usage of a resource group may exceed the configured amount when one or more queries running in the group is allocated memory from the global shared memory pool. (If no global shared memory is available, queries fail and do not impact the memory resources of other resource groups.)

  When global shared memory is available, memory usage may exceed the configured amount when a transaction spills to disk. Greenplum Database statements continue to request memory when they start to spill to disk because:
  
  - Spilling to disk requires extra memory to work.
  
    - Other operators may continue to request memory.
Memory usage grows in spill situations; when global shared memory is available, the resource group may eventually use up to 200-300% of its configured group memory limit.

Concurrency

- Why is the number of running transactions lower than the \texttt{CONCURRENCY} limit configured for the resource group?

Greenplum Database considers memory availability before running a transaction, and will queue the transaction if there is not enough memory available to serve it. If you use \texttt{ALTER RESOURCE GROUP} to increase the \texttt{CONCURRENCY} limit for a resource group but do not also adjust memory limits, currently running transactions may be consuming all allotted memory resources for the group. When in this state, Greenplum Database queues subsequent transactions in the resource group.

- Why is the number of running transactions in the resource group higher than the configured \texttt{CONCURRENCY} limit?

The resource group may be running \texttt{SET} and \texttt{SHOW} commands, which bypass resource group transaction checks.

Using Resource Queues

Use Greenplum Database resource queues to prioritize and allocate resources to queries according to business requirements and to prevent queries from starting when resources are unavailable.

Resource queues are one tool to manage the degree of concurrency in a Greenplum Database system. Resource queues are database objects that you create with the \texttt{CREATE RESOURCE QUEUE} SQL statement. You can use them to manage the number of active queries that may execute concurrently, the amount of memory each type of query is allocated, and the relative priority of queries. Resource queues can also guard against queries that would consume too many resources and degrade overall system performance.

Each database role is associated with a single resource queue; multiple roles can share the same resource queue. Roles are assigned to resource queues using the \texttt{RESOURCE QUEUE} phrase of the \texttt{CREATE ROLE} or \texttt{ALTER ROLE} statements. If a resource queue is not specified, the role is associated with the default resource queue, \texttt{pg_default}.

When the user submits a query for execution, the query is evaluated against the resource queue's limits. If the query does not cause the queue to exceed its resource limits, then that query will run immediately. If the query causes the queue to exceed its limits (for example, if the maximum number of active statement slots are currently in use), then the query must wait until queue resources are free before it can run.

Queries are evaluated on a first in, first out basis. If query prioritization is enabled, the active workload on the system is periodically assessed and processing resources are reallocated according to query priority (see \textit{How Priorities Work}). Roles with the \texttt{SUPERUSER} attribute are exempt from resource queue limits. Superuser queries always run immediately regardless of limits imposed by their assigned resource queue.
Figure 33: Resource Queue Process

Resource queues define classes of queries with similar resource requirements. Administrators should create resource queues for the various types of workloads in their organization. For example, you could create resource queues for the following classes of queries, corresponding to different service level agreements:

- ETL queries
- Reporting queries
- Executive queries

A resource queue has the following characteristics:

**MEMORY_LIMIT**

The amount of memory used by all the queries in the queue (per segment). For example, setting `MEMORY_LIMIT` to 2GB on the ETL queue allows ETL queries to use up to 2GB of memory in each segment.

**ACTIVE_STATEMENTS**

The number of slots for a queue; the maximum concurrency level for a queue. When all slots are used, new queries must wait. Each query uses an equal amount of memory by default.

For example, the `pg_default` resource queue has `ACTIVE_STATEMENTS = 20`.

**PRIORITY**

The relative CPU usage for queries. This may be one of the following levels: LOW, MEDIUM, HIGH, MAX. The default level is MEDIUM. The query prioritization mechanism monitors the CPU usage of all the queries running in the system, and adjusts the CPU usage for each to conform to its priority level. For example, you could set MAX priority to the executive resource queue and MEDIUM to other queues to ensure that executive queries receive a greater share of CPU.

**MAX_COST**

Query plan cost limit.

The Greenplum Database optimizer assigns a numeric cost to each query. If the cost exceeds the `MAX_COST` value set for the resource queue, the query is rejected as too expensive.

**Note:** GPORCA and the legacy Greenplum Database query optimizer utilize different query costing models and may compute different costs for the same query. The Greenplum Database resource queue resource management scheme neither differentiates nor aligns costs between GPORCA and the
legacy optimizer; it uses the literal cost value returned from the optimizer to throttle queries.

When resource queue-based resource management is active, use the MEMORY_LIMIT and ACTIVE_STATEMENTS limits for resource queues rather than configuring cost-based limits. Even when using GPORCA, Greenplum Database may fall back to using the legacy query optimizer for certain queries, so using cost-based limits can lead to unexpected results.

The default configuration for a Greenplum Database system has a single default resource queue named pg_default. The pg_default resource queue has an ACTIVE_STATEMENTS setting of 20, no MEMORY_LIMIT, medium PRIORITY, and no set MAX_COST. This means that all queries are accepted and run immediately, at the same priority and with no memory limitations; however, only twenty queries may execute concurrently.

The number of concurrent queries a resource queue allows depends on whether the MEMORY_LIMIT parameter is set:

- If no MEMORY_LIMIT is set for a resource queue, the amount of memory allocated per query is the value of the statement_mem server configuration parameter. The maximum memory the resource queue can use is the product of statement_mem and ACTIVE_STATEMENTS.
- When a MEMORY_LIMIT is set on a resource queue, the number of queries that the queue can execute concurrently is limited by the queue's available memory.

A query admitted to the system is allocated an amount of memory and a query plan tree is generated for it. Each node of the tree is an operator, such as a sort or hash join. Each operator is a separate execution thread and is allocated a fraction of the overall statement memory, at minimum 100KB. If the plan has a large number of operators, the minimum memory required for operators can exceed the available memory and the query will be rejected with an insufficient memory error. Operators determine if they can complete their tasks in the memory allocated, or if they must spill data to disk, in work files. The mechanism that allocates and controls the amount of memory used by each operator is called memory quota.

Not all SQL statements submitted through a resource queue are evaluated against the queue limits. By default only SELECT, SELECT INTO, CREATE TABLE AS SELECT, and DECLARE CURSOR statements are evaluated. If the server configuration parameter resource_select_only is set to off, then INSERT, UPDATE, and DELETE statements will be evaluated as well.

Also, an SQL statement that is run during the execution of an EXPLAIN ANALYZE command is excluded from resource queues.

**Resource Queue Example**

The default resource queue, pg_default, allows a maximum of 20 active queries and allocates the same amount of memory to each. This is generally not adequate resource control for production systems. To ensure that the system meets performance expectations, you can define classes of queries and assign them to resource queues configured to execute them with the concurrency, memory, and CPU resources best suited for that class of query.

The following illustration shows an example resource queue configuration for a Greenplum Database system with gp_vmem_protect_limit set to 8GB:
Figure 34: Resource Queue Configuration Example

This example has three classes of queries with different characteristics and service level agreements (SLAs). Three resource queues are configured for them. A portion of the segment memory is reserved as a safety margin.

<table>
<thead>
<tr>
<th>Resource Queue Name</th>
<th>Active Statements</th>
<th>Memory Limit</th>
<th>Memory per Query</th>
</tr>
</thead>
<tbody>
<tr>
<td>ETL</td>
<td>3</td>
<td>2GB</td>
<td>667MB</td>
</tr>
<tr>
<td>Reporting</td>
<td>7</td>
<td>3GB</td>
<td>429MB</td>
</tr>
<tr>
<td>Executive</td>
<td>1</td>
<td>1.4GB</td>
<td>1.4GB</td>
</tr>
</tbody>
</table>

The total memory allocated to the queues is 6.4GB, or 80% of the total segment memory defined by the `gp_vmem_protect_limit` server configuration parameter. Allowing a safety margin of 20% accommodates some operators and queries that are known to use more memory than they are allocated by the resource queue.

See the `CREATE RESOURCE QUEUE` and `CREATE/ALTER ROLE` statements in the *Greenplum Database Reference Guide* for help with command syntax and detailed reference information.

**How Memory Limits Work**

Setting `MEMORY_LIMIT` on a resource queue sets the maximum amount of memory that all active queries submitted through the queue can consume for a segment instance. The amount of memory allotted to a query is the queue memory limit divided by the active statement limit. (Use the memory limits in conjunction with statement-based queues rather than cost-based queues.) For example, if a queue has a memory limit of 2000MB and an active statement limit of 10, each query submitted through the queue is allotted 200MB of memory by default. The default memory allotment can be overridden on a per-query basis using the `statement_mem` server configuration parameter (up to the queue memory limit). Once a query has started executing, it holds its allotted memory in the queue until it completes, even if during execution it actually consumes less than its allotted amount of memory.

You can use the `statement_mem` server configuration parameter to override memory limits set by the current resource queue. At the session level, you can increase `statement_mem` up to the resource queue’s `MEMORY_LIMIT`. This will allow an individual query to use all of the memory allocated for the entire queue without affecting other resource queues.

The value of `statement_mem` is capped using the `max_statement_mem` configuration parameter (a superuser parameter). For a query in a resource queue with `MEMORY_LIMIT` set, the maximum value for `statement_mem` is `min(MEMORY_LIMIT, max_statement_mem)`. When a query is admitted, the memory allocated to it is subtracted from `MEMORY_LIMIT`. If `MEMORY_LIMIT` is exhausted, new queries in the same resource queue must wait. This happens even if `ACTIVE_STATEMENTS` has not yet been reached. Note that this can happen only when `statement_mem` is used to override the memory allocated by the resource queue.

For example, consider a resource queue named `adhoc` with the following settings:

- `MEMORY_LIMIT` is 1.5GB
- `ACTIVE_STATEMENTS` is 3
By default each statement submitted to the queue is allocated 500MB of memory. Now consider the following series of events:

1. User ADHOC_1 submits query Q1, overriding STATEMENT_MEM to 800MB. The Q1 statement is admitted into the system.
2. User ADHOC_2 submits query Q2, using the default 500MB.
3. With Q1 and Q2 still running, user ADHOC3 submits query Q3, using the default 500MB.

Queries Q1 and Q2 have used 1300MB of the queue's 1500MB. Therefore, Q3 must wait for Q1 or Q2 to complete before it can run.

If MEMORY_LIMIT is not set on a queue, queries are admitted until all of the ACTIVE_STATEMENTS slots are in use, and each query can set an arbitrarily high statement_mem. This could lead to a resource queue using unbounded amounts of memory.

For more information on configuring memory limits on a resource queue, and other memory utilization controls, see Creating Queues with Memory Limits.

statement_mem and Low Memory Queries

A low statement_mem setting (for example, in the 1-3MB range) has been shown to increase the performance of queries with low memory requirements. Use the statement_mem server configuration parameter to override the setting on a per-query basis. For example:

```
SET statement_mem='2MB';
```

How Priorities Work

The PRIORITY setting for a resource queue differs from the MEMORY_LIMIT and ACTIVE_STATEMENTS settings, which determine whether a query will be admitted to the queue and eventually executed. The PRIORITY setting applies to queries after they become active. Active queries share available CPU resources as determined by the priority settings for its resource queue. When a statement from a high-priority queue enters the group of actively running statements, it may claim a greater share of the available CPU, reducing the share allocated to already-running statements in queues with a lesser priority setting.

The comparative size or complexity of the queries does not affect the allotment of CPU. If a simple, low-cost query is running simultaneously with a large, complex query, and their priority settings are the same, they will be allocated the same share of available CPU resources. When a new query becomes active, the CPU shares will be recalculated, but queries of equal priority will still have equal amounts of CPU.

For example, an administrator creates three resource queues: adhoc for ongoing queries submitted by business analysts, reporting for scheduled reporting jobs, and executive for queries submitted by executive user roles. The administrator wants to ensure that scheduled reporting jobs are not heavily affected by unpredictable resource demands from ad-hoc analyst queries. Also, the administrator wants to make sure that queries submitted by executive roles are allotted a significant share of CPU. Accordingly, the resource queue priorities are set as shown:

- adhoc — Low priority
- reporting — High priority
- executive — Maximum priority

At runtime, the CPU share of active statements is determined by these priority settings. If queries 1 and 2 from the reporting queue are running simultaneously, they have equal shares of CPU. When an ad-hoc query becomes active, it claims a smaller share of CPU. The exact share used by the reporting queries is adjusted, but remains equal due to their equal priority setting:
Figure 35: CPU share readjusted according to priority

**Note:**

The percentages shown in these illustrations are approximate. CPU usage between high, low and maximum priority queues is not always calculated in precisely these proportions.

When an executive query enters the group of running statements, CPU usage is adjusted to account for its maximum priority setting. It may be a simple query compared to the analyst and reporting queries, but until it is completed, it will claim the largest share of CPU.
Steps to Enable Resource Management

Enabling and using resource management in Greenplum Database involves the following high-level tasks:

2. Create the resource queues and set limits on them. See Creating Resource Queues and Modifying Resource Queues.
3. Assign a queue to one or more user roles. See Assigning Roles (Users) to a Resource Queue.
4. Use the resource management system views to monitor and manage the resource queues. See Checking Resource Queue Status.

Configuring Resource Management

Resource scheduling is enabled by default when you install Greenplum Database, and is required for all roles. The default resource queue, pg_default, has an active statement limit of 20, no memory limit, and a medium priority setting. Create resource queues for the various types of workloads.

To configure resource management

1. The following parameters are for the general configuration of resource queues:
   - max_resource_queues - Sets the maximum number of resource queues.
   - max_resource_portals_per_transaction - Sets the maximum number of simultaneously open cursors allowed per transaction. Note that an open cursor will hold an active query slot in a resource queue.
• resource_select_only - If set to on, then SELECT, SELECT INTO, CREATE TABLE AS SELECT, and DECLARE CURSOR commands are evaluated. If set to off, INSERT, UPDATE, and DELETE commands will be evaluated as well.
• resource_cleanup_gangs_on_wait - Cleans up idle segment worker processes before taking a slot in the resource queue.
• stats_queue_level - Enables statistics collection on resource queue usage, which can then be viewed by querying the pg_stat_resqueues system view.

2. The following parameters are related to memory utilization:

• gp_resqueue_memory_policy - Enables Greenplum Database memory management features. In Greenplum Database 4.2 and later, the distribution algorithm eager_free takes advantage of the fact that not all operators execute at the same time. The query plan is divided into stages and Greenplum Database eagerly frees memory allocated to a previous stage at the end of that stage's execution, then allocates the eagerly freed memory to the new stage.

When set to none, memory management is the same as in Greenplum Database releases prior to 4.1. When set to auto, query memory usage is controlled by statement_mem and resource queue memory limits.

• statement_mem and max_statement_mem - Used to allocate memory to a particular query at runtime (override the default allocation assigned by the resource queue). max_statement_mem is set by database superusers to prevent regular database users from over-allocation.
• gp_vmem_protect_limit - Sets the upper boundary that all query processes can consume and should not exceed the amount of physical memory of a segment host. When a segment host reaches this limit during query execution, the queries that cause the limit to be exceeded will be cancelled.

• gp_vmem_idle_resource_timeout and gp_vmem_protect.segworker_cache_limit - used to free memory on segment hosts held by idle database processes. Administrators may want to adjust these settings on systems with lots of concurrency.
• shared_buffers - Sets the amount of memory a Greenplum server instance uses for shared memory buffers. This setting must be at least 128 kilobytes and at least 16 kilobytes times max_connections. The value must not exceed the operating system shared memory maximum allocation request size, shmmax on Linux. See the Greenplum Database Installation Guide for recommended OS memory settings for your platform.

3. The following parameters are related to query prioritization. Note that the following parameters are all local parameters, meaning they must be set in the postgresql.conf files of the master and all segments:

• gp_resqueue_priority - The query prioritization feature is enabled by default.
• gp_resqueue_priority_sweeper_interval - Sets the interval at which CPU usage is recalculated for all active statements. The default value for this parameter should be sufficient for typical database operations.
• gp_resqueue_priority_cpucores_per_segment - Specifies the number of CPU cores allocated per segment instance. The default value is 4 for the master and segments. For Greenplum Data Computing Appliance Version 2, the default value is 4 for segments and 25 for the master.

Each host checks its own postgresql.conf file for the value of this parameter. This parameter also affects the master node, where it should be set to a value reflecting the higher ratio of CPU cores. For example, on a cluster that has 10 CPU cores per host and 4 segments per host, you would specify these values for gp_resqueue_priority_cpucores.per_segment:

10 for the master and standby master. Typically, only the master instance is on the master host.

2.5 for segment instances on the segment hosts.

If the parameter value is not set correctly, either the CPU might not be fully utilized, or query prioritization might not work as expected. For example, if the Greenplum Database cluster has fewer than one segment instance per CPU core on your segment hosts, make sure you adjust this value accordingly.
Actual CPU core utilization is based on the ability of Greenplum Database to parallelize a query and the resources required to execute the query.

Note: Any CPU core that is available to the operating system is included in the number of CPU cores. For example, virtual CPU cores are included in the number of CPU cores.

4. If you wish to view or change any of the resource management parameter values, you can use the `gpconfig` utility.

5. For example, to see the setting of a particular parameter:

   ```
   $ gpconfig --show gp_vmem_protect_limit
   ```

6. For example, to set one value on all segment instances and a different value on the master:

   ```
   $ gpconfig -c gp_resqueue_priority_cpucores_per_segment -v 2 -m 8
   ```

7. Restart Greenplum Database to make the configuration changes effective:

   ```
   $ gpstop -r
   ```

### Creating Resource Queues

Creating a resource queue involves giving it a name, setting an active query limit, and optionally a query priority on the resource queue. Use the `CREATE RESOURCE QUEUE` command to create new resource queues.

#### Creating Queues with an Active Query Limit

Resource queues with an `ACTIVE_STATEMENTS` setting limit the number of queries that can be executed by roles assigned to that queue. For example, to create a resource queue named `adhoc` with an active query limit of three:

```
=# CREATE RESOURCE QUEUE adhoc WITH (ACTIVE_STATEMENTS=3);
```

This means that for all roles assigned to the `adhoc` resource queue, only three active queries can be running on the system at any given time. If this queue has three queries running, and a fourth query is submitted by a role in that queue, that query must wait until a slot is free before it can run.

#### Creating Queues with Memory Limits

Resource queues with a `MEMORY_LIMIT` setting control the amount of memory for all the queries submitted through the queue. The total memory should not exceed the physical memory available per-segment. Set `MEMORY_LIMIT` to 90% of memory available on a per-segment basis. For example, if a host has 48 GB of physical memory and 6 segment instances, then the memory available per segment instance is 8 GB. You can calculate the recommended `MEMORY_LIMIT` for a single queue as 0.90*8=7.2 GB. If there are multiple queues created on the system, their total memory limits must also add up to 7.2 GB.

When used in conjunction with `ACTIVE_STATEMENTS`, the default amount of memory allotted per query is: `MEMORY_LIMIT / ACTIVE_STATEMENTS`. When used in conjunction with `MAX_COST`, the default amount of memory allotted per query is: `MEMORY_LIMIT * (query_cost / MAX_COST)`. Use `MEMORY_LIMIT` in conjunction with `ACTIVE_STATEMENTS` rather than with `MAX_COST`.

For example, to create a resource queue with an active query limit of 10 and a total memory limit of 2000MB (each query will be allocated 200MB of segment host memory at execution time):

```
=# CREATE RESOURCE QUEUE myqueue WITH (ACTIVE_STATEMENTS=20, MEMORY_LIMIT='2000MB');
```
The default memory allotment can be overridden on a per-query basis using the `statement_mem` server configuration parameter, provided that `MEMORY_LIMIT` or `max_statement_mem` is not exceeded. For example, to allocate more memory to a particular query:

```sql
=> SET statement_mem='2GB';
=> SELECT * FROM my_big_table WHERE column='value' ORDER BY id;
=> RESET statement_mem;
```

As a general guideline, `MEMORY_LIMIT` for all of your resource queues should not exceed the amount of physical memory of a segment host. If workloads are staggered over multiple queues, it may be OK to oversubscribe memory allocations, keeping in mind that queries may be cancelled during execution if the segment host memory limit (`gp_vmem_protect_limit`) is exceeded.

### Setting Priority Levels

To control a resource queue's consumption of available CPU resources, an administrator can assign an appropriate priority level. When high concurrency causes contention for CPU resources, queries and statements associated with a high-priority resource queue will claim a larger share of available CPU than lower priority queries and statements.

Priority settings are created or altered using the `WITH` parameter of the commands `CREATE RESOURCE QUEUE` and `ALTER RESOURCE QUEUE`. For example, to specify priority settings for the `adhoc` and `reporting` queues, an administrator would use the following commands:

```sql
=# ALTER RESOURCE QUEUE adhoc WITH (PRIORITY=LOW);
=# ALTER RESOURCE QUEUE reporting WITH (PRIORITY=HIGH);
```

To create the `executive` queue with maximum priority, an administrator would use the following command:

```sql
=# CREATE RESOURCE QUEUE executive WITH (ACTIVE_STATEMENTS=3, PRIORITY=MAX);
```

When the query prioritization feature is enabled, resource queues are given a **MEDIUM** priority by default if not explicitly assigned. For more information on how priority settings are evaluated at runtime, see *How Priorities Work*.

**Important:** In order for resource queue priority levels to be enforced on the active query workload, you must enable the query prioritization feature by setting the associated server configuration parameters. See *Configuring Resource Management*.

### Assigning Roles (Users) to a Resource Queue

Once a resource queue is created, you must assign roles (users) to their appropriate resource queue. If roles are not explicitly assigned to a resource queue, they will go to the default resource queue, `pg_default`. The default resource queue has an active statement limit of 20, no cost limit, and a medium priority setting.

Use the `ALTER ROLE` or `CREATE ROLE` commands to assign a role to a resource queue. For example:

```sql
=# ALTER ROLE name RESOURCE QUEUE queue_name;
=# CREATE ROLE name WITH LOGIN RESOURCE QUEUE queue_name;
```

A role can only be assigned to one resource queue at any given time, so you can use the `ALTER ROLE` command to initially assign or change a role's resource queue.

Resource queues must be assigned on a user-by-user basis. If you have a role hierarchy (for example, a group-level role) then assigning a resource queue to the group does not propagate down to the users in that group.

Superusers are always exempt from resource queue limits. Superuser queries will always run regardless of the limits set on their assigned queue.
Removing a Role from a Resource Queue

All users must be assigned to a resource queue. If not explicitly assigned to a particular queue, users will go into the default resource queue, \textit{pg\_default}. If you wish to remove a role from a resource queue and put them in the default queue, change the role's queue assignment to none. For example:

```
=# ALTER ROLE role\_name RESOURCE QUEUE none;
```

Modifying Resource Queues

After a resource queue has been created, you can change or reset the queue limits using the \texttt{ALTER RESOURCE QUEUE} command. You can remove a resource queue using the \texttt{DROP RESOURCE QUEUE} command. To change the roles (users) assigned to a resource queue, \textit{Assigning Roles (Users) to a Resource Queue}.

Altering a Resource Queue

The \texttt{ALTER RESOURCE QUEUE} command changes the limits of a resource queue. To change the limits of a resource queue, specify the new values you want for the queue. For example:

```
=# ALTER RESOURCE QUEUE adhoc WITH (ACTIVE\_STATEMENTS=5);
=# ALTER RESOURCE QUEUE exec WITH (PRIORITY=MAX);
```

To reset active statements or memory limit to no limit, enter a value of \texttt{-1}. To reset the maximum query cost to no limit, enter a value of \texttt{-1.0}. For example:

```
=# ALTER RESOURCE QUEUE adhoc WITH (MAX\_COST=-1.0, MEMORY\_LIMIT='2GB');
```

You can use the \texttt{ALTER RESOURCE QUEUE} command to change the priority of queries associated with a resource queue. For example, to set a queue to the minimum priority level:

```
ALTER RESOURCE QUEUE webuser WITH (PRIORITY=MIN);
```

Dropping a Resource Queue

The \texttt{DROP RESOURCE QUEUE} command drops a resource queue. To drop a resource queue, the queue cannot have any roles assigned to it, nor can it have any statements waiting in the queue. See \textit{Removing a Role from a Resource Queue} and \textit{Clearing a Waiting Statement From a Resource Queue} for instructions on emptying a resource queue. To drop a resource queue:

```
=# DROP RESOURCE QUEUE name;
```

Checking Resource Queue Status

Checking resource queue status involves the following tasks:

- \textit{Viewing Queued Statements and Resource Queue Status}
- \textit{Viewing Resource Queue Statistics}
- \textit{Viewing the Roles Assigned to a Resource Queue}
- \textit{Viewing the Waiting Queries for a Resource Queue}
- \textit{Clearing a Waiting Statement From a Resource Queue}
- \textit{Viewing the Priority of Active Statements}
- \textit{Resetting the Priority of an Active Statement}
**Viewing Queued Statements and Resource Queue Status**

The `gp_toolkit.gp_resqueue_status` view allows administrators to see status and activity for a resource queue. It shows how many queries are waiting to run and how many queries are currently active in the system from a particular resource queue. To see the resource queues created in the system, their limit attributes, and their current status:

```
=# SELECT * FROM gp_toolkit.gp_resqueue_status;
```

**Viewing Resource Queue Statistics**

If you want to track statistics and performance of resource queues over time, you can enable statistics collecting for resource queues. This is done by setting the following server configuration parameter in your `master_postgresql.conf` file:

```
stats_queue_level = on
```

Once this is enabled, you can use the `pg_stat_resqueues` system view to see the statistics collected on resource queue usage. Note that enabling this feature does incur slight performance overhead, as each query submitted through a resource queue must be tracked. It may be useful to enable statistics collecting on resource queues for initial diagnostics and administrative planning, and then disable the feature for continued use.

See the Statistics Collector section in the PostgreSQL documentation for more information about collecting statistics in Greenplum Database.

**Viewing the Roles Assigned to a Resource Queue**

To see the roles assigned to a resource queue, perform the following query of the `pg_roles` and `gp_toolkit.gp_resqueue_status` system catalog tables:

```
=# SELECT rolname, rsqname FROM pg_roles, gp_toolkit.gp_resqueue_status
    WHERE pg_roles.rolresqueue=gp_toolkit.gp_resqueue_status.queueid;
```

You may want to create a view of this query to simplify future inquiries. For example:

```
=# CREATE VIEW role2queue AS
    SELECT rolname, rsqname FROM pg_roles, pg_resqueue
    WHERE pg_roles.rolresqueue=gp_toolkit.gp_resqueue_status.queueid;
```

Then you can just query the view:

```
=# SELECT * FROM role2queue;
```

**Viewing the Waiting Queries for a Resource Queue**

When a slot is in use for a resource queue, it is recorded in the `pg_locks` system catalog table. This is where you can see all of the currently active and waiting queries for all resource queues. To check that statements are being queued (even statements that are not waiting), you can also use the `gp_toolkit.gp_locks_on_resqueue` view. For example:

```
=# SELECT * FROM gp_toolkit.gp_locks_on_resqueue WHERE lorwaiting='true';
```

If this query returns no results, then that means there are currently no statements waiting in a resource queue.
Clearing a Waiting Statement From a Resource Queue

In some cases, you may want to clear a waiting statement from a resource queue. For example, you may want to remove a query that is waiting in the queue but has not been executed yet. You may also want to stop a query that has been started if it is taking too long to execute, or if it is sitting idle in a transaction and taking up resource queue slots that are needed by other users. To do this, you must first identify the statement you want to clear, determine its process id (pid), and then, use `pg_cancel_backend` with the process id to end that process, as shown below. An optional message to the process can be passed as the second parameter, to indicate to the user why the process was cancelled.

For example, to see process information about all statements currently active or waiting in all resource queues, run the following query:

```sql
=# SELECT rolname, rsqname, pid, granted,
    current_query, datname
    FROM pg_roles, gp_toolkit.gp_resqueue_status, pg_locks, pg_stat_activity
    WHERE pg_roles.rolresqueue=pg_locks.objid
    AND pg_locks.objid=gp_toolkit.gp_resqueue_status.queueid
    AND pg_stat_activity.procpid=pg_locks.pid
    AND pg_stat_activity.usename=pg_roles.rolname;
```

If this query returns no results, then that means there are currently no statements in a resource queue. A sample of a resource queue with two statements in it looks something like this:

<table>
<thead>
<tr>
<th>rolname</th>
<th>rsqname</th>
<th>pid</th>
<th>granted</th>
<th>current_query</th>
<th>datname</th>
</tr>
</thead>
<tbody>
<tr>
<td>sammy</td>
<td>webuser</td>
<td>31861</td>
<td>t</td>
<td>&lt;IDLE&gt; in transaction</td>
<td>namesdb</td>
</tr>
<tr>
<td>daria</td>
<td>webuser</td>
<td>31905</td>
<td>f</td>
<td>SELECT * FROM topten;</td>
<td>namesdb</td>
</tr>
</tbody>
</table>

Use this output to identify the process id (pid) of the statement you want to clear from the resource queue. To clear the statement, you would then open a terminal window (as the `gpadmin` database superuser or as root) on the master host and cancel the corresponding process. For example:

```sql
=# pg_cancel_backend(31905)
```

**Note:**
Do not use any operating system `KILL` command.

Viewing the Priority of Active Statements

The `gp_toolkit` administrative schema has a view called `gp_resq_priority_statement`, which lists all statements currently being executed and provides the priority, session ID, and other information.

This view is only available through the `gp_toolkit` administrative schema. See the Greenplum Database Reference Guide for more information.

Resetting the Priority of an Active Statement

Superusers can adjust the priority of a statement currently being executed using the built-in function `gp_adjust_priority(session_id, statement_count, priority)`. Using this function, superusers can raise or lower the priority of any query. For example:

```sql
=# SELECT gp_adjust_priority(752, 24905, 'HIGH')
```

To obtain the session ID and statement count parameters required by this function, superusers can use the `gp_toolkit` administrative schema view, `gp_resq_priority_statement`. From the view, use these values for the function parameters.

- The value of the `rqpsession` column for the `session_id` parameter
• The value of the `rqpcommand` column for the `statement_count` parameter
• The value of `rqppriority` column is the current priority. You can specify a string value of `MAX`, `HIGH`, `MEDIUM`, or `LOW` as the priority.

Note: The `gp_adjust_priority()` function affects only the specified statement. Subsequent statements in the same resource queue are executed using the queue's normally assigned priority.

**Investigating a Performance Problem**

This section provides guidelines for identifying and troubleshooting performance problems in a Greenplum Database system.

This topic lists steps you can take to help identify the cause of a performance problem. If the problem affects a particular workload or query, you can focus on tuning that particular workload. If the performance problem is system-wide, then hardware problems, system failures, or resource contention may be the cause.

**Checking System State**

Use the `gpstate` utility to identify failed segments. A Greenplum Database system will incur performance degradation when segment instances are down because other hosts must pick up the processing responsibilities of the down segments.

Failed segments can indicate a hardware failure, such as a failed disk drive or network card. Greenplum Database provides the hardware verification tool `gpcheckperf` to help identify the segment hosts with hardware issues.

