  Moves temporary files to a new filespace or to the default location.

--movetransfilespace {filespace_name | default}
  Moves transaction files to a new filespace or to the default location.

  Warning: Do not move transaction files to a non-default location. Moving transaction files might cause data loss.

--showtempfilespace
  Show the name of the filespace currently associated with temporary files. This option checks that all primary and mirror segments, master and master standby are using the same filespace or temporary files. You will receive a warning message and an email if any inconsistencies exist.

--showtransfilespace
  Show the name of the filespace currently associated with transaction files. This option checks that all primary and mirror segments, master and master standby are using the same filespace or transaction files. You will receive a warning message and an email if any inconsistencies exist.

-v | --version (show utility version)
  Displays the version of this utility.

-? | --help (help)
  Displays the utility usage and syntax.

Connection Options

-h host | --host host
  The host name of the machine on which the Greenplum master database server is running. If not specified, reads from the environment variable PGHOST or defaults to localhost.

-p port | --port port
  The TCP port on which the Greenplum master database server is listening for connections. If not specified, reads from the environment variable PGPORT or defaults to 5432.

-U username | --username superuser_name
  The database superuser role name to connect as. If not specified, reads from the environment variable PGUSER or defaults to the current system user name. Only database superusers are allowed to create filespaces.

-W | --password
  Force a password prompt.

Examples

Create a filespace configuration file. You will be prompted to enter a name for the filespace, a master file system location, the primary segment file system locations, and the mirror segment file system locations. For example, if your configuration has 2 primary and 2 mirror segments per host, you will be prompted for a total of 5 locations (including the master). The file system locations must exist on all hosts in your system prior to running the gpfilespace utility:

```
$ gpfilespace -o .
```
Enter a name for this filespace
> fastdisk

Checking your configuration:

Your system has 2 hosts with 2 primary and 2 mirror segments per host.

Configuring hosts: [sdw1, sdw2]

Please specify 2 locations for the primary segments, one per line:
primary location 1> /gp_pri_filespc
primary location 2> /gp_pri_filespc

Please specify 2 locations for the mirror segments, one per line:
mirror location 1> /gp_mir_filespc
mirror location 2> /gp_mir_filespc

Enter a file system location for the master:
master location> /gp_master_filespc

Example filespace configuration file:

```
filespace:fastdisk
mdw:1:/gp_master_filespc/gp-1
sdw1:2:/gp_pri_filespc/gp0
sdw1:3:/gp_mir_filespc/gp1
sdw2:4:/gp_mir_filespc/gp0
sdw2:5:/gp_pri_filespc/gp1
```

Execute the configuration file to create the filespace in Greenplum Database:

```
$ gpfilespace -c gpfilespace_config_1
```

CREATE TABLESPACE in the Greenplum Database Reference Guide

**gpinitstandby**

Adds and/or initializes a standby master host for a Greenplum Database system.

**Synopsis**

```
gpinitstandby { -s standby_hostname [-P port]  
               [-F list_of_filespaces] | -r | -n }  
               [-a] [-q] [-D] [-l logfile_directory] 

gpinitstandby -v

gpinitstandby -?
```

**Description**

The gpinitstandby utility adds a backup, standby master host to your Greenplum Database system. If your system has an existing standby master host configured, use the -r option to remove it before adding the new standby master host.
Before running this utility, make sure that the Greenplum Database software is installed on the standby master host and that you have exchanged SSH keys between the hosts. It is recommended that the master port is set to the same port number on the master host and the backup master host.

This utility should be run on the currently active primary master host. See the Greenplum Database Installation Guide for instructions.

The utility performs the following steps:

- Updates the Greenplum Database system catalog to remove the existing standby master host information (if the \(-r\) option is supplied)
- Updates the Greenplum Database system catalog to add the new standby master host information
- Edits the `pg_hba.conf` file of the Greenplum Database master to allow access from the newly added standby master.
- Sets up the standby master instance on the alternate master host
- Starts the synchronization process

A backup, standby master host serves as a ‘warm standby’ in the event of the primary master host becoming non-operational. The standby master is kept up to date by transaction log replication processes (the `walsender` and `walreceiver`), which run on the primary master and standby master hosts and keep the data between the primary and standby master hosts synchronized. If the primary master fails, the log replication process is shut down, and the standby master can be activated in its place by using the `gpactivate standby` utility. Upon activation of the standby master, the replicated logs are used to reconstruct the state of the master host at the time of the last successfully committed transaction.

The activated standby master effectively becomes the Greenplum Database master, accepting client connections on the master port and performing normal master operations such as SQL command processing and resource management.

**Important:** If the `gpinitstandby` utility previously failed to initialize the standby master, you must delete the files in the standby master data directory before running `gpinitstandby` again. The standby master data directory is not cleaned up after an initialization failure because it contains log files that can help in determining the reason for the failure.

If an initialization failure occurs, a summary report file is generated in the standby host directory `/tmp`. The report file lists the directories on standby host that require clean up.

**Options**

- \(-a\) (do not prompt)
  - Do not prompt the user for confirmation.

- \(-D\) (debug)
  - Sets logging level to debug.

- \(-F list_of_filespaces\)
  - A list of filesystem names and the associated locations. Each filesystem name and its location is separated by a colon. If there is more than one file space name, each pair (name and location) is separated by a comma. For example:

  ```
  filesystem1_name:fs1_location,filesystem2_name:fs2_location
  ```

  If this option is not specified, `gpinitstandby` prompts the user for the filesystem names and locations.

  If the list is not formatted correctly or number of filesystems do not match the number of filesystems already created in the system, `gpinitstandby` returns an error.

- \(-l logfile_directory\)
  - The directory to write the log file. Defaults to `~/gpAdminLogs`.

- \(-n\) (restart standby master)
Specify this option to start a Greenplum Database standby master that has been configured but has stopped for some reason.

**-P port**
This option specifies the port that is used by the Greenplum Database standby master. The default is the same port used by the active Greenplum Database master.

If the Greenplum Database standby master is on the same host as the active master, the ports must be different. If the ports are the same for the active and standby master and the host is the same, the utility returns an error.

**-q (no screen output)**
Run in quiet mode. Command output is not displayed on the screen, but is still written to the log file.

**-r (remove standby master)**
Removes the currently configured standby master host from your Greenplum Database system.

**-s standby_hostname**
The host name of the standby master host.

**-v (show utility version)**
Displays the version, status, last updated date, and check sum of this utility.

**-? (help)**
Displays the online help.

**Examples**
Add a standby master host to your Greenplum Database system and start the synchronization process:

```
gpinitstandby -s host09
```

Start an existing standby master host and synchronize the data with the current primary master host:

```
gpinitstandby -n
```

**Note:** Do not specify the -n and -s options in the same command.

Add a standby master host to your Greenplum Database system specifying a different port:

```
gpinitstandby -s myhost -P 2222
```

If you specify the same host name as the active Greenplum Database master, the installed Greenplum Database software that is used as a standby master must be in a separate location from the active Greenplum Database master. Also, filesystem locations that are used by the standby master must be different than the filesystem locations used by the active Greenplum Database master.

Remove the existing standby master from your Greenplum system configuration:

```
gpinitstandby -r
```

**See Also**

`gpinitsystem, gpaddmirrors, gpactivatestandby`
gpinitsystem

Initializes a Greenplum Database system using configuration parameters specified in the gpinitsystem_config file.

Synopsis

    gpinitsystem -c cluster_configuration_file
               [-h hostfile_gpinitsystem]
               [-p postgresql_conf_param_file]
               [-s standby_master_host [-P standby_master_port]
                [-F standby_master_filespaces]]
               [-m number | --max_connections=number]
               [-b size | --shared_buffers=size]
               [-n locale | --locale=locale] [--lc-collate=locale]
               [--lc-ctype=locale] [--lc-messages=locale]
               [--lc-monetary=locale] [--lc-numeric=locale]
               [--lc-time=locale] [-e password | --su_password=password]
               [-I input_configuration_file]
               [-O output_configuration_file]

Description

The gpinitsystem utility creates a Greenplum Database instance or writes an input configuration file using the values defined in a cluster configuration file and any command-line options that you provide. See Initialization Configuration File Format for more information about the configuration file. Before running this utility, make sure that you have installed the Greenplum Database software on all the hosts in the array.

With the -O output_configuration_file option, gpinitsystem does not create a new database instance but instead writes all provided configuration information to the specified output file. This file uses the QD_PRIMARY_ARRAY and PRIMARY_ARRAY parameters to define each member using its hostname, port, data directory, segment prefix, segment ID, and content ID. Details of the array configuration can be modified as necessary to match values available in a Greenplum Database backup, or can simply be used to recreate the same cluster configuration at a later time. Configuration files that use QD_PRIMARY_ARRAY and PRIMARY_ARRAY must be passed into gpinitsystem using the -I input_configuration_file option. See Initialization Configuration File Format for more information.