**Checking Database Activity**

- Checking for Active Sessions (Workload)
- Checking for Locks (Contention)
- Checking Query Status and System Utilization

**Checking for Active Sessions (Workload)**

The `pg_stat_activity` system catalog view shows one row per server process; it shows the database OID, database name, process ID, user OID, user name, current query, time at which the current query began execution, time at which the process was started, client address, and port number. To obtain the most information about the current system workload, query this view as the database superuser. For example:

```sql
SELECT * FROM pg_stat_activity;
```

Note that the information does not update instantaneously.

**Checking for Locks (Contention)**

The `pg_locks` system catalog view allows you to see information about outstanding locks. If a transaction is holding a lock on an object, any other queries must wait for that lock to be released before they can continue. This may appear to the user as if a query is hanging.

Examine `pg_locks` for ungranted locks to help identify contention between database client sessions. `pg_locks` provides a global view of all locks in the database system, not only those relevant to the current database. You can join its relation column against `pg_class.oid` to identify locked relations (such as tables), but this works correctly only for relations in the current database. You can join the `pid` column to the `pg_stat_activity.procpid` to see more information about the session holding or waiting to hold a lock. For example:

```sql
SELECT locktype, database, c.relname, l.relation, l.transactionid, l.pid, l.mode, l.granted,
```
Checking Query Status and System Utilization

You can use system monitoring utilities such as `ps`, `top`, `iostat`, `vmstat`, `netstat` and so on to monitor database activity on the hosts in your Greenplum Database array. These tools can help identify Greenplum Database processes (`postgres` processes) currently running on the system and the most resource intensive tasks with regards to CPU, memory, disk I/O, or network activity. Look at these system statistics to identify queries that degrade database performance by overloading the system and consuming excessive resources. Greenplum Database's management tool `gpssh` allows you to run these system monitoring commands on several hosts simultaneously.

You can create and use the Greenplum Database `session_level_memory_consumption` view that provides information about the current memory utilization and idle time for sessions that are running queries on Greenplum Database. For information about the view, see `Viewing Session Memory Usage Information`.

You can enable a dedicated database, `gpperfmon`, in which data collection agents running on each segment host save query and system utilization metrics. Refer to the `gperfmon_install` management utility reference in the `Greenplum Database Management Utility Reference Guide` for help creating the `gpperfmon` database and managing the agents. See documentation for the tables and views in the `gpperfmon` database in the `Greenplum Database Reference Guide`.

The optional Greenplum Command Center web-based user interface graphically displays query and system utilization metrics saved in the `gpperfmon` database. See the `Greenplum Command Center Documentation` web site for procedures to enable Greenplum Command Center.

Troubleshooting Problem Queries

If a query performs poorly, look at its query plan to help identify problems. The `EXPLAIN` command shows the query plan for a given query. See `Query Profiling` for more information about reading query plans and identifying problems.

When an out of memory event occurs during query execution, the Greenplum Database memory accounting framework reports detailed memory consumption of every query running at the time of the event. The information is written to the Greenplum Database segment logs.

Investigating Error Messages

Greenplum Database log messages are written to files in the `pg_log` directory within the master's or segment's data directory. Because the master log file contains the most information, you should always check it first. Log files roll over daily and use the naming convention: `gpdb-YYYY-MM-DD_hhmmss.csv`. To locate the log files on the master host:

```
$ cd $MASTER_DATA_DIRECTORY/pg_log
```
Log lines have the format of:

```
timestamp | user | database | statement_id | con#cmd#
|:--LOG_LEVEL: | log_message
```

You may want to focus your search for WARNING, ERROR, FATAL or PANIC log level messages. You can use the Greenplum utility `gplogfilter` to search through Greenplum Database log files. For example, when you run the following command on the master host, it checks for problem log messages in the standard logging locations:

```
$ gplogfilter -t
```

To search for related log entries in the segment log files, you can run `gplogfilter` on the segment hosts using `gpssh`. You can identify corresponding log entries by the `statement_id` or `con#` (session identifier). For example, to search for log messages in the segment log files containing the string `con6` and save output to a file:

```
gpssh -f seg_hosts_file -e 'source /usr/local/greenplum-db/greenplum_path.sh ; gplogfilter -f con6 /gpdata/*/pg_log/gpdb*.csv' > seglog.out
```

**Gathering Information for Pivotal Customer Support**

The Greenplum Magic Tool (GPMT) utility can run diagnostics and collect information from a Greenplum Database system. You can then send the information to Pivotal Customer Support to aid the diagnosis of Greenplum Database errors or system failures.

The GPMT utility is available from the [Pivotal Knowledge Base](https://knowledge.pivotal.io) on the [GPMT](https://knowledge.pivotal.io) page.
Chapter 8

Greenplum Database Security Configuration Guide

This guide describes how to secure a Greenplum Database system. The guide assumes knowledge of Linux/UNIX system administration and database management systems. Familiarity with structured query language (SQL) is helpful.

Because Greenplum Database is based on PostgreSQL 8.3.23, this guide assumes some familiarity with PostgreSQL. References to PostgreSQL documentation are provided throughout this guide for features that are similar to those in Greenplum Database.

This information is intended for system administrators responsible for administering a Greenplum Database system.
Securing the Database

Introduces Greenplum Database security topics.

The intent of security configuration is to configure the Greenplum Database server to eliminate as many security vulnerabilities as possible. This guide provides a baseline for minimum security requirements, and is supplemented by additional security documentation.

The essential security requirements fall into the following categories:

- **Authentication** covers the mechanisms that are supported and that can be used by the Greenplum database server to establish the identity of a client application.
- **Authorization** pertains to the privilege and permission models used by the database to authorize client access.
- **Auditing**, or log settings, covers the logging options available in Greenplum Database to track successful or failed user actions.
- **Data Encryption** addresses the encryption capabilities that are available for protecting data at rest and data in transit. This includes the security certifications that are relevant to the Greenplum Database.

Accessing a Kerberized Hadoop Cluster

Greenplum Database can read or write external tables in a Hadoop file system. If the Hadoop cluster is secured with Kerberos ("Kerberized"), Greenplum Database must be configured to allow external table owners to authenticate with Kerberos. See Configuring PXF for Secure HDFS for the configuration procedure for PXF. See Enabling gphdfs Authentication with a Kerberos-secured Hadoop Cluster (Deprecated) for the steps to perform this setup for gphdfs (deprecated).

Platform Hardening

Platform hardening involves assessing and minimizing system vulnerability by following best practices and enforcing federal security standards. Hardening the product is based on the US Department of Defense (DoD) guidelines Security Template Implementation Guides (STIG). Hardening removes unnecessary packages, disables services that are not required, sets up restrictive file and directory permissions, removes unowned files and directories, performs authentication for single-user mode, and provides options for end users to configure the package to be compliant to the latest STIGs.
Greenplum Database Ports and Protocols

Lists network ports and protocols used within the Greenplum cluster.

Greenplum Database clients connect with TCP to the Greenplum master instance at the client connection port, 5432 by default. The listen port can be reconfigured in the `postgresql.conf` configuration file. Client connections use the PostgreSQL libpq API. The `psql` command-line interface, several Greenplum utilities, and language-specific programming APIs all either use the libpq library directly or implement the libpq protocol internally.

Each segment instance also has a client connection port, used solely by the master instance to coordinate database operations with the segments. The `gpstate -p` command, executed on the Greenplum master, lists the port assignments for the Greenplum master and the primary segments and mirrors. For example:

```
[gadmin@mdw ~]$ gpstate -p
20190403:02:57:04:011030 gpstate:mdw:gadmin-[INFO]:-Starting gpstate with args: -p

```
Additional Greenplum Database network connections are created for features such as standby replication, segment mirroring, statistics collection, and data exchange between segments. Some persistent connections are established when the database starts up and other transient connections are created during operations such as query execution. Transient connections for query execution processes, data movement, and statistics collection use available ports in the range 1025 to 65535 with both TCP and UDP protocols.

**Note:** To avoid port conflicts between Greenplum Database and other applications when initializing Greenplum Database, do not specify Greenplum Database ports in the range specified by the operating system parameter `net.ipv4.ip_local_port_range`. For example, if `net.ipv4.ip_local_port_range = 10000 65535`, you could set the Greenplum Database base port numbers to values outside of that range:

```
PORT_BASE = 6000
MIRROR_PORT_BASE = 7000
REPLICATION_PORT_BASE = 8000
MIRROR_REPLICATION_PORT_BASE = 9000
```

Some add-on products and services that work with Greenplum Database have additional networking requirements. The following table lists ports and protocols used within the Greenplum cluster, and includes services and applications that integrate with Greenplum Database.

### Table 88: Greenplum Database Ports and Protocols

<table>
<thead>
<tr>
<th>Service</th>
<th>Protocol/Port</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Master SQL client connection</td>
<td>TCP 5432, libpq</td>
<td>SQL client connection port on the Greenplum master host. Supports clients using the PostgreSQL libpq API. Configurable.</td>
</tr>
<tr>
<td>Segment SQL client connection</td>
<td>varies, libpq</td>
<td>The SQL client connection port for a segment instance. Each primary and mirror segment on a host must have a unique port. Ports are assigned when the Greenplum system is initialized or expanded. The <code>gp_segment_configuration</code> system catalog records port numbers for each primary (p) or mirror (m) segment in the <code>port</code> column. Run <code>gpstate -p</code> to view the ports in use.</td>
</tr>
<tr>
<td>Segment mirroring port</td>
<td>varies, libpq</td>
<td>The port where a segment receives mirrored blocks from its primary. The port is assigned when the mirror is set up. The <code>gp_segment_configuration</code> system catalog records port numbers for each primary (p) or mirror (m) segment in the <code>port</code> column. Run <code>gpstate -p</code> to view the ports in use.</td>
</tr>
<tr>
<td>Service</td>
<td>Protocol/Port</td>
<td>Description</td>
</tr>
<tr>
<td>----------------------------------------------</td>
<td>--------------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Greenplum Database Interconnect</td>
<td>UDP 1025-65535, dynamically allocated</td>
<td>The Interconnect transports database tuples between Greenplum segments during query execution.</td>
</tr>
<tr>
<td>Standby master client listener</td>
<td>TCP 5432, libpq</td>
<td>SQL client connection port on the standby master host. Usually the same as the master client connection port. Configure with the <code>gpinitstandby</code> utility <code>-P</code> option.</td>
</tr>
<tr>
<td>Standby master replicator</td>
<td>TCP 1025-65535, gpsyncmaster</td>
<td>The <code>gpsyncmaster</code> process on the master host establishes a connection to the secondary master host to replicate the master's log to the standby master.</td>
</tr>
<tr>
<td>Greenplum database file load and transfer utilities: gpfdist, gpload, gptransfer</td>
<td>TCP 8080, HTTP TCP 9000, HTTPS</td>
<td>The <code>gpfdist</code> file serving utility can run on Greenplum hosts or external hosts. Specify the connection port with the <code>-p</code> option when starting the server. The <code>gpload</code> and <code>gptransfer</code> utilities run one or more instances of <code>gpfdist</code> with ports or port ranges specified in a configuration file. Note: The <code>gptransfer</code> utility is deprecated and will be removed in the next major release of Greenplum Database.</td>
</tr>
<tr>
<td>Gpperfmon agents</td>
<td>TCP 8888</td>
<td>Connection port for <code>gpperfmon</code> agents (<code>gpmmon</code> and <code>gpsmon</code>) executing on Greenplum Database hosts. Configure by setting the <code>gpperfmon_port</code> configuration variable in <code>postgresql.conf</code> on master and segment hosts.</td>
</tr>
<tr>
<td>Backup completion notification</td>
<td>TCP 25, TCP 587, SMTP</td>
<td>The <code>gpcrondump</code> backup utility can optionally send email to a list of email addresses at completion of a backup. The SMTP service must be enabled on the Greenplum master host.</td>
</tr>
<tr>
<td>Greenplum Database secure shell (SSH): gpssh, gpscp, gpssh-exkeys, gppkg, gpseginstall</td>
<td>TCP 22, SSH</td>
<td>Many Greenplum utilities use scp and ssh to transfer files between hosts and manage the Greenplum system within the cluster.</td>
</tr>
<tr>
<td>gphdfs (deprecated)</td>
<td>TCP 8020</td>
<td>The gphdfs protocol allows access to data in a Hadoop file system via Greenplum external tables. The URL in the <code>LOCATION</code> clause of the <code>CREATE EXTERNAL TABLE</code> command specifies the host address and port number for the Hadoop namenode service.</td>
</tr>
<tr>
<td>Greenplum Platform Extension Framework (PXF)</td>
<td>TCP 5888</td>
<td>The PXF Java service runs on port number 5888 on each Greenplum Database segment host.</td>
</tr>
<tr>
<td>Greenplum Command Center (GPCC)</td>
<td>TCP 28080, HTTP/HTTPS, WebSocket (WS), Secure WebSocket (WSS)</td>
<td>The GPCC web server (<code>gpccws</code> process) executes on the Greenplum Database master host or standby master host. The port number is configured at installation time.</td>
</tr>
<tr>
<td>Service</td>
<td>Protocol/Port</td>
<td>Description</td>
</tr>
<tr>
<td>-------------------------</td>
<td>--------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td></td>
<td>TCP 8899, rcp port</td>
<td>A GPCC agent (ccagent process) on each Greenplum Database segment host connects to the GPCC rpc backend at port number 8899 on the GPCC web server host.</td>
</tr>
<tr>
<td></td>
<td>UNIX domain socket, agent</td>
<td>Greenplum Database processes transmit datagrams to the GPCC agent (ccagent process) on each segment host using a UNIX domain socket.</td>
</tr>
<tr>
<td>GPText</td>
<td>TCP 2188 (base port)</td>
<td>ZooKeeper client ports. ZooKeeper uses a range of ports beginning at the base port number. The base port number and maximum port number are set in the GPText installation configuration file at installation time. The default base port number is 2188.</td>
</tr>
<tr>
<td></td>
<td>TCP 18983 (base port)</td>
<td>GPText (Apache Solr) nodes. GPText nodes use a range of ports beginning at the base port number. The base port number and maximum port number are set in the GPText installation configuration file at installation time. The default base port number is 18983.</td>
</tr>
<tr>
<td>EMC Data Domain and DD Boost</td>
<td>TCP/UDP 111, NFS portmapper</td>
<td>Used to assign a random port for the mountd service used by NFS and DD Boost. The mountd service port can be statically assigned on the Data Domain server.</td>
</tr>
<tr>
<td></td>
<td>TCP 2052</td>
<td>Main port used by NFS mountd. This port can be set on the Data Domain system using the <code>nfs set mountd-port</code> command.</td>
</tr>
<tr>
<td></td>
<td>TCP 2049, NFS</td>
<td>Main port used by NFS. This port can be configured using the <code>nfs set server-port</code> command on the Data Domain server.</td>
</tr>
<tr>
<td></td>
<td>TCP 2051, replication</td>
<td>Used when replication is configured on the Data Domain system. This port can be configured using the <code>replication modify</code> command on the Data Domain server.</td>
</tr>
<tr>
<td>Symantec NetBackup</td>
<td>TCP/UDP 1556, veritas-pbx</td>
<td>The Symantec NetBackup client network port.</td>
</tr>
<tr>
<td></td>
<td>TCP 13724, vnetd</td>
<td>Symantec NetBackup vnetd communication port.</td>
</tr>
<tr>
<td>Service</td>
<td>Protocol/Port</td>
<td>Description</td>
</tr>
<tr>
<td>-------------------------</td>
<td>---------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Pgbouncer connection pooler</td>
<td>TCP, libpq</td>
<td>The pgbouncer connection pooler runs between libpq clients and Greenplum (or PostgreSQL) databases. It can be run on the Greenplum master host, but running it on a host outside of the Greenplum cluster is recommended. When it runs on a separate host, pgbouncer can act as a warm standby mechanism for the Greenplum master host, switching to the Greenplum standby host without requiring clients to reconfigure. Set the client connection port and the Greenplum master host address and port in the <code>pgbouncer.ini</code> configuration file.</td>
</tr>
</tbody>
</table>
Configuring Client Authentication

Describes the available methods for authenticating Greenplum Database clients.

When a Greenplum Database system is first initialized, the system contains one predefined superuser role. This role will have the same name as the operating system user who initialized the Greenplum Database system. This role is referred to as gpadmin. By default, the system is configured to only allow local connections to the database from the gpadmin role. If you want to allow any other roles to connect, or if you want to allow connections from remote hosts, you have to configure Greenplum Database to allow such connections. This section explains how to configure client connections and authentication to Greenplum Database.

- Allowing Connections to Greenplum Database
- Editing the pg_hba.conf File
- Authentication Methods
- Limiting Concurrent Connections
- Encrypting Client/Server Connections

Allowing Connections to Greenplum Database

Client access and authentication is controlled by a configuration file named pg_hba.conf (the standard PostgreSQL host-based authentication file). For detailed information about this file, see The pg_hba.conf File in the PostgreSQL documentation.

In Greenplum Database, the pg_hba.conf file of the master instance controls client access and authentication to your Greenplum system. The segments also have pg_hba.conf files, but these are already correctly configured to only allow client connections from the master host. The segments never accept outside client connections, so there is no need to alter the pg_hba.conf file on segments.

The general format of the pg_hba.conf file is a set of records, one per line. Blank lines are ignored, as is any text after a # comment character. A record is made up of a number of fields which are separated by spaces and/or tabs. Fields can contain white space if the field value is quoted. Records cannot be continued across lines. Each remote client access record is in this format:

```
host   database   role   address   authentication-method
```

A UNIX-domain socket access record is in this format:

```
local   database   role   authentication-method
```

The meaning of the pg_hba.conf fields is as follows:

**local**

Matches connection attempts using UNIX-domain sockets. Without a record of this type, UNIX-domain socket connections are disallowed.

**host**

Matches connection attempts made using TCP/IP. Remote TCP/IP connections will not be possible unless the server is started with an appropriate value for the listen_addresses server configuration parameter.

**hostssl**

Matches connection attempts made using TCP/IP, but only when the connection is made with SSL encryption. SSL must be enabled at server start time by setting the ssl configuration parameter. Requires SSL authentication be configured in postgresql.conf. See Configuring postgresql.conf for SSL Authentication.
**hostnossl**

Matches connection attempts made over TCP/IP that do not use SSL. Requires SSL authentication be configured in `postgresql.conf`. See Configuring `postgresql.conf` for SSL Authentication.

**database**

Specifies which database names this record matches. The value `all` specifies that it matches all databases. Multiple database names can be supplied by separating them with commas. A separate file containing database names can be specified by preceding the file name with `@`.

**role**

Specifies which database role names this record matches. The value `all` specifies that it matches all roles. If the specified role is a group and you want all members of that group to be included, precede the role name with a `+`. Multiple role names can be supplied by separating them with commas. A separate file containing role names can be specified by preceding the file name with a `@`.

**address**

Specifies the client machine addresses that this record matches. This field can contain an IP address, an IP address range, or a host name.

An IP address range is specified using standard numeric notation for the range's starting address, then a slash `/` and a CIDR mask length. The mask length indicates the number of high-order bits of the client IP address that must match. Bits to the right of this should be zero in the given IP address. There must not be any white space between the IP address, the `/`, and the CIDR mask length.

Typical examples of an IPv4 address range specified this way are `172.20.143.89/32` for a single host, or `172.20.143.0/24` for a small network, or `10.6.0.0/16` for a larger one. An IPv6 address range might look like `::1/128` for a single host (in this case the IPv6 loopback address) or `fe80::7a31:c1ff:0000:0000/96` for a small network. `0.0.0.0/0` represents all IPv4 addresses, and `::0/0` represents all IPv6 addresses. To specify a single host, use a mask length of 32 for IPv4 or 128 for IPv6. In a network address, do not omit trailing zeroes.

An entry given in IPv4 format will match only IPv4 connections, and an entry given in IPv6 format will match only IPv6 connections, even if the represented address is in the IPv4-in-IPv6 range.

**Note:** Entries in IPv6 format will be rejected if the host system C library does not have support for IPv6 addresses.

If a host name is specified (an address that is not an IP address or IP range is treated as a host name), that name is compared with the result of a reverse name resolution of the client IP address (for example, reverse DNS lookup, if DNS is used). Host name comparisons are case insensitive. If there is a match, then a forward name resolution (for example, forward DNS lookup) is performed on the host name to check whether any of the addresses it resolves to are equal to the client IP address. If both directions match, then the entry is considered to match.

Some host name databases allow associating an IP address with multiple host names, but the operating system only returns one host name when asked to resolve an IP address. The host name that is used in `pg_hba.conf` must be the one that the address-to-name resolution of the client IP address returns, otherwise the line will not be considered a match.

When host names are specified in `pg_hba.conf`, you should ensure that name resolution is reasonably fast. It can be of advantage to set up a local name resolution cache such as `nscd`. Also, you can enable the server configuration parameter `log_hostname` to see the client host name instead of the IP address in the log.
IP-address
IP-mask

These fields can be used as an alternative to the CIDR address notation. Instead of specifying the mask length, the actual mask is specified in a separate column. For example, 255.0.0.0 represents an IPv4 CIDR mask length of 8, and 255.255.255.255 represents a CIDR mask length of 32.

authentication-method

Specifies the authentication method to use when connecting. See Authentication Methods for options.

Caution: For a more secure system, consider removing records for remote connections that use trust authentication from the pg_hba.conf file. Trust authentication grants any user who can connect to the server access to the database using any role they specify. You can safely replace trust authentication with ident authentication for local UNIX-socket connections. You can also use ident authentication for local and remote TCP clients, but the client host must be running an ident service and you must trust the integrity of that machine.

Editing the pg_hba.conf File

Initially, the pg_hba.conf file is set up with generous permissions for the gpadmin user and no database access for other Greenplum Database roles. You will need to edit the pg_hba.conf file to enable users' access to databases and to secure the gpadmin user. Consider removing entries that have trust authentication, since they allow anyone with access to the server to connect with any role they choose. For local (UNIX socket) connections, use ident authentication, which requires the operating system user to match the role specified. For local and remote TCP connections, ident authentication requires the client's host to run an indent service. You could install an ident service on the master host and then use ident authentication for local TCP connections, for example 127.0.0.1/28. Using ident authentication for remote TCP connections is less secure because it requires you to trust the integrity of the ident service on the client's host.

This example shows how to edit the pg_hba.conf file of the master to allow remote client access to all databases from all roles using encrypted password authentication.

To edit pg_hba.conf:

1. Open the file $MASTER_DATA_DIRECTORY/pg_hba.conf in a text editor.
2. Add a line to the file for each type of connection you want to allow. Records are read sequentially, so the order of the records is significant. Typically, earlier records will have tight connection match parameters and weaker authentication methods, while later records will have looser match parameters and stronger authentication methods. For example:

```bash
# allow the gpadmin user local access to all databases
# using ident authentication
local all gpadmin ident sameuser
host all gpadmin 127.0.0.1/32 ident
host all gpadmin ::1/128 ident
# allow the 'dba' role access to any database from any host with IP address 192.168.x.x and use md5 encrypted passwords to authenticate the user
# Note that to use SHA-256 encryption, replace md5 with password in the line below
host all dba 192.168.0.0/32 md5
```

Authentication Methods

- Basic Authentication
- Kerberos Authentication
LDAP Authentication
SSL Client Authentication
PAM Based Authentication
Radius Authentication

Basic Authentication
The following basic authentication methods are supported:

Password or MD5
Requires clients to provide a password, one of either:
- Md5 – password transmitted as an MD5 hash.
- Password – A password transmitted in clear text. Always use SSL connections to prevent password sniffing during transit. This is configurable, see "Encrypting Passwords" in the Greenplum Database Administrator Guide for more information.

Reject
Reject the connections with the matching parameters. You should typically use this to restrict access from specific hosts or insecure connections.

Ident
Authenticates based on the client's operating system user name. This is secure for local socket connections. Using ident for TCP connections from remote hosts requires that the client’s host is running an ident service. The ident authentication method should only be used with remote hosts on a trusted, closed network.

Following are some sample pg_hba.conf basic authentication entries:

<table>
<thead>
<tr>
<th>Type</th>
<th>Host</th>
<th>User</th>
<th>Address</th>
<th>Authentication</th>
</tr>
</thead>
<tbody>
<tr>
<td>reject</td>
<td>host</td>
<td>all</td>
<td>0.0.0.0</td>
<td>reject</td>

Kerberos Authentication
You can authenticate against a Kerberos server (RFC 2743, 1964).

The format for Kerberos authentication in the pg_hba.conf file is:

```
servicename/hostname@realm
```

The following options may be added to the entry:

Map
Map system and database users.

Include_realm
Option to specify realm name included in the system-user name in the ident map file.

Krb_realm
Specify the realm name for matching the principals.

Krb_server_hostname
The hostname of the service principal.

Following is an example pg_hba.conf entry for Kerberos:

<table>
<thead>
<tr>
<th>Type</th>
<th>Host</th>
<th>User</th>
<th>Address</th>
<th>Authentication</th>
</tr>
</thead>
<tbody>
<tr>
<td>krb5</td>
<td>host</td>
<td>all</td>
<td>0.0.0.0/0</td>
<td>krb5</td>
</tr>
<tr>
<td>krbmap</td>
<td>hostssl</td>
<td>all</td>
<td>0.0.0.0/0</td>
<td>krbmap</td>
</tr>
</tbody>
</table>

The following Kerberos server settings are specified in postgresql.conf:
**Kerberos Configuration Parameters**

- **krb_server_key_file**
  Sets the location of the Kerberos server key file.

- **krb_srvname string**
  Kerberos service name.

- **krb_caseins_users boolean**
  Case-sensitivity. The default is off.

The following client setting is specified as a connection parameter:

- **Krbsrvname**
  The Kerberos service name to use for authentication.

**LDAP Authentication**

You can authenticate against an LDAP directory.

- LDAPS and LDAP over TLS options encrypt the connection to the LDAP server.
- The connection from the client to the server is not encrypted unless SSL is enabled. Configure client connections to use SSL to encrypt connections from the client.
- To configure or customize LDAP settings, set the LDAPCONF environment variable with the path to the ldap.conf file and add this to the greenplum_path.sh script.

Following are the recommended steps for configuring your system for LDAP authentication:

1. Set up the LDAP server with the database users/roles to be authenticated via LDAP.
2. On the database:
   a. Verify that the database users to be authenticated via LDAP exist on the database. LDAP is only used for verifying username/password pairs, so the roles should exist in the database.
   b. Update the pg_hba.conf file in the $MASTER_DATA_DIRECTORY to use LDAP as the authentication method for the respective users. Note that the first entry to match the user/role in the pg_hba.conf file will be used as the authentication mechanism, so the position of the entry in the file is important.
   c. Reload the server for the pg_hba.conf configuration settings to take effect (gpstop -u).

Specify the following parameter auth-options.

- **ldapservers**
  Names or IP addresses of LDAP servers to connect to. Multiple servers may be specified, separated by spaces.

- **ldapprefix**
  String to prepend to the user name when forming the DN to bind as, when doing simple bind authentication.

- **ldapsuffix**
  String to append to the user name when forming the DN to bind as, when doing simple bind authentication.

- **ldapport**
  Port number on LDAP server to connect to. If no port is specified, the LDAP library’s default port setting will be used.

- **ldaptls**
  Set to 1 to make the connection between PostgreSQL and the LDAP server use TLS encryption. Note that this only encrypts the traffic to the LDAP server — the connection to the client will still be unencrypted unless SSL is used.

- **ldapbasedn**
  Root DN to begin the search for the user in, when doing search+bind authentication.
**ldapbinddn**

DN of user to bind to the directory with to perform the search when doing search+bind authentication.

**ldapbindpasswd**

Password for user to bind to the directory with to perform the search when doing search+bind authentication.

**ldapsearchattribute**

Attribute to match against the user name in the search when doing search+bind authentication.

Example:

```
ldapserver=ldap.greenplum.com prefix="cn=" suffix=", dc=greenplum, dc=com"
```

Following are sample `pg_hba.conf` file entries for LDAP authentication:

```
host all testuser 0.0.0.0/0 ldap ldap
ldapserver=ldapserver.greenplum.com ldapport=389 ldapprefix="cn="
ldapsuffix=",ou=people,dc=greenplum,dc=com" hostssl all ldaprole 0.0.0.0/0 ldap
ldapserver=ldapserver.greenplum.com ldaptls=1 ldapprefix="cn="
ldapsuffix=",ou=people,dc=greenplum,dc=com"
```

**SSL Client Authentication**

SSL authentication compares the Common Name (cn) attribute of an SSL certificate provided by the connecting client during the SSL handshake to the requested database user name. The database user should exist in the database. A map file can be used for mapping between system and database user names.

**SSL Authentication Parameters**

Authentication method:

- Cert

Authentication options:

**Hostssl**

Connection type must be hostssl.

**map=mapping**

mapping.

This is specified in the `pg_ident.conf`, or in the file specified in the `ident_file server` setting.

Following are sample `pg_hba.conf` entries for SSL client authentication:

```
Hostssl testdb certuser 192.168.0.0/16 cert
Hostssl testdb all 192.168.0.0/16 cert map=gpuser
```

**OpenSSL Configuration**

Greenplum Database reads the OpenSSL configuration file specified in `$GP_HOME/etc/openssl.cnf` by default. You can make changes to the default configuration for OpenSSL by modifying or updating this file and restarting the server.
Creating a Self-Signed Certificate

A self-signed certificate can be used for testing, but a certificate signed by a certificate authority (CA) (either one of the global CAs or a local one) should be used in production so that clients can verify the server's identity. If all the clients are local to the organization, using a local CA is recommended.

To create a self-signed certificate for the server:

1. Enter the following `openssl` command:
   ```bash
   openssl req -new -text -out server.req
   ```
2. Enter the requested information at the prompts.
   Make sure you enter the local host name for the Common Name. The challenge password can be left blank.
3. The program generates a key that is passphrase-protected; it does not accept a passphrase that is less than four characters long. To remove the passphrase (and you must if you want automatic start-up of the server), run the following command:
   ```bash
   openssl rsa -in privkey.pem -out server.key rm privkey.pem
   ```
4. Enter the old passphrase to unlock the existing key. Then run the following command:
   ```bash
   openssl req -x509 -in server.req -text -key server.key -out server.crt
   ```
   This turns the certificate into a self-signed certificate and copies the key and certificate to where the server will look for them.
5. Finally, run the following command:
   ```bash
   chmod og-rwx server.key
   ```

For more details on how to create your server private key and certificate, refer to the OpenSSL documentation.

Configuring `postgresql.conf` for SSL Authentication

The following Server settings need to be specified in the `postgresql.conf` configuration file:

- `ssl boolean`. Enables SSL connections.
- `ssl_renegotiation_limit integer`. Specifies the data limit before key renegotiation.
- `ssl_ciphers string`. Lists SSL ciphers that are allowed.

The following SSL server files can be found in the Master Data Directory:

- `server.crt`. Server certificate.
- `server.key`. Server private key.
- `root.crt`. Trusted certificate authorities.
- `root.crl`. Certificates revoked by certificate authorities.

Configuring the SSL Client Connection

SSL options:

- `require`  
  Only use SSL connection. If a root CA file is present, verify the certificate in the same way as if `verify-ca` was specified.

- `verify-ca`  
  Only use an SSL connection. Verify that the server certificate is issued by a trusted CA.

- `verify-full`
Only use an SSL connection. Verify that the server certificate is issued by a trusted CA and that the server host name matches that in the certificate.

**sslcert**
The file name of the client SSL certificate. The default is `~/.postgresql/postgresql.crt`.

**sslkey**
The secret key used for the client certificate. The default is `~/.postgresql/postgresql.key`.

**sslrootcert**
The name of a file containing SSL Certificate Authority certificate(s). The default is `~/.postgresql/root.crt`.

**sslcrl**
The name of the SSL certificate revocation list. The default is `~/.postgresql/root.crl`.

The client connection parameters can be set using the following environment variables:

- `sslmode` – `PGSSLMODE`
- `sslkey` – `PGSSLKEY`
- `sslrootcert` – `PGSSLROOTCERT`
- `sslcert` – `PGSSLCERT`
- `sslcrl` – `PGSSLCRL`

**PAM Based Authentication**

“PAM” (Pluggable Authentication Modules) is used to validate username/password pairs, similar to basic authentication. PAM authentication only works if the users already exist in the database.

**Parameters**

**pamservice**
The default PAM service is `postgresql`. Note that if PAM is set up to read `/etc/shadow`, authentication will fail because the PostgreSQL server is started by a non-root user.

Following are sample `pg_hba.conf` entries for PAM client authentication:

```
local all gpuser am pamservice=postgresql
```

**Radius Authentication**

RADIUS (Remote Authentication Dial In User Service) authentication works by sending an Access Request message of type 'Authenticate Only' to a configured RADIUS server. It includes parameters for user name, password (encrypted), and the Network Access Server (NAS) Identifier. The request is encrypted using the shared secret specified in the `radiussecret` option. The RADIUS server responds with either Access Accept or Access Reject.

**Note:** RADIUS accounting is not supported.

RADIUS authentication only works if the users already exist in the database.

The RADIUS encryption vector requires SSL to be enabled in order to be cryptographically strong.

**RADIUS Authentication Options**

**radiusserver**
The name of the RADIUS server.

**radiussecret**
The RADIUS shared secret.

**radiusport**
The port to connect to on the RADIUS server.

**radiusidentifier**
NAS identifier in RADIUS requests.

Following are sample `pg_hba.conf` entries for RADIUS client authentication:

```plaintext
hostssl all all 0.0.0.0/0 radius radiusserver=servername
radiussecret=sharedsecret
```

## Limiting Concurrent Connections

To limit the number of active concurrent sessions to your Greenplum Database system, you can configure the `max_connections` server configuration parameter. This is a local parameter, meaning that you must set it in the `postgresql.conf` file of the master, the standby master, and each segment instance (primary and mirror). The value of `max_connections` on segments must be 5-10 times the value on the master.

When you set `max_connections`, you must also set the dependent parameter `max_prepared_transactions`. This value must be at least as large as the value of `max_connections` on the master, and segment instances should be set to the same value as the master.

In `$MASTER_DATA_DIRECTORY/postgresql.conf` (including standby master):

```plaintext
max_connections=100
max_prepared_transactions=100
```

In `SEGMENT_DATA_DIRECTORY/postgresql.conf` for all segment instances:

```plaintext
max_connections=500
max_prepared_transactions=100
```

**Note:** Raising the values of these parameters may cause Greenplum Database to request more shared memory. To mitigate this effect, consider decreasing other memory-related parameters such as `gp_cached_segworkers_threshold`.

To change the number of allowed connections:

1. Stop your Greenplum Database system:

   ```bash
   $ gpstop
   ```

2. On the master host, edit `$MASTER_DATA_DIRECTORY/postgresql.conf` and change the following two parameters:
   ```plaintext
   • max_connections – the number of active user sessions you want to allow plus the number of superuser_reserved_connections.
   • max_prepared_transactions – must be greater than or equal to max_connections.
   ```

3. On each segment instance, edit `SEGMENT_DATA_DIRECTORY/postgresql.conf` and change the following two parameters:
   ```plaintext
   • max_connections – must be 5-10 times the value on the master.
   • max_prepared_transactions – must be equal to the value on the master.
   ```
4. Restart your Greenplum Database system:

   $ gpstart

**Encrypting Client/Server Connections**

Greenplum Database has native support for SSL connections between the client and the master server. SSL connections prevent third parties from snooping on the packets, and also prevent man-in-the-middle attacks. SSL should be used whenever the client connection goes through an insecure link, and must be used whenever client certificate authentication is used.

**Note:** For information about encrypting data between the gpfdist server and Greenplum Database segment hosts, see *Encrypting gpfdist Connections*.

To enable SSL requires that OpenSSL be installed on both the client and the master server systems. Greenplum can be started with SSL enabled by setting the server configuration parameter `ssl=on` in the master `postgresql.conf`. When starting in SSL mode, the server will look for the files `server.key` (server private key) and `server.crt` (server certificate) in the master data directory. These files must be set up correctly before an SSL-enabled Greenplum system can start.

**Important:** Do not protect the private key with a passphrase. The server does not prompt for a passphrase for the private key, and the database startup fails with an error if one is required.

A self-signed certificate can be used for testing, but a certificate signed by a certificate authority (CA) should be used in production, so the client can verify the identity of the server. Either a global or local CA can be used. If all the clients are local to the organization, a local CA is recommended. See *Creating a Self-Signed Certificate* for steps to create a self-signed certificate.
Configuring Database Authorization

Describes how to restrict authorization access to database data at the user level by using roles and permissions.

**Access Permissions and Roles**

Greenplum Database manages database access permissions using *roles*. The concept of roles subsumes the concepts of users and groups. A role can be a database user, a group, or both. Roles can own database objects (for example, tables) and can assign privileges on those objects to other roles to control access to the objects. Roles can be members of other roles, thus a member role can inherit the object privileges of its parent role.

Every Greenplum Database system contains a set of database roles (users and groups). Those roles are separate from the users and groups managed by the operating system on which the server runs. However, for convenience you may want to maintain a relationship between operating system user names and Greenplum Database role names, since many of the client applications use the current operating system user name as the default.

In Greenplum Database, users log in and connect through the master instance, which verifies their role and access privileges. The master then issues out commands to the segment instances behind the scenes using the currently logged in role.

Roles are defined at the system level, so they are valid for all databases in the system.

To bootstrap the Greenplum Database system, a freshly initialized system always contains one predefined superuser role (also referred to as the system user). This role will have the same name as the operating system user that initialized the Greenplum Database system. Customarily, this role is named *gpadmin*. To create more roles you first must connect as this initial role.

**Managing Object Privileges**

When an object (table, view, sequence, database, function, language, schema, or tablespace) is created, it is assigned an owner. The owner is normally the role that executed the creation statement. For most kinds of objects, the initial state is that only the owner (or a superuser) can do anything with the object. To allow other roles to use it, privileges must be granted. Greenplum Database supports the following privileges for each object type:

<table>
<thead>
<tr>
<th>Object Type</th>
<th>Privileges</th>
</tr>
</thead>
<tbody>
<tr>
<td>Tables, Views, Sequences</td>
<td>SELECT INSERT UPDATE DELETE RULE ALL</td>
</tr>
<tr>
<td>External Tables</td>
<td>SELECT RULE ALL</td>
</tr>
<tr>
<td>Object Type</td>
<td>Privileges</td>
</tr>
<tr>
<td>---------------------</td>
<td>-------------------------------------------------</td>
</tr>
<tr>
<td>Databases</td>
<td>CONNECT</td>
</tr>
<tr>
<td></td>
<td>CREATE</td>
</tr>
<tr>
<td></td>
<td>TEMPORARY</td>
</tr>
<tr>
<td></td>
<td>ALL</td>
</tr>
<tr>
<td>Functions</td>
<td>EXECUTE</td>
</tr>
<tr>
<td>Procedural Languages</td>
<td>USAGE</td>
</tr>
<tr>
<td>Schemas</td>
<td>CREATE</td>
</tr>
<tr>
<td></td>
<td>USAGE</td>
</tr>
<tr>
<td></td>
<td>ALL</td>
</tr>
</tbody>
</table>

Privileges must be granted for each object individually. For example, granting `ALL` on a database does not grant full access to the objects within that database. It only grants all of the database-level privileges (CONNECT, CREATE, TEMPORARY) to the database itself.

Use the `GRANT` SQL command to give a specified role privileges on an object. For example:

```
=# GRANT INSERT ON mytable TO jsmith;
```

To revoke privileges, use the `REVOKE` command. For example:

```
=# REVOKE ALL PRIVILEGES ON mytable FROM jsmith;
```

You can also use the `DROP OWNED` and `REASSIGN OWNED` commands for managing objects owned by deprecated roles. (Note: only an object's owner or a superuser can drop an object or reassign ownership.) For example:

```
=# REASSIGN OWNED BY sally TO bob;
=# DROP OWNED BY visitor;
```

### Using SSH-256 Encryption

Greenplum Database access control corresponds roughly to the Orange Book 'C2' level of security, not the 'B1' level. Greenplum Database currently supports access privileges at the object level. Row-level or column-level access is not supported, nor is labeled security.

Row-level and column-level access can be simulated using views to restrict the columns and/or rows that are selected. Row-level labels can be simulated by adding an extra column to the table to store sensitivity information, and then using views to control row-level access based on this column. Roles can then be granted access to the views rather than the base table. While these workarounds do not provide the same as "B1" level security, they may still be a viable alternative for many organizations.

To use SHA-256 encryption, you must set a parameter either at the system or the session level. This section outlines how to use a server parameter to implement SHA-256 encrypted password storage. Note that in order to use SHA-256 encryption for storage, the client authentication method must be set to password rather than the default, MD5. (See `Configuring the SSL Client Connection` for more details.) This means that the password is transmitted in clear text over the network, so we highly recommend that you set up SSL to encrypt the client server communication channel.

You can set your chosen encryption method system-wide or on a per-session basis. The available encryption methods are SHA-256 and MD5 (for backward compatibility).
Setting Encryption Method System-wide

To set the `password_hash_algorithm` server parameter on a complete Greenplum system (master and its segments):

1. Log in to your Greenplum Database instance as a superuser.
2. Execute `gpconfig` with the `password_hash_algorithm` set to SHA-256:

   ```bash
   $ gpconfig -c password_hash_algorithm -v 'SHA-256'
   ```

3. Verify the setting:

   ```bash
   $ gpconfig -s
   ```

   You will see:

   ```
   Master value: SHA-256
   Segment value: SHA-256
   ```

Setting Encryption Method for an Individual Session

To set the `password_hash_algorithm` server parameter for an individual session:

1. Log in to your Greenplum Database instance as a superuser.
2. Set the `password_hash_algorithm` to SHA-256:

   ```bash
   # set password_hash_algorithm = 'SHA-256'
   ```

3. Verify the setting:

   ```bash
   # show password_hash_algorithm;
   ```

   You will see:

   ```
   SHA-256
   ```

Following is an example of how the new setting works:

1. Log in as a super user and verify the password hash algorithm setting:

   ```bash
   # show password_hash_algorithm
   password_hash_algorithm
   -----------------------------------
   SHA-256
   ```

2. Create a new role with password that has login privileges.

   ```bash
   create role testdb with password 'testdb12345#' LOGIN;
   ```

3. Change the client authentication method to allow for storage of SHA-256 encrypted passwords:

   Open the `pg_hba.conf` file on the master and add the following line:

   ```bash
   host all testdb 0.0.0.0/0 password
   ```

4. Restart the cluster.
5. Log in to the database as the user just created, testdb.

```
psql -U testdb
```

6. Enter the correct password at the prompt.
7. Verify that the password is stored as a SHA-256 hash.

```
Password hashes are stored in pg_authid.rolpassword.
```

8. Log in as the super user.
9. Execute the following query:

```
# SELECT rolpassword FROM pg_authid WHERE rolname = 'testdb';
Rolpassword
----------
sha256<64 hexadecimal characters>
```

## Restricting Access by Time

Greenplum Database enables the administrator to restrict access to certain times by role. Use the `CREATE ROLE` or `ALTER ROLE` commands to specify time-based constraints.

Access can be restricted by day or by day and time. The constraints are removable without deleting and recreating the role.

Time-based constraints only apply to the role to which they are assigned. If a role is a member of another role that contains a time constraint, the time constraint is not inherited.

Time-based constraints are enforced only during login. The `SET ROLE` and `SET SESSION AUTHORIZATION` commands are not affected by any time-based constraints.

Superuser or `CREATEROLE` privileges are required to set time-based constraints for a role. No one can add time-based constraints to a superuser.

There are two ways to add time-based constraints. Use the keyword `DENY` in the `CREATE ROLE` or `ALTER ROLE` command followed by one of the following.

- A day, and optionally a time, when access is restricted. For example, no access on Wednesdays.
- An interval—that is, a beginning and ending day and optional time—when access is restricted. For example, no access from Wednesday 10 p.m. through Thursday at 8 a.m.

You can specify more than one restriction; for example, no access Wednesdays at any time and no access on Fridays between 3:00 p.m. and 5:00 p.m.

There are two ways to specify a day. Use the word `DAY` followed by either the English term for the weekday, in single quotation marks, or a number between 0 and 6, as shown in the table below.

<table>
<thead>
<tr>
<th>English Term</th>
<th>Number</th>
</tr>
</thead>
<tbody>
<tr>
<td>DAY 'Sunday'</td>
<td>DAY 0</td>
</tr>
<tr>
<td>DAY 'Monday'</td>
<td>DAY 1</td>
</tr>
<tr>
<td>DAY 'Tuesday'</td>
<td>DAY 2</td>
</tr>
<tr>
<td>DAY 'Wednesday'</td>
<td>DAY 3</td>
</tr>
<tr>
<td>DAY 'Thursday'</td>
<td>DAY 4</td>
</tr>
<tr>
<td>DAY 'Friday'</td>
<td>DAY 5</td>
</tr>
<tr>
<td>DAY 'Saturday'</td>
<td>DAY 6</td>
</tr>
</tbody>
</table>
A time of day is specified in either 12- or 24-hour format. The word `TIME` is followed by the specification in single quotation marks. Only hours and minutes are specified and are separated by a colon ( : ). If using a 12-hour format, add `AM` or `PM` at the end. The following examples show various time specifications.

```
TIME '14:00'    # 24-hour time implied
TIME '02:00 PM' # 12-hour time specified by PM
TIME '02:00'    # 24-hour time implied. This is equivalent to TIME '02:00 AM'.
```

**Important:** Time-based authentication is enforced with the server time. Timezones are disregarded.

To specify an interval of time during which access is denied, use two day/time specifications with the words `BETWEEN` and `AND`, as shown. `DAY` is always required.

```
BETWEEN DAY 'Monday' AND DAY 'Tuesday'
BETWEEN DAY 'Monday' TIME '00:00' AND DAY 'Monday' TIME '01:00'
BETWEEN DAY 'Monday' TIME '12:00 AM' AND DAY 'Tuesday' TIME '02:00 AM'
BETWEEN DAY 'Monday' TIME '00:00' AND DAY 'Tuesday' TIME '02:00'
```

The last three statements are equivalent.

**Note:** Intervals of days cannot wrap past Saturday.

The following syntax is not correct:

```
DENY BETWEEN DAY 'Saturday' AND DAY 'Sunday'
```

The correct specification uses two DENY clauses, as follows:

```
DENY DAY 'Saturday'
DENY DAY 'Sunday'
```

The following examples demonstrate creating a role with time-based constraints and modifying a role to add time-based constraints. Only the statements needed for time-based constraints are shown. For more details on creating and altering roles see the descriptions of `CREATE ROLE` and `ALTER ROLE` in the Greenplum Database Reference Guide.

**Example 1 – Create a New Role with Time-based Constraints**

No access is allowed on weekends.

```
CREATE ROLE generaluser
DENY DAY 'Saturday'
DENY DAY 'Sunday'
...
```

**Example 2 – Alter a Role to Add Time-based Constraints**

No access is allowed every night between 2:00 a.m. and 4:00 a.m.

```
ALTER ROLE generaluser
DENY BETWEEN DAY 'Monday' TIME '02:00' AND DAY 'Monday' TIME '04:00'
```
### Example 3 – Alter a Role to Add Time-based Constraints

No access is allowed Wednesdays or Fridays between 3:00 p.m. and 5:00 p.m.

```sql
ALTER ROLE generaluser
  DENY DAY 'Wednesday'
  DENY BETWEEN DAY 'Friday' TIME '15:00' AND DAY 'Friday' TIME '17:00'
```

### Dropping a Time-based Restriction

To remove a time-based restriction, use the ALTER ROLE command. Enter the keywords DROP DENY FOR followed by a day/time specification to drop.

```sql
DROP DENY FOR DAY 'Sunday'
```

Any constraint containing all or part of the conditions in a DROP clause is removed. For example, if an existing constraint denies access on Mondays and Tuesdays, and the DROP clause removes constraints for Mondays, the existing constraint is completely dropped. The DROP clause completely removes all constraints that overlap with the constraint in the drop clause. The overlapping constraints are completely removed even if they contain more restrictions that the restrictions mentioned in the DROP clause.

**Example 1 - Remove a Time-based Restriction from a Role**

```sql
ALTER ROLE generaluser
  DROP DENY FOR DAY 'Monday'
  ...
```

This statement would remove all constraints that overlap with a Monday constraint for the role `generaluser` in Example 2, even if there are additional constraints.
Greenplum Command Center Security

Greenplum Command Center (GPCC) is a web-based application for monitoring and managing Greenplum clusters. GPCC works with data collected by agents running on the segment hosts and saved to the gpperfmon database. The gpperfmon database is created by running the gpperfmon_install utility, which also creates the gpmon database role that GPCC uses to access the gpperfmon database.

The gpmon User

The gpperfmon_install utility creates the gpmon database role and adds the role to the pg_hba.conf file with the following entries:

<p>| | | | | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>local</td>
<td>gpperfmon</td>
<td>gpmon</td>
<td>md5</td>
<td></td>
</tr>
<tr>
<td>host</td>
<td>all</td>
<td>gpmon</td>
<td>127.0.0.1/28</td>
<td>md5</td>
</tr>
<tr>
<td>host</td>
<td>all</td>
<td>gpmon</td>
<td>::1/128</td>
<td>md5</td>
</tr>
</tbody>
</table>

These entries allow gpmon to establish a local socket connection to the gpperfmon database and a TCP/IP connection to any database.

The gpmon database role is a superuser. In a secure or production environment, it may be desirable to restrict the gpmon user to just the gpperfmon database. Do this by editing the gpmon host entry in the pg_hba.conf file and changing all in the database field to gpperfmon:

<p>| | | | | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>local</td>
<td>gpperfmon</td>
<td>gpmon</td>
<td>md5</td>
<td></td>
</tr>
<tr>
<td>host</td>
<td>gpperfmon</td>
<td>gpmon</td>
<td>127.0.0.1/28</td>
<td>md5</td>
</tr>
<tr>
<td>host</td>
<td>gpperfmon</td>
<td>gpmon</td>
<td>::1/128</td>
<td>md5</td>
</tr>
</tbody>
</table>

The password used to authenticate the gpmon user is set by the gpperfmon_install utility and is stored in the gpadmin home directory in the ~/.pgpass file. The ~/.pgpass file must be owned by the gpadmin user and be RW-accessible only by the gpadmin user. To change the gpmon password, use the ALTER ROLE command to change the password in the database, change the password in the ~/.pgpass file, and then restart GPCC with the gpcmdr --restart instance_name command.

Note: The GPCC web server can be configured to encrypt connections with SSL. Two-way authentication with public keys can also be enabled for GPCC users. However, the gpmon user always uses md5 authentication with the password saved in the ~/.pgpass file.

GPCC does not allow logins from any role configured with trust authentication, including the gpadmin user.

The gpmon user can log in to the Command Center Console and has access to all of the application’s features. You can allow other database roles access to GPCC so that you can secure the gpmon user and restrict other users’ access to GPCC features. Setting up other GPCC users is described in the next section.

Greenplum Command Center Users

GPCC has the following types of users:

- **Self Only** users can view metrics and view and cancel their own queries. Any Greenplum Database user successfully authenticated through the Greenplum Database authentication system can access Greenplum Command Center with Self Only permission. Higher permission levels are required to view and cancel other’s queries and to access the System and Admin Control Center features.
- **Basic** users can view metrics, view all queries, and cancel their own queries. Users with Basic permission are members of the Greenplum Database gpcc_basic group.
• **Operator Basic** users can view metrics, view their own and others’ queries, cancel their own queries, and view the System and Admin screens. Users with Operator Basic permission are members of the Greenplum Database `gpcc_operator_basic` group.

• **Operator** users can view their own and others’ queries, cancel their own and other’s queries, and view the System and Admin screens. Users with Operator permission are members of the Greenplum Database `gpcc_operator` group.

• **Admin** users can access all views and capabilities in the Command Center. Greenplum Database users with the `SUPERUSER` privilege have Admin permissions in Command Center.

To log in to the GPCC web application, a user must be allowed access to the `gpperfmon` database in `pg_hba.conf`. For example, to make `user1` a regular GPCC user, edit the `pg_hba.conf` file and either add or edit a line for the user so that the `gpperfmon` database is included in the database field. For example:

```
host  gpperfmon,accounts user1 127.0.0.1/28  md5
```

To designate a user as an operator, grant the `gpcc_operator` role to the user:

```
=# GRANT gpcc_operator TO user1;
```

You can also grant `gpcc_operator` to a group role to make all members of the group GPCC operators.

See the `gpperfmon_install` reference in *Greenplum Database Utility Guide* for more information about managing the `gpperfmon` database.

### Enabling SSL for Greenplum Command Center

The GPCC web server can be configured to support SSL so that client connections are encrypted. A server certificate can be generated when the Command Center instance is created or you can supply an existing certificate.

Two-way authentication with public key encryption can also be enabled for GPCC. See the *Greenplum Command Center Administration Guide* for instructions.

### Enabling Kerberos Authentication for Greenplum Command Center Users

If Kerberos authentication is enabled for Greenplum Database, Command Center users can also authenticate with Kerberos. Command Center supports three Kerberos authentication modes: **strict**, **normal**, and **gpmon-only**.

#### Strict

Command Center has a Kerberos keytab file containing the Command Center service principal and a principal for every Command Center user. If the principal in the client’s connection request is in the keytab file, the web server grants the client access and the web server connects to Greenplum Database using the client’s principal name. If the principal is not in the keytab file, the connection request fails.

#### Normal

The Command Center Kerberos keytab file contains the Command Center principal and may contain principals for Command Center users. If the principal in the client’s connection request is in Command Center’s keytab file, it uses the client’s principal for database connections. Otherwise, Command Center uses the `gpmon` user for database connections.

#### gpmon-only

The Command Center uses the `gpmon` database role for all Greenplum Database connections. No client principals are needed in the Command Center’s keytab file.
See the Greenplum Command Center documentation for instructions to enable Kerberos authentication with Greenplum Command Center.
Auditing

Describes Greenplum Database events that are logged and should be monitored to detect security threats. Greenplum Database is capable of auditing a variety of events, including startup and shutdown of the system, segment database failures, SQL statements that result in an error, and all connection attempts and disconnections. Greenplum Database also logs SQL statements and information regarding SQL statements, and can be configured in a variety of ways to record audit information with more or less detail. The log_error_verbosity configuration parameter controls the amount of detail written in the server log for each message that is logged. Similarly, the log_min_error_statement parameter allows administrators to configure the level of detail recorded specifically for SQL statements, and the log_statement parameter determines the kind of SQL statements that are audited. Greenplum Database records the username for all auditable events, when the event is initiated by a subject outside the Greenplum Database.

Greenplum Database prevents unauthorized modification and deletion of audit records by only allowing administrators with an appropriate role to perform any operations on log files. Logs are stored in a proprietary format using comma-separated values (CSV). Each segment and the master stores its own log files, although these can be accessed remotely by an administrator. Greenplum Database also authorizes overwriting of old log files via the log_truncate_on_rotation parameter. This is a local parameter and must be set on each segment and master configuration file.

Greenplum provides an administrative schema called gp_toolkit that you can use to query log files, as well as system catalogs and operating environment for system status information. For more information, including usage, refer to The gp_toolkit Administrative Schema appendix in the Greenplum Database Reference Guide.

Viewing the Database Server Log Files

Every database instance in Greenplum Database (master and segments) is a running PostgreSQL database server with its own server log file. Daily log files are created in the pg_log directory of the master and each segment data directory.

The server log files are written in comma-separated values (CSV) format. Not all log entries will have values for all of the log fields. For example, only log entries associated with a query worker process will have the slice_id populated. Related log entries of a particular query can be identified by its session identifier (gp_session_id) and command identifier (gp_command_count).

## Greenplum Database Security Configuration Guide

### Field Name | Data Type | Description
--- | --- | ---
25 | debug_query_string | text | User-supplied query string with full detail for debugging. This string can be modified for internal use.
26 | error_cursor_pos | int | The cursor index into the query string
27 | func_name | text | The function in which this message is generated
28 | file_name | text | The internal code file where the message originated
29 | file_line | int | The line of the code file where the message originated
30 | stack_trace | text | Stack trace text associated with this message

Greenplum provides a utility called `gplogfilter` that can be used to search through a Greenplum Database log file for entries matching the specified criteria. By default, this utility searches through the Greenplum master log file in the default logging location. For example, to display the last three lines of the master log file:

```
$ gplogfilter -n 3
```

You can also use `gplogfilter` to search through all segment log files at once by running it through the `gpssh` utility. For example, to display the last three lines of each segment log file:

```
$ gpssh -f seg_host_file
  => source /usr/local/greenplum-db/greenplum_path.sh
  => gplogfilter -n 3 /gpdata/gp*/pg_log/gpdb*.csv
```

The following are the Greenplum security-related audit (or logging) server configuration parameters that are set in the `postgresql.conf` configuration file:

<table>
<thead>
<tr>
<th>Field Name</th>
<th>Value Range</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>log_connections</td>
<td>Boolean</td>
<td>off</td>
<td>This outputs a line to the server log detailing each successful connection. Some client programs, like <code>psql</code>, attempt to connect twice while determining if a password is required, so duplicate “connection received” messages do not always indicate a problem.</td>
</tr>
<tr>
<td>log_disconnections</td>
<td>Boolean</td>
<td>off</td>
<td>This outputs a line in the server log at termination of a client session, and includes the duration of the session.</td>
</tr>
<tr>
<td>Field Name</td>
<td>Value Range</td>
<td>Default</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------------</td>
<td>------------------------------</td>
<td>---------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>log_statement</td>
<td>NONE, DDL, MOD, ALL</td>
<td>ALL</td>
<td>Controls which SQL statements are logged. DDL logs all data definition commands like CREATE, ALTER, and DROP commands. MOD logs all DDL statements, plus INSERT, UPDATE, DELETE, TRUNCATE, and COPY FROM. PREPARE and EXPLAIN ANALYZE statements are also logged if their contained command is of an appropriate type.</td>
</tr>
<tr>
<td>log_hostname</td>
<td>Boolean</td>
<td>off</td>
<td>By default, connection log messages only show the IP address of the connecting host. Turning on this option causes logging of the host name as well. Note that depending on your host name resolution setup this might impose a non-negligible performance penalty.</td>
</tr>
<tr>
<td>log_duration</td>
<td>Boolean</td>
<td>off</td>
<td>Causes the duration of every completed statement which satisfies log_statement to be logged.</td>
</tr>
<tr>
<td>log_error_verbosity</td>
<td>TERSE, DEFAULT, VERBOSE</td>
<td>DEFAULT</td>
<td>Controls the amount of detail written in the server log for each message that is logged.</td>
</tr>
<tr>
<td>log_min_duration_</td>
<td>number of milliseconds, 0, -1</td>
<td>-1</td>
<td>Logs the statement and its duration on a single log line if its duration is greater than or equal to the specified number of milliseconds. Setting this to 0 will print all statements and their durations. -1 disables the feature. For example, if you set it to 250 then all SQL statements that run 250ms or longer will be logged. Enabling this option can be useful in tracking down unoptimized queries in your applications.</td>
</tr>
<tr>
<td>Field Name</td>
<td>Value Range</td>
<td>Default</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------------------</td>
<td>------------------------------</td>
<td>---------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>log_min_messages</td>
<td>DEBUG5, DEBUG4, DEBUG3, DEBUG2, DEBUG1, INFO, NOTICE, WARNING, ERROR, LOG, FATAL, PANIC</td>
<td>NOTICE</td>
<td>Controls which message levels are written to the server log. Each level includes all the levels that follow it. The later the level, the fewer messages are sent to the log.</td>
</tr>
<tr>
<td>log_rotation_age</td>
<td>Any valid time expression (number and unit)</td>
<td>1d</td>
<td>Determines the maximum lifetime of an individual log file. After this time has elapsed, a new log file will be created. Set to zero to disable time-based creation of new log files.</td>
</tr>
<tr>
<td>log_statement_stats</td>
<td>Boolean</td>
<td>off</td>
<td>For each query, write total performance statistics of the query parser, planner, and executor to the server log. This is a crude profiling instrument.</td>
</tr>
<tr>
<td>log_truncate_on_rotation</td>
<td>Boolean</td>
<td>off</td>
<td>Truncates (overwrites), rather than appends to, any existing log file of the same name. Truncation will occur only when a new file is being opened due to time-based rotation. For example, using this setting in combination with a log_filename such as gpseg#-%H. log would result in generating twenty-four hourly log files and then cyclically overwriting them. When off, pre-existing files will be appended to in all cases.</td>
</tr>
</tbody>
</table>
Encrypting Data and Database Connections

Describes how to encrypt data at rest in the database or in transit over the network, to protect from evesdroppers or man-in-the-middle attacks.

- Connections between clients and the master database can be encrypted with SSL. This is enabled with the `ssl` server configuration parameter, which is `off` by default. Setting the `ssl` parameter to `on` allows client communications with the master to be encrypted. The master database must be set up for SSL. See OpenSSL Configuration for more about encrypting client connections with SSL.
- Greenplum Database allows SSL encryption of data in transit between the Greenplum parallel file distribution server, `gpfdist`, and segment hosts. See Encrypting gpfdist Connections for more information.
- The `pgcrypto` module of encryption/decryptions functions protect data at rest in the database. Encryption at the column level protects sensitive information, such as social security numbers or credit card numbers. See Encrypting Data at Rest with pgcrypto for more information.

Encrypting gpfdist Connections

The `gpfdists` protocol is a secure version of the `gpfdist` protocol that securely identifies the file server and the Greenplum Database and encrypts the communications between them. Using `gpfdists` protects against eavesdropping and man-in-the-middle attacks.

The `gpfdists` protocol implements client/server SSL security with the following notable features:

- Client certificates are required.
- Multilingual certificates are not supported.
- A Certificate Revocation List (CRL) is not supported.
- The TLSv1 protocol is used with the `TLS_RSA_WITH_AES_128_CBC_SHA` encryption algorithm. These SSL parameters cannot be changed.
- SSL renegotiation is supported.
- The SSL ignore host mismatch parameter is set to false.
- Private keys containing a passphrase are not supported for the `gpfdist` file server (`server.key`) or for the Greenplum Database (`client.key`).
- It is the user’s responsibility to issue certificates that are appropriate for the operating system in use. Generally, converting certificates to the required format is supported, for example using the SSL Converter at [https://www.sslshopper.com/ssl-converter.html](https://www.sslshopper.com/ssl-converter.html).