In a Greenplum Database DBMS, each database instance (the master and all segments) must be initialized across all of the hosts in the system in such a way that they can all work together as a unified DBMS. The gpinitsystem utility takes care of initializing the Greenplum master and each segment instance, and configuring the system as a whole.

Before running gpinitsystem, you must set the $GPHOME environment variable to point to the location of your Greenplum Database installation on the master host and exchange SSH keys between all host addresses in the array using gpssh-exkeys.

This utility performs the following tasks:

• Verifies that the parameters in the configuration file are correct.
• Ensures that a connection can be established to each host address. If a host address cannot be reached, the utility will exit.
• Verifies the locale settings.
• Displays the configuration that will be used and prompts the user for confirmation.
• Initializes the master instance.
• Initializes the standby master instance (if specified).
• Initializes the primary segment instances.
• Initializes the mirror segment instances (if mirroring is configured).
• Configures the Greenplum Database system and checks for errors.
• Starts the Greenplum Database system.

Note: This utility uses secure shell (SSH) connections between systems to perform its tasks. In large Greenplum Database deployments, cloud deployments, or deployments with a large number of segments per host, this utility may exceed the host’s maximum threshold for unauthenticated connections. Consider updating the SSH MaxStartups and MaxSessions configuration parameters to increase this threshold. For more information about SSH configuration options, refer to the SSH documentation for your Linux distribution.

Options

-a
Do not prompt the user for confirmation.

-B parallel_processes
The number of segments to create in parallel. If not specified, the utility will start up to 4 parallel processes at a time.

-c cluster_configuration_file
Required. The full path and filename of the configuration file, which contains all of the defined parameters to configure and initialize a new Greenplum Database system. See Initialization Configuration File Format for a description of this file. You must provide either the -c cluster_configuration_file option or the -I input_configuration_file option to gpinitsystem.

-D
Sets log output level to debug.

-h hostfile_gpinitsystem
Optional. The full path and filename of a file that contains the host addresses of your segment hosts. If not specified on the command line, you can specify the host file using the MACHINE_LIST_FILE parameter in the gpinitsystem_config file.

-I input_configuration_file
The full path and filename of an input configuration file, which defines the Greenplum Database members and segments using the QD_PRIMARY_ARRAY and PRIMARY_ARRAY parameters. The input configuration file is typically created by using gpinitsystem with the -O output_configuration_file option. You must provide either the -c cluster_configuration_file option or the -I input_configuration_file option to gpinitsystem.

--locale=locale | -n locale
Sets the default locale used by Greenplum Database. If not specified, the LC_ALL, LC_COLLATE, or LANG environment variable of the master host determines the locale. If these are not set, the default locale is C (POSIX). A locale identifier consists of a language identifier and a region identifier, and optionally a character set encoding. For example, sv_SE is Swedish as spoken in Sweden, en_US is U.S. English, and fr_CA is French Canadian. If more than one character set can be useful for a locale, then the specifications look like this: en_US.UTF-8 (locale specification and character set encoding). On most systems, the command locale will show the locale environment settings and locale -a will show a list of all available locales.

--lc-collate=locale
Similar to --locale, but sets the locale used for collation (sorting data). The sort order cannot be changed after Greenplum Database is initialized, so it is important to choose a
collation locale that is compatible with the character set encodings that you plan to use for your data. There is a special collation name of \texttt{C} or \texttt{POSIX} (byte-order sorting as opposed to dictionary-order sorting). The \texttt{C} collation can be used with any character encoding.

\texttt{--lc-ctype=locale}  
Similar to \texttt{--locale}, but sets the locale used for character classification (what character sequences are valid and how they are interpreted). This cannot be changed after Greenplum Database is initialized, so it is important to choose a character classification locale that is compatible with the data you plan to store in Greenplum Database.

\texttt{--lc-messages=locale}  
Similar to \texttt{--locale}, but sets the locale used for messages output by Greenplum Database. The current version of Greenplum Database does not support multiple locales for output messages (all messages are in English), so changing this setting will not have any effect.

\texttt{--lc-monetary=locale}  
Similar to \texttt{--locale}, but sets the locale used for formatting currency amounts.

\texttt{--lc-numeric=locale}  
Similar to \texttt{--locale}, but sets the locale used for formatting numbers.

\texttt{--lc-time=locale}  
Similar to \texttt{--locale}, but sets the locale used for formatting dates and times.

\texttt{-l logfile_directory}  
The directory to write the log file. Defaults to \texttt{~/gpAdminLogs}.

\texttt{--max_connections=number | -m number}  
Sets the maximum number of client connections allowed to the master. The default is 250.

\texttt{-O output_configuration_file}  
When used with the \texttt{--} option, \texttt{gpinitsystem} does not create a new Greenplum Database cluster but instead writes the supplied cluster configuration information to the specified \texttt{output_configuration_file}. This file defines Greenplum Database members and segments using the \texttt{QD_PRIMARY_ARRAY}, \texttt{PRIMARY_ARRAY}, and \texttt{MIRROR_ARRAY} parameters, and can be later used with \texttt{-I input_configuration_file} to initialize a new cluster.

\texttt{-p postgresql_conf_param_file}  
Optional. The name of a file that contains \texttt{postgresql.conf} parameter settings that you want to set for Greenplum Database. These settings will be used when the individual master and segment instances are initialized. You can also set parameters after initialization using the \texttt{gpconfig} utility.

\texttt{-q}  
Run in quiet mode. Command output is not displayed on the screen, but is still written to the log file.

\texttt{--shared_buffers=size | -b size}  
Sets the amount of memory a Greenplum server instance uses for shared memory buffers. You can specify sizing in kilobytes (kB), megabytes (MB) or gigabytes (GB). The default is 125MB.

\texttt{-s standby_master_host}  
Optional. If you wish to configure a backup master host, specify the host name using this option. The Greenplum Database software must already be installed and configured on this host.

\texttt{-P standby_master_port}
Optional. If you configure a standby master host, specify its port number using this option. The Greenplum Database software must already be installed and configured on this host.

-F **standby_master_filespaces**

Optional. If you configure a standby master host, specify a list of filesystem names and the associated locations using this option. Each filesystem name and its location is separated by a colon. If there is more than one file space name, each pair (name and location) is separated by a comma. For example:

```
filesystem1_name:fs1_location,filesystem2_name:fs2_location
```

If this option is not specified, `gpinitstandby` prompts the user for the filesystem names and locations.

If the list is not formatted correctly or number of filesystems do not match the number of filesystems already created in the system, `gpinitstandby` returns an error.

--su_password=superuser_password | -e superuser_password

Use this option to specify the password to set for the Greenplum Database superuser account (such as `gpadmin`). If this option is not specified, the default password `gparray` is assigned to the superuser account. You can use the `ALTER ROLE` command to change the password at a later time.

Recommended security best practices:

- Do not use the default password option for production environments.
- Change the password immediately after installation.

-S

If mirroring parameters are specified, spreads the mirror segments across the available hosts. The default is to group the set of mirror segments together on an alternate host from their primary segment set. Mirror spreading places each mirror on a different host within the Greenplum Database array. Spreading is only allowed if the number of hosts is greater than the number of segment instances.

-v

Displays the version of this utility.

-h

Displays the online help.

# Initialization Configuration File Format

gpinitsystem requires a cluster configuration file with the following parameters defined. An example initialization configuration file can be found in `$GPHOME/docs/cli_help/gpconfigs/gpinitsystem_config`.

To avoid port conflicts between Greenplum Database and other applications, the Greenplum Database port numbers should not be in the range specified by the operating system parameter `net.ipv4.ip_local_port_range`. For example, if `net.ipv4.ip_local_port_range = 10000 65535`, you could set Greenplum Database base port numbers to these values.

```
PORT_BASE = 6000
MIRROR_PORT_BASE = 7000
REPLICATION_PORT_BASE = 8000
MIRROR_REPLICATION_PORT_BASE = 9000
```

**ARRAY_NAME**  

Required. A name for the array you are configuring. You can use any name you like. Enclose the name in quotes if the name contains spaces.
MACHINE_LIST_FILE

Optional. Can be used in place of the -h option. This specifies the file that contains the list of segment host address names that comprise the Greenplum Database system. The master host is assumed to be the host from which you are running the utility and should not be included in this file. If your segment hosts have multiple network interfaces, then this file would include all addresses for the host. Give the absolute path to the file.