A `gpfdist` server started with the `--ssl` option can only communicate with the `gpfdists` protocol. A `gpfdist` server started without the `--ssl` option can only communicate with the `gpfdist` protocol. For more detail about `gpfdist` refer to the Greenplum Database Administrator Guide.

There are two ways to enable the `gpfdists` protocol:

- Run `gpfdist` with the `--ssl` option and then use the `gpfdists` protocol in the `LOCATION` clause of a `CREATE EXTERNAL TABLE` statement.
- Use a YAML control file with the SSL option set to true and run `gpload`. Running `gpload` starts the `gpfdist` server with the `--ssl` option and then uses the `gpfdists` protocol.

When using `gpfdists`, the following client certificates must be located in the `$PGDATA/gpfdists` directory on each segment:

- The client certificate file, `client.crt`
- The client private key file, `client.key`
- The trusted certificate authorities, `root.crt`

**Important:** Do not protect the private key with a passphrase. The server does not prompt for a passphrase for the private key, and loading data fails with an error if one is required.
When using `gpload` with SSL you specify the location of the server certificates in the YAML control file. When using `gpfdist` with SSL, you specify the location of the server certificates with the `--ssl` option.

The following example shows how to securely load data into an external table. The example creates a readable external table named `ext_expenses` from all files with the `txt` extension, using the `gpfdists` protocol. The files are formatted with a pipe (|) as the column delimiter and an empty space as null.

1. Run `gpfdist` with the `--ssl` option on the segment hosts.
2. Log into the database and execute the following command:

```sql
=# CREATE EXTERNAL TABLE ext_expenses
  ( name text, date date, amount float4, category text, desc1 text )
LOCATION ('gpfdists://etlhost-1:8081/*.txt', 'gpfdists://etlhost-2:8082/*.txt')
FORMAT 'TEXT' ( DELIMITER '|' NULL ' ');
```

---

**Encrypting Data at Rest with pgcrypto**

The pgcrypto module for Greenplum Database provides functions for encrypting data at rest in the database. Administrators can encrypt columns with sensitive information, such as social security numbers or credit card numbers, to provide an extra layer of protection. Database data stored in encrypted form cannot be read by users who do not have the encryption key, and the data cannot be read directly from disk.

pgcrypto is installed by default when you install Greenplum Database. You must explicitly enable pgcrypto in each database in which you want to use the module.

pgcrypto allows PGP encryption using symmetric and asymmetric encryption. Symmetric encryption encrypts and decrypts data using the same key and is faster than asymmetric encryption. It is the preferred method in an environment where exchanging secret keys is not an issue. With asymmetric encryption, a public key is used to encrypt data and a private key is used to decrypt data. This is slower than symmetric encryption and it requires a stronger key.

Using pgcrypto always comes at the cost of performance and maintainability. It is important to use encryption only with the data that requires it. Also, keep in mind that you cannot search encrypted data by indexing the data.

Before you implement in-database encryption, consider the following PGP limitations.

- No support for signing. That also means that it is not checked whether the encryption sub-key belongs to the master key.
- No support for encryption key as master key. This practice is generally discouraged, so this limitation should not be a problem.
- No support for several subkeys. This may seem like a problem, as this is common practice. On the other hand, you should not use your regular GPG/PGP keys with pgcrypto, but create new ones, as the usage scenario is rather different.

Greenplum Database is compiled with zlib by default; this allows PGP encryption functions to compress data before encrypting. When compiled with OpenSSL, more algorithms will be available.

Because pgcrypto functions run inside the database server, the data and passwords move between pgcrypto and the client application in clear-text. For optimal security, you should connect locally or use SSL connections and you should trust both the system and database administrators.

pgcrypto configures itself according to the findings of the main PostgreSQL configure script.

When compiled with zlib, pgcrypto encryption functions are able to compress data before encrypting.

Pgcrypto has various levels of encryption ranging from basic to advanced built-in functions. The following table shows the supported encryption algorithms.
Table 89: Pgcrypto Supported Encryption Functions

<table>

Creating PGP Keys

To use PGP asymmetric encryption in Greenplum Database, you must first create public and private keys and install them.

This section assumes you are installing Greenplum Database on a Linux machine with the Gnu Privacy Guard (gpg) command line tool. Use the latest version of GPG to create keys. Download and install Gnu Privacy Guard (GPG) for your operating system from https://www.gnupg.org/download/. On the GnuPG website you will find installers for popular Linux distributions and links for Windows and Mac OS X installers.

1. As root, execute the following command and choose option 1 from the menu:

```
# gpg --gen-key
```

   gpg (GnuPG) 2.0.14; Copyright (C) 2009 Free Software Foundation, Inc.
   This is free software: you are free to change and redistribute it.
   There is NO WARRANTY, to the extent permitted by law.

   gpg: directory '/root/.gnupg' created
   gpg: new configuration file '/root/.gnupg/gpg.conf' created
   gpg: WARNING: options in '/root/.gnupg/gpg.conf' are not yet active during this run
   gpg: keyring '/root/.gnupg/secring.gpg' created
   gpg: keyring '/root/.gnupg/pubring.gpg' created
   Please select what kind of key you want:
   (1) RSA and RSA (default)
   (2) DSA and Elgamal
   (3) DSA (sign only)
   (4) RSA (sign only)
   Your selection? 1

2. Respond to the prompts and follow the instructions, as shown in this example:

```
RSA keys may be between 1024 and 4096 bits long.
```

³ SHA2 algorithms were added to OpenSSL in version 0.9.8. For older versions, pgcrypto will use built-in code.
⁴ Any digest algorithm OpenSSL supports is automatically picked up. This is not possible with ciphers, which need to be supported explicitly.
⁵ AES is included in OpenSSL since version 0.9.7. For older versions, pgcrypto will use built-in code.
What keysize do you want? (2048) Press enter to accept default key size
Requested keysize is 2048 bits
Please specify how long the key should be valid.
  0 = key does not expire
  <n> = key expires in n days
  <n>W = key expires in n weeks
  <n>M = key expires in n months
  <n>Y = key expires in n years
Key is valid for? (0) 365
Key expires at Wed 13 Jan 2016 10:35:39 AM PST
Is this correct? (y/N) y

GnuPG needs to construct a user ID to identify your key.

Real name: John Doe
Email address: jdoe@email.com
Comment:
You selected this USER-ID:
"John Doe <jdoe@email.com>"

Change (N)ame, (C)omment, (E)mail or (O)kay/(Q)uit? O
You need a Passphrase to protect your secret key.
(For this demo the passphrase is blank.)
can't connect to '/root/.gnupg/S.gpg-agent': No such file or directory
You don't want a passphrase - this is probably a *bad* idea!
I will do it anyway. You can change your passphrase at any time,
using this program with the option "--edit-key".

We need to generate a lot of random bytes. It is a good idea to perform
some other action (type on the keyboard, move the mouse, utilize the
disks) during the prime generation; this gives the random number
generator a better chance to gain enough entropy.
We need to generate a lot of random bytes. It is a good idea to perform
some other action (type on the keyboard, move the mouse, utilize the
disks) during the prime generation; this gives the random number
generator a better chance to gain enough entropy.
gpg: /root/.gnupg/trustdb.gpg: trustdb created
gpg: key 2027CC30 marked as ultimately trusted
public and secret key created and signed.
gpg: checking the trustdb
  3 marginal(s) needed, 1 complete(s) needed, PGP trust model
gpg: depth: 0 valid: 1 signed: 0 trust: 0-, 0q, 0n, 0m, 0f, 1u
gpg: next trustdb check due at 2016-01-13
pub 2048R/2027CC30 2015-01-13 [expires: 2016-01-13]
  Key fingerprint = 7EDA 6AD0 F5E0 400F 4D45 3259 077D 725E 2027 CC30
uid                  John Doe <jdoe@email.com>
sub 2048R/4FD2EFBB 2015-01-13 [expires: 2016-01-13]

3. List the PGP keys by entering the following command:

    gpg --list-secret-keys
    /root/.gnupg/secring.gpg
    ------------------------
    sec  2048R/2027CC30 2015-01-13 [expires: 2016-01-13]
    uid   John Doe <jdoe@email.com>
    ssb  2048R/4FD2EFBB 2015-01-13

2027CC30 is the public key and will be used to encrypt data in the database. 4FD2EFBB is the private (secret) key and will be used to decrypt data.
4. Export the keys using the following commands:

```
# gpg -a --export 4FD2EFBB > public.key
# gpg -a --export-secret-keys 2027CC30 > secret.key
```

See the `pgcrypto` documentation for more information about PGP encryption functions.

**Encrypting Data in Tables using PGP**

This section shows how to encrypt data inserted into a column using the PGP keys you generated.

1. Dump the contents of the `public.key` file and then copy it to the clipboard:

```
# cat public.key
-----BEGIN PGP PUBLIC KEY BLOCK-----
Version: GnuPG v2.0.14 (GNU/Linux)

-----END PGP PUBLIC KEY BLOCK-----');

pgp_key_id | 9D4D255F4F2DEFFB
```

This shows that the PGP key ID used to encrypt the `ssn` column is 9D4D255F4F2DEFFB. It is recommended to perform this step whenever a new key is created and then store the ID for tracking.

You can use this key to see which key pair was used to encrypt the data:

```sql
SELECT username, pgp_key_id(ssn) As key_used
FROM userssn;
```
Note: Different keys may have the same ID. This is rare, but is a normal event. The client application should try to decrypt with each one to see which fits — like handling ANYKEY. See pgp_key_id() in the pgcrypto documentation.

5. Decrypt the data using the private key.

```
SELECT username, pgp_pub_decrypt(ssn, keys.privkey) 
AS decrypted_ssn FROM userssn 
CROSS JOIN
(SELECT dearmor('-----BEGIN PGP PRIVATE KEY BLOCK-----

If you created a key with passphrase, you may have to enter it here. However for the purpose of this example, the passphrase is blank.

**Key Management**

Whether you are using symmetric (single private key) or asymmetric (public and private key) cryptography, it is important to store the master or private key securely. There are many options for storing encryption keys, for example, on a file system, key vault, encrypted USB, trusted platform module (TPM), or hardware security module (HSM).

Consider the following questions when planning for key management:

- Where will the keys be stored?
- When should keys expire?
- How are keys protected?
- How are keys accessed?
- How can keys be recovered and revoked?

The Open Web Application Security Project (OWASP) provides a very comprehensive guide to securing encryption keys.
Enabling gphdfs Authentication with a Kerberos-secured Hadoop Cluster (Deprecated)

Provides steps for configuring Greenplum Database to access external tables in a Hadoop cluster secured with Kerberos.

Note: The gphdfs external table protocol is deprecated and will be removed in the next major release of Greenplum Database. Consider using the Greenplum Platform Extension Framework (PXF) pxf external table protocol to access data stored in a Hadoop file system.

Using external tables and the gphdfs protocol, Greenplum Database can read files from and write files to a Hadoop File System (HDFS). Greenplum segments read and write files in parallel from HDFS for fast performance.

When a Hadoop cluster is secured with Kerberos (“Kerberized”), Greenplum Database must be configured to allow the Greenplum Database gpadmin role, which owns external tables in HDFS, to authenticate through Kerberos. This topic provides the steps for configuring Greenplum Database to work with a Kerberized HDFS, including verifying and troubleshooting the configuration.

- Prerequisites
- Configuring the Greenplum Cluster
- Creating and Installing Keytab Files
- Configuring gphdfs for Kerberos
- Testing Greenplum Database Access to HDFS
- Troubleshooting HDFS with Kerberos

Prerequisites

Make sure the following components are functioning and accessible on the network:

- Greenplum Database cluster
- Kerberos-secured Hadoop cluster. See the Greenplum Database Release Notes for supported Hadoop versions.
- Kerberos Key Distribution Center (KDC) server.

Configuring the Greenplum Cluster

The hosts in the Greenplum Cluster must have a Java JRE, Hadoop client files, and Kerberos clients installed.

Follow these steps to prepare the Greenplum Cluster.

1. Install a Java 1.6 or later JRE on all Greenplum cluster hosts.
   
   Match the JRE version the Hadoop cluster is running. You can find the JRE version by running `java --version` on a Hadoop node.

2. (Optional) Confirm that Java Cryptography Extension (JCE) is present.
   
   The default location of the JCE libraries is `JAVA_HOME/lib/security`. If a JDK is installed, the directory is `JAVA_HOME/jre/lib/security`. The files `local_policy.jar` and `US_export_policy.jar` should be present in the JCE directory.

   The Greenplum cluster and the Kerberos server should, preferably, use the same version of the JCE libraries. You can copy the JCE files from the Kerberos server to the Greenplum cluster, if needed.
3. Set the `JAVA_HOME` environment variable to the location of the JRE in the `.bashrc` or `.bash_profile` file for the `gpadmin` account. For example:

```
export JAVA_HOME=/usr/java/default
```

4. Source the `.bashrc` or `.bash_profile` file to apply the change to your environment. For example:

```
$ source ~/.bashrc
```

5. Install the Kerberos client utilities on all cluster hosts. Ensure the libraries match the version on the KDC server before you install them.

For example, the following command installs the Kerberos client files on Red Hat or CentOS Linux:

```
$ sudo yum install krb5-libs krb5-workstation
```

Use the `kinit` command to confirm the Kerberos client is installed and correctly configured.

6. Install Hadoop client files on all hosts in the Greenplum Cluster. Refer to the documentation for your Hadoop distribution for instructions.

7. Set the Greenplum Database server configuration parameters for Hadoop. The `gp_hadoop_target_version` parameter specifies the version of the Hadoop cluster. See the `Greenplum Database Release Notes` for the target version value that corresponds to your Hadoop distribution. The `gp_hadoop_home` parameter specifies the Hadoop installation directory.

```
$ gpconfig -c gp_hadoop_target_version -v "hdp2"
$ gpconfig -c gp_hadoop_home -v "/usr/lib/hadoop"
```

See the `Greenplum Database Reference Guide` for more information.

8. Reload the updated `postgresql.conf` files for master and segments:

```
gpstop -u
```

You can confirm the changes with the following commands:

```
$ gpconfig -s gp_hadoop_target_version
$ gpconfig -s gp_hadoop_home
```

9. Grant Greenplum Database `gphdfs` protocol privileges to roles that own external tables in HDFS, including `gpadmin` and other superuser roles. Grant `SELECT` privileges to enable creating readable external tables in HDFS. Grant `INSERT` privileges to enable creating writable external tables on HDFS.

```
#= GRANT SELECT ON PROTOCOL gphdfs TO gpadmin;
#= GRANT INSERT ON PROTOCOL gphdfs TO gpadmin;
```

10. Grant Greenplum Database external table privileges to external table owner roles:

```
ALTER ROLE HDFS_USER CREATEEXTTABLE (type='readable');
ALTER ROLE HDFS_USER CREATEEXTTABLE (type='writable');
```

**Note:** It is best practice to review database privileges, including gphdfs external table privileges, at least annually.

**Creating and Installing Keytab Files**

1. Log in to the KDC server as root.
2. Use the `kadmin.local` command to create a new principal for the `gpadmin` user:

   ```
   # kadmin.local -q "addprinc -randkey gpadmin@LOCAL.DOMAIN"
   ```

3. Use `kadmin.local` to generate a Kerberos service principal for each host in the Greenplum Database cluster. The service principal should be of the form `name/role@REALM`, where:

   - `name` is the gphdfs service user name. This example uses `gphdfs`.
   - `role` is the DNS-resolvable host name of a Greenplum cluster host (the output of the `hostname -f` command).
   - `REALM` is the Kerberos realm, for example `LOCAL.DOMAIN`.

   For example, the following commands add service principals for four Greenplum Database hosts, `mdw.example.com`, `smdw.example.com`, `sdw1.example.com`, and `sdw2.example.com`:

   ```
   # kadmin.local -q "addprinc -randkey gphdfs/mdw.example.com@LOCAL.DOMAIN"
   # kadmin.local -q "addprinc -randkey gphdfs/smdw.example.com@LOCAL.DOMAIN"
   # kadmin.local -q "addprinc -randkey gphdfs/sdw1.example.com@LOCAL.DOMAIN"
   # kadmin.local -q "addprinc -randkey gphdfs/sdw2.example.com@LOCAL.DOMAIN"
   ```

   Create a principal for each Greenplum cluster host. Use the same principal name and realm, substituting the fully-qualified domain name for each host.

4. Generate a keytab file for each principal that you created (`gpadmin` and each `gphdfs` service principal). You can store the keytab files in any convenient location (this example uses the directory `/etc/security/keytabs`). You will deploy the service principal keytab files to their respective Greenplum host machines in a later step:

   ```
   # kadmin.local -q "xst -k /etc/security/keytabs/gphdfs.service.keytab gpadmin@LOCAL.DOMAIN"
   # kadmin.local -q "xst -k /etc/security/keytabs/mdw.service.keytab gpadmin/mdw gphdfs/mdw.example.com@LOCAL.DOMAIN"
   # kadmin.local -q "xst -k /etc/security/keytabs/smdw.service.keytab gpadmin/smdw gphdfs/smdw.example.com@LOCAL.DOMAIN"
   # kadmin.local -q "xst -k /etc/security/keytabs/sdw1.service.keytab gpadmin/sdw1 gphdfs/sdw1.example.com@LOCAL.DOMAIN"
   # kadmin.local -q "xst -k /etc/security/keytabs/sdw2.service.keytab gpadmin/sdw2 gphdfs/sdw2.example.com@LOCAL.DOMAIN"
   # kadmin.local -q "listprincs"
   ```

5. Change the ownership and permissions on `gphdfs.service.keytab` as follows:

   ```
   # chown gpadmin:gpadmin /etc/security/keytabs/gphdfs.service.keytab
   # chmod 440 /etc/security/keytabs/gphdfs.service.keytab
   ```

6. Copy the keytab file for `gpadmin@LOCAL.DOMAIN` to the Greenplum master host:

   ```
   # scp /etc/security/keytabs/gphdfs.service.keytab mdw_fqdn:/home/gpadmin/gphdfs.service.keytab
   ```

7. Copy the keytab file for each service principal to its respective Greenplum host:

   ```
   # scp /etc/security/keytabs/mdw.service.keytab mdw_fqdn:/home/gpadmin/mdw.service.keytab
   # scp /etc/security/keytabs/smdw.service.keytab smdw_fqdn:/home/gpadmin/smdw.service.keytab
   # scp /etc/security/keytabs/sdw1.service.keytab sdw1_fqdn:/home/gpadmin/sdw1.service.keytab
   # scp /etc/security/keytabs/sdw2.service.keytab sdw2_fqdn:/home/gpadmin/sdw2.service.keytab
   ```
Configuring gphdfs for Kerberos

1. Edit the Hadoop core-site.xml client configuration file on all Greenplum cluster hosts. Enable service-level authorization for Hadoop by setting the hadoop.security.authorization property to true. For example:

   ```xml
   <property>
     <name>hadoop.security.authorization</name>
     <value>true</value>
   </property>
   ```

2. Edit the yarn-site.xml client configuration file on all cluster hosts. Set the resource manager address and yarn Kerberos service principle. For example:

   ```xml
   <property>
     <name>yarn.resourcemanager.address</name>
     <value>hostname:8032</value>
   </property>
   <property>
     <name>yarn.resourcemanager.principal</name>
     <value>yarn/hostname@DOMAIN</value>
   </property>
   ```

3. Edit the hdfs-site.xml client configuration file on all cluster hosts. Set properties to identify the NameNode Kerberos principals, the location of the Kerberos keytab file, and the principal it is for:

   - dfs.namenode.kerberos.principal - the Kerberos principal name the gphdfs protocol will use for the NameNode, for example gpadmin@LOCAL.DOMAIN.
   - dfs.namenode.https.principal - the Kerberos principal name the gphdfs protocol will use for the NameNode's secure HTTP server, for example gpadmin@LOCAL.DOMAIN.
   - com.emc.greenplum.gpdb.hdfsconnector.security.user.keytab.file - the path to the keytab file for the Kerberos HDFS service, for example /home/gpadmin/mdw.service.keytab.
   - com.emc.greenplum.gpdb.hdfsconnector.security.user.name - the gphdfs service principal for the host, for example gphdfs/mdw.example.com@LOCAL.DOMAIN.

   For example:

   ```xml
   <property>
     <name>dfs.namenode.kerberos.principal</name>
     <value>gphdfs/gpadmin@LOCAL.DOMAIN</value>
   </property>
   <property>
     <name>dfs.namenode.https.principal</name>
     <value>gphdfs/gpadmin@LOCAL.DOMAIN</value>
   </property>
   <property>
     <name>com.emc.greenplum.gpdb.hdfsconnector.security.user.keytab.file</name>
     <value>/home/gpadmin/gpadmin.hdfs.keytab</value>
   </property>
   <property>
     <name>com.emc.greenplum.gpdb.hdfsconnector.security.user.name</name>
     <value>gpadmin@LOCAL.DOMAIN</value>
   </property>
   ```
Testing Greenplum Database Access to HDFS

Confirm that HDFS is accessible via Kerberos authentication on all hosts in the Greenplum cluster. For example, enter the following command to list an HDFS directory:

```
hdfs dfs -ls hdfs://namenode:8020
```

Create a Readable External Table in HDFS

Follow these steps to verify that you can create a readable external table in a Kerberized Hadoop cluster.

1. Create a comma-delimited text file, `test1.txt`, with contents such as the following:

   25, Bill  
   19, Anne  
   32, Greg  
   27, Gloria

2. Persist the sample text file in HDFS:

   ```
hdfs dfs -put test1.txt hdfs://namenode:8020/tmp
```

3. Log in to Greenplum Database and create a readable external table that points to the `test1.txt` file in Hadoop:

   ```
CREATE EXTERNAL TABLE test_hdfs (age int, name text)
    LOCATION('gphdfs://namenode:8020/tmp/test1.txt')
    FORMAT 'text' (delimiter ',');
```

4. Read data from the external table:

   ```
SELECT * FROM test_hdfs;
```

Create a Writable External Table in HDFS

Follow these steps to verify that you can create a writable external table in a Kerberized Hadoop cluster. The steps use the `test_hdfs` readable external table created previously.

1. Log in to Greenplum Database and create a writable external table pointing to a text file in HDFS:

   ```
CREATE WRITABLE EXTERNAL TABLE test_hdfs2 (LIKE test_hdfs)
    LOCATION ('gphdfs://namenode:8020/tmp/test2.txt'
    FORMAT 'text' (DELIMITER ',');
```

2. Load data into the writable external table:

   ```
INSERT INTO test_hdfs2
SELECT * FROM test_hdfs;
```

3. Check that the file exists in HDFS:

   ```
hdfs dfs -ls hdfs://namenode:8020/tmp/test2.txt
```

4. Verify the contents of the external file:

   ```
hdfs dfs -cat hdfs://namenode:8020/tmp/test2.txt
```
Troubleshooting HDFS with Kerberos

Forcing Classpaths
If you encounter "class not found" errors when executing SELECT statements from gphdfs external tables, edit the $GPHOME/lib/hadoop-env.sh file and add the following lines towards the end of the file, before the JAVA_LIBRARY_PATH is set. Update the script on all of the cluster hosts.

```bash
if [ -d "/usr/hdp/current" ]; then
  for f in /usr/hdp/current/**/*.*.jar; do
    CLASSPATH=${CLASSPATH}:$f;
  done
fi
```

Enabling Kerberos Client Debug Messages
To see debug messages from the Kerberos client, edit the $GPHOME/lib/hadoop-env.sh client shell script on all cluster hosts and set the HADOOP_OPTS variable as follows:

```bash
export HADOOP_OPTS="-Djava.net.prefIPv4Stack=true -Dsun.security.krb5.debug=true ${HADOOP_OPTS}"
```

Adjusting JVM Process Memory on Segment Hosts
Each segment launches a JVM process when reading or writing an external table in HDFS. To change the amount of memory allocated to each JVM process, configure the GP_JAVA_OPT environment variable.

Edit the $GPHOME/lib/hadoop-env.sh client shell script on all cluster hosts.

For example:

```bash
export GP_JAVA_OPT=-Xmx1000m
```

Verify Kerberos Security Settings
Review the /etc/krb5.conf file:

- If AES256 encryption is not disabled, ensure that all cluster hosts have the JCE Unlimited Strength Jurisdiction Policy Files installed.
- Ensure all encryption types in the Kerberos keytab file match definitions in the krb5.conf file.

```bash
cat /etc/krb5.conf | egrep supported_enctypes
```

Test Connectivity on an Individual Segment Host
Follow these steps to test that a single Greenplum Database host can read HDFS data. This test method executes the Greenplum HDFSReader Java class at the command-line, and can help to troubleshoot connectivity problems outside of the database.

1. Save a sample data file in HDFS.

   ```bash
   hdfs dfs -put test1.txt hdfs://namenode:8020/tmp
   ```

2. On the segment host to be tested, create an environment script, env.sh, like the following:

   ```bash
   export JAVA_HOME=/usr/java/default
   export HADOOP_HOME=/usr/lib/hadoop
   ```
export GP_HADOOP_CON_VERSION=hdp2
export GP_HADOOP_CON_JARDIR=/usr/lib/hadoop

3. Source all environment scripts:

    source /usr/local/greenplum-db/greenplum_path.sh
    source env.sh
    source $GPHOME/lib/hadoop-env.sh

4. Test the Greenplum Database HDFS reader:

    java com.emc.greenplum.gpdb.hdfsconnector.HDFSReader 0 32 TEXT hdp2
gphdfs://namenode:8020/tmp/test1.txt
Security Best Practices

Describes basic security best practices that you should follow to ensure the highest level of system security.

In the default Greenplum Database security configuration:

- Only local connections are allowed.
- Basic authentication is configured for the superuser (gpadmin).
- The superuser is authorized to do anything.
- Only database role passwords are encrypted.

System User (gpadmin)

Secure and limit access to the gpadmin system user.

Greenplum requires a UNIX user id to install and initialize the Greenplum Database system. This system user is referred to as gpadmin in the Greenplum documentation. The gpadmin user is the default database superuser in Greenplum Database, as well as the file system owner of the Greenplum installation and its underlying data files. The default administrator account is fundamental to the design of Greenplum Database. The system cannot run without it, and there is no way to limit the access of the gpadmin user id.

The gpadmin user can bypass all security features of Greenplum Database. Anyone who logs on to a Greenplum host with this user id can read, alter, or delete any data, including system catalog data and database access rights. Therefore, it is very important to secure the gpadmin user id and only allow essential system administrators access to it.

Administrators should only log in to Greenplum as gpadmin when performing certain system maintenance tasks (such as upgrade or expansion).

Database users should never log on as gpadmin, and ETL or production workloads should never run as gpadmin.

Superusers

Roles granted the SUPERUSER attribute are superusers. Superusers bypass all access privilege checks and resource queues. Only system administrators should be given superuser rights.

See “Altering Role Attributes” in the Greenplum Database Administrator Guide.

Login Users

Assign a distinct role to each user who logs in and set the LOGIN attribute.

For logging and auditing purposes, each user who is allowed to log in to Greenplum Database should be given their own database role. For applications or web services, consider creating a distinct role for each application or service. See “Creating New Roles (Users)” in the Greenplum Database Administrator Guide.

Each login role should be assigned to a single, non-default resource queue.

Groups

Use groups to manage access privileges.

Create a group for each logical grouping of object/access permissions.

Every login user should belong to one or more roles. Use the GRANT statement to add group access to a role. Use the REVOKE statement to remove group access from a role.
The **LOGIN** attribute should not be set for group roles.

See "Creating Groups (Role Membership)" in the *Greenplum Database Administrator Guide*.

**Object Privileges**

Only the owner and superusers have full permissions to new objects. Permission must be granted to allow other rules (users or groups) to access objects. Each type of database object has different privileges that may be granted. Use the **GRANT** statement to add a permission to a role and the **REVOKE** statement to remove the permission.

You can change the owner of an object using the **REASSIGN OWNED BY** statement. For example, to prepare to drop a role, change the owner of the objects that belong to the role. Use the **DROP OWNED BY** to drop objects, including dependent objects, that are owned by a role.

Schemas can be used to enforce an additional layer of object permissions checking, but schema permissions do not override object privileges set on objects contained within the schema.

**Operating System Users and File System**

To protect the network from intrusion, system administrators should verify the passwords used within an organization are sufficiently strong. The following recommendations can strengthen a password:

- **Minimum password length recommendation:** At least 9 characters. MD5 passwords should be 15 characters or longer.
- Mix upper and lower case letters.
- Mix letters and numbers.
- Include non-alphanumeric characters.
- Pick a password you can remember.

The following are recommendations for password cracker software that you can use to determine the strength of a password.

- **John The Ripper.** A fast and flexible password cracking program. It allows the use of multiple word lists and is capable of brute-force password cracking. It is available online at [http://www.openwall.com/john/](http://www.openwall.com/john/).
- **Crack.** Perhaps the most well-known password cracking software, Crack is also very fast, though not as easy to use as John The Ripper. It can be found online at [https://dropsafe.crypticide.com/alecm/software/crack/c50-faq.html](https://dropsafe.crypticide.com/alecm/software/crack/c50-faq.html).

The security of the entire system depends on the strength of the root password. This password should be at least 12 characters long and include a mix of capitalized letters, lowercase letters, special characters, and numbers. It should not be based on any dictionary word.

Password expiration parameters should be configured.

Ensure the following line exists within the file `/etc/libuser.conf` under the `[import]` section.

```
login_defs = /etc/login.defs
```

Ensure no lines in the `[userdefaults]` section begin with the following text, as these words override settings from `/etc/login.defs`:

- **LU_SHADOWMAX**
- **LU_SHADOWMIN**
- **LU_SHADOWWARNING**

Ensure the following command produces no output. Any accounts listed by running this command should be locked.

```
grep "^+:" /etc/passwd /etc/shadow /etc/group
```
Note: We strongly recommend that customers change their passwords after initial setup.

```bash
cd /etc
chown root:root passwd shadow group gshadow
chmod 644 passwd group
chmod 400 shadow gshadow
```

Find all the files that are world-writable and that do not have their sticky bits set.

```bash
find / -xdev -type d \( -perm -0002 -a ! -perm -1000 \) -print
```

Set the sticky bit (# chmod +t {dir}) for all the directories that result from running the previous command.

Find all the files that are world-writable and fix each file listed.

```bash
find / -xdev -type f -perm -0002 -print
```

Set the right permissions (# chmod o-w {file}) for all the files generated by running the aforementioned command.

Find all the files that do not belong to a valid user or group and either assign an owner or remove the file, as appropriate.

```bash
find / -xdev \( -nouser -o -nogroup \) -print
```

Find all the directories that are world-writable and ensure they are owned by either root or a system account (assuming only system accounts have a User ID lower than 500). If the command generates any output, verify the assignment is correct or reassign it to root.