SEG_PREFIX

Required. This specifies a prefix that will be used to name the data directories on the master and segment instances. The naming convention for data directories in a Greenplum Database system is SEG_PREFIXnumber where number starts with 0 for segment instances (the master is always -1). So for example, if you choose the prefix gpseg, your master instance data directory would be named gpseg-1, and the segment instances would be named gpseg0, gpseg1, gpseg2, gpseg3, and so on.

PORT_BASE

Required. This specifies the base number by which primary segment port numbers are calculated. The first primary segment port on a host is set as PORT_BASE, and then incremented by one for each additional primary segment on that host. Valid values range from 1 through 65535.

DATA_DIRECTORY

Required. This specifies the data storage location(s) where the utility will create the primary segment data directories. The number of locations in the list dictate the number of primary segments that will get created per physical host (if multiple addresses for a host are listed in the host file, the number of segments will be spread evenly across the specified interface addresses). It is OK to list the same data storage area multiple times if you want your data directories created in the same location. The user who runs gpinitsystem (for example, the gpadmin user) must have permission to write to these directories. For example, this will create six primary segments per host:

```
declare -a DATA_DIRECTORY=((-data1/primary /data1/primary
/data1/primary /data2/primary /data2/primary /data2/primary)
```

MASTER_HOSTNAME

Required. The host name of the master instance. This host name must exactly match the configured host name of the machine (run the hostname command to determine the correct hostname).

MASTER_DIRECTORY

Required. This specifies the location where the data directory will be created on the master host. You must make sure that the user who runs gpinitsystem (for example, the gpadmin user) has permissions to write to this directory.

MASTER_PORT

Required. The port number for the master instance. This is the port number that users and client connections will use when accessing the Greenplum Database system.

TRUSTED_SHELL

Required. The shell the gpinitsystem utility uses to execute commands on remote hosts. Allowed values are ssh. You must set up your trusted host environment before running the gpinitsystem utility (you can use gpssh-exkeys to do this).

CHECK_POINT_SEGMENTS

Required. Maximum distance between automatic write ahead log (WAL) checkpoints, in log file segments (each segment is normally 16 megabytes). This will set the checkpoint_segments parameter in the postgresql.conf file for each segment instance in the Greenplum Database system.
ENCODING
   Required. The character set encoding to use. This character set must be compatible with the --locale settings used, especially --lc-collate and --lc-ctype. Greenplum Database supports the same character sets as PostgreSQL.

DATABASE_NAME
   Optional. The name of a Greenplum Database database to create after the system is initialized. You can always create a database later using the CREATE DATABASE command or the createdb utility.

MIRROR_PORT_BASE
   Optional. This specifies the base number by which mirror segment port numbers are calculated. The first mirror segment port on a host is set as MIRROR_PORT_BASE, and then incremented by one for each additional mirror segment on that host. Valid values range from 1 through 65535 and cannot conflict with the ports calculated by PORT_BASE.

REPLICATION_PORT_BASE
   Optional. This specifies the base number by which the port numbers for the primary file replication process are calculated. The first replication port on a host is set as REPLICATION_PORT_BASE, and then incremented by one for each additional primary segment on that host. Valid values range from 1 through 65535 and cannot conflict with the ports calculated by PORT_BASE or MIRROR_PORT_BASE.

MIRROR_REPLICATION_PORT_BASE
   Optional. This specifies the base number by which the port numbers for the mirror file replication process are calculated. The first mirror replication port on a host is set as MIRROR_REPLICATION_PORT_BASE, and then incremented by one for each additional mirror segment on that host. Valid values range from 1 through 65535 and cannot conflict with the ports calculated by PORT_BASE, MIRROR_PORT_BASE, or REPLICATION_PORT_BASE.

MIRROR_DATA_DIRECTORY
   Optional. This specifies the data storage location(s) where the utility will create the mirror segment data directories. There must be the same number of data directories declared for mirror segment instances as for primary segment instances (see the DATA_DIRECTORY parameter). The user who runs gpinitsystem (for example, the gpadmin user) must have permission to write to these directories. For example:

```
declare -a MIRROR_DATA_DIRECTORY=(/data1/mirror /data1/mirror /data1/mirror /data2/mirror /data2/mirror)
```

QD_PRIMARY_ARRAY, PRIMARY_ARRAY, MIRROR_ARRAY
   These parameters can only be provided using an input configuration file, with the gpinitsystem -I input_configuration_file option. QD_PRIMARY_ARRAY, PRIMARY_ARRAY, and MIRROR_ARRAY define the Greenplum Database master host and the primary and mirror instances on the segment hosts, respectively, using the format:

```
host~port~data_directory/seg_prefix<segment_id>~dbid~content_id~replication_port
```

The Greenplum Database master always uses the value -1 for the segment ID and content ID. For example:

```
QD_PRIMARY_ARRAY=127.0.0.1~5432~/gpmaster/gpsne-1~1~-1~0
declare -a PRIMARY_ARRAY=(
  127.0.0.1~40000~/gpdata1/gpsne0~2~0~6000
  127.0.0.1~40001~/gpdata2/gpsne1~3~1~6001)
```
You can use the `gpinitsystem -O output_configuration_file` to populate `QD_PRIMARY_ARRAY`, `PRIMARY_ARRAY`, `MIRROR_ARRAY` using the hosts, data directories, segment prefix, and base port values that you provide to the command. For recovery purposes, you can edit the segment and content IDs to match the values of an existing Greenplum Database backup.

**HEAP_CHECKSUM**

Optional. This parameter specifies if checksums are enabled for heap data. When enabled, checksums are calculated for heap storage in all databases, enabling Greenplum Database to detect corruption in the I/O system. This option is set when the system is initialized and cannot be changed later.

The `HEAP_CHECKSUM` option is on by default and turning it off is strongly discouraged. If you set this option to off, data corruption in storage can go undetected and make recovery much more difficult.

To determine if heap checksums are enabled in a Greenplum Database system, you can query the `data_checksums` server configuration parameter with the `gpconfig` management utility:

```
$ gpconfig -s data_checksums
```

**HBA_HOSTNAMES**

Optional. This parameter controls whether `gpinitsystem` uses IP addresses or host names in the `pg_hba.conf` file when updating the file with addresses that can connect to Greenplum Database. The default value is 0, the utility uses IP addresses when updating the file. When initializing a Greenplum Database system, specify `HBA_HOSTNAMES=1` to have the utility use host names in the `pg_hba.conf` file.

For information about how Greenplum Database resolves host names in the `pg_hba.conf` file, see *Configuring Client Authentication*.

**Examples**

Initialize a Greenplum Database array by supplying a cluster configuration file and a segment host address file, and set up a spread mirroring (`-S`) configuration:

```
$ gpinitsystem -c gpinitsystem_config -h hostfile_gpinitsystem -S
```

Initialize a Greenplum Database array and set the superuser remote password:

```
$ gpinitsystem -c gpinitsystem_config -h hostfile_gpinitsystem --su-password=mypassword
```

Initialize a Greenplum Database array with an optional standby master host:

```
$ gpinitsystem -c gpinitsystem_config -h hostfile_gpinitsystem -s host09
```

Instead of initializing a Greenplum Database array, write the provided configuration to an output file. The output file uses the `QD_PRIMARY_ARRAY` and `PRIMARY_ARRAY` parameters to define master and segment hosts:

```
$ gpinitsystem -c gpinitsystem_config -h
```
Initialize a Greenplum Database using an input configuration file (a file that defines the Greenplum Database array using QD_PRIMARY_ARRAY and PRIMARY_ARRAY parameters):

```bash
$ gpinitsystem -I cluster_init.config
```

gpssh-exkeys, gpdeletesystem

gload

Runs a load job as defined in a YAML formatted control file.

#### Synopsis

```bash
gload -f control_file [-l log_file] [-h hostname] [-p port]
[-U username] [-d database] [-W] [--gpfdist_timeout seconds]
[--no_auto_trans] [--max_retries retry_times] [-v | -V | -q] [-D]

```

```
gload -?
gload --version
```

#### Requirements

The client machine where gload is executed must have the following:

- The `gpfdist` parallel file distribution program installed and in your $PATH. This program is located in $GPHOME/bin of your Greenplum Database server installation.
- Network access to and from all hosts in your Greenplum Database array (master and segments).
- Network access to and from the hosts where the data to be loaded resides (ETL servers).

#### Description

**gload** is a data loading utility that acts as an interface to the Greenplum Database external table parallel loading feature. Using a load specification defined in a YAML formatted control file, gload executes a load by invoking the Greenplum Database parallel file server (`gpfdist`), creating an external table definition based on the source data defined, and executing an `INSERT`, `UPDATE` or `MERGE` operation to load the source data into the target table in the database.

**Note:** `gpfdist` is compatible only with the Greenplum Database major version in which it is shipped. For example, a `gpfdist` utility that is installed with Greenplum Database 4.x cannot be used with Greenplum Database 5.x or 6.x.

**Note:** The Greenplum Database 5.22 and later gload for Linux is compatible with Greenplum Database 6.x. The Greenplum Database 6.x gload for both Linux and Windows is compatible with Greenplum 5.x.

**Note:** `MERGE` and `UPDATE` operations are not supported if the target table column name is a reserved keyword, has capital letters, or includes any character that requires quotes (" ") to identify the column.

The operation, including any SQL commands specified in the SQL collection of the YAML control file (see *Control File Format*), are performed as a single transaction to prevent inconsistent data when performing multiple, simultaneous load operations on a target table.
Options

- **f control_file**
  Required. A YAML file that contains the load specification details. See Control File Format.

--**gpfdist_timeout** seconds
Sets the timeout for the gpfdist parallel file distribution program to send a response.
Enter a value from 0 to 30 seconds (entering "0" to disables timeouts). Note that you might need to increase this value when operating on high-traffic networks.

- **l log_file**
  Specifies where to write the log file. Defaults to ~/$gpAdminLogs/gpload_YYYYMMDD. For more information about the log file, see Log File Format.

--**no_auto_trans**
Specify --no_auto_trans to disable processing the load operation as a single transaction if you are performing a single load operation on the target table.

By default, gpload processes each load operation as a single transaction to prevent inconsistent data when performing multiple, simultaneous operations on a target table.

- **q (no screen output)**
  Run in quiet mode. Command output is not displayed on the screen, but is still written to the log file.

- **D (debug mode)**
  Check for error conditions, but do not execute the load.

- **v (verbose mode)**
  Show verbose output of the load steps as they are executed.

- **V (very verbose mode)**
  Shows very verbose output.

- **? (show help)**
  Show help, then exit.

--**version**
Show the version of this utility, then exit.

Connection Options

- **d database**
  The database to load into. If not specified, reads from the load control file, the environment variable $PGDATABASE or defaults to the current system user name.

- **h hostname**
  Specifies the host name of the machine on which the Greenplum Database master database server is running. If not specified, reads from the load control file, the environment variable $PGHOST or defaults to localhost.

- **p port**
  Specifies the TCP port on which the Greenplum Database master database server is listening for connections. If not specified, reads from the load control file, the environment variable $PGPORT or defaults to 5432.

--**max_retries retry_times**
Specifies the maximum number of times gpload attempts to connect to Greenplum Database after a connection timeout. The default value is 0, do not attempt to connect after a connection timeout. A negative integer, such as -1, specifies an unlimited number of attempts.
-U username
   The database role name to connect as. If not specified, reads from the load control file, the environment variable $PGUSER or defaults to the current system user name.

-W (force password prompt)
   Force a password prompt. If not specified, reads the password from the environment variable $PGPASSWORD or from a password file specified by $PGPASSFILE or in ~/.pgpass. If these are not set, then gpload will prompt for a password even if -W is not supplied.

Control File Format
The gpload control file uses the YAML 1.1 document format and then implements its own schema for defining the various steps of a Greenplum Database load operation. The control file must be a valid YAML document.

The gpload program processes the control file document in order and uses indentation (spaces) to determine the document hierarchy and the relationships of the sections to one another. The use of white space is significant. White space should not be used simply for formatting purposes, and tabs should not be used at all.