```bash
find / -xdev -type d -perm -0002 -uid +500 -print
```

Authentication settings such as password quality, password expiration policy, password reuse, password retry attempts, and more can be configured using the Pluggable Authentication Modules (PAM) framework. PAM looks in the directory `/etc/pam.d` for application-specific configuration information. Running `authconfig` or `system-config-authentication` will re-write the PAM configuration files, destroying any manually made changes and replacing them with system defaults.

The default `pam_cracklib` PAM module provides strength checking for passwords. To configure `pam_cracklib` to require at least one uppercase character, lowercase character, digit, and special character, as recommended by the U.S. Department of Defense guidelines, edit the file `/etc/pam.d/system-auth` to include the following parameters in the line corresponding to password requisite

```bash
pam_cracklib.so try_first_pass
retry=3:
dcredit=-1. Require at least one digit
ucredit=-1. Require at least one uppercase character
ocredit=-1. Require at least one special character
lcredit=-1. Require at least one lowercase character
minlen-14. Require a minimum password length of 14.
```

For example:
password required pam_cracklib.so try_first_pass retry=3\minlen=14
dcredit=-1 ucredit=-1 ocredit=-1 lcredit=-1

These parameters can be set to reflect your security policy requirements. Note that the password restrictions are not applicable to the root password.

The `pam_tally2` PAM module provides the capability to lock out user accounts after a specified number of failed login attempts. To enforce password lockout, edit the file `/etc/pam.d/system-auth` to include the following lines:

- The first of the auth lines should include:
  ```
  auth required pam_tally2.so deny=5 onerr=fail unlock_time=900
  ```

- The first of the account lines should include:
  ```
  account required pam_tally2.so
  ```

Here, the deny parameter is set to limit the number of retries to 5 and the `unlock_time` has been set to 900 seconds to keep the account locked for 900 seconds before it is unlocked. These parameters may be configured appropriately to reflect your security policy requirements. A locked account can be manually unlocked using the `pam_tally2` utility:

```
/sbin/pam_tally2 --user {username} -reset
```

You can use PAM to limit the reuse of recent passwords. The remember option for the `pam_unix` module can be set to remember the recent passwords and prevent their reuse. To accomplish this, edit the appropriate line in `/etc/pam.d/system-auth` to include the remember option.

For example:

```
password sufficient pam_unix.so [ ... existing_options ...]
remember=5
```

You can set the number of previous passwords to remember to appropriately reflect your security policy requirements.

```bash
cd /etc
chown root:root passwd shadow group gshadow
chmod 644 passwd group
chmod 400 shadow gshadow
```
Chapter 9

Greenplum Database Best Practices

A best practice is a method or technique that has consistently shown results superior to those achieved with other means. Best practices are found through experience and are proven to reliably lead to a desired result. Best practices are a commitment to use any product correctly and optimally, by leveraging all the knowledge and expertise available to ensure success.

This document does not teach you how to use Greenplum Database features. Links are provided to other relevant parts of the Greenplum Database documentation for information on how to use and implement specific Greenplum Database features. This document addresses the most important best practices to follow when designing, implementing, and using Greenplum Database.

It is not the intent of this document to cover the entire product or compendium of features, but rather to provide a summary of what matters most in Greenplum Database. This document does not address edge use cases. While edge use cases can further leverage and benefit from Greenplum Database features, they require a proficient knowledge and expertise with these features, as well as a deep understanding of your environment, including SQL access, query execution, concurrency, workload, and other factors.

By mastering these best practices, you will increase the success of your Greenplum Database clusters in the areas of maintenance, support, performance, and scalability.
Best Practices Summary

A summary of best practices for Greenplum Database.

Data Model
Greenplum Database is an analytical MPP shared-nothing database. This model is significantly different from a highly normalized/transactional SMP database. Because of this, the following best practices are recommended.

- Greenplum Database performs best with a denormalized schema design suited for MPP analytical processing for example, Star or Snowflake schema, with large fact tables and smaller dimension tables.
- Use the same data types for columns used in joins between tables.

See Schema Design.

Heap vs. Append-Optimized Storage

- Use heap storage for tables and partitions that will receive iterative batch and singleton `UPDATE`, `DELETE`, and `INSERT` operations.
- Use heap storage for tables and partitions that will receive concurrent `UPDATE`, `DELETE`, and `INSERT` operations.
- Use append-optimized storage for tables and partitions that are updated infrequently after the initial load and have subsequent inserts only performed in large batch operations.
- Avoid performing singleton `INSERT`, `UPDATE`, or `DELETE` operations on append-optimized tables.
- Avoid performing concurrent batch `UPDATE` or `DELETE` operations on append-optimized tables. Concurrent batch `INSERT` operations are acceptable.

See Heap Storage or Append-Optimized Storage.

Row vs. Column Oriented Storage

- Use row-oriented storage for workloads with iterative transactions where updates are required and frequent inserts are performed.
- Use row-oriented storage when selects against the table are wide.
- Use row-oriented storage for general purpose or mixed workloads.
- Use column-oriented storage where selects are narrow and aggregations of data are computed over a small number of columns.
- Use column-oriented storage for tables that have single columns that are regularly updated without modifying other columns in the row.

See Row or Column Orientation.

Compression

- Use compression on large append-optimized and partitioned tables to improve I/O across the system.
- Set the column compression settings at the level where the data resides.
- Balance higher levels of compression with the time and CPU cycles needed to compress and uncompress data.

See Compression.

Distributions

- Explicitly define a column or random distribution for all tables. Do not use the default.
- Use a single column that will distribute data across all segments evenly.
• Do not distribute on columns that will be used in the WHERE clause of a query.
• Do not distribute on dates or timestamps.
• Never distribute and partition tables on the same column.
• Achieve local joins to significantly improve performance by distributing on the same column for large tables commonly joined together.
• To ensure there is no data skew, validate that data is evenly distributed after the initial load and after incremental loads.

See Distributions.

Resource Queue Memory Management
• Set vm.overcommit_memory to 2.
• Do not configure the OS to use huge pages.
• Use gp_vmem_protect_limit to set the maximum memory that the instance can allocate for all work being done in each segment database.
• You can use gp_vmem_protect_limit by calculating:
  
  \[
  \text{gp\_vmem} = \frac{(\text{SWAP} + \text{RAM}) - (7.5\text{GB} + 0.05 \times \text{RAM})}{1.7}
  \]

  where \text{SWAP} is the host's swap space in GB, and \text{RAM} is the host's RAM in GB

  \text{max\_acting\_primary\_segments} – the maximum number of primary segments that could be running on a host when mirror segments are activated due to a host or segment failure

  \text{gp\_vmem\_protect\_limit}

  \[
  \text{gp\_vmem\_protect\_limit} = \frac{\text{gp\_vmem}}{\text{acting\_primary\_segments}}
  \]

  Convert to MB to set the value of the configuration parameter.

  • In a scenario where a large number of workfiles are generated calculate the \text{gp\_vmem} factor with this formulat to account for the workfiles:

  \[
  \text{gp\_vmem} = \frac{(\text{SWAP} + \text{RAM}) - (7.5\text{GB} + 0.05 \times \text{RAM} - (300\text{KB} \times \text{total\_#\_workfiles}))}{1.7}
  \]

  • Never set \text{gp\_vmem\_protect\_limit} too high or larger than the physical RAM on the system.

  • Use the calculated \text{gp\_vmem} value to calculate the setting for the \text{vm\_overcommit\_ratio} operating system parameter:

  \[
  \text{vm\_overcommit\_ratio} = \frac{(\text{RAM} - 0.026 \times \text{gp\_vmem})}{\text{RAM}}
  \]

  • Use \text{statement\_mem} to allocate memory used for a query per segment db.

  • Use resource queues to set both the numbers of active queries (\text{ACTIVE\_STATEMENTS}) and the amount of memory (\text{MEMORY\_LIMIT}) that can be utilized by queries in the queue.

  • Associate all users with a resource queue. Do not use the default queue.

  • Set \text{PRIORITY} to match the real needs of the queue for the workload and time of day. Avoid using MAX priority.

  • Ensure that resource queue memory allocations do not exceed the setting for \text{gp\_vmem\_protect\_limit}.

  • Dynamically update resource queue settings to match daily operations flow.

  See Memory and Resource Management with Resource Queues.

Partitioning
• Partition large tables only. Do not partition small tables.
• Use partitioning only if partition elimination (partition pruning) can be achieved based on the query criteria.
• Choose range partitioning over list partitioning.
• Partition the table based on a commonly-used column, such as a date column.
• Never partition and distribute tables on the same column.
• Do not use default partitions.
• Do not use multi-level partitioning; create fewer partitions with more data in each partition.
• Validate that queries are selectively scanning partitioned tables (partitions are being eliminated) by examining the query EXPLAIN plan.
• Do not create too many partitions with column-oriented storage because of the total number of physical files on every segment:

\[
\text{physical files} = \text{segments} \times \text{columns} \times \text{partitions}
\]

See Partitioning.

Indexes

• In general indexes are not needed in Greenplum Database.
• Create an index on a single column of a columnar table for drill-through purposes for high cardinality tables that require queries with high selectivity.
• Do not index columns that are frequently updated.
• Consider dropping indexes before loading data into a table. After the load, re-create the indexes for the table.
• Create selective B-tree indexes.
• Do not create bitmap indexes on columns that are updated.
• Avoid using bitmap indexes for unique columns, very high or very low cardinality data. Bitmap indexes perform best when the column has a low cardinality—100 to 100,000 distinct values.
• Do not use bitmap indexes for transactional workloads.
• In general do not index partitioned tables. If indexes are needed, the index columns must be different than the partition columns.

See Indexes.

Resource Queues

• Use resource queues to manage the workload on the cluster.
• Associate all roles with a user-defined resource queue.
• Use the ACTIVE_STATEMENTS parameter to limit the number of active queries that members of the particular queue can run concurrently.
• Use the MEMORY_LIMIT parameter to control the total amount of memory that queries running through the queue can utilize.
• Alter resource queues dynamically to match the workload and time of day.

See Configuring Resource Queues.

Monitoring and Maintenance

• Implement the "Recommended Monitoring and Maintenance Tasks" in the Greenplum Database Administrator Guide.
• Run gpccheckperf at install time and periodically thereafter, saving the output to compare system performance over time.
• Use all the tools at your disposal to understand how your system behaves under different loads.
• Examine any unusual event to determine the cause.
• Monitor query activity on the system by running explain plans periodically to ensure the queries are running optimally.
• Review plans to determine whether indexes are being used and partition elimination is occurring as expected.
• Know the location and content of system log files and monitor them on a regular basis, not just when problems arise.

See System Monitoring and Maintenance, Query Profiling and Monitoring Greenplum Database Log Files.

ANALYZE
• Determine if analyzing the database is actually needed. Analyzing is not needed if gp_autostats_mode is set to on_no_stats (the default) and the table is not partitioned.
• Use analyzedb in preference to ANALYZE when dealing with large sets of tables, as it does not require analyzing the entire database. The analyzedb utility updates statistics data for the specified tables incrementally and concurrently. For append optimized tables, analyzedb updates statistics incrementally only if the statistics are not current. For heap tables, statistics are always updated. ANALYZE does not update the table metadata that the analyzedb utility uses to determine whether table statistics are up to date.
• Selectively run ANALYZE at the table level when needed.
• Always run ANALYZE after INSERT, UPDATE, and DELETE operations that significantly changes the underlying data.
• Always run ANALYZE after CREATE INDEX operations.
• If ANALYZE on very large tables takes too long, run ANALYZE only on the columns used in a join condition, WHERE clause, SORT, GROUP BY, or HAVING clause.
• When dealing with large sets of tables, use analyzedb instead of ANALYZE.

See Updating Statistics with ANALYZE.

Vacuum
• Run VACUUM after large UPDATE and DELETE operations.
• Do not run VACUUM FULL. Instead run a CREATE TABLE...AS operation, then rename and drop the original table.
• Frequently run VACUUM on the system catalogs to avoid catalog bloat and the need to run VACUUM FULL on catalog tables.
• Never kill VACUUM on catalog tables.

See Managing Bloat in the Database.

Loading
• Maximize the parallelism as the number of segments increase.
• Spread the data evenly across as many ETL nodes as possible.
  • Split very large data files into equal parts and spread the data across as many file systems as possible.
  • Run two gpfdist instances per file system.
  • Run gpfdist on as many interfaces as possible.
  • Use gp_external_max_segs to control the number of segments that will request data from the gpfdist process.
  • Always keep gp_external_max_segs and the number of gpfdist processes an even factor.
• Always drop indexes before loading into existing tables and re-create the index after loading.
• Run VACUUM after load errors to recover space.

See Loading Data.
gptransfer (deprecated)

Note: gptransfer is deprecated and will be removed in the next major release of Greenplum Database.

- Avoid using the --full or --schema-only options. Instead, copy schemas to the destination database using a different method, and then transfer the table data.
- Drop indexes before transferring tables and recreate them when the transfer is complete.
- Transfer smaller tables to the destination database using the SQL COPY command.
- Transfer larger tables in batches using gptransfer.
- Test running gptransfer before performing a production migration. Experiment with the --batch-size and --sub-batch-size options to obtain maximum parallelism. Determine proper batching of tables for iterative gptransfer runs.
- Use only fully qualified table names. Periods (.), whitespace, quotes (') and double quotes (") in table names may cause problems.
- If you use the --validation option to validate the data after transfer, be sure to also use the --x option to place an exclusive lock on the source table.
- Ensure any roles, functions, and resource queues are created in the destination database. These objects are not transferred when you use the gptransfer -t option.
- Copy the postgresql.conf and pg_hba.conf configuration files from the source to the destination cluster.
- Install needed extensions in the destination database with gppkg.

See Migrating Data with gptransfer.

Security

- Secure the gpadmin user id and only allow essential system administrators access to it.
- Administrators should only log in to Greenplum as gpadmin when performing certain system maintenance tasks (such as upgrade or expansion).
- Limit users who have the SUPERUSER role attribute. Roles that are superusers bypass all access privilege checks in Greenplum Database, as well as resource queuing. Only system administrators should be given superuser rights. See "Altering Role Attributes" in the Greenplum Database Administrator Guide.
- Database users should never log on as gpadmin, and ETL or production workloads should never run as gpadmin.
- Assign a distinct Greenplum Database role to each user, application, or service that logs in.
- For applications or web services, consider creating a distinct role for each application or service.
- Use groups to manage access privileges.
- Protect the root password.
- Enforce a strong password password policy for operating system passwords.
- Ensure that important operating system files are protected.

See Security.

Encryption

- Encrypting and decrypting data has a performance cost; only encrypt data that requires encryption.
- Do performance testing before implementing any encryption solution in a production system.
- Server certificates in a production Greenplum Database system should be signed by a certificate authority (CA) so that clients can authenticate the server. The CA may be local if all clients are local to the organization.
- Client connections to Greenplum Database should use SSL encryption whenever the connection goes through an insecure link.
- A symmetric encryption scheme, where the same key is used to both encrypt and decrypt, has better performance than an asymmetric scheme and should be used when the key can be shared safely.
• Use cryptographic functions to encrypt data on disk. The data is encrypted and decrypted in the database process, so it is important to secure the client connection with SSL to avoid transmitting unencrypted data.

• Use the gpfdists protocol to secure ETL data as it is loaded into or unloaded from the database.

See *Encrypting Data and Database Connections*

**High Availability**

*Note:* The following guidelines apply to actual hardware deployments, but not to public cloud-based infrastructure, where high availability solutions may already exist.

• Use a hardware RAID storage solution with 8 to 24 disks.
• Use RAID 1, 5, or 6 so that the disk array can tolerate a failed disk.
• Configure a hot spare in the disk array to allow rebuild to begin automatically when disk failure is detected.
• Protect against failure of the entire disk array and degradation during rebuilds by mirroring the RAID volume.
• Monitor disk utilization regularly and add additional space when needed.
• Monitor segment skew to ensure that data is distributed evenly and storage is consumed evenly at all segments.
• Set up a standby master instance to take over if the primary master fails.
• Plan how to switch clients to the new master instance when a failure occurs, for example, by updating the master address in DNS.
• Set up monitoring to send notifications in a system monitoring application or by email when the primary fails.
• Set up mirrors for all segments.
• Locate primary segments and their mirrors on different hosts to protect against host failure.
• Recover failed segments promptly, using the `gprecoverseg` utility, to restore redundancy and return the system to optimal balance.
• Configure Greenplum Database to send SNMP notifications to your network monitor.
• Set up email notification in the `$MASTER_DATA_DIRECTORY/postgresql.conf` configuration file so that the Greenplum system can email administrators when a critical issue is detected.
• Consider a Dual Cluster configuration to provide an additional level of redundancy and additional query processing throughput.
• Backup Greenplum databases regularly unless the data is easily restored from sources.
• Use incremental backups if heap tables are relatively small and few append-optimized or column-oriented partitions are modified between backups.
• If backups are saved to local cluster storage, move the files to a safe, off-cluster location when the backup is complete.
• If backups are saved to NFS mounts, use a scale-out NFS solution such as Dell EMC Isilon to prevent IO bottlenecks.
• Consider using Greenplum integration to stream backups to the Dell EMC Data Domain or Veritas NetBackup enterprise backup platforms.

See *High Availability.*
System Configuration

Requirements and best practices for system administrators who are configuring Greenplum Database cluster hosts.

Configuration of the Greenplum Database cluster is usually performed as root.

Configuring the Timezone

Greenplum Database selects a timezone to use from a set of internally stored PostgreSQL timezones. The available PostgreSQL timezones are taken from the Internet Assigned Numbers Authority (IANA) Time Zone Database, and Greenplum Database updates its list of available timezones as necessary when the IANA database changes for PostgreSQL.

Greenplum selects the timezone by matching a PostgreSQL timezone with the user specified time zone, or the host system time zone if no time zone is configured. For example, when selecting a default timezone, Greenplum uses an algorithm to select a PostgreSQL timezone based on the host system timezone files. If the system timezone includes leap second information, Greenplum Database cannot match the system timezone with a PostgreSQL timezone. In this case, Greenplum Database calculates a "best match" with a PostgreSQL timezone based on information from the host system.

As a best practice, configure Greenplum Database and the host systems to use a known, supported timezone. This sets the timezone for the Greenplum Database master and segment instances, and prevents Greenplum Database from recalculating a "best match" timezone each time the cluster is restarted, using the current system timezone and Greenplum timezone files (which may have been updated from the IANA database since the last restart). Use the `gpconfig` utility to show and set the Greenplum Database timezone. For example, these commands show the Greenplum Database timezone and set the timezone to US/Pacific.

```
# gpconfig -s TimeZone
# gpconfig -c TimeZone -v 'US/Pacific'
```

You must restart Greenplum Database after changing the timezone. The command `gpstop -ra` restarts Greenplum Database. The catalog view `pg_timezone_names` provides Greenplum Database timezone information.

File System

XFS is the file system used for Greenplum Database data directories. XFS should be mounted with the following mount options:

```
rw,nodev,noatime,nobarrier,inode64
```

Port Configuration

Set up `ip_local_port_range` so it does not conflict with the Greenplum Database port ranges. For example, setting this range in `/etc/sysctl.conf`:

```
net.ipv4.ip_local_port_range = 10000  65535
```

you could set the Greenplum Database base port numbers to these values.

```
PORT_BASE = 6000
MIRROR_PORT_BASE = 7000
REPLICATION_PORT_BASE = 8000
MIRROR_REPLICATION_PORT_BASE = 9000
```
**I/O Configuration**

Set the blockdev read-ahead size to 16384 on the devices that contain data directories. This command sets the read-ahead size for `/dev/sdb`.

```bash
# /sbin/blockdev --setra 16384 /dev/sdb
```

This command returns the read-ahead size for `/dev/sdb`.

```bash
# /sbin/blockdev --getra /dev/sdb
16384
```

The deadline IO scheduler should be set for all data directory devices.

```bash
# cat /sys/block/sdb/queue/scheduler
noop anticipatory [deadline] cfq
```

The maximum number of OS files and processes should be increased in the `/etc/security/limits.conf` file.

```bash
* soft  nofile 524288
* hard  nofile 524288
* soft  nproc 131072
* hard  nproc 131072
```

Enable core files output to a known location and make sure `limits.conf` allows core files.

```bash
kernel.core_pattern = /var/core/core.%h.%t
# grep core /etc/security/limits.conf
* soft  core unlimited
```

**OS Memory Configuration**

The Linux `sysctl` `vm.overcommit_memory` and `vm.overcommit_ratio` variables affect how the operating system manages memory allocation. These variables should be set as follows:

`vm.overcommit_memory` determines the method the OS uses for determining how much memory can be allocated to processes. This should be always set to 2, which is the only safe setting for the database.

*Note:* For information on configuration of overcommit memory, refer to:

- [https://en.wikipedia.org/wiki/Memory_overcommitment](https://en.wikipedia.org/wiki/Memory_overcommitment)

`vm.overcommit_ratio` is the percent of RAM that is used for application processes. The default is 50 on Red Hat Enterprise Linux. See Resource Queue Segment Memory Configuration for a formula to calculate an optimal value.

Do not enable huge pages in the operating system.

See also Memory and Resource Management with Resource Queues.

**Shared Memory Settings**

Greenplum Database uses shared memory to communicate between `postgres` processes that are part of the same `postgres` instance. The following shared memory settings should be set in `sysctl` and are rarely modified.

```bash
kernel.shmmax = 500000000
kernel.shmmin = 4096
kernel.shmall = 4000000000
```
Validate the Operating System

Run `gpcheck` to validate the operating system configuration. See `gpcheck` in the Greenplum Database Utility Guide.

Number of Segments per Host

Determining the number of segments to execute on each segment host has immense impact on overall system performance. The segments share the host's CPU cores, memory, and NICs with each other and with other processes running on the host. Over-estimating the number of segments a server can accommodate is a common cause of suboptimal performance.

The factors that must be considered when choosing how many segments to run per host include the following:

- Number of cores
- Amount of physical RAM installed in the server
- Number of NICs
- Amount of storage attached to server
- Mixture of primary and mirror segments
- ETL processes that will run on the hosts
- Non-Greenplum processes running on the hosts

Resource Queue Segment Memory Configuration

The `gp_vmem_protect_limit` server configuration parameter specifies the amount of memory that all active postgres processes for a single segment can consume at any given time. Queries that exceed this amount will fail. Use the following calculations to estimate a safe value for `gp_vmem_protect_limit`.

1. Calculate `gp_vmem`, the host memory available to Greenplum Database, using this formula:

   \[
   \text{gp_vmem} = \frac{\left((\text{SWAP} + \text{RAM}) - (7.5\text{GB} + 0.05 \times \text{RAM})\right)}{1.7}
   \]

   where `SWAP` is the host's swap space in GB and `RAM` is the RAM installed on the host in GB.

2. Calculate `max_acting_primary_segments`. This is the maximum number of primary segments that can be running on a host when mirror segments are activated due to a segment or host failure on another host in the cluster. With mirrors arranged in a 4-host block with 8 primary segments per host, for example, a single segment host failure would activate two or three mirror segments on each remaining host in the failed host's block. The `max_acting_primary_segments` value for this configuration is 11 (8 primary segments plus 3 mirrors activated on failure).

3. Calculate `gp_vmem_protect_limit` by dividing the total Greenplum Database memory by the maximum number of acting primaries:

   \[
   \text{gp_vmem_protect_limit} = \frac{\text{gp_vmem}}{\text{max_acting_primary_segments}}
   \]

   Convert to megabytes to find the value to set for the `gp_vmem_protect_limit` system configuration parameter.

For scenarios where a large number of workfiles are generated, adjust the calculation for `gp_vmem` to account for the workfiles:

\[
\text{gp_vmem} = \frac{\left((\text{SWAP} + \text{RAM}) - (7.5\text{GB} + 0.05 \times \text{RAM} - (300\text{KB} \times \text{total}_\#\_workfiles))\right)}{1.7}
\]

For information about monitoring and managing workfile usage, see the Greenplum Database Administrator Guide.
You can calculate the value of the `vm.overcommit_ratio` operating system parameter from the value of `gp_vmem`:

\[
    vm\_overcommit\_ratio = \frac{\text{RAM} - 0.026 \times \text{gp\_vmem}}{\text{RAM}}
\]

See [OS Memory Configuration](#) for more about `vm.overcommit_ratio`.
See also [Memory and Resource Management with Resource Queues](#).

**Resource Queue Statement Memory Configuration**

The `statement_mem` server configuration parameter is the amount of memory to be allocated to any single query in a segment database. If a statement requires additional memory it will spill to disk. Calculate the value for `statement_mem` with the following formula:

\[
    \frac{(\text{gp\_vmem\_protect\_limit} \times 0.9)}{\text{max\_expected\_concurrent\_queries}}
\]

For example, for 40 concurrent queries with `gp_vmem_protect_limit` set to 8GB (8192MB), the calculation for `statement_mem` would be:

\[
    \frac{(8192\text{MB} \times 0.9)}{40} = 184\text{MB}
\]

Each query would be allowed 184MB of memory before it must spill to disk.

To increase `statement_mem` safely you must either increase `gp_vmem_protect_limit` or reduce the number of concurrent queries. To increase `gp_vmem_protect_limit`, you must add physical RAM and/or swap space, or reduce the number of segments per host.

Note that adding segment hosts to the cluster cannot help out-of-memory errors unless you use the additional hosts to decrease the number of segments per host.

Spill files are created when there is not enough memory to fit all the mapper output, usually when 80% of the buffer space is occupied.

Also, see [Resource Management](#) for best practices for managing query memory using resource queues.

**Resource Queue Spill File Configuration**

Greenplum Database creates **spill files** (also called **workfiles**) on disk if a query is allocated insufficient memory to execute in memory. A single query can create no more than 100,000 spill files, by default, which is sufficient for the majority of queries.

You can control the maximum number of spill files created per query and per segment with the configuration parameter `gp_workfile_limit_files_per_query`. Set the parameter to 0 to allow queries to create an unlimited number of spill files. Limiting the number of spill files permitted prevents runaway queries from disrupting the system.

A query could generate a large number of spill files if not enough memory is allocated to it or if data skew is present in the queried data. If a query creates more than the specified number of spill files, Greenplum Database returns this error:

**ERROR:** number of workfiles per query limit exceeded

Before raising the `gp_workfile_limit_files_per_query`, try reducing the number of spill files by changing the query, changing the data distribution, or changing the memory configuration.

The `gp_toolkit` schema includes views that allow you to see information about all the queries that are currently using spill files. This information can be used for troubleshooting and for tuning queries:

- The `gp_workfile_entries` view contains one row for each operator using disk space for workfiles on a segment at the current time. See [How to Read Explain Plans](#) for information about operators.
- The `gp_workfile_usage_per_query` view contains one row for each query using disk space for workfiles on a segment at the current time.
- The `gp_workfile_usage_per_segment` view contains one row for each segment. Each row displays the total amount of disk space used for workfiles on the segment at the current time.

See the *Greenplum Database Reference Guide* for descriptions of the columns in these views.

The `gp_workfile_compress_algorithm` configuration parameter specifies a compression algorithm to apply to spill files. It can have the value `none` (the default) or `zlib`. Setting this parameter to `zlib` can improve performance when spill files are used.
Schema Design

Best practices for designing Greenplum Database schemas.

Greenplum Database is an analytical, shared-nothing database, which is much different than a highly normalized, transactional SMP database. Greenplum Database performs best with a denormalized schema design suited for MPP analytical processing, a star or snowflake schema, with large centralized fact tables connected to multiple smaller dimension tables.

Data Types

Use Types Consistently

Use the same data types for columns used in joins between tables. If the data types differ, Greenplum Database must dynamically convert the data type of one of the columns so the data values can be compared correctly. With this in mind, you may need to increase the data type size to facilitate joins to other common objects.

Choose Data Types that Use the Least Space

You can increase database capacity and improve query execution by choosing the most efficient data types to store your data.

Use TEXT or VARCHAR rather than CHAR. There are no performance differences among the character data types, but using TEXT or VARCHAR can decrease the storage space used.

Use the smallest numeric data type that will accommodate your data. Using BIGINT for data that fits in INT or SMALLINT wastes storage space.

Storage Model

Greenplum Database provides an array of storage options when creating tables. It is very important to know when to use heap storage versus append-optimized (AO) storage, and when to use row-oriented storage versus column-oriented storage. The correct selection of heap versus AO and row versus column is extremely important for large fact tables, but less important for small dimension tables.

The best practices for determining the storage model are:

1. Design and build an insert-only model, truncating a daily partition before load.
2. For large partitioned fact tables, evaluate and use optimal storage options for different partitions. One storage option is not always right for the entire partitioned table. For example, some partitions can be row-oriented while others are column-oriented.
3. When using column-oriented storage, every column is a separate file on every Greenplum Database segment. For tables with a large number of columns consider columnar storage for data often accessed (hot) and row-oriented storage for data not often accessed (cold).
4. Storage options should be set at the partition level.
5. Compress large tables to improve I/O performance and to make space in the cluster.

Heap Storage or Append-Optimized Storage

Heap storage is the default model, and is the model PostgreSQL uses for all database tables. Use heap storage for tables and partitions that will receive iterative UPDATE, DELETE, and singleton INSERT operations. Use heap storage for tables and partitions that will receive concurrent UPDATE, DELETE, and INSERT operations.
Use append-optimized storage for tables and partitions that are updated infrequently after the initial load and have subsequent inserts performed only in batch operations. Avoid performing singleton `INSERT`, `UPDATE`, or `DELETE` operations on append-optimized tables. Concurrent batch `INSERT` operations are acceptable, but never perform concurrent batch `UPDATE` or `DELETE` operations.

The append-optimized storage model is inappropriate for frequently updated tables, because space occupied by rows that are updated and deleted in append-optimized tables is not recovered and reused as efficiently as with heap tables. Append-optimized storage is intended for large tables that are loaded once, updated infrequently, and queried frequently for analytical query processing.

**Row or Column Orientation**

Row orientation is the traditional way to store database tuples. The columns that comprise a row are stored on disk contiguously, so that an entire row can be read from disk in a single I/O.

Column orientation stores column values together on disk. A separate file is created for each column. If the table is partitioned, a separate file is created for each column and partition. When a query accesses only a small number of columns in a column-oriented table with many columns, the cost of I/O is substantially reduced compared to a row-oriented table; any columns not referenced do not have to be retrieved from disk.

Row-oriented storage is recommended for transactional type workloads with iterative transactions where updates are required and frequent inserts are performed. Use row-oriented storage when selects against the table are wide, where many columns of a single row are needed in a query. If the majority of columns in the `SELECT` list or `WHERE` clause is selected in queries, use row-oriented storage. Use row-oriented storage for general purpose or mixed workloads, as it offers the best combination of flexibility and performance.

Column-oriented storage is optimized for read operations but it is not optimized for write operations; column values for a row must be written to different places on disk. Column-oriented tables can offer optimal query performance on large tables with many columns where only a small subset of columns are accessed by the queries.

Another benefit of column orientation is that a collection of values of the same data type can be stored together in less space than a collection of mixed type values, so column-oriented tables use less disk space (and consequently less disk I/O) than row-oriented tables. Column-oriented tables also compress better than row-oriented tables.

Use column-oriented storage for data warehouse analytic workloads where selects are narrow or aggregations of data are computed over a small number of columns. Use column-oriented storage for tables that have single columns that are regularly updated without modifying other columns in the row. Reading a complete row in a wide columnar table requires more time than reading the same row from a row-oriented table. It is important to understand that each column is a separate physical file on every segment in Greenplum Database.

**Compression**

Greenplum Database offers a variety of options to compress append-optimized tables and partitions. Use compression to improve I/O across the system by allowing more data to be read with each disk read operation. The best practice is to set the column compression settings at the partition level.

Note that new partitions added to a partitioned table do not automatically inherit compression defined at the table level; you must specifically define compression when you add new partitions.

Run-length encoding (RLE) compression provides the best levels of compression. Higher levels of compression usually result in more compact storage on disk, but require additional time and CPU cycles when compressing data on writes and uncompressing on reads. Sorting data, in combination with the various compression options, can achieve the highest level of compression.

Data compression should never be used for data that is stored on a compressed file system.
Test different compression types and ordering methods to determine the best compression for your specific data. For example, you might start zlib compression at level 4 or 5 and adjust for best results. RLE compression works best with files that contain repetitive data.

**Distributions**

An optimal distribution that results in evenly distributed data is the most important factor in Greenplum Database. In an MPP shared nothing environment overall response time for a query is measured by the completion time for all segments. The system is only as fast as the slowest segment. If the data is skewed, segments with more data will take more time to complete, so every segment must have an approximately equal number of rows and perform approximately the same amount of processing. Poor performance and out of memory conditions may result if one segment has significantly more data to process than other segments.

Consider the following best practices when deciding on a distribution strategy:

- Explicitly define a column or random distribution for all tables. Do not use the default.
- Ideally, use a single column that will distribute data across all segments evenly.
- Do not distribute on columns that will be used in the `WHERE` clause of a query.
- Do not distribute on dates or timestamps.
- The distribution key column data should contain unique values or very high cardinality.
- If a single column cannot achieve an even distribution, use a multi-column distribution key with a maximum of two columns. Additional column values do not typically yield a more even distribution and they require additional time in the hashing process.
- If a two-column distribution key cannot achieve an even distribution of data, use a random distribution. Multi-column distribution keys in most cases require motion operations to join tables, so they offer no advantages over a random distribution.

Greenplum Database random distribution is not round-robin, so there is no guarantee of an equal number of records on each segment. Random distributions typically fall within a target range of less than ten percent variation.

Optimal distributions are critical when joining large tables together. To perform a join, matching rows must be located together on the same segment. If data is not distributed on the same join column, the rows needed from one of the tables are dynamically redistributed to the other segments. In some cases a broadcast motion, in which each segment sends its individual rows to all other segments, is performed rather than a redistribution motion, where each segment rehashes the data and sends the rows to the appropriate segments according to the hash key.

**Local (Co-located) Joins**

Using a hash distribution that evenly distributes table rows across all segments and results in local joins can provide substantial performance gains. When joined rows are on the same segment, much of the processing can be accomplished within the segment instance. These are called local or co-located joins. Local joins minimize data movement; each segment operates independently of the other segments, without network traffic or communications between segments.

To achieve local joins for large tables commonly joined together, distribute the tables on the same column. Local joins require that both sides of a join be distributed on the same columns (and in the same order) and that all columns in the distribution clause are used when joining tables. The distribution columns must also be the same data type—although some values with different data types may appear to have the same representation, they are stored differently and hash to different values, so they are stored on different segments.
Data Skew

Data skew is often the root cause of poor query performance and out of memory conditions. Skewed data affects scan (read) performance, but it also affects all other query execution operations, for instance, joins and group by operations.

It is very important to validate distributions to ensure that data is evenly distributed after the initial load. It is equally important to continue to validate distributions after incremental loads.

The following query shows the number of rows per segment as well as the variance from the minimum and maximum numbers of rows:

```
SELECT 'Example Table' AS "Table Name",
       max(c) AS "Max Seg Rows", min(c) AS "Min Seg Rows",
       (max(c) - min(c)) * 100.0 / max(c) AS "Percentage Difference Between Max & Min"
FROM (SELECT count(*) c, gp_segment_id FROM facts GROUP BY 2) AS a;
```

The gp_toolkit schema has two views that you can use to check for skew.

- The gp_toolkit.gp_skew_coefficients view shows data distribution skew by calculating the coefficient of variation (CV) for the data stored on each segment. The skcoeff column shows the coefficient of variation (CV), which is calculated as the standard deviation divided by the average. It takes into account both the average and variability around the average of a data series. The lower the value, the better. Higher values indicate greater data skew.

- The gp_toolkit.gp_skew_idle_fractions view shows data distribution skew by calculating the percentage of the system that is idle during a table scan, which is an indicator of computational skew. The siffraction column shows the percentage of the system that is idle during a table scan. This is an indicator of uneven data distribution or query processing skew. For example, a value of 0.1 indicates 10% skew, a value of 0.5 indicates 50% skew, and so on. Tables that have more than 10% skew should have their distribution policies evaluated.

Processing Skew

Processing skew results when a disproportionate amount of data flows to, and is processed by, one or a few segments. It is often the culprit behind Greenplum Database performance and stability issues. It can happen with operations such as join, sort, aggregation, and various OLAP operations. Processing skew happens in flight while a query is executing and is not as easy to detect as data skew, which is caused by uneven data distribution due to the wrong choice of distribution keys. Data skew is present at the table level, so it can be easily detected and avoided by choosing optimal distribution keys.

If single segments are failing, that is, not all segments on a host, it may be a processing skew issue. Identifying processing skew is currently a manual process. First look for spill files. If there is skew, but not enough to cause spill, it will not become a performance issue. If you determine skew exists, then find the query responsible for the skew. Following are the steps and commands to use. (Change names like the host file name passed to gpssh accordingly):

1. Find the OID for the database that is to be monitored for skew processing:

```
SELECT oid, datname FROM pg_database;
```

Example output:

<table>
<thead>
<tr>
<th>oid</th>
<th>datname</th>
</tr>
</thead>
<tbody>
<tr>
<td>17088</td>
<td>gpadmin</td>
</tr>
<tr>
<td>10899</td>
<td>postgres</td>
</tr>
<tr>
<td>1</td>
<td>template1</td>
</tr>
<tr>
<td>10898</td>
<td>template0</td>
</tr>
<tr>
<td>38817</td>
<td>pws</td>
</tr>
<tr>
<td>39682</td>
<td>gpperfmon</td>
</tr>
</tbody>
</table>
2. Run a `gpssh` command to check file sizes across all of the segment nodes in the system. Replace `<OID>` with the OID of the database from the prior command:

```
[gpmadmin@mdw kend]$ gpssh -f ~/hosts -e "du -b /data[1-2]/primary/gpseg*/base/<OID>/pgsql_tmp/*" | \
  grep -v "du -b" | sort | awk -F" " '{ arr[$1] = arr[$1] + $2 ; tot = tot + $2 }'; END \
  { for ( i in arr ) print "Segment node" i, arr[i], "bytes (" arr[i] / (1024**3) " GB)"; \
  print "Total", tot, "bytes (" tot / (1024**3) " GB)" ) ' -
```

Example output:

```
Segment node[sdw1] 2443370457 bytes (2.27557 GB)
Segment node[sdw2] 1766575328 bytes (1.64525 GB)
Segment node[sdw3] 1761686551 bytes (1.6407 GB)
Segment node[sdw4] 1780301617 bytes (1.65804 GB)
Segment node[sdw5] 1742543599 bytes (1.62287 GB)
Segment node[sdw6] 1830073754 bytes (1.70439 GB)
Segment node[sdw7] 1767310099 bytes (1.64594 GB)
Segment node[sdw8] 1765105802 bytes (1.64388 GB)
Total 14856967207 bytes (13.8366 GB)
```

If there is a **significant and sustained** difference in disk usage, then the queries being executed should be investigated for possible skew (the example output above does not reveal significant skew). In monitoring systems, there will always be some skew, but often it is **transient** and will be **short in duration**.

3. If significant and sustained skew appears, the next task is to identify the offending query.

The command in the previous step sums up the entire node. This time, find the actual segment directory. You can do this from the master or by logging into the specific node identified in the previous step. Following is an example run from the master.

This example looks specifically for sort files. Not all spill files or skew situations are caused by sort files, so you will need to customize the command:

```
$ gpssh -f ~/hosts -e "ls -l /data[1-2]/primary/gpseg*/base/19979/pgsql_tmp/*" | \
  grep -i sort | awk '{sub(/base.*tmp\//, "...", $10); print $1,$6, \
  $10}'; sort -k2 -n
```

Here is output from this command:

```
[sdw1] 288718848
  /data1/primary/gpseg2/.../pgsql_tmp_slice0_sort_17758_0001.0[sdw1]
  291176448
  /data2/primary/gpseg5/.../pgsql_tmp_slice0_sort_17764_0001.0[sdw8]
  924581888
  /data2/primary/gpseg45/.../pgsql_tmp_slice10_sort_15673_0010.9[sdw4]
  980582400
  /data1/primary/gpseg18/.../pgsql_tmp_slice10_sort_29425_0001.0[sdw6]
  986447872
  /data2/primary/gpseg35/.../pgsql_tmp_slice10_sort_29602_0001.0...
  [sdw5] 999620608
  /data1/primary/gpseg26/.../pgsql_tmp_slice10_sort_28637_0001.0[sdw2]
  999751680
  /data2/primary/gpseg9/.../pgsql_tmp_slice10_sort_3969_0001.0[sdw3]
  1000112128
  /data1/primary/gpseg13/.../pgsql_tmp_slice10_sort_24723_0001.0[sdw5]
  1000898560
```

(6 rows)
Scanning this output reveals that segment gpseg45 on host sdw8 is the culprit, as its sort files are larger than the others in the output.

4. Log in to the offending node with ssh and become root. Use the lsof command to find the PID for the process that owns one of the sort files:

```
[root@sdw8 ~]# lsof /data2/primary/gpseg45/base/19979/pgsql_tmp/
pgsql_tmp_slice10_sort_15673_0002.1
COMMAND  PID    USER    FD   TYPE DEVICE  SIZE        NODE        NAME
postgres 15673  gpadmin 11u  REG  8,48    1073741824  64424546751 /data2/
primary/gpseg45/base/19979/pgsql_tmp/pgsql_tmp_slice10_sort_15673_0002.1
```

The PID, 15673, is also part of the file name, but this may not always be the case.

5. Use the ps command with the PID to identify the database and connection information:

```
[root@sdw8 ~]# ps -eaf | grep 15673
gpadmin  15673 27471 28 12:05 ?        00:12:59 postgres: port 40003,
sbaskin bdw 172.28.12.250(21813) con699238 seg45 cmd32 slice10 MPPEXEC SELECT
root     29622 29566  0          00:00:00 grep 15673
```

6. On the master, check the pg_log log file for the user in the previous command (sbaskin), connection (con699238, and command (cmd32). The line in the log file with these three values should be the line that contains the query, but occasionally, the command number may differ slightly. For example, the ps output may show cmd32, but in the log file it is cmd34. If the query is still running, the last query for the user and connection is the offending query.

The remedy for processing skew in almost all cases is to rewrite the query. Creating temporary tables can eliminate skew. Temporary tables can be randomly distributed to force a two-stage aggregation.

**Partitioning**

A good partitioning strategy reduces the amount of data to be scanned by reading only the partitions needed to satisfy a query.
Each partition is a separate physical file or set of tiles (in the case of column-oriented tables) on every segment. Just as reading a complete row in a wide columnar table requires more time than reading the same row from a heap table, reading all partitions in a partitioned table requires more time than reading the same data from a non-partitioned table.

Following are partitioning best practices:

• Partition large tables only, do not partition small tables.
• Use partitioning on large tables only when partition elimination (partition pruning) can be achieved based on query criteria and is accomplished by partitioning the table based on the query predicate. Whenever possible, use range partitioning instead of list partitioning.
• The query planner can selectively scan partitioned tables only when the query contains a direct and simple restriction of the table using immutable operators, such as =, <, <=, >, >=, and <>.
• Selective scanning recognizes STABLE and IMMUTABLE functions, but does not recognize VOLATILE functions within a query. For example, WHERE clauses such as
  \[
  \text{date} > \text{CURRENT\_DATE}
  \]
  cause the query planner to selectively scan partitioned tables, but a WHERE clause such as
  \[
  \text{time} > \text{TIMEOFDAY}
  \]
  does not. It is important to validate that queries are selectively scanning partitioned tables (partitions are being eliminated) by examining the query EXPLAIN plan.
• Do not use default partitions. The default partition is always scanned but, more importantly, in many environments they tend to overfill resulting in poor performance.
• Never partition and distribute tables on the same column.
• Do not use multi-level partitioning. While sub-partitioning is supported, it is not recommended because typically subpartitions contain little or no data. It is a myth that performance increases as the number of partitions or subpartitions increases; the administrative overhead of maintaining many partitions and subpartitions will outweigh any performance benefits. For performance, scalability and manageability, balance partition scan performance with the number of overall partitions.
• Beware of using too many partitions with column-oriented storage.
• Consider workload concurrency and the average number of partitions opened and scanned for all concurrent queries.

**Number of Partition and Columnar Storage Files**

The only hard limit for the number of files Greenplum Database supports is the operating system's open file limit. It is important, however, to consider the total number of files in the cluster, the number of files on every segment, and the total number of files on a host. In an MPP shared nothing environment, every node operates independently of other nodes. Each node is constrained by its disk, CPU, and memory. CPU and I/O constraints are not common with Greenplum Database, but memory is often a limiting factor because the query execution model optimizes query performance in memory.

The optimal number of files per segment also varies based on the number of segments on the node, the size of the cluster, SQL access, concurrency, workload, and skew. There are generally six to eight segments per host, but large clusters should have fewer segments per host. When using partitioning and columnar storage it is important to balance the total number of files in the cluster, but it is more important to consider the number of files per segment and the total number of files on a node.

**Example DCA 64GB Memory per Node**

• Number of nodes: 16
• Number of segments per node: 8
• Average number of files per segment: 10,000
The total number of files per node is \(8 \times 10,000 = 80,000\) and the total number of files for the cluster is \(8 \times 16 \times 10,000 = 1,280,000\). The number of files increases quickly as the number of partitions and the number of columns increase.

As a general best practice, limit the total number of files per node to under 100,000. As the previous example shows, the optimal number of files per segment and total number of files per node depends on the hardware configuration for the nodes (primarily memory), size of the cluster, SQL access, concurrency, workload and skew.

**Indexes**

Indexes are not generally needed in Greenplum Database. Most analytical queries operate on large volumes of data, while indexes are intended for locating single rows or small numbers of rows of data. In Greenplum Database, a sequential scan is an efficient method to read data as each segment contains an equal portion of the data and all segments work in parallel to read the data.

If adding an index does not produce performance gains, drop it. Verify that every index you create is used by the optimizer.

For queries with high selectivity, indexes may improve query performance. Create an index on a single column of a columnar table for drill through purposes for high cardinality columns that are required for highly selective queries.

Do not index columns that are frequently updated. Creating an index on a column that is frequently updated increases the number of writes required on updates.

Indexes on expressions should be used only if the expression is used frequently in queries.

An index with a predicate creates a partial index that can be used to select a small number of rows from large tables.

Avoid overlapping indexes. Indexes that have the same leading column are redundant.

Indexes can improve performance on compressed append-optimized tables for queries that return a targeted set of rows. For compressed data, an index access method means only the necessary pages are uncompressed.

Create selective B-tree indexes. Index selectivity is a ratio of the number of distinct values a column has divided by the number of rows in a table. For example, if a table has 1000 rows and a column has 800 distinct values, the selectivity of the index is 0.8, which is considered good.

As a general rule, drop indexes before loading data into a table. The load will run an order of magnitude faster than loading data into a table with indexes. After the load, re-create the indexes.

Bitmap indexes are suited for querying and not updating. Bitmap indexes perform best when the column has a low cardinality—100 to 100,000 distinct values. Do not use bitmap indexes for unique columns, very high, or very low cardinality data. Do not use bitmap indexes for transactional workloads.

If indexes are needed on partitioned tables, the index columns must be different than the partition columns. A benefit of indexing partitioned tables is that because the b-tree performance degrades exponentially as the size of the b-tree grows, creating indexes on partitioned tables creates smaller b-trees that perform better than with non-partitioned tables.

**Column Sequence and Byte Alignment**

For optimum performance lay out the columns of a table to achieve data type byte alignment. Lay out the columns in heap tables in the following order:

1. Distribution and partition columns
2. Fixed numeric types
3. Variable data types
Lay out the data types from largest to smallest, so that BIGINT and TIMESTAMP come before INT and DATE, and all of these types come before TEXT, VARCHAR, or NUMERIC(x, y). For example, 8-byte types first (BIGINT, TIMESTAMP), 4-byte types next (INT, DATE), 2-byte types next (SMALLINT), and variable data type last (VARCHAR).

Instead of defining columns in this sequence:

Int, Bigint, Timestamp, Bigint, Timestamp, Int (distribution key), Date (partition key), Bigint, Smallint

define the columns in this sequence:

Int (distribution key), Date (partition key), Bigint, Bigint, Timestamp, Bigint, Timestamp, Int, Smallint
Memory and Resource Management with Resource Groups

Managing Greenplum Database resources with resource groups.

Memory, CPU, and concurrent transaction management have a significant impact on performance in a Greenplum Database cluster. Resource groups are a newer resource management scheme that enforce memory, CPU, and concurrent transaction limits in Greenplum Database.

• Configuring Memory for Greenplum Database
• Memory Considerations when using Resource Groups
• Configuring Resource Groups
• Low Memory Queries
• Administrative Utilities and admin_group Concurrency

Configuring Memory for Greenplum Database

While it is not always possible to increase system memory, you can avoid many out-of-memory conditions by configuring resource groups to manage expected workloads.

The following operating system and Greenplum Database memory settings are significant when you manage Greenplum Database resources with resource groups:

• vm.overcommit_memory
  This Linux kernel parameter, set in /etc/sysctl.conf, identifies the method that the operating system uses to determine how much memory can be allocated to processes. vm.overcommit_memory must always be set to 2 for Greenplum Database systems.

• vm.overcommit_ratio
  This Linux kernel parameter, set in /etc/sysctl.conf, identifies the percentage of RAM that is used for application processes; the remainder is reserved for the operating system. Tune the setting as necessary. If your memory utilization is too low, increase the value; if your memory or swap usage is too high, decrease the setting.

• gp_resource_group_memory_limit
  The percentage of system memory to allocate to Greenplum Database. The default value is .7 (70%).

• gp_workfile_limit_files_per_query
  Set gp_workfile_limit_files_per_query to limit the maximum number of temporary spill files (workfiles) allowed per query. Spill files are created when a query requires more memory than it is allocated. When the limit is exceeded the query is terminated. The default is zero, which allows an unlimited number of spill files and may fill up the file system.

• gp_workfile_compress_algorithm
  If there are numerous spill files then set gp_workfile_compress_algorithm to compress the spill files. Compressing spill files may help to avoid overloading the disk subsystem with IO operations.

• memory_spill_ratio
  Set memory_spill_ratio to increase or decrease the amount of query operator memory Greenplum Database allots to a query. When memory_spill_ratio is larger than 0, it represents the percentage of resource group memory to allot to query operators. If concurrency is high, this memory amount may be small even when memory_spill_ratio is set to the max value of 100. When you set memory_spill_ratio to 0, Greenplum Database uses the statement_mem setting to determine the initial amount of query operator memory to allot.

• statement_mem
When `memory_spill_ratio` is 0, Greenplum Database uses the `statement_mem` setting to determine the amount of memory to allocate to a query.

Other considerations:
- Do not configure the operating system to use huge pages.
- When you configure resource group memory, consider memory requirements for mirror segments that become primary segments during a failure to ensure that database operations can continue when primary segments or segment hosts fail.

**Memory Considerations when using Resource Groups**

Available memory for resource groups may be limited on systems that use low or no swap space, and that use the default `vm.overcommit_ratio` and `gp_resource_group_memory_limit` settings. To ensure that Greenplum Database has a reasonable per-segment-host memory limit, you may be required to increase one or more of the following configuration settings:

1. The swap size on the system.
2. The system's `vm.overcommit_ratio` setting.
3. The resource group `gp_resource_group_memory_limit` setting.

**Configuring Resource Groups**

Greenplum Database resource groups provide a powerful mechanism for managing the workload of the cluster. Consider these general guidelines when you configure resource groups for your system:

- A transaction submitted by any Greenplum Database role with `SUPERUSER` privileges runs under the default resource group named `admin_group`. Keep this in mind when scheduling and running Greenplum administration utilities.
- Ensure that you assign each non-admin role a resource group. If you do not assign a resource group to a role, queries submitted by the role are handled by the default resource group named `default_group`.
- Use the `CONCURRENCY` resource group parameter to limit the number of active queries that members of a particular resource group can run concurrently.
- Use the `MEMORY_LIMIT` and `MEMORY_SPILL_RATIO` parameters to control the maximum amount of memory that queries running in the resource group can consume.
- Greenplum Database assigns unreserved memory (100 - (sum of all resource group `MEMORY_LIMITS`) to a global shared memory pool. This memory is available to all queries on a first-come, first-served basis.
- Alter resource groups dynamically to match the real requirements of the group for the workload and the time of day.
- Use the `gptoolkit` views to examine resource group resource usage and to monitor how the groups are working.
- Consider using Pivotal Greenplum Command Center to create and manage resource groups, and to define the criteria under which Command Center dynamically assigns a transaction to a resource group.

**Low Memory Queries**

A low `statement_mem` setting (for example, in the 10MB range) has been shown to increase the performance of queries with low memory requirements. Use the `memory_spill_ratio` and `statement_mem` server configuration parameter to override the setting on a per-query basis. For example:

```sql
SET memory_spill_ratio=0;
SET statement_mem='10 MB';
```
Administrative Utilities and admin_group Concurrency

The default resource group for database transactions initiated by Greenplum Database SUPERUSERS is the group named admin_group. The default CONCURRENCY value for the admin_group resource group is 10.

Certain Greenplum Database administrative utilities may use more than one CONCURRENCY slot at runtime, such as gpbackup that you invoke with the --jobs option. If the utility(s) you run require more concurrent transactions than that configured for admin_group, consider temporarily increasing the group's MEMORY_LIMIT and CONCURRENCY values to meet the utility's requirement, making sure to return these parameters back to their original settings when the utility completes.

**Note:** Memory allocation changes that you initiate with ALTER RESOURCE GROUP may not take affect immediately due to resource consumption by currently running queries. Be sure to alter resource group parameters in advance of your maintenance window.
Memory and Resource Management with Resource Queues

Avoid memory errors and manage Greenplum Database resources.

**Note:** Resource groups are a newer resource management scheme that enforces memory, CPU, and concurrent transaction limits in Greenplum Database. The *Managing Resources* topic provides a comparison of the resource queue and the resource group management schemes. Refer to *Using Resource Groups* for configuration and usage information for this resource management scheme.

Memory management has a significant impact on performance in a Greenplum Database cluster. The default settings are suitable for most environments. Do not change the default settings until you understand the memory characteristics and usage on your system.

- Resolving Out of Memory Errors
- Low Memory Queries
- Configuring Memory for Greenplum Database
- Configuring Resource Queues

**Resolving Out of Memory Errors**

An out of memory error message identifies the Greenplum segment, host, and process that experienced the out of memory error. For example:

```
Out of memory (seg27 host.example.com pid=47093)
VM Protect failed to allocate 4096 bytes, 0 MB available
```

Some common causes of out-of-memory conditions in Greenplum Database are:

- Insufficient system memory (RAM) available on the cluster
- Improperly configured memory parameters
- Data skew at the segment level
- Operational skew at the query level

Following are possible solutions to out of memory conditions:

- Tune the query to require less memory
- Reduce query concurrency using a resource queue
- Validate the `gp_vmem_protect_limit` configuration parameter at the database level. See calculations for the maximum safe setting in *Configuring Memory for Greenplum Database*.
- Set the memory quota on a resource queue to limit the memory used by queries executed within the resource queue
- Use a session setting to reduce the `statement_mem` used by specific queries
- Decrease `statement_mem` at the database level
- Decrease the number of segments per host in the Greenplum Database cluster. This solution requires a re-initializing Greenplum Database and reloading your data.
- Increase memory on the host, if possible. (Additional hardware may be required.)

Adding segment hosts to the cluster will not in itself alleviate out of memory problems. The memory used by each query is determined by the `statement_mem` parameter and it is set when the query is invoked. However, if adding more hosts allows decreasing the number of segments per host, then the amount of memory allocated in `gp_vmem_protect_limit` can be raised.
Low Memory Queries

A low statement_mem setting (for example, in the 1-3MB range) has been shown to increase the performance of queries with low memory requirements. Use the statement_mem server configuration parameter to override the setting on a per-query basis. For example:

```sql
SET statement_mem='2MB';
```

Configuring Memory for Greenplum Database

Most out of memory conditions can be avoided if memory is thoughtfully managed.

It is not always possible to increase system memory, but you can prevent out-of-memory conditions by configuring memory use correctly and setting up resource queues to manage expected workloads.

It is important to include memory requirements for mirror segments that become primary segments during a failure to ensure that the cluster can continue when primary segments or segment hosts fail.

The following are recommended operating system and Greenplum Database memory settings:

- Do not configure the OS to use huge pages.
- **vm.overcommit_memory**
  
  This is a Linux kernel parameter, set in /etc/sysctl.conf. It should always be set to 2. It determines the method the OS uses for determining how much memory can be allocated to processes and 2 is the only safe setting for Greenplum Database.

- **vm.overcommit_ratio**
  
  This is a Linux kernel parameter, set in /etc/sysctl.conf. It is the percentage of RAM that is used for application processes. The remainder is reserved for the operating system. The default on Red Hat is 50. Setting `vm.overcommit_ratio` too high may result in not enough memory being reserved for the operating system, which can result in segment host failure or database failure. Setting the value too low reduces the amount of concurrency and query complexity that can be run by reducing the amount of memory available to Greenplum Database. When increasing the setting it is important to remember to always reserve some memory for operating system activities.

  See Resource Queue Segment Memory Configuration for instructions to calculate a value for `vm.overcommit_ratio`.

- **gp_vmem_protect_limit**
  
  Use `gp_vmem_protect_limit` to set the maximum memory that the instance can allocate for all work being done in each segment database. Never set this value larger than the physical RAM on the system. If `gp_vmem_protect_limit` is too high, it is possible for memory to become exhausted on the system and normal operations may fail, causing segment failures. If `gp_vmem_protect_limit` is set to a safe lower value, true memory exhaustion on the system is prevented; queries may fail for hitting the limit, but system disruption and segment failures are avoided, which is the desired behavior.

  See Resource Queue Segment Memory Configuration for instructions to calculate a safe value for `gp_vmem_protect_limit`.

- **runaway_detector_activation_percent**
  
  Runaway Query Termination, introduced in Greenplum Database 4.3.4, prevents out of memory conditions. The `runaway_detector_activation_percent` system parameter controls the percentage of `gp_vmem_protect_limit` memory utilized that triggers termination of queries. It is set on by default at 90%. If the percentage of `gp_vmem_protect_limit` memory that is utilized for a segment exceeds the specified value, Greenplum Database terminates queries based on memory usage, beginning with the query consuming the largest amount of memory. Queries are terminated until the utilized percentage of `gp_vmem_protect_limit` is below the specified percentage.

- **statement_mem**
Use `statement_mem` to allocate memory used for a query per segment database. If additional memory is required it will spill to disk. Set the optimal value for `statement_mem` as follows:

```
(vmprotect * .9) / max_expected_concurrent_queries
```

The default value of `statement_mem` is 125MB. For example, a query running on a Dell EMC DCA system using the default `statement_mem` value will use 1GB of memory on each segment server (8 segments # 125MB). Set `statement_mem` at the session level for specific queries that require additional memory to complete. This setting works well to manage query memory on clusters with low concurrency. For clusters with high concurrency also use resource queues to provide additional control on what and how much is running on the system.

- **gp_workfile_limit_files_per_query**

  Set `gp_workfile_limit_files_per_query` to limit the maximum number of temporary spill files (workfiles) allowed per query. Spill files are created when a query requires more memory than it is allocated. When the limit is exceeded the query is terminated. The default is zero, which allows an unlimited number of spill files and may fill up the file system.

- **gp_workfile_compress_algorithm**

  If there are numerous spill files then set `gp_workfile_compress_algorithm` to compress the spill files. Compressing spill files may help to avoid overloading the disk subsystem with IO operations.

### Configuring Resource Queues

Greenplum Database resource queues provide a powerful mechanism for managing the workload of the cluster. Queues can be used to limit both the numbers of active queries and the amount of memory that can be used by queries in the queue. When a query is submitted to Greenplum Database, it is added to a resource queue, which determines if the query should be accepted and when the resources are available to execute it.

- Associate all roles with an administrator-defined resource queue.
  
  Each login user (role) is associated with a single resource queue; any query the user submits is handled by the associated resource queue. If a queue is not explicitly assigned the user's queries are handed by the default queue, `pg_default`.

- Do not run queries with the gpadmin role or other superuser roles.

  Superusers are exempt from resource queue limits, therefore superuser queries always run regardless of the limits set on their assigned queue.

- Use the `ACTIVE_STATEMENTS` resource queue parameter to limit the number of active queries that members of a particular queue can run concurrently.

- Use the `MEMORY_LIMIT` parameter to control the total amount of memory that queries running through the queue can utilize. By combining the `ACTIVE_STATEMENTS` and `MEMORY_LIMIT` attributes an administrator can fully control the activity emitted from a given resource queue.

  The allocation works as follows: Suppose a resource queue, `sample_queue`, has `ACTIVE_STATEMENTS` set to 10 and `MEMORY_LIMIT` set to 2000MB. This limits the queue to approximately 2 gigabytes of memory per segment. For a cluster with 8 segments per server, the total usage per server is 16 GB for `sample_queue` (2GB * 8 segments/server). If a segment server has 64GB of RAM, there could be no more than four of this type of resource queue on the system before there is a chance of running out of memory (4 queues * 16GB per queue).

  Note that by using `STATEMENT_MEM`, individual queries running in the queue can allocate more than their "share" of memory, thus reducing the memory available for other queries in the queue.

- Resource queue priorities can be used to align workloads with desired outcomes. Queues with `MAX` priority throttle activity in all other queues until the `MAX` queue completes running all queries.

- Alter resource queues dynamically to match the real requirements of the queue for the workload and time of day. You can script an operational flow that changes based on the time of day and type of usage of the system and add `crontab` entries to execute the scripts.
• Use gp Toolkit to view resource queue usage and to understand how the queues are working.
System Monitoring and Maintenance

Best practices for regular maintenance that will ensure Greenplum Database high availability and optimal performance.

Monitoring

Greenplum Database includes utilities that are useful for monitoring the system.

The `gp_toolkit` schema contains several views that can be accessed using SQL commands to query system catalogs, log files, and operating environment for system status information.

The `gp_stats_missing` view shows tables that do not have statistics and require `ANALYZE` to be run.

For additional information on `gpstate` and `gpcheckperf` refer to the Greenplum Database Utility Guide. For information about the `gp_toolkit` schema, see the Greenplum Database Reference Guide.

`gpstate`

The `gpstate` utility program displays the status of the Greenplum system, including which segments are down, master and segment configuration information (hosts, data directories, etc.), the ports used by the system, and mapping of primary segments to their corresponding mirror segments.

Run `gpstate -Q` to get a list of segments that are marked "down" in the master system catalog.

To get detailed status information for the Greenplum system, run `gpstate -s`.

`gpcheckperf`

The `gpcheckperf` utility tests baseline hardware performance for a list of hosts. The results can help identify hardware issues. It performs the following checks:

- **disk I/O test** – measures I/O performance by writing and reading a large file using the `dd` operating system command. It reports read and write rates in megabytes per second.
- **memory bandwidth test** – measures sustainable memory bandwidth in megabytes per second using the STREAM benchmark.
- **network performance test** – runs the `gpnetbench` network benchmark program (optionally `netperf`) to test network performance. The test is run in one of three modes: parallel pair test (`-r N`), serial pair test (`-r n`), or full-matrix test (`-r M`). The minimum, maximum, average, and median transfer rates are reported in megabytes per second.

To obtain valid numbers from `gpcheckperf`, the database system must be stopped. The numbers from `gpcheckperf` can be inaccurate even if the system is up and running with no query activity.

`gpcheckperf` requires a trusted host setup between the hosts involved in the performance test. It calls `gpssh` and `gpscp`, so these utilities must also be in your `PATH`. Specify the hosts to check individually (`-h host1 -h host2 ...`) or with `-f hosts_file`, where `hosts_file` is a text file containing a list of the hosts to check. If you have more than one subnet, create a separate host file for each subnet so that you can test the subnets separately.

By default, `gpcheckperf` runs the disk I/O test, the memory test, and a serial pair network performance test. With the disk I/O test, you must use the `-d` option to specify the file systems you want to test. The following command tests disk I/O and memory bandwidth on hosts listed in the `subnet_1_hosts` file:

```
$ gpcheckperf -f subnet_1_hosts -d /data1 -d /data2 -r ds
```

The `-r` option selects the tests to run: disk I/O (`d`), memory bandwidth (`s`), network parallel pair (`N`), network serial pair test (`n`), network full-matrix test (`M`). Only one network mode can be selected per execution. See the Greenplum Database Reference Guide for the detailed `gpcheckperf` reference.
Monitoring with Operating System Utilities

The following Linux/UNIX utilities can be used to assess host performance:

- `iostat` allows you to monitor disk activity on segment hosts.
- `top` displays a dynamic view of operating system processes.
- `vmstat` displays memory usage statistics.

You can use `gpssh` to run utilities on multiple hosts.

Best Practices

- Implement the “Recommended Monitoring and Maintenance Tasks” in the *Greenplum Database Administrator Guide*.
- Run `gpcheckperf` at install time and periodically thereafter, saving the output to compare system performance over time.
- Use all the tools at your disposal to understand how your system behaves under different loads.
- Examine any unusual event to determine the cause.
- Monitor query activity on the system by running explain plans periodically to ensure the queries are running optimally.
- Review plans to determine whether index are being used and partition elimination is occurring as expected.

Additional Information

- `gpcheckperf` reference in the *Greenplum Database Utility Guide*.
- “Recommended Monitoring and Maintenance Tasks” in the *Greenplum Database Administrator Guide*.
- [www.netperf.org](http://www.netperf.org) to use netperf, netperf must be installed on each host you test. See `gpcheckperf` reference for more information.

**Updating Statistics with ANALYZE**

The most important prerequisite for good query performance is to begin with accurate statistics for the tables. Updating statistics with the `ANALYZE` statement enables the query planner to generate optimal query plans. When a table is analyzed, information about the data is stored in the system catalog tables. If the stored information is out of date, the planner can generate inefficient plans.

Generating Statistics Selectively

Running `ANALYZE` with no arguments updates statistics for all tables in the database. This can be a very long-running process and it is not recommended. You should `ANALYZE` tables selectively when data has changed or use the `analyzedb` utility.

Running `ANALYZE` on a large table can take a long time. If it is not feasible to run `ANALYZE` on all columns of a very large table, you can generate statistics for selected columns only using `ANALYZE table(column, ...)`. Be sure to include columns used in joins, WHERE clauses, SORT clauses, GROUP BY clauses, or HAVING clauses.

For a partitioned table, you can run `ANALYZE` on just partitions that have changed, for example, if you add a new partition. Note that for partitioned tables, you can run `ANALYZE` on the parent (main) table, or on the leaf nodes—the partition files where data and statistics are actually stored. The intermediate files for sub-partitioned tables store no data or statistics, so running `ANALYZE` on them does not work. You can find the names of the partition tables in the `pg_partitions` system catalog:

```
SELECT partitiontablename from pg_partitions WHERE tablename='parent_table';
```
Improving Statistics Quality

There is a trade-off between the amount of time it takes to generate statistics and the quality, or accuracy, of the statistics.

To allow large tables to be analyzed in a reasonable amount of time, `ANALYZE` takes a random sample of the table contents, rather than examining every row. To increase the number of sample values for all table columns adjust the `default_statistics_target` configuration parameter. The target value ranges from 1 to 1000; the default target value is 100. The `default_statistics_target` variable applies to all columns by default, and specifies the number of values that are stored in the list of common values. A larger target may improve the quality of the query planner’s estimates, especially for columns with irregular data patterns. `default_statistics_target` can be set at the master/session level and requires a reload.

The `gp_analyze_relative_error` configuration parameter affects the sampling rate during statistics collection to determine cardinality in a column. For example, a value of .5 is equivalent to an acceptable error of 50%. The default is .25. Use the `gp_analyze_relative_error` parameter to set the acceptable estimated relative error in the cardinality of a table. If statistics do not produce good estimates of cardinality for a particular table attribute, decreasing the relative error fraction (accepting less errors) tells the system to sample more rows. However, it is not recommended to reduce this below 0.1 as it will increase `ANALYZE` time substantially.

When to Run `ANALYZE`

Run `ANALYZE`:

- after loading data,
- after `CREATE INDEX` operations,
- and after `INSERT`, `UPDATE`, and `DELETE` operations that significantly change the underlying data.

`ANALYZE` requires only a read lock on the table, so it may be run in parallel with other database activity, but do not run `ANALYZE` while performing `LOAD`, `INSERT`, `UPDATE`, `DELETE`, and `CREATE INDEX` operations.

Configuring Automatic Statistics Collection

The `gp_autostats_mode` configuration parameter, together with the `gp_autostats_on_change_threshold` parameter, determines when an automatic analyze operation is triggered. When automatic statistics collection is triggered, the planner adds an `ANALYZE` step to the query.

By default, `gp_autostats_mode` is `on_no_stats`, which triggers statistics collection for `CREATE TABLE AS SELECT`, `INSERT`, or `COPY` operations on any table that has no existing statistics.

Setting `gp_autostats_mode` to `on_change` triggers statistics collection only when the number of rows affected exceeds the threshold defined by `gp_autostats_on_change_threshold`, which has a default value of 2147483647. Operations that can trigger automatic statistics collection with `on_change` are: `CREATE TABLE AS SELECT`, `UPDATE`, `DELETE`, `INSERT`, and `COPY`.

Setting `gp_autostats_mode` to `none` disables automatic statistics collection.

For partitioned tables, automatic statistics collection is not triggered if data is inserted from the top-level parent table of a partitioned table. But automatic statistics collection is triggered if data is inserted directly in a leaf table (where the data is stored) of the partitioned table.

Managing Bloat in the Database

Greenplum Database heap tables use the PostgreSQL Multiversion Concurrency Control (MVCC) storage implementation. A deleted or updated row is logically deleted from the database, but a non-visible image of the row remains in the table. These deleted rows, also called expired rows, are tracked in a free space.
map. Running VACUUM marks the expired rows as free space that is available for reuse by subsequent inserts.

If the free space map is not large enough to accommodate all of the expired rows, the VACUUM command is unable to reclaim space for expired rows that overflowed the free space map. The disk space may only be recovered by running VACUUM FULL, which locks the table, copies rows one-by-one to the beginning of the file, and truncates the file. This is an expensive operation that can take an exceptional amount of time to complete with a large table. It should be used only on smaller tables. If you attempt to kill a VACUUM FULL operation, the system can be disrupted.

**Important:**

It is very important to run VACUUM after large UPDATE and DELETE operations to avoid the necessity of ever running VACUUM FULL.

If the free space map overflows and it is necessary to recover the space it is recommended to use the CREATE TABLE...AS SELECT command to copy the table to a new table, which will create a new compact table. Then drop the original table and rename the copied table.

It is normal for tables that have frequent updates to have a small or moderate amount of expired rows and free space that will be reused as new data is added. But when the table is allowed to grow so large that active data occupies just a small fraction of the space, the table has become significantly “bloated.” Bloated tables require more disk storage and additional I/O that can slow down query execution.

Bloat affects heap tables, system catalogs, and indexes.

Running the VACUUM statement on tables regularly prevents them from growing too large. If the table does become significantly bloated, the VACUUM FULL statement (or an alternative procedure) must be used to compact the file. If a large table becomes significantly bloated, it is better to use one of the alternative methods described in Removing Bloat from Database Tables to remove the bloat.

**Caution:** Never run VACUUM FULL <database_name> and do not run VACUUM FULL on large tables in a Greenplum Database.

### Sizing the Free Space Map

Expired rows in heap tables are added to a shared free space map when you run VACUUM. The free space map must be adequately sized to accommodate these rows. If the free space map is not large enough, any space occupied by rows that overflow the free space map cannot be reclaimed by a regular VACUUM statement. You will have to use VACUUM FULL or an alternative method to recover the space.

You can avoid overflowing the free space map by running the VACUUM statement regularly. The more bloated a table becomes, the more rows that must be tracked in the free space map. For very large databases with many objects, you may need to increase the size of the free space map to prevent overflow.

The max_fsm_pages configuration parameter sets the maximum number of disk pages for which free space will be tracked in the shared free-space map. Each page slot consumes six bytes of shared memory. The default value for max_fsm_pages is 200,000.

The max_fsm_relations configuration parameter sets the maximum number of relations for which free space will be tracked in the shared memory free-space map. It should be set to a value larger than the total number of tables, indexes, and system tables in the database. It costs about 60 bytes of memory for each relation per segment instance. The default value is 1000.

See the Greenplum Database Reference Guide for detailed information about these configuration parameters.

### Detecting Bloat

The statistics collected by the ANALYZE statement can be used to calculate the expected number of disk pages required to store a table. The difference between the expected number of pages and the actual number of pages is a measure of bloat. The gp_toolkit schema provides a gp_bloat_diag view that
identifies table bloat by comparing the ratio of expected to actual pages. To use it, make sure statistics are up to date for all of the tables in the database, then run the following SQL:

```
gpadmin=# SELECT * FROM gp_toolkit.gp_bloat_diag;
bdirelid | bdinspname | bdirelname | bdirelpages | bdiexppages | bdidiag
----------+------------+------------+-------------+-------------
        +---------------------------------------
  21488 | public     | t1         | 97          | 1           |
significant amount of bloat suspected
(1 row)
```

The results include only tables with moderate or significant bloat. Moderate bloat is reported when the ratio of actual to expected pages is greater than four and less than ten. Significant bloat is reported when the ratio is greater than ten.

The `gp_toolkit.gp_bloat_expected_pages` view lists the actual number of used pages and expected number of used pages for each database object.

```
gpadmin=# SELECT * FROM gp_toolkit.gp_bloat_expected_pages LIMIT 5;
btdrelid | btdrelpages | btdexppages
----------+-------------+-------------
10789     | 1           | 1           
10794     | 1           | 1           
10799     | 1           | 1           
5004      | 1           | 1           
7175      | 1           | 1           
(5 rows)
```

The `btdrelid` is the object ID of the table. The `btdrelpages` column reports the number of pages the table uses; the `btdexppages` column is the number of pages expected. Again, the numbers reported are based on the table statistics, so be sure to run `ANALYZE` on tables that have changed.

Removing Bloat from Database Tables

The `VACUUM` command adds expired rows to the free space map so that the space can be reused. When `VACUUM` is run regularly on a table that is frequently updated, the space occupied by the expired rows can be promptly reused, preventing the table file from growing larger. It is also important to run `VACUUM` before the free space map is filled. For heavily updated tables, you may need to run `VACUUM` at least once a day to prevent the table from becoming bloated.

**Warning:** When a table is significantly bloated, it is better to run `VACUUM` before running `ANALYZE`. Analyzing a severely bloated table can generate poor statistics if the sample contains empty pages, so it is good practice to vacuum a bloated table before analyzing it.

When a table accumulates significant bloat, running the `VACUUM` command is insufficient. For small tables, running `VACUUM FULL <table_name>` can reclaim space used by rows that overflowed the free space map and reduce the size of the table file. However, a `VACUUM FULL` statement is an expensive operation that requires an `ACCESS EXCLUSIVE` lock and may take an exceptionally long and unpredictable amount of time to finish. Rather than run `VACUUM FULL` on a large table, an alternative method is required to remove bloat from a large file. Note that every method for removing bloat from large tables is resource intensive and should be done only under extreme circumstances.

The first method to remove bloat from a large table is to create a copy of the table excluding the expired rows, drop the original table, and rename the copy. This method uses the `CREATE TABLE <table_name> AS SELECT statement` to create the new table, for example:

```
gpadmin=# CREATE TABLE mytable_tmp AS SELECT * FROM mytable;
gpadmin=# DROP TABLE mytable;
gpadmin=# ALTER TABLE mytable_tmp RENAME TO mytable;
```
A second way to remove bloat from a table is to redistribute the table, which rebuilds the table without the expired rows. Follow these steps:

1. Make a note of the table’s distribution columns.
2. Change the table’s distribution policy to random:

   ```sql
   ALTER TABLE mytable SET WITH (REORGANIZE=false)
   DISTRIBUTED randomly;
   ```

   This changes the distribution policy for the table, but does not move any data. The command should complete instantly.
3. Change the distribution policy back to its initial setting:

   ```sql
   ALTER TABLE mytable SET WITH (REORGANIZE=true)
   DISTRIBUTED BY (<original distribution columns>);  
   ```

   This step redistributes the data. Since the table was previously distributed with the same distribution key, the rows are simply rewritten on the same segment, excluding expired rows.

**Removing Bloat from Indexes**

The `VACUUM` command only recovers space from tables. To recover the space from indexes, recreate them using the `REINDEX` command.

To rebuild all indexes on a table run `REINDEX table_name;`. To rebuild a particular index, run `REINDEX index_name;`. `REINDEX` sets the reltuples and relpages to 0 (zero) for the index, To update those statistics, run `ANALYZE` on the table after reindexing.

**Removing Bloat from System Catalogs**

Greenplum Database system catalogs are also heap tables and can become bloated over time. As database objects are created, altered, or dropped, expired rows are left in the system catalogs. Using `gpload` to load data contributes to the bloat since `gpload` creates and drops external tables. (Rather than use `gpload`, it is recommended to use `gpfdist` to load data.)

Bloat in the system catalogs increases the time require to scan the tables, for example, when creating explain plans. System catalogs are scanned frequently and if they become bloated, overall system performance is degraded.

It is recommended to run `VACUUM` on the system catalog nightly and at least weekly. At the same time, running `REINDEX SYSTEM` removes bloat from the indexes. Alternatively, you can reindex system tables using the `reindexdb` utility with the `-s` (`--system`) option. After removing catalog bloat, run `ANALYZE` to update catalog table statistics.

These are Greenplum Database system catalog maintenance steps.

1. Perform a `REINDEX` on the system catalog tables to rebuild the system catalog indexes. This removes bloat in the indexes and improves `VACUUM` performance.
   
   **Note:** When performing `REINDEX` on the system catalog tables, locking will occur on the tables and might have an impact on currently running queries. You can schedule the `REINDEX` operation during a period of low activity to avoid disrupting ongoing business operations.

2. Perform a `VACUUM` on system catalog tables.

3. Perform an `ANALYZE` on the system catalog tables to update the table statistics.

If you are performing catalog maintenance during a maintenance period and you need to stop a process due to time constraints, run the Greenplum Database function `pg_cancel_backend(<PID>)` to safely stop a Greenplum Database process.

The following script runs `REINDEX`, `VACUUM`, and `ANALYZE` on the system catalogs.

```bash
#!/bin/bash
```
If the system catalogs become significantly bloated, you must perform an intensive system catalog maintenance procedure. The `CREATE TABLE AS SELECT` and redistribution key methods for removing bloat cannot be used with system catalogs. You must instead run `VACUUM FULL` during a scheduled downtime period. During this period, stop all catalog activity on the system; `VACUUM FULL` takes exclusive locks against the system catalog. Running `VACUUM` regularly can prevent the need for this more costly procedure.

These are steps for intensive system catalog maintenance.

1. Stop all catalog activity on the Greenplum Database system.
2. Perform a `REINDEX` on the system catalog tables to rebuild the system catalog indexes. This removes bloat in the indexes and improves `VACUUM` performance.
3. Perform a `VACUUM FULL` on the system catalog tables. See the following Note.
4. Perform an `ANALYZE` on the system catalog tables to update the catalog table statistics.

Note: The system catalog table `pg_attribute` is usually the largest catalog table. If the `pg_attribute` table is significantly bloated, a `VACUUM FULL` operation on the table might require a significant amount of time and might need to be performed separately. The presence of both of these conditions indicate a significantly bloated `pg_attribute` table that might require a long `VACUUM FULL` time:

- The `pg_attribute` table contains a large number of records.
- The diagnostic message for `pg_attribute` is significant amount of bloat in the `gp_toolkit.gp_bloat_diag` view.

### Removing Bloat from Append-Optimized Tables

Append-optimized tables are handled much differently than heap tables. Although append-optimized tables allow updates, inserts, and deletes, they are not optimized for these operations and it is recommended to not use them with append-optimized tables. If you heed this advice and use append-optimized for load-once/read-many workloads, `VACUUM` on an append-optimized table runs almost instantaneously.

If you do run `UPDATE` or `DELETE` commands on an append-optimized table, expired rows are tracked in an auxiliary bitmap instead of the free space map. `VACUUM` is the only way to recover the space. Running `VACUUM` on an append-optimized table with expired rows compacts a table by rewriting the entire table without the expired rows. However, no action is performed if the percentage of expired rows in the table exceeds the value of the `gp_appendonly_compaction_threshold` configuration parameter, which is 10 (10%) by default. The threshold is checked on each segment, so it is possible that a `VACUUM` statement will compact an append-only table on some segments and not others. Compacting append-only tables can be disabled by setting the `gp_appendonly_compaction` parameter to `no`.

### Monitoring Greenplum Database Log Files

Know the location and content of system log files and monitor them on a regular basis and not just when problems arise.

The following table shows the locations of the various Greenplum Database log files. In file paths:

- `$GPADMIN_HOME` refers to the home directory of the `gpadmin` operating system user.
- `$MASTER_DATA_DIRECTORY` refers to the master data directory on the Greenplum Database master host.
- `$GPDATA_DIR` refers to a data directory on the Greenplum Database segment host.
- `host` identifies the Greenplum Database segment host name.
- `segprefix` identifies the segment prefix.
- `N` identifies the segment instance number.
- `date` is a date in the format `YYYYMMDD`.

<table>
<thead>
<tr>
<th>Path</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>$GPADMIN_HOME/gpAdminLogs/*</code></td>
<td>Many different types of log files, directory on each server. <code>$GPADMIN_HOME</code> is the default location for the <code>gpAdminLogs/</code> directory. You can specify a different location when you run an administrative utility command.</td>
</tr>
<tr>
<td><code>$GPADMIN_HOME/gpAdminLogs/gpinitsystem_date.log</code></td>
<td>system initialization log</td>
</tr>
<tr>
<td><code>$GPADMIN_HOME/gpAdminLogs/gpstart_date.log</code></td>
<td>start log</td>
</tr>
<tr>
<td><code>$GPADMIN_HOME/gpAdminLogs/gpstop_date.log</code></td>
<td>stop log</td>
</tr>
<tr>
<td><code>$GPADMIN_HOME/gpAdminLogs/gpsegstart.py_host:gpadmin_date.log</code></td>
<td>segment host start log</td>
</tr>
<tr>
<td><code>$GPADMIN_HOME/gpAdminLogs/gpsegstop.py_host:gpadmin_date.log</code></td>
<td>segment host stop log</td>
</tr>
<tr>
<td><code>$MASTER_DATA_DIRECTORY/pg_log/startup.log</code>, <code>$GPDATA_DIR/segprefixN/pg_log/startup.log</code></td>
<td>segment instance start log</td>
</tr>
<tr>
<td><code>$MASTER_DATA_DIRECTORY/gpperfmon/logs/gpperfmon.*.log</code></td>
<td>gpperfmon logs</td>
</tr>
<tr>
<td><code>$MASTER_DATA_DIRECTORY/pg_log/*.csv</code>, <code>$GPDATA_DIR/segprefixN/pg_log/*.csv</code></td>
<td>master and segment database logs</td>
</tr>
<tr>
<td><code>$GPDATA_DIR/mirror/segprefixN/pg_log/*.csv</code></td>
<td>mirror segment database logs</td>
</tr>
<tr>
<td><code>$GPDATA_DIR/primary/segprefixN/pg_log/*.csv</code></td>
<td>primary segment database logs</td>
</tr>
<tr>
<td><code>/var/log/messages</code></td>
<td>Global Linux system messages</td>
</tr>
</tbody>
</table>

Use `gplogfilter -t (--trouble)` first to search the master log for messages beginning with `ERROR:`, `FATAL:`, or `PANIC:`. Messages beginning with `WARNING` may also provide useful information.

To search log files on the segment hosts, use the Greenplum `gplogfilter` utility with `gpssh` to connect to segment hosts from the master host. You can identify corresponding log entries in segment logs by the `statement_id`.

The `log_rotation_age` configuration parameter specifies when a new log file is automatically created while a database instance is running. By default, a new log file is created every day.
Loading Data

Description of the different ways to add data to Greenplum Database.

**INSERT Statement with Column Values**

A singleton `INSERT` statement with values adds a single row to a table. The row flows through the master and is distributed to a segment. This is the slowest method and is not suitable for loading large amounts of data.

**COPY Statement**

The PostgreSQL `COPY` statement copies data from an external file into a database table. It can insert multiple rows more efficiently than an `INSERT` statement, but the rows are still passed through the master. All of the data is copied in one command; it is not a parallel process.

Data input to the `COPY` command is from a file or the standard input. For example:

```
COPY table FROM '/data/mydata.csv' WITH CSV HEADER;
```

Use `COPY` to add relatively small sets of data, for example dimension tables with up to ten thousand rows, or one-time data loads.

Use `COPY` when scripting a process that loads small amounts of data, less than 10 thousand rows.

Since `COPY` is a single command, there is no need to disable autocommit when you use this method to populate a table.

You can run multiple concurrent `COPY` commands to improve performance.

**External Tables**

External tables provide access to data in sources outside of Greenplum Database. They can be accessed with `SELECT` statements and are commonly used with the Extract, Load, Transform (ELT) pattern, a variant of the Extract, Transform, Load (ETL) pattern that takes advantage of Greenplum Database’s fast parallel data loading capability.

With ETL, data is extracted from its source, transformed outside of the database using external transformation tools, such as Informatica or Datastage, and then loaded into the database.

With ELT, Greenplum external tables provide access to data in external sources, which could be read-only files (for example, text, CSV, or XML files), Web servers, Hadoop file systems, executable OS programs, or the Greenplum `gpfdist` file server, described in the next section. External tables support SQL operations such as select, sort, and join so the data can be loaded and transformed simultaneously, or loaded into a `load table` and transformed in the database into target tables.

The external table is defined with a `CREATE EXTERNAL TABLE` statement, which has a `LOCATION` clause to define the location of the data and a `FORMAT` clause to define the formatting of the source data so that the system can parse the input data. Files use the `file://` protocol, and must reside on a segment host in a location accessible by the Greenplum superuser. The data can be spread out among the segment hosts with no more than one file per primary segment on each host. The number of files listed in the `LOCATION` clause is the number of segments that will read the external table in parallel.

**External Tables with Gpfdist**

The fastest way to load large fact tables is to use external tables with `gpdist`. `gpdist` is a file server program using an HTTP protocol that serves external data files to Greenplum Database segments.
in parallel. A `gpfdist` instance can serve 200 MB/second and many `gpfdist` processes can run simultaneously, each serving up a portion of the data to be loaded. When you begin the load using a statement such as `INSERT INTO <table> SELECT * FROM <external_table>`, the INSERT statement is parsed by the master and distributed to the primary segments. The segments connect to the `gpfdist` servers and retrieve the data in parallel, parse and validate the data, calculate a hash from the distribution key data and, based on the hash key, send the row to its destination segment. By default, each `gpfdist` instance will accept up to 64 connections from segments. With many segments and `gpfdist` servers participating in the load, data can be loaded at very high rates.

Primary segments access external files in parallel when using `gpfdist` up to the value of `gp_external_max_segments`. When optimizing `gpfdist` performance, maximize the parallelism as the number of segments increase. Spread the data evenly across as many ETL nodes as possible. Split very large data files into equal parts and spread the data across as many file systems as possible.

Run two `gpfdist` instances per file system. `gpfdist` tends to be CPU bound on the segment nodes when loading. But if, for example, there are eight racks of segment nodes, there is lot of available CPU on the segments to drive more `gpfdist` processes. Run `gpfdist` on as many interfaces as possible. Be aware of bonded NICs and be sure to start enough `gpfdist` instances to work them.

It is important to keep the work even across all these resources. The load is as fast as the slowest node. Skew in the load file layout will cause the overall load to bottleneck on that resource.

The `gp_external_max_segs` configuration parameter controls the number of segments each `gpfdist` process serves. The default is 64. You can set a different value in the `postgresql.conf` configuration file on the master. Always keep `gp_external_max_segs` and the number of `gpfdist` processes an even factor; that is, the `gp_external_max_segs` value should be a multiple of the number of `gpfdist` processes. For example, if there are 12 segments and 4 `gpfdist` processes, the planner round robin the segment connections as follows:

<table>
<thead>
<tr>
<th>Segment</th>
<th><code>gpfdist</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>1</td>
</tr>
<tr>
<td>2</td>
<td>2</td>
</tr>
<tr>
<td>3</td>
<td>3</td>
</tr>
<tr>
<td>4</td>
<td>4</td>
</tr>
<tr>
<td>5</td>
<td>1</td>
</tr>
<tr>
<td>6</td>
<td>2</td>
</tr>
<tr>
<td>7</td>
<td>3</td>
</tr>
<tr>
<td>8</td>
<td>4</td>
</tr>
<tr>
<td>9</td>
<td>1</td>
</tr>
<tr>
<td>10</td>
<td>2</td>
</tr>
<tr>
<td>11</td>
<td>3</td>
</tr>
<tr>
<td>12</td>
<td>4</td>
</tr>
</tbody>
</table>

Drop indexes before loading into existing tables and re-create the index after loading. Creating an index on pre-existing data is faster than updating it incrementally as each row is loaded.

Run `ANALYZE` on the table after loading. Disable automatic statistics collection during loading by setting `gp_autostats_mode` to `NONE`. Run `VACUUM` after load errors to recover space.

Performing small, high frequency data loads into heavily partitioned column-oriented tables can have a high impact on the system because of the number of physical files accessed per time interval.

**Gpload**

gpload is a data loading utility that acts as an interface to the Greenplum external table parallel loading feature.

Beware of using `gpload` as it can cause catalog bloat by creating and dropping external tables. Use `gpfdist` instead, since it provides the best performance.

`gpload` executes a load using a specification defined in a YAML-formatted control file. It performs the following operations:
The load is accomplished in a single transaction.

**Best Practices**

- Drop any indexes on an existing table before loading data and recreate the indexes after loading. Newly creating an index is faster than updating an index incrementally as each row is loaded.
- Disable automatic statistics collection during loading by setting the `gp_autostats_mode` configuration parameter to `NONE`.
- External tables are not intended for frequent or ad hoc access.
- External tables have no statistics to inform the optimizer. You can set rough estimates for the number of rows and disk pages for the external table in the `pg_class` system catalog with a statement like the following:

  ```sql
  UPDATE pg_class SET reltuples=400000, relpages=400
  WHERE relname='myexttable';
  ```

- When using `gpfdist`, maximize network bandwidth by running one `gpfdist` instance for each NIC on the ETL server. Divide the source data evenly between the `gpfdist` instances.
- When using `gpload`, run as many simultaneous `gpload` instances as resources allow. Take advantage of the CPU, memory, and networking resources available to increase the amount of data that can be transferred from ETL servers to the Greenplum Database.
- Use the `SEGMENT REJECT LIMIT` clause of the `COPY` statement to set a limit for the number or percentage of rows that can have errors before the `COPY FROM` command is aborted. The reject limit is per segment; when any one segment exceeds the limit, the command is aborted and no rows are added. Use the `LOG ERRORS` clause to save error rows. If a row has errors in the formatting—for example missing or extra values, or incorrect data types—Greenplum Database stores the error information and row internally. Use the `gp_read_error_log()` built-in SQL function to access this stored information.
- If the load has errors, run `VACUUM` on the table to recover space.
- After you load data into a table, run `VACUUM` on heap tables, including system catalogs, and `ANALYZE` on all tables. It is not necessary to run `VACUUM` on append-optimized tables. If the table is partitioned, you can vacuum and analyze just the partitions affected by the data load. These steps clean up any rows from aborted loads, deletes, or updates and update statistics for the table.
- Recheck for segment skew in the table after loading a large amount of data. You can use a query like the following to check for skew:

  ```sql
  SELECT * FROM system.runtime_skew;
  ```

- By default, `gpfdist` assumes a maximum record size of 32K. To load data records larger than 32K, you must increase the maximum row size parameter by specifying the `-m <bytes>` option on the `gpfdist` command line. If you use `gpload`, set the `MAX_LINE_LENGTH` parameter in the `gpload` control file.

  **Note:** Integrations with Informatica Power Exchange are currently limited to the default 32K record length.

**Additional Information**

See the *Greenplum Database Reference Guide* for detailed instructions for loading data using `gpfdist` and `gpload`. 
Migrating Data with gptransfer

Information about the gptransfer migration utility, which transfers Greenplum Database metadata and data from one Greenplum database to another.

Note: Greenplum Database provides two utilities for migrating data between Greenplum Database installations, gpcopy and gptransfer. Use gpcopy to migrate data to a Greenplum Database cluster version 5.9.0 and later. Use the gptransfer utility to migrate data between Greenplum Database installations running software version 5.8.0 or earlier.

The gptransfer utility is deprecated and will be removed in the next major release of Greenplum Database. For information about migrating data with gpcopy, see Migrating Data with gpcopy.

The gptransfer migration utility transfers Greenplum Database metadata and data from one Greenplum database to another Greenplum database, allowing you to migrate the entire contents of a database, or just selected tables, to another database. The source and destination databases may be in the same or a different cluster. Data is transferred in parallel across all the segments, using the gpfdist data loading utility to attain the highest transfer rates.

gptransfer handles the setup and execution of the data transfer. Participating clusters must already exist, have network access between all hosts in both clusters, and have certificate-authenticated ssh access between all hosts in both clusters.

The interface includes options to transfer one or more full databases, or one or more database tables. A full database transfer includes the database schema, table data, indexes, views, roles, user-defined functions, and resource queues. Configuration files, including postgresql.conf and pg_hba.conf, must be transferred manually by an administrator. Extensions installed in the database with gppkg, such as MADlib, must be installed in the destination database by an administrator.

See the Greenplum Database Utility Guide for complete syntax and usage information for the gptransfer utility.

Prerequisites

• The gptransfer utility can only be used with Greenplum Database. Apache HAWQ is not supported as a source or destination.
• The source and destination Greenplum clusters must both be version 4.2 or higher.
• At least one Greenplum instance must include the gptransfer utility in its distribution. If neither the source or destination includes gptransfer, you must upgrade one of the clusters to use gptransfer.
• The gptransfer utility can be run from the cluster with the source or destination database.
• The number of segments in the destination cluster must be greater than or equal to the number of hosts in the source cluster. The number of segments in the destination may be smaller than the number of segments in the source, but the data will transfer at a slower rate.
• The segment hosts in both clusters must have network connectivity with each other.
• Every host in both clusters must be able to connect to every other host with certificate-authenticated SSH. You can use the gpssh_exkeys utility to exchange public keys between the hosts of both clusters.

What gptransfer Does

gptransfer uses writable and readable external tables, the Greenplum gpfdist parallel data-loading utility, and named pipes to transfer data from the source database to the destination database. Segments on the source cluster select from the source database table and insert into a writable external table. Segments in the destination cluster select from a readable external table and insert into the destination database table. The writable and readable external tables are backed by named pipes on the source
cluster’s segment hosts, and each named pipe has a gpfdist process serving the pipe’s output to the readable external table on the destination segments.

gptransfer orchestrates the process by processing the database objects to be transferred in batches. For each table to be transferred, it performs the following tasks:

- creates a writable external table in the source database
- creates a readable external table in the destination database
- creates named pipes and gpfdist processes on segment hosts in the source cluster
- executes a SELECT INTO statement in the source database to insert the source data into the writable external table
- executes a SELECT INTO statement in the destination database to insert the data from the readable external table into the destination table
- optionally validates the data by comparing row counts or MD5 hashes of the rows in the source and destination
- cleans up the external tables, named pipes, and gpfdist processes

**Fast Mode and Slow Mode**

gptransfer sets up data transfer using the gpfdist parallel file serving utility, which serves the data evenly to the destination segments. Running more gpfdist processes increases the parallelism and the data transfer rate. When the destination cluster has the same or a greater number of segments than the source cluster, gptransfer sets up one named pipe and one gpfdist process for each source segment. This is the configuration for optimal data transfer rates and is called fast mode. The following figure illustrates a setup on a segment host when the destination cluster has at least as many segments as the source cluster.

The configuration of the input end of the named pipes differs when there are fewer segments in the destination cluster than in the source cluster. gptransfer handles this alternative setup automatically. The difference in configuration means that transferring data into a destination cluster with fewer segments than the source cluster is not as fast as transferring into a destination cluster of the same or greater size.
It is called slow mode because there are fewer gpfdist processes serving the data to the destination cluster, although the transfer is still quite fast with one gpfdist per segment host.

When the destination cluster is smaller than the source cluster, there is one named pipe per segment host and all segments on the host send their data through it. The segments on the source host write their data to a writable external web table connected to a gpfdist process on the input end of the named pipe. This consolidates the table data into a single named pipe. A gpfdist process on the output of the named pipe serves the consolidated data to the destination cluster. The following figure illustrates this configuration.

On the destination side, gptransfer defines a readable external table with the gpfdist server on the source host as input and selects from the readable external table into the destination table. The data is distributed evenly to all the segments in the destination cluster.

**Batch Size and Sub-batch Size**

The degree of parallelism of a gptransfer execution is determined by two command-line options: --batch-size and --sub-batch-size. The --batch-size option specifies the number of tables to transfer in a batch. The default batch size is 2, which means that two table transfers are in process at any time. The minimum batch size is 1 and the maximum is 10. The --sub-batch-size parameter specifies the maximum number of parallel sub-processes to start to do the work of transferring a table. The default is 25 and the maximum is 50. The product of the batch size and sub-batch size is the amount of parallelism. If set to the defaults, for example, gptransfer can perform 50 concurrent tasks. Each thread is a Python process and consumes memory, so setting these values too high can cause a Python Out of Memory error. For this reason, the batch sizes should be tuned for your environment.

**Preparing Hosts for gptransfer**

When you install a Greenplum Database cluster, you set up all the master and segment hosts so that the Greenplum Database administrative user (gpadmin) can connect with SSH from every host in the cluster to any other host in the cluster without providing a password. The gptransfer utility requires this capability between every host in the source and destination clusters. First, ensure that the clusters have network connectivity with each other. Then, prepare a hosts file containing a list of all the hosts in both
clusters, and use the gpssh-exkeys utility to exchange keys. See the reference for gpssh-exkeys in the Greenplum Database Utility Guide.

The host map file is a text file that lists the segment hosts in the source cluster. It is used to enable communication between the hosts in Greenplum clusters. The file is specified on the gptransfer command line with the --source-map-file=host_map_file command option. It is a required option when using gptransfer to copy data between two separate Greenplum clusters.

The file contains a list in the following format:

```
host1_name,host1_ip_addr
host2_name,host2_ipaddr
...
```

The file uses IP addresses instead of host names to avoid any problems with name resolution between the clusters.

**Limitations**

gptransfer transfers data from user databases only; the postgres, template0, and template1 databases cannot be transferred. Administrators must transfer configuration files manually and install extensions into the destination database with gppkg.

The destination cluster must have at least as many segments as the source cluster has segment hosts. Transferring data to a smaller cluster is not as fast as transferring data to a larger cluster.

Transferring small or empty tables can be unexpectedly slow. There is significant fixed overhead in setting up external tables and communications processes for parallel data loading between segments that occurs whether or not there is actual data to transfer. It can be more efficient to transfer the schema and smaller tables to the destination database using other methods, then use gptransfer with the -t option to transfer large tables.

When transferring data between databases, you can run only one instance of gptransfer at a time. Running multiple, concurrent instances of gptransfer is not supported.

**Full Mode and Table Mode**

When run with the --full option, gptransfer copies all user-created databases, tables, views, indexes, roles, user-defined functions, and resource queues in the source cluster to the destination cluster. The destination system cannot contain any user-defined databases, only the default databases postgres, template0, and template1. If gptransfer finds a database on the destination it fails with a message like the following:

```
[ERROR]:- gptransfer: error: --full option specified but tables exist on destination system
```

**Note:** The --full option cannot be specified with the -t, -d, -f, or --partition-transfer options.

To copy tables individually, specify the tables using either the -t command-line option (one option per table) or by using the -f command-line option to specify a file containing a list of tables to transfer. Tables are specified in the fully-qualified format database.schema.table. The table definition, indexes, and table data are copied. The database must already exist on the destination cluster.

By default, gptransfer fails if you attempt to transfer a table that already exists in the destination database:

```
[INFO]:-Validating transfer table set...
[CRITICAL]:- gptransfer failed. (Reason='Table database.schema.table exists in database database.') exiting...
```
Override this behavior with the `--skip-existing`, `--truncate`, or `--drop` options.

The following table shows the objects that are copied in full mode and table mode.

<table>
<thead>
<tr>
<th>Object</th>
<th>Full Mode</th>
<th>Table Mode</th>
</tr>
</thead>
<tbody>
<tr>
<td>Data</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>Indexes</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>

<td>No</td>
</tr>
<tr>
<td>Resource Queues</td>
<td>Yes</td>
<td>No</td>
</tr>
<tr>
<td>postgresql.conf</td>
<td>No</td>
<td>No</td>
</tr>
<tr>
<td>pg_hba.conf</td>
<td>No</td>
<td>No</td>
</tr>
<tr>
<td>gppkg</td>
<td>No</td>
<td>No</td>
</tr>
</tbody>
</table>

The `--full` option and the `--schema-only` option can be used together if you want to copy databases in phases, for example, during scheduled periods of downtime or low activity. Run `gptransfer --full --schema-only ...` to create the databases on the destination cluster, but with no data. Then you can transfer the tables in stages during scheduled down times or periods of low activity. Be sure to include the `--truncate` or `--drop` option when you later transfer tables to prevent the transfer from failing because the table already exists at the destination.

**Locking**

The `-x` option enables table locking. An exclusive lock is placed on the source table until the copy and validation, if requested, are complete.

**Validation**

By default, `gptransfer` does not validate the data transferred. You can request validation using the `--validate=type` option. The validation type can be one of the following:

- **count** – Compares the row counts for the tables in the source and destination databases.
- **md5** – Sorts tables on both source and destination, and then performs a row-by-row comparison of the MD5 hashes of the sorted rows.

If the database is accessible during the transfer, be sure to add the `-x` option to lock the table. Otherwise, the table could be modified during the transfer, causing validation to fail.

**Failed Transfers**

A failure on a table does not end the `gptransfer` job. When a transfer fails, `gptransfer` displays an error message and adds the table name to a failed transfers file. At the end of the `gptransfer` session, `gptransfer` writes a message telling you there were failures, and providing the name of the failed transfer file. For example:

```
[WARNING]:-Some tables failed to transfer. A list of these tables
[WARNING]:-has been written to the file
failed_transfer_tables_20140808_101813.txt
[WARNING]:-This file can be used with the -f option to continue
```

The failed transfers file is in the format required by the `-f` option, so you can use it to start a new `gptransfer` session to retry the failed transfers.
Best Practices

gptransfer creates a configuration that allows transferring large amounts of data at very high rates. For small or empty tables, however, the gptransfer set up and clean up are too expensive. The best practice is to use gptransfer for large tables and to use other methods for copying smaller tables.

1. Before you begin to transfer data, replicate the schema or schemas from the source cluster to the destination cluster. Options for copying the schema include:
   - Use the PostgreSQL pg_dump or pg_dumpall utility with the --schema-only option.
   - DDL scripts, or any other method for recreating schema in the destination database.

2. Divide the non-empty tables to be transferred into large and small categories, using criteria of your own choice. For example, you could decide large tables have more than one million rows or a raw data size greater than 1GB.

3. Transfer data for small tables using the SQL COPY command. This eliminates the warm-up/cool-down time each table incurs when using the gptransfer utility.
   - Optionally, write or reuse existing shell scripts to loop through a list of table names to copy with the COPY command.

4. Use gptransfer to transfer the large table data in batches of tables.
   - It is best to transfer to the same size cluster or to a larger cluster so that gptransfer runs in fast mode.
   - If any indexes exist, drop them before starting the transfer process.
   - Use the gptransfer table (-t) or file (-f) options to execute the migration in batches of tables. Do not run gptransfer using the full mode; the schema and smaller tables have already been transferred.
   - Perform test runs of the gptransfer process before the production migration. This ensures tables can be transferred successfully. You can experiment with the --batch-size and --sub-batch-size options to obtain maximum parallelism. Determine proper batching of tables for iterative gptransfer runs.
   - Include the --skip-existing option because the schema already exists on the destination cluster.
   - Use only fully qualified table names. Be aware that periods (.), whitespace, quotes (') and double quotes (") in table names may cause problems.
   - If you decide to use the --validation option to validate the data after transfer, be sure to also use the -x option to place an exclusive lock on the source table.

5. After all tables are transferred, perform the following tasks:
   - Check for and correct any failed transfers.
   - Recreate the indexes that were dropped before the transfer.
   - Ensure any roles, functions, and resource queues are created in the destination database. These objects are not transferred when you use the gptransfer -t option.
   - Copy the postgresql.conf and pg_hba.conf configuration files from the source to the destination cluster.
   - Install needed extensions in the destination database with gppkg.
Security

Best practices to ensure the highest level of system security.

Basic Security Best Practices

- Secure the $gpadmin$ system user. Greenplum requires a UNIX user id to install and initialize the Greenplum Database system. This system user is referred to as $gpadmin$ in the Greenplum documentation. The $gpadmin$ user is the default database superuser in Greenplum Database, as well as the file system owner of the Greenplum installation and its underlying data files. The default administrator account is fundamental to the design of Greenplum Database. The system cannot run without it, and there is no way to limit the access of the $gpadmin$ user id. This $gpadmin$ user can bypass all security features of Greenplum Database. Anyone who logs on to a Greenplum host with this user id can read, alter, or delete any data, including system catalog data and database access rights. Therefore, it is very important to secure the $gpadmin$ user id and only allow essential system administrators access to it. Administrators should only log in to Greenplum as $gpadmin$ when performing certain system maintenance tasks (such as upgrade or expansion). Database users should never log on as $gpadmin$, and ETL or production workloads should never run as $gpadmin$.
- Assign a distinct role to each user who logs in. For logging and auditing purposes, each user who is allowed to log in to Greenplum Database should be given their own database role. For applications or web services, consider creating a distinct role for each application or service. See "Creating New Roles (Users)" in the Greenplum Database Administrator Guide.
- Use groups to manage access privileges. See "Creating Groups (Role Membership)" in the Greenplum Database Administrator Guide.
- Limit users who have the SUPERUSER role attribute. Roles that are superusers bypass all access privilege checks in Greenplum Database, as well as resource queuing. Only system administrators should be given superuser rights. See "Altering Role Attributes" in the Greenplum Database Administrator Guide.

Password Strength Guidelines

To protect the network from intrusion, system administrators should verify the passwords used within an organization are strong ones. The following recommendations can strengthen a password:

- Minimum password length recommendation: At least 9 characters. MD5 passwords should be 15 characters or longer.
- Mix upper and lower case letters.
- Mix letters and numbers.
- Include non-alphanumeric characters.
- Pick a password you can remember.

The following are recommendations for password cracker software that you can use to determine the strength of a password.

- John The Ripper. A fast and flexible password cracking program. It allows the use of multiple word lists and is capable of brute-force password cracking. It is available online at http://www.openwall.com/john/.
- Crack. Perhaps the most well-known password cracking software, Crack is also very fast, though not as easy to use as John The Ripper. It can be found online at http://www.crypticide.com/alecm/security/crack/c50-faq.html.

The security of the entire system depends on the strength of the root password. This password should be at least 12 characters long and include a mix of capitalized letters, lowercase letters, special characters, and numbers. It should not be based on any dictionary word.

Password expiration parameters should be configured.
Ensure the following line exists within the file /etc/libuser.conf under the [import] section.

```
login_defs = /etc/login.defs
```

Ensure no lines in the [userdefaults] section begin with the following text, as these words override settings from /etc/login.defs:

- LU_SHADOWMAX
- LU_SHADOWMIN
- LU_SHADOWWARNING

Ensure the following command produces no output. Any accounts listed by running this command should be locked.

```
grep "^+:" /etc/passwd /etc/shadow /etc/group
```

Note: We strongly recommend that customers change their passwords after initial setup.

```
cd /etc
chown root:root passwd shadow group gshadow
chmod 644 passwd group
chmod 400 shadow gshadow
```

Find all the files that are world-writable and that do not have their sticky bits set.

```
find / -xdev -type d \( -perm -0002 -a ! -perm -1000 \) -print
```

Set the sticky bit (# chmod +t {dir}) for all the directories that result from running the previous command.

Find all the files that are world-writable and fix each file listed.

```
find / -xdev -type f -perm -0002 -print
```

Set the right permissions (# chmod o-w {file}) for all the files generated by running the aforementioned command.

Find all the files that do not belong to a valid user or group and either assign an owner or remove the file, as appropriate.

```
find / -xdev \( -nouser -o nogroup \) -print
```

Find all the directories that are world-writable and ensure they are owned by either root or a system account (assuming only system accounts have a User ID lower than 500). If the command generates any output, verify the assignment is correct or reassign it to root.

```
find / -xdev -type d -perm -0002 -uid +500 -print
```

Authentication settings such as password quality, password expiration policy, password reuse, password retry attempts, and more can be configured using the Pluggable Authentication Modules (PAM) framework. PAM looks in the directory /etc/pam.d for application-specific configuration information. Running authconfig or system-config-authentication will re-write the PAM configuration files, destroying any manually made changes and replacing them with system defaults.
The default `pam_cracklib` PAM module provides strength checking for passwords. To configure `pam_cracklib` to require at least one uppercase character, lowercase character, digit, and special character, as recommended by the U.S. Department of Defense guidelines, edit the file `/etc/pam.d/system-auth` to include the following parameters in the line corresponding to password requisite `pam_cracklib.so` try_first_pass.

<table>
<thead>
<tr>
<th>retry=3:</th>
</tr>
</thead>
<tbody>
<tr>
<td>dcredit=-1. Require at least one digit</td>
</tr>
<tr>
<td>ucredit=-1. Require at least one upper case character</td>
</tr>
<tr>
<td>ocredit=-1. Require at least one special character</td>
</tr>
<tr>
<td>lcredit=-1. Require at least one lower case character</td>
</tr>
<tr>
<td>minlen-14. Require a minimum password length of 14.</td>
</tr>
</tbody>
</table>

For example:

```bash
password required pam_cracklib.so try_first_pass retry=3
  dcredit=-1 ucredit=-1 ocredit=-1 lcredit=-1
  minlen=14
```

These parameters can be set to reflect your security policy requirements. Note that the password restrictions are not applicable to the root password.

The `pam_tally2` PAM module provides the capability to lock out user accounts after a specified number of failed login attempts. To enforce password lockout, edit the file `/etc/pam.d/system-auth` to include the following lines:

- The first of the auth lines should include:

  ```bash
  auth required pam_tally2.so deny=5 onerr=fail unlock_time=900
  ```

- The first of the account lines should include:

  ```bash
  account required pam_tally2.so
  ```

Here, the deny parameter is set to limit the number of retries to 5 and the `unlock_time` has been set to 900 seconds to keep the account locked for 900 seconds before it is unlocked. These parameters may be configured appropriately to reflect your security policy requirements. A locked account can be manually unlocked using the `pam_tally2` utility:

```bash
/sbin/pam_tally2 --user {username} -reset
```

You can use PAM to limit the reuse of recent passwords. The remember option for the `pam_unix` module can be set to remember the recent passwords and prevent their reuse. To accomplish this, edit the appropriate line in `/etc/pam.d/system-auth` to include the remember option.

For example:

```bash
password sufficient pam_unix.so [ ... existing_options ...]
  remember=5
```

You can set the number of previous passwords to remember to appropriately reflect your security policy requirements.

```bash
cd /etc
csh
chown root:root passwd shadow group gshadow
chmod 644 passwd group
chmod 400 shadow gshadow
```
Encrypting Data and Database Connections

Best practices for implementing encryption and managing keys.

Encryption can be used to protect data in a Greenplum Database system in the following ways:

• Connections between clients and the master database can be encrypted with SSL. This is enabled by setting the `ssl` server configuration parameter to `on` and editing the `pg_hba.conf` file. See "Encrypting Client/Server Connections" in the Greenplum Database Administrator Guide for information about enabling SSL in Greenplum Database.

• Greenplum Database 4.2.1 and above allow SSL encryption of data in transit between the Greenplum parallel file distribution server, `gpfdist`, and segment hosts. See Encrypting `gpfdist` Connections for more information.

• Network communications between hosts in the Greenplum Database cluster can be encrypted using IPSec. An authenticated, encrypted VPN is established between every pair of hosts in the cluster. Check your operating system documentation for IPSec support, or consider a third-party solution such as that provided by Zettaset.

• The `pgcrypto` module of encryption/decryption functions protects data at rest in the database. Encryption at the column level protects sensitive information, such as passwords, Social Security numbers, or credit card numbers. See Encrypting Data in Tables using PGP for an example.

Best Practices

• Encryption ensures that data can be seen only by users who have the key required to decrypt the data.

• Encrypting and decrypting data has a performance cost; only encrypt data that requires encryption.

• Do performance testing before implementing any encryption solution in a production system.

• Server certificates in a production Greenplum Database system should be signed by a certificate authority (CA) so that clients can authenticate the server. The CA may be local if all clients are local to the organization.

• Client connections to Greenplum Database should use SSL encryption whenever the connection goes through an insecure link.

• A symmetric encryption scheme, where the same key is used to both encrypt and decrypt, has better performance than an asymmetric scheme and should be used when the key can be shared safely.

• Use functions from the `pgcrypto` module to encrypt data on disk. The data is encrypted and decrypted in the database process, so it is important to secure the client connection with SSL to avoid transmitting unencrypted data.

• Use the `gpfdists` protocol to secure ETL data as it is loaded into or unloaded from the database. See Encrypting `gpfdist` Connections.

Key Management

Whether you are using symmetric (single private key) or asymmetric (public and private key) cryptography, it is important to store the master or private key securely. There are many options for storing encryption keys, for example, on a file system, key vault, encrypted USB, trusted platform module (TPM), or hardware security module (HSM).

Consider the following questions when planning for key management:

• Where will the keys be stored?

• When should keys expire?

• How are keys protected?

• How are keys accessed?

• How can keys be recovered and revoked?
The Open Web Application Security Project (OWASP) provides a very comprehensive guide to securing encryption keys.

Encrypting Data at Rest with pgcrypto

The pgcrypto module for Greenplum Database provides functions for encrypting data at rest in the database. Administrators can encrypt columns with sensitive information, such as social security numbers or credit card numbers, to provide an extra layer of protection. Database data stored in encrypted form cannot be read by users who do not have the encryption key, and the data cannot be read directly from disk.

pgcrypto is installed by default when you install Greenplum Database. You must explicitly enable pgcrypto in each database in which you want to use the module.

pgcrypto allows PGP encryption using symmetric and asymmetric encryption. Symmetric encryption encrypts and decrypts data using the same key and is faster than asymmetric encryption. It is the preferred method in an environment where exchanging secret keys is not an issue. With asymmetric encryption, a public key is used to encrypt data and a private key is used to decrypt data. This is slower than symmetric encryption and it requires a stronger key.

Using pgcrypto always comes at the cost of performance and maintainability. It is important to use encryption only with the data that requires it. Also, keep in mind that you cannot search encrypted data by indexing the data.

Before you implement in-database encryption, consider the following PGP limitations.

- No support for signing. That also means that it is not checked whether the encryption sub-key belongs to the master key.
- No support for encryption key as master key. This practice is generally discouraged, so this limitation should not be a problem.
- No support for several subkeys. This may seem like a problem, as this is common practice. On the other hand, you should not use your regular GPG/PGP keys with pgcrypto, but create new ones, as the usage scenario is rather different.

Greenplum Database is compiled with zlib by default; this allows PGP encryption functions to compress data before encrypting. When compiled with OpenSSL, more algorithms will be available.

Because pgcrypto functions run inside the database server, the data and passwords move between pgcrypto and the client application in clear-text. For optimal security, you should connect locally or use SSL connections and you should trust both the system and database administrators.

pgcrypto configures itself according to the findings of the main PostgreSQL configure script.

When compiled with zlib, pgcrypto encryption functions are able to compress data before encrypting.

Pgcrypto has various levels of encryption ranging from basic to advanced built-in functions. The following table shows the supported encryption algorithms.

Table 90: Pgcrypto Supported Encryption Functions

<table>
<thead>
<tr>
<th>Value</th>
<th>Built-in</th>

### Creating PGP Keys

To use PGP asymmetric encryption in Greenplum Database, you must first create public and private keys and install them.

This section assumes you are installing Greenplum Database on a Linux machine with the Gnu Privacy Guard (gpg) command line tool. Pivotal recommends using the latest version of GPG to create keys. Download and install Gnu Privacy Guard (GPG) for your operating system from https://www.gnupg.org/download/. On the GnuPG website you will find installers for popular Linux distributions and links for Windows and Mac OS X installers.

1. As root, execute the following command and choose option 1 from the menu:

   ```bash
   # gpg --gen-key
   gpg (GnuPG) 2.0.14; Copyright (C) 2009 Free Software Foundation, Inc.
   This is free software: you are free to change and redistribute it.
   There is NO WARRANTY, to the extent permitted by law.
   gpg: directory `/root/.gnupg' created
   gpg: new configuration file `/root/.gnupg/gpg.conf' created
   gpg: WARNING: options in `/root/.gnupg/gpg.conf' are not yet active during this run
   gpg: keyring `/root/.gnupg/secring.gpg' created
   gpg: keyring `/root/.gnupg/pubring.gpg' created
   Please select what kind of key you want:
   (1) RSA and RSA (default)
   (2) DSA and Elgamal
   (3) DSA (sign only)
   (4) RSA (sign only)
   Your selection? 1
   ```

2. Respond to the prompts and follow the instructions, as shown in this example:

   ```bash
   RSA keys may be between 1024 and 4096 bits long.
   What keysize do you want? (2048) Press enter to accept default key size
   Requested keysize is 2048 bits
   Please specify how long the key should be valid.
   0 = key does not expire
   <n> = key expires in n days
   <n>w = key expires in n weeks
   <n>m = key expires in n months
   <n>y = key expires in n years
   Key is valid for? (0) 365
   ```

---

<sup>7</sup> Any digest algorithm OpenSSL supports is automatically picked up. This is not possible with ciphers, which need to be supported explicitly.

<sup>8</sup> AES is included in OpenSSL since version 0.9.7. For older versions, pgcrypto will use built-in code.
Key expires at Wed 13 Jan 2016 10:35:39 AM PST
Is this correct? (y/N) y

GnuPG needs to construct a user ID to identify your key.

Real name: John Doe
Email address: jdoe@email.com
Comment:
You selected this USER-ID:
"John Doe <jdoe@email.com>"

Change (N)ame, (C)omment, (E)mail or (O)kay/(Q)uit? O
You need a Passphrase to protect your secret key.
(For this demo the passphrase is blank.)
can't connect to `/root/.gnupg/S.gpg-agent': No such file or directory
You don't want a passphrase - this is probably a *bad* idea!
I will do it anyway. You can change your passphrase at any time,
using this program with the option "--edit-key".

We need to generate a lot of random bytes. It is a good idea to perform
some other action (type on the keyboard, move the mouse, utilize the
disks) during the prime generation; this gives the random number
generator a better chance to gain enough entropy.
We need to generate a lot of random bytes. It is a good idea to perform

disks) during the prime generation; this gives the random number
generator a better chance to gain enough entropy.
gpg: /root/.gnupg/trustdb.gpg: trustdb created
gpg: key 2027CC30 marked as ultimately trusted
public and secret key created and signed.

gpg: checking the trustdb
  3 marginal(s) needed, 1 complete(s) needed, PGP trust model
gpg: depth: 0 valid: 1 signed: 0 trust: 0-, 0q, 0n, 0m, 0f, 1u

gpg: next trustdb check due at 2016-01-13
pub 2048R/2027CC30 2015-01-13 [expires: 2016-01-13]
  Key fingerprint = 7EDA 6AD0 F5E0 400F 4D45 3259 077D 725E 2027
  CC30
uid                  John Doe <jdoe@email.com>
sub 2048R/4FD2EFBB 2015-01-13 [expires: 2016-01-13]

3. List the PGP keys by entering the following command:

gpg --list-secret-keys
/root/.gnupg/secring.gpg
------------------------
sec   2048R/2027CC30 2015-01-13 [expires: 2016-01-13]
uid                  John Doe <jdoe@email.com>
sub   2048R/4FD2EFBB 2015-01-13

2027CC30 is the public key and will be used to encrypt data in the database. 4FD2EFBB is the private
(secret) key and will be used to decrypt data.

4. Export the keys using the following commands:

  # gpg -a --export 4FD2EFBB > public.key
  # gpg -a --export-secret-keys 2027CC30 > secret.key

See the pgcrypto documentation for for more information about PGP encryption functions.
Encrypting Data in Tables using PGP
This section shows how to encrypt data inserted into a column using the PGP keys you generated.

1. Dump the contents of the public.key file and then copy it to the clipboard:

```
# cat public.key
-----BEGIN PGP PUBLIC KEY BLOCK-----

=XZ8J
-----END PGP PUBLIC KEY BLOCK-----
```

2. Create a table called `userssn` and insert some sensitive data, social security numbers for Bob and Alice, in this example. Paste the public.key contents after "dearmor".

```
CREATE TABLE userssn( ssn_id SERIAL PRIMARY KEY, 
username varchar(100), ssn bytea);

INSERT INTO userssn(username, ssn) 
SELECT robotccs.username, pgp_pub_encrypt(robotccs.ssn, keys.pubkey) AS ssn 
FROM ( 
VALUES ('Alice', '123-45-6788'), ('Bob', '123-45-6799')) 
AS robotccs(username, ssn) 
CROSS JOIN (SELECT  dearmor('-----BEGIN PGP PUBLIC KEY BLOCK-----' AS pubkey) AS keys;
```

3. Verify that the `ssn` column is encrypted.

```
test_db=# select * from userssn;
ssn_id | 1
username | Alice
ssn    | 301\300L\003\235M\_O
| \322\357\273|001|010|000|272|227|010|341|216|360|217C|020|261|\_367
| (\127T\343|\313C\354d<\137\06Q\351(\"\330|031L|263Qf
\341\262|200|301V\235\036AK|242fL\+\315g\322
7\127T0\343|\361\355|220|021|\320*|200\264|274|B
\341\277\363\235|\366|030|233|364|\330|330T\237T\277=
\f |\015V0|04|242|\231|263|225|\032|271a|001|035|277|021|375x|232|304|305|
\340|334|031L|325f|344|\~362|0
37\251\336|303|340|377\_011L\275|301\M\334\343\245|244|372y\257S
\374V230|346|277|373W|346|230|276 |
017f\226Q\307|012|326|364|\000|326|005\:E\364W\252=zz\010\:343Y
\237\257i\u0326|350|v0\362|327|350\n```
4. Extract the public.key ID from the database:

```sql
SELECT pgp_key_id(dearmor('-----BEGIN PGP PUBLIC KEY BLOCK-----
Version: GnuPG v2.0.14 (GNU/Linux)
mQENBFS1Zf0BCADNWQvk1V1C36Kfcwd3Kpm/dijFryEyEw6PqKyA05jtWiXZTh2HislojSP6LI0cSKigMO9gLAnce29HiBhuVgK1Gsd9ttxg2nnSL9admqik/yX
R5syVKG+qcdWuvyZg9oOonemyjhc3n+kkbRTEMuM3f1bMs8shOwZmvstCUuMhu/V ...
WH+N2lasoUaoJjb2kQGhLoNfBjuevkyBylRz+hI/+8rJKcZOjQkmmK8HKk8q5b/5X
HMUC55Hq2qQAYOBpNJHgO0Q456pK3G/7Dbek5WJ6KiUrFy5laNIGW8pvgEx
/UUZBD+yQyCwtwX0nnBuiKnCMx2AkEcFK3YoliCxmOxhFOv9AKjojDyC65KJci
Pv2MiKPS2fKOAg1R3lpMa8zdET14wv3ckPQMrQnYuUtffj6ZoCvx
=XZ8J
-----END PGP PUBLIC KEY BLOCK-----'));
pgp_key_id | 9D4D255F4FD2EFBB
```

This shows that the PGP key ID used to encrypt the `ssn` column is 9D4D255F4FD2EFBB. It is recommended to perform this step whenever a new key is created and then store the ID for tracking.
You can use this key to see which key pair was used to encrypt the data:

```sql
SELECT username, pgp_key_id(ssn) AS key_used
FROM userrsn;
```

<table>
<thead>
<tr>
<th>username</th>
<th>key_used</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bob</td>
<td>9D4D255F4FD2E8BF</td>
</tr>
<tr>
<td>Alice</td>
<td>9D4D255F4FD2E8BF</td>
</tr>
</tbody>
</table>

**Note:** Different keys may have the same ID. This is rare, but is a normal event. The client application should try to decrypt with each one to see which fits — like handling ANYKEY. See `pgp_key_id()` in the pgcrypto documentation.

5. Decrypt the data using the private key.

```sql
SELECT username, pgp_pub_decrypt(ssn, keys.privkey) AS decrypted_ssn FROM userrsn
CROSS JOIN
(SELECT dearmor('-----BEGIN PGP PRIVATE KEY BLOCK-----