The basic structure of a load control file is:

```yaml
---
VERSION: 1.0.0.1
DATABASE: db_name
USER: db_username
HOST: master_hostname
PORT: master_port
GPLOAD:
  INPUT:
    - SOURCE:
      LOCAL_HOSTNAME:
        - hostname_or_ip
      PORT: http_port
      | PORT_RANGE: [start_port_range, end_port_range]
    FILE:
      - /path/to/input_file
    SSL: true | false
    CERTIFICATES_PATH: /path/to/certificates
    - FULLY_QUALIFIED_DOMAIN_NAME: true | false
  COLUMNS:
    - field_name: data_type
  TRANSFORM: 'transformation'
  TRANSFORM_CONFIG: 'configuration-file-path'
  MAX_LINE_LENGTH: integer
  FORMAT: text | csv
  DELIMITER: 'delimiter_character'
  ESCAPE: 'escape_character' | 'OFF'
  NULL_AS: 'null_string'
  FORCE_NOT_NULL: true | false
  QUOTE: 'csv_quote_character'
  HEADER: true | false
  ENCODING: database_encoding
  ERROR_LIMIT: integer
  LOG_ERRORS: true | false
EXTERNAL:
  - SCHEMA: schema | '%'
OUTPUT:
  - TABLE: schema.table_name
  - MODE: insert | update | merge
  - MATCH_COLUMNS:
- `target_column_name`
- `UPDATE_COLUMNS`:
  - `target_column_name`
- `UPDATE_CONDITION`: 'boolean_condition'
- `MAPPING`:
  - `target_column_name`: `source_column_name` | 'expression'

**PRELOAD**:
- `TRUNCATE`: true | false
- `REUSE_TABLES`: true | false
- `STAGING_TABLE`: `external_table_name`
- `FAST_MATCH`: true | false

**SQL**:
- `BEFORE`: "sql_command"
- `AFTER`: "sql_command"

**VERSION**
Optional. The version of the `gpload` control file schema. The current version is 1.0.0.1.

**DATABASE**
Optional. Specifies which database in the Greenplum Database system to connect to. If not specified, defaults to `$PGDATABASE` if set or the current system user name. You can also specify the database on the command line using the `-d` option.

**USER**
Optional. Specifies which database role to use to connect. If not specified, defaults to the current user or `$PGUSER` if set. You can also specify the database role on the command line using the `-U` option.

If the user running `gpload` is not a Greenplum Database superuser, then the appropriate rights must be granted to the user for the load to be processed. See the `Greenplum Database Reference Guide` for more information.

**HOST**
Optional. Specifies Greenplum Database master host name. If not specified, defaults to localhost or `$PGHOST` if set. You can also specify the master host name on the command line using the `-h` option.

**PORT**
Optional. Specifies Greenplum Database master port. If not specified, defaults to 5432 or `$PGPORT` if set. You can also specify the master port on the command line using the `-p` option.

**GPLOAD**
Required. Begins the load specification section. A `GPLOAD` specification must have an `INPUT` and an `OUTPUT` section defined.

**INPUT**
Required. Defines the location and the format of the input data to be loaded. `gpload` will start one or more instances of the `gpfdist` file distribution program on the current host and create the required external table definition(s) in Greenplum Database that point to the source data. Note that the host from which you run `gpload` must be accessible over the network by all Greenplum Database hosts (master and segments).

**SOURCE**
Required. The `SOURCE` block of an `INPUT` specification defines the location of a source file. An `INPUT` section can have more than one `SOURCE` block defined. Each `SOURCE` block defined corresponds to one instance of the `gpfdist` file distribution program that will be started on the local machine. Each `SOURCE` block defined must have a `FILE` specification.

For more information about using the `gpfdist` parallel file server and single and multiple `gpfdist` instances, see "Loading and Unloading Data" in the `Greenplum Database Administrator Guide`. 
LOCAL_HOSTNAME
Optional. Specifies the host name or IP address of the local machine on which `gpload` is running. If this machine is configured with multiple network interface cards (NICs), you can specify the host name or IP of each individual NIC to allow network traffic to use all NICs simultaneously. The default is to use the local machine's primary host name or IP only.

PORT
Optional. Specifies the specific port number that the `gpfdist` file distribution program should use. You can also supply a PORT_RANGE to select an available port from the specified range. If both PORT and PORT_RANGE are defined, then PORT takes precedence. If neither PORT or PORT_RANGE are defined, the default is to select an available port between 8000 and 9000.

If multiple host names are declared in LOCAL_HOSTNAME, this port number is used for all hosts. This configuration is desired if you want to use all NICs to load the same file or set of files in a given directory location.

PORT_RANGE
Optional. Can be used instead of PORT to supply a range of port numbers from which `gpload` can choose an available port for this instance of the `gpfdist` file distribution program.

FILE
Required. Specifies the location of a file, named pipe, or directory location on the local file system that contains data to be loaded. You can declare more than one file so long as the data is of the same format in all files specified.

If the files are compressed using gzip or bzip2 (have a .gz or .bz2 file extension), the files will be uncompressed automatically (provided that gunzip or bunzip2 is in your path).

When specifying which source files to load, you can use the wildcard character (*) or other C-style pattern matching to denote multiple files. The files specified are assumed to be relative to the current directory from which `gpload` is executed (or you can declare an absolute path).

SSL
Optional. Specifies usage of SSL encryption. If SSL is set to true, `gpload` starts the `gpfdist` server with the --ssl option and uses the gpfdists:// protocol.

CERTIFICATES_PATH
Required when SSL is true; cannot be specified when SSL is false or unspecified. The location specified in CERTIFICATES_PATH must contain the following files:

- The server certificate file, server.crt
- The server private key file, server.key
- The trusted certificate authorities, root.crt

The root directory (/) cannot be specified as CERTIFICATES_PATH.

FULLY_QUALIFIED_DOMAIN_NAME
Optional. Specifies whether `gpload` resolve hostnames to the fully qualified domain name (FQDN) or the local hostname. If the value is set to true, names are resolved to the FQDN. If the value is set to false, resolution is to the local hostname. The default is false.

A fully qualified domain name might be required in some situations. For example, if the Greenplum Database system is in a different domain than an ETL application that is being accessed by `gpload`.

COLUMNS
Optional. Specifies the schema of the source data file(s) in the format of `field_name:data_type`. The `DELIMITER` character in the source file is what separates two data value fields (columns). A row is determined by a line feed character (0x0a).

If the input `COLUMNS` are not specified, then the schema of the output `TABLE` is implied, meaning that the source data must have the same column order, number of columns, and data format as the target table.

The default source-to-target mapping is based on a match of column names as defined in this section and the column names in the target `TABLE`. This default mapping can be overridden using the `MAPPING` section.

**TRANSFORM**

Optional. Specifies the name of the input transformation passed to `gpload`. For information about XML transformations, see "Loading and Unloading Data" in the *Greenplum Database Administrator Guide*.

**TRANSFORM_CONFIG**

Required when `TRANSFORM` is specified. Specifies the location of the transformation configuration file that is specified in the `TRANSFORM` parameter, above.

**MAX_LINE_LENGTH**

Optional. An integer that specifies the maximum length of a line in the XML transformation data passed to `gpload`.

**FORMAT**

Optional. Specifies the format of the source data file(s) - either plain text (`TEXT`) or comma separated values (`CSV`) format. Defaults to `TEXT` if not specified. For more information about the format of the source data, see "Loading and Unloading Data" in the *Greenplum Database Administrator Guide*.

**DELIMITER**

Optional. Specifies a single ASCII character that separates columns within each row (line) of data. The default is a tab character in TEXT mode, a comma in CSV mode. You can also specify a non-printable ASCII character or a non-printable unicode character, for example: "\x1B" or "\u001B". The escape string syntax, `E'character-code'`, is also supported for non-printable characters. The ASCII or unicode character must be enclosed in single quotes. For example: `E'\x1B'` or `E'\u001B'`.

**ESCAPE**

Specifies the single character that is used for C escape sequences (such as `\n`, `\t`, `\100`, and so on) and for escaping data characters that might otherwise be taken as row or column delimiters. Make sure to choose an escape character that is not used anywhere in your actual column data. The default escape character is a `\` (backslash) for text-formatted files and a `"` (double quote) for csv-formatted files, however it is possible to specify another character to represent an escape. It is also possible to disable escaping in text-formatted files by specifying the value `'OFF'` as the escape value. This is very useful for data such as text-formatted web log data that has many embedded backslashes that are not intended to be escapes.

**NULL_AS**

Optional. Specifies the string that represents a null value. The default is `\N` (backslash-N) in `TEXT` mode, and an empty value with no quotations in `CSV` mode. You might prefer an empty string even in `TEXT` mode for cases where you do not want to distinguish nulls from empty strings. Any source data item that matches this string will be considered a null value.

**FORCE_NOT_NULL**
Optional. In CSV mode, processes each specified column as though it were quoted and hence not a NULL value. For the default null string in CSV mode (nothing between two delimiters), this causes missing values to be evaluated as zero-length strings.

**QUOTE**

Required when **FORMAT** is **CSV**. Specifies the quotation character for **CSV** mode. The default is double-quote (").

**HEADER**

Optional. Specifies that the first line in the data file(s) is a header row (contains the names of the columns) and should not be included as data to be loaded. If using multiple data source files, all files must have a header row. The default is to assume that the input files do not have a header row.

**ENCODING**

Optional. Character set encoding of the source data. Specify a string constant (such as 'SQL_ASCII'), an integer encoding number, or 'DEFAULT' to use the default client encoding. If not specified, the default client encoding is used. For information about supported character sets, see the Greenplum Database Reference Guide.

**Note:** If you change the **ENCODING** value in an existing gpload control file, you must manually drop any external tables that were creating using the previous **ENCODING** configuration. gpload does not drop and recreate external tables to use the new **ENCODING** if **REUSE_TABLES** is set to true.

**ERROR_LIMIT**

Optional. Enables single row error isolation mode for this load operation. When enabled, input rows that have format errors will be discarded provided that the error limit count is not reached on any Greenplum Database segment instance during input processing. If the error limit is not reached, all good rows will be loaded and any error rows will either be discarded or captured as part of error log information. The default is to abort the load operation on the first error encountered. Note that single row error isolation only applies to data rows with format errors; for example, extra or missing attributes, attributes of a wrong data type, or invalid client encoding sequences. Constraint errors, such as primary key violations, will still cause the load operation to abort if encountered. For information about handling load errors, see “Loading and Unloading Data” in the Greenplum Database Administrator Guide.

**LOG_ERRORS**

Optional when **ERROR_LIMIT** is declared. Value is either true or false. The default value is false. If the value is true, rows with formatting errors are logged internally when running in single row error isolation mode. You can examine formatting errors with the Greenplum Database built-in SQL function gp_read_error_log('table_name'). If formatting errors are detected when loading data, gpload generates a warning message with the name of the table that contains the error information similar to this message.

```
| timestamp | WARN | 1 bad row, please use GPDB built-in function gp_read_error_log('table-name') to access the detailed error row |
```

If **LOG_ERRORS**: true is specified, **REUSE_TABLES**: true must be specified to retain the formatting errors in Greenplum Database error logs. If **REUSE_TABLES**: true is not specified, the error information is deleted after the gpload operation. Only summary information about formatting errors is returned. You can delete the formatting errors from the error logs with the Greenplum Database function gp_truncate_error_log().

**Note:** When gpfdist reads data and encounters a data formatting error, the error message includes a row number indicating the location of the formatting
error. gpfdist attempts to capture the row that contains the error. However, gpfdist might not capture the exact row for some formatting errors.

For more information about handling load errors, see "Loading and Unloading Data" in the Greenplum Database Administrator Guide. For information about the gp_read_error_log() function, see the CREATE EXTERNAL TABLE command in the Greenplum Database Reference Guide

EXTERNAL
Optional. Defines the schema of the external table database objects created by gpload. The default is to use the Greenplum Database search_path.

SCHEMA
Required when EXTERNAL is declared. The name of the schema of the external table. If the schema does not exist, an error is returned.

If % (percent character) is specified, the schema of the table name specified by TABLE in the OUTPUT section is used. If the table name does not specify a schema, the default schema is used.

OUTPUT
Required. Defines the target table and final data column values that are to be loaded into the database.

TABLE
Required. The name of the target table to load into.

MODE
Optional. Defaults to INSERT if not specified. There are three available load modes:

INSERT - Loads data into the target table using the following method:

    INSERT INTO target_table SELECT * FROM input_data;

UPDATE - Updates the UPDATE_COLUMNS of the target table where the rows have MATCH_COLUMNS attribute values equal to those of the input data, and the optional UPDATE_CONDITION is true. UPDATE is not supported if the target table column name is a reserved keyword, has capital letters, or includes any character that requires quotes (" ") to identify the column.

MERGE - Inserts new rows and updates the UPDATE_COLUMNS of existing rows where FOOBAR attribute values are equal to those of the input data, and the optional MATCH_COLUMNS is true. New rows are identified when the MATCH_COLUMNS value in the source data does not have a corresponding value in the existing data of the target table. In those cases, the entire row from the source file is inserted, not only the MATCH and UPDATE columns. If there are multiple new MATCH_COLUMNS values that are the same, only one new row for that value will be inserted. Use UPDATE_CONDITION to filter out the rows to discard. MERGE is not supported if the target table column name is a reserved keyword, has capital letters, or includes any character that requires quotes (" ") to identify the column.

MATCH_COLUMNS
Required if MODE is UPDATE or MERGE. Specifies the column(s) to use as the join condition for the update. The attribute value in the specified target column(s) must be equal to that of the corresponding source data column(s) in order for the row to be updated in the target table.

UPDATE_COLUMNS
Required if MODE is UPDATE or MERGE. Specifies the column(s) to update for the rows that meet the MATCH_COLUMNS criteria and the optional UPDATE_CONDITION.
UPDATE_CONDITION
Optional. Specifies a Boolean condition (similar to what you would declare in a \texttt{WHERE} clause) that must be met in order for a row in the target table to be updated (or inserted in the case of a \texttt{MERGE}).

MAPPING
Optional. If a mapping is specified, it overrides the default source-to-target column mapping. The default source-to-target mapping is based on a match of column names as defined in the source \texttt{COLUMNS} section and the column names of the target \texttt{TABLE}. A mapping is specified as either:

\begin{itemize}
\item \texttt{target_column_name: source_column_name}
\item \texttt{target_column_name: 'expression'}
\end{itemize}

Where \texttt{expression} is any expression that you would specify in the \texttt{SELECT} list of a query, such as a constant value, a column reference, an operator invocation, a function call, and so on.

PRELOAD
Optional. Specifies operations to run prior to the load operation. Right now the only preload operation is \texttt{TRUNCATE}.

TRUNCATE
Optional. If set to true, \texttt{gpload} will remove all rows in the target table prior to loading it. Default is false.

REUSE_TABLES
Optional. If set to true, \texttt{gpload} will not drop the external table objects and staging table objects it creates. These objects will be reused for future load operations that use the same load specifications. This improves performance of trickle loads (ongoing small loads to the same target table).

\textbf{Note}: If \texttt{LOG_ERRORS: true} is specified, \texttt{REUSE_TABLES: true} must be specified to retain the formatting errors in Greenplum Database error logs. If \texttt{REUSE_TABLES: true} is not specified, formatting error information is deleted after the \texttt{gpload} operation.

If the \texttt{external_table_name} exists, the utility uses the existing table. The utility returns an error if the existing table schema does not match the \texttt{OUTPUT} table schema.

STAGING_TABLE
Optional. Specify the name of the temporary external table that is created during a \texttt{gpload} operation. The external table is used by \texttt{gpfdist}. \texttt{REUSE_TABLES: true} must also be specified. If \texttt{REUSE_TABLES} is false or not specified, \texttt{STAGING_TABLE} is ignored. By default, \texttt{gpload} creates a temporary external table with a randomly generated name.

If \texttt{external_table_name} contains a period (.), \texttt{gpload} returns an error. If the table exists, the utility uses the table. The utility returns an error if the existing table schema does not match the \texttt{OUTPUT} table schema.

The utility uses the value of \texttt{SCHEMA} in the \texttt{EXTERNAL} section as the schema for \texttt{external_table_name}. If the \texttt{SCHEMA} value is \texttt{%}, the schema for \texttt{external_table_name} is the same as the schema of the target table, the schema of \texttt{TABLE} in the \texttt{OUTPUT} section.

If \texttt{SCHEMA} is not set, the utility searches for the table (using the schemas in the database \texttt{search_path}). If the table is not found, \texttt{external_table_name} is created in the default \texttt{PUBLIC} schema.

FAST_MATCH
Optional. If set to true, \texttt{gpload} only searches the database for matching external table objects when reusing external tables. The utility does not check the external table column
names and column types in the catalog table `pg_attribute` to ensure that the table can be used for a `gpload` operation. Set the value to true to improve `gpload` performance when reusing external table objects and the database catalog table `pg_attribute` contains a large number of rows. The utility returns an error and quits if the column definitions are not compatible.

The default value is false, the utility checks the external table definition column names and column types.

`REUSE_TABLES: true` must also be specified. If `REUSE_TABLES` is false or not specified and `FAST_MATCH: true` is specified, `gpload` returns a warning message.

**SQL**

Optional. Defines SQL commands to run before and/or after the load operation. You can specify multiple `BEFORE` and/or `AFTER` commands. List commands in the order of desired execution.

**BEFORE**

Optional. An SQL command to run before the load operation starts. Enclose commands in quotes.

**AFTER**

Optional. An SQL command to run after the load operation completes. Enclose commands in quotes.

**Log File Format**

Log files output by `gpload` have the following format:

```
timestamp| level | message
```

Where `timestamp` takes the form: `YYYY-MM-DD HH:MM:SS`, `level` is one of `DEBUG`, `LOG`, `INFO`, `ERROR`, and `message` is a normal text message.

Some `INFO` messages that may be of interest in the log files are (where `#` corresponds to the actual number of seconds, units of data, or failed rows):

```
INFO| running time: #.## seconds
INFO| transferred #.# kB of #.# kB.
INFO| gpload succeeded
INFO| gpload succeeded with warnings
INFO| gpload failed
INFO| 1 bad row
INFO| # bad rows
```

**Notes**

If your database object names were created using a double-quoted identifier (delimited identifier), you must specify the delimited name within single quotes in the `gpload` control file. For example, if you create a table as follows:

```
CREATE TABLE "MyTable" ("MyColumn" text);
```

Your YAML-formatted `gpload` control file would refer to the above table and column names as follows:

```
- COLUMNS:
  - "MyColumn": text
OUTPUT:
  - TABLE: public."MyTable"
```
If the YAML control file contains the `ERROR_TABLE` element that was available in Greenplum Database 4.3.x, `gpload` logs a warning stating that `ERROR_TABLE` is not supported, and load errors are handled as if the `LOG_ERRORS` and `REUSE_TABLE` elements were set to `true`. Rows with formatting errors are logged internally when running in single row error isolation mode.

**Examples**

Run a load job as defined in `my_load.yml`:

```
gpload -f my_load.yml
```

**Example load control file:**

```yaml
---
VERSION: 1.0.0.1
DATABASE: ops
USER: gpadmin
HOST: mdw-1
PORT: 5432
GPLOAD:
  INPUT:
    - SOURCE:
    - LOCAL_HOSTNAME:
      - etl1-1
      - etl1-2
      - etl1-3
      - etl1-4
    PORT: 8081
    FILE:
      - /var/load/data/*
  COLUMNS:
    - name: text
    - amount: float4
    - category: text
    - descr: text
    - date: date
  FORMAT: text
  DELIMITER: '|'
  ERROR_LIMIT: 25
  LOG_ERRORS: true
OUTPUT:
  - TABLE: payables.expenses
  - MODE: INSERT
PRELOAD:
  - REUSE_TABLES: true
SQL:
  - BEFORE: "INSERT INTO audit VALUES('start', current_timestamp)"
  - AFTER: "INSERT INTO audit VALUES('end', current_timestamp)"
```

**See Also**

`gpfdist`, `CREATE EXTERNAL TABLE` in the *Greenplum Database Reference Guide*

**gplogfilter**

Searches through Greenplum Database log files for specified entries.

**Synopsis**

```
gplogfilter [timestamp_options] [pattern_options]
```
**Description**

The `gplogfilter` utility can be used to search through a Greenplum Database log file for entries matching the specified criteria. If an input file is not supplied, then `gplogfilter` will use the `$MASTER_DATA_DIRECTORY` environment variable to locate the Greenplum master log file in the standard logging location. To read from standard input, use a dash (-) as the input file name. Input files may be compressed using `gzip`. In an input file, a log entry is identified by its timestamp in `YYYY-MM-DD [hh:mm[:ss]]` format.

You can also use `gplogfilter` to search through all segment log files at once by running it through the `gpssh` utility. For example, to display the last three lines of each segment log file:

```
gpssh -f seg_host_file
  => source /usr/local/greenplum-db/greenplum_path.sh
  => gplogfilter -n 3 /gpdata/*/pg_log/gpdb*.csv
```

By default, the output of `gplogfilter` is sent to standard output. Use the `-o` option to send the output to a file or a directory. If you supply an output file name ending in `.gz`, the output file will be compressed by default using maximum compression. If the output destination is a directory, the output file is given the same name as the input file.

**Options**

**Timestamp Options**

`-b` `datetime` | `--begin=datatime`

Specifies a starting date and time to begin searching for log entries in the format of `YYYY-MM-DD [hh:mm[:ss]]`.

If a time is specified, the date and time must be enclosed in either single or double quotes. This example encloses the date and time in single quotes:

```
gplogfilter -b '2013-05-23 14:33'
```

`-e` `datetime` | `--end=datatime`

Specifies an ending date and time to stop searching for log entries in the format of `YYYY-MM-DD [hh:mm[:ss]]`.

If a time is specified, the date and time must be enclosed in either single or double quotes. This example encloses the date and time in single quotes:

```
gplogfilter -e '2013-05-23 14:33'
```

`-d` `time` | `--duration=time`

Specifies a time duration to search for log entries in the format of `[hh][:mm][ss]`. If used without either the `-b` or `-e` option, will use the current time as a basis.

**Pattern Matching Options**

`-c` [ignore] | [espect] | `--case=i` [ignore] | r [espect]

Matching of alphabetic characters is case sensitive by default unless proceeded by the `--case=ignore` option.

`-C` `'string'` | `--columns='string'`
Selects specific columns from the log file. Specify the desired columns as a comma-delimited string of column numbers beginning with 1, where the second column from left is 2, the third is 3, and so on. See "Viewing the Database Server Log Files" in the Greenplum Database Administrator Guide for details about the log file format and for a list of the available columns and their associated number.

- **f 'string' | --find='string'**
  Finds the log entries containing the specified string.

- **F 'string' | --nofind='string'**
  Rejects the log entries containing the specified string.

- **m regex | --match=regex**
  Finds log entries that match the specified Python regular expression. See https://docs.python.org/library/re.html for Python regular expression syntax.

- **M regex | --nomatch=regex**
  Rejects log entries that match the specified Python regular expression. See https://docs.python.org/library/re.html for Python regular expression syntax.

- **t | --trouble**
  Finds only the log entries that have ERROR:, FATAL:, or PANIC: in the first line.

**Output Options**

- **n integer | --tail=integer**
  Limits the output to the last integer of qualifying log entries found.

- **s offset [limit] | --slice=offset [limit]**
  From the list of qualifying log entries, returns the limit number of entries starting at the offset entry number, where an offset of zero (0) denotes the first entry in the result set and an offset of any number greater than zero counts back from the end of the result set.

- **o output_file | --out=output_file**
  Writes the output to the specified file or directory location instead of STDOUT.

- **z 0–9 | --zip=0–9**
  Compresses the output file to the specified compression level using gzip, where 0 is no compression and 9 is maximum compression. If you supply an output file name ending in .gz, the output file will be compressed by default using maximum compression.

- **a | --append**
  If the output file already exists, appends to the file instead of overwriting it.

**Input Options**

- **input_file**
  The name of the input log file(s) to search through. If an input file is not supplied, gplogfilter will use the $MASTER_DATA_DIRECTORY environment variable to locate the Greenplum Database master log file. To read from standard input, use a dash (-) as the input file name.

- **u | --unzip**
  Uncompress the input file using gunzip. If the input file name ends in .gz, it will be uncompressed by default.

- **--help**
  Displays the online help.

- **--version**
  Displays the version of this utility.
Examples
Display the last three error messages in the master log file:

```
gplogfilter -t -n 3
```

Display all log messages in the master log file timestamped in the last 10 minutes:

```
gplogfilter -d :10
```

Display log messages in the master log file containing the string `|con6 cmd11|`:

```
gplogfilter -f '|con6 cmd11|'
```

Using `gpssh`, run `gplogfilter` on the segment hosts and search for log messages in the segment log files containing the string `con6` and save output to a file.

```
gpssh -f seg_hosts_file -e 'source /usr/local/greenplum-db/greenplum_path.sh ; gplogfilter -f con6 /gpdata/*/pg_log/gpdb*.csv' > seglog.out
```

See Also
`gpssh, gpscp`

gpmapreduce

Runs Greenplum MapReduce jobs as defined in a YAML specification document.

Synopsis

```
gpmapreduce -f yaml_file [dbname [username]]

[-k name=value | --key name=value]
[-h hostname | --host hostname] [-p port | --port port]
[-U username | --username username] [-W] [-v]
```

```
gpmapreduce -x | --explain
```

```
gpmapreduce -X | --explain-analyze
```

```
gpmapreduce -V | --version
```

```
gpmapreduce -h | --help
```

Prerequisites
The following are required prior to running this program:

- You must have your MapReduce job defined in a YAML file. See the Greenplum MapReduce Specification in the Greenplum Database Reference Guide for more information.
- You must be a Greenplum Database superuser to run MapReduce jobs written in untrusted Perl or Python.
- You must be a Greenplum Database superuser to run MapReduce jobs with EXEC and FILE inputs.
- You must be a Greenplum Database superuser to run MapReduce jobs with GPFDIST input unless the user has the appropriate rights granted. See the Greenplum Database Reference Guide for more information.
Description

MapReduce is a programming model developed by Google for processing and generating large data sets on an array of commodity servers. Greenplum MapReduce allows programmers who are familiar with the MapReduce paradigm to write map and reduce functions and submit them to the Greenplum Database parallel engine for processing.

In order for Greenplum to be able to process MapReduce functions, the functions need to be defined in a YAML document, which is then passed to the Greenplum MapReduce program, gpmapreduce, for execution by the Greenplum Database parallel engine. The Greenplum system takes care of the details of distributing the input data, executing the program across a set of machines, handling machine failures, and managing the required inter-machine communication.

Options

-f yaml_file
   Required. The YAML file that contains the Greenplum MapReduce job definitions. See the Greenplum Database Reference Guide.

-? | --help
   Show help, then exit.

-v | --version
   Show version information, then exit.

-v | --verbose
   Show verbose output.

-x | --explain
   Do not run MapReduce jobs, but produce explain plans.

-X | --explain-analyze
   Run MapReduce jobs and produce explain-analyze plans.

-k | --keyname=value
   Sets a YAML variable. A value is required. Defaults to "key" if no variable name is specified.

Connection Options

-h host | --host host
   Specifies the host name of the machine on which the Greenplum master database server is running. If not specified, reads from the environment variable PGHOST or defaults to localhost.

-p port | --port port
   Specifies the TCP port on which the Greenplum master database server is listening for connections. If not specified, reads from the environment variable PGPORT or defaults to 5432.

-U username | --username username
   The database role name to connect as. If not specified, reads from the environment variable PGUSER or defaults to the current system user name.

-W | --password
   Force a password prompt.

Examples

Run a MapReduce job as defined in my_yaml.txt and connect to the database mydatabase:

    gpmapreduce -f my_yaml.txt mydatabase
See Also
Greenplum MapReduce specification in the *Greenplum Database Reference Guide*

gpmfr

Manages the Greenplum Database backup images that are stored on a local Data Domain system and a remote Data Domain system that is used for disaster recovery. Managed file replication is used for disaster recovery by the Data Domain Boost software option to transfer a backup image from one Data Domain system to another.

Synopsis

```
gpmfr --delete {LATEST | OLDEST | timestamp}[--remote]
    [--master-port=master_port] [--skip-ping]
    [--ddboost-storage-unit=unit-ID]
    [-a] [-v | --verbose]

gpmfr {--replicate | --recover} {LATEST | OLDEST | timestamp}
    --max-streams max_IO_streams [--master-port master_port] [--skip-ping]
    [--ddboost-storage-unit=unit-ID]
    [-a] [-q | --quiet] [-v | --verbose]

gpmfr {--list {LATEST | OLDEST | timestamp} }
    [--ddboost-storage-unit=unit-ID]
    [--master-port=master_port] [--remote] [--skip-ping]
    [-v | --verbose]

gpmfr --list-files {LATEST | OLDEST | timestamp}
    [--ddboost-storage-unit=unit-ID]
    [--master-port=master_port] [--remote] [--skip-ping]
    [-v | --verbose]

gpmfr --show-streams [--skip-ping] [-v | --verbose]

gpmfr -h | --help

gpmfr --version
```

Prerequisites

The Data Domain systems that are used as local and remote backup systems for managed file replication must have Data Domain Boost and Replicator enabled.

The Greenplum Database master host must be able to connect to both the local Data Domain system and the remote Data Domain system.

The login credentials for the local and remote Data Domain systems must be configured on the Greenplum master host with the `gpcrondump` utility. See "Backing Up and Restoring Databases" in the *Greenplum Database Administrator Guide* for information about setting up Data Domain systems for use with Greenplum Database.

See the *Greenplum Database Release Notes* for information about the supported version of Data Domain Boost.

Description

The *gpmfr* utility provides these capabilities:

- Lists the backup data sets that are on the local or the remote Data Domain system.
- Replicates a backup data set that is on the local Data Domain system to the remote system.
• Recovers a backup data set that is on the remote Data Domain system to the local system.
• Deletes a backup data set that is on the local or the remote Data Domain system.

The Greenplum Database backup sets are identified by timestamps (yyyymmddhhmmss).

gpmfr attempts to schedule the replication task for the files in backup data set. It ensures that the limit on the maximum number of I/O streams used for replication is never exceeded. The I/O streams limit is set with the --max-streams option that accompanies the --replicate or --recover option.

When cancelling a replication operation, gpmfr kills all active replication processes and cleans up all the files on replication Data Domain system.

Options

-a
Do not prompt the user for confirmation. Progress information is displayed on the output. Specify the option -q or --quiet to write progress information to the log file.

--ddboost-storage-unit=unit-ID
Optional. Specify a valid storage unit ID for the Data Domain system that is used for the gpmfr operation. A replicate or recover operation uses the same storage unit ID on both local and remote Data Domain systems. If the storage unit on the destination Data Domain system (where the backup is being copied) is created if it does not exist.

If this option is not specified, the utility uses the storage unit specified when configuring the DD Boost credentials or the default ID GPDB.

--delete {LATEST | OLDEST | timestamp}
Deletes a Greenplum Database backup set from the local Data Domain system. Specify the option --remote to delete the backup set from the remote Data Domain system.
LATEST specifies deleting the latest backup set (first in chronological order).
OLDEST specifies deleting the backup set that is oldest in chronological order.
timestamp specifies deleting the Greenplum Database backup set identified by the timestamp.

--list
Lists the Greenplum Database backup sets that are on the local Data Domain system. The backup sets are identified by timestamps (yyyymmddhhmmss).
Specify the option --remote to list the Greenplum Database backup sets that are on the remote Data Domain system.

--list-files {LATEST | OLDEST | timestamp}
Lists the files in a Greenplum Database backup that is on the local Data Domain system. Specify the option --remote to list the files in the backup set that is on the remote Data Domain system.
LATEST specifies listing the files in the latest backup set (first in chronological order).
OLDEST specifies listing the files in the backup set that is oldest in chronological order.
timestamp specifies listing the file in the backup set identified by the timestamp.

--master-port=master_port
Specifies the Greenplum Database master port number. To validate backup sets, the utility retrieves information from the Greenplum Database instance that uses the port number. If the option is not specified, the default value is 5432.

If gpmfr does not find a Greenplum Database, validation is skipped and a warning is displayed.

--max-streams max_IO_streams
Specifies the maximum number of Data Domain I/O streams that can be used when copying the backup set between the local and remote Data Domain systems.

-q | --quiet
Runs in quiet mode. File transfer progress information is not displayed on the output, it is written to the log file. If this option is not specified, progress information is only displayed on screen, it is not written to the log file.

--recover {LATEST | OLDEST | timestamp}
Recovers a Greenplum Database backup set that is available on the remote Data Domain system to the local system.
LATEST specifies recovering the most recent backup set (first in chronological order).
OLDEST specifies recovering the backup set that is oldest in chronological order.
timestamp specifies recovering the backup set identified by the timestamp.
If a backup set with the same timestamp exists on local Data Domain system, the utility prompts you to confirm replacing the backup.
A progress bar indicating transfer status of the backup set is shown on shown at the output.

--replicate {LATEST | OLDEST | timestamp}
Replicates a Greenplum Database backup set that is on the local Data Domain system to the remote system.
LATEST specifies replicating the most recent backup set (first in chronological order).
OLDEST specifies replicating the backup set that is oldest in chronological order.
timestamp specifies replicating the backup set identified by the timestamp.
If a backup set with the same timestamp exists on remote Data Domain system, the utility prompts you to confirm replacing the backup.
A progress bar indicating transfer status of the backup set is shown at the output.
A backup set must be completely backed up to the local Domain system before it can be replicated to the remote Data Domain system.

--remote
Perform the operation on the remote Data Domain system that is used for disaster recovery.
For example, gpmfr --list lists the backup sets that are on the local Data Domain system that is used to back up Greenplum Database. gpmfr --list --remote lists the backup sets that are on the remote system.

--show-streams
Displays the replication I/O stream soft limit and the number of I/O streams that are in use.

--skip-ping
Specify this option to skip the ping of a Data Domain system. gpmfr uses ping to ensure that the Data Domain system is reachable. If the Data Domain host is configured to block ICMP ping probes, specify this option to skip the ping of the Data Domain system.

-h | --help
Displays the online help.

-v | --verbose
Specifies verbose logging mode. Additional log information is written to the log file during command execution.

--version
Displays the version of this utility.

Example
The following example replicates the latest backup set on the local Data Domain server to the remote server. The maximum number of I/O streams that can be used for the replication is 30.

```
gpmfr --replicate LATEST --max-streams 30
```

`gpcrondump, gpdbrestore`

**gpmovemirrors**

Moves mirror segment instances to new locations.

**Synopsis**

```
gpmovemirrors -i move_config_file [-d master_data_directory]
   [-l logfile_directory]
   [-B parallel_processes] [-v]
gpmovemirrors -?
gpmovemirrors --version
```

**Description**

The `gpmovemirrors` utility moves mirror segment instances to new locations. You may want to move mirrors to new locations to optimize distribution or data storage.

Before moving segments, the utility verifies that they are mirrors, and that their corresponding primary segments are up and are in synchronizing or resynchronizing mode.

By default, the utility will prompt you for the file system location(s) where it will move the mirror segment data directories.

You must make sure that the user who runs `gpmovemirrors` (the `gpadmin` user) has permissions to write to the data directory locations specified. You may want to create these directories on the segment hosts and `chown` them to the appropriate user before running `gpmovemirrors`.

**Options**

- `-B parallel_processes`
  The number of mirror segments to move in parallel. If not specified, the utility will start up to 4 parallel processes depending on how many mirror segment instances it needs to move.

- `-d master_data_directory`
  The master data directory. If not specified, the value set for `$MASTER_DATA_DIRECTORY` will be used.

- `-i move_config_file`
  A configuration file containing information about which mirror segments to move, and where to move them.

  You must have one mirror segment listed for each primary segment in the system. Each line inside the configuration file has the following format (as per attributes in the
gp_segment_configuration, pg_filespace, and pg_filespace_entry catalog
tables):

```
filespaceOrder=[filespace1_fsname:[filespace2_fsname:...]
old_address:port:fseolocation
[new_address:port:replication_port:fseolocation:[fseolocation:...]]
```

Note that you only need to specify a name for `filespaceOrder` if your system has
multiple filesystems configured. If your system does not have additional filesystems
configured besides the default `pg_system` filesystem, this file will only have one location
(for the default data directory filesystem, `pg_system`). `pg_system` does not need to
be listed in the `filespaceOrder` line. It will always be the first `fseolocation` listed after
`replication_port`.

```
-l logfile_directory
```
The directory to write the log file. Defaults to `~/gpAdminLogs`.

```
-v (verbose)
```
Sets logging output to verbose.

```
--version (show utility version)
```
Displays the version of this utility.

```
-? (help)
```
Displays the online help.

**Examples**

Moves mirrors from an existing Greenplum Database system to a different set of hosts:

```
$ gpmovemirrors -i move_config_file
```
Where the `move_config_file` looks something like this (if you do not have additional filesystems
configured besides the default `pg_system` filesystem):

```
filespaceOrder=filespacea
sdw1-1:61001:/data/mirrors/database/dbfast22/gp1
sdw2-1:61001:43001:/data/mirrors/database/dbfast22/gp1:
/data/mirrors/database/dbfast22fs1
```

**gpperfmon_install**

Installs the `gpperfmon` database, which is used by Greenplum Command Center, and optionally enables
the data collection agents.

**Synopsis**

```
gpperfmon_install --port gpdb_port
                [--enable --password gpmon_password [--pgpass path_to_file]]
                [--verbose]
gpperfmon_install --help | -h | -?
```

**Description**

The `gpperfmon_install` utility automates the steps required to enable the data collection agents.
You must be the Greenplum Database system user (`gpadmin`) to run this utility. The `--port` option is
required. When using the `--enable` option, the `--password` option is also required. Use the `--port`
option to supply the port of the Greenplum Database master instance. If using the --enable option, Greenplum Database must be restarted after the utility completes.

When run without the --enable option, the utility just creates the gpperfmon database (the database used to store system metrics collected by the data collection agents). When run with the --enable option, the utility also runs the following additional tasks necessary to enable the performance monitor data collection agents:

1. Creates the gpmon superuser role in Greenplum Database. The data collection agents require this role to connect to the database and write their data. The gpmon superuser role uses MD5-encrypted password authentication by default. Use the --password option to set the gpmon superuser's password.

2. Updates the $MASTER_DATA_DIRECTORY/pg_hba.conf file. The utility adds these lines to the host-based authentication file (pg_hba.conf):

<p>| | | | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>local</td>
<td>gpperfmon</td>
<td>gpmon</td>
<td>md5</td>
</tr>
<tr>
<td>host all</td>
<td>gpmon</td>
<td>127.0.0.1/28</td>
<td>md5</td>
</tr>
<tr>
<td>host all</td>
<td>gpmon</td>
<td>::1/128</td>
<td>md5</td>
</tr>
</tbody>
</table>

The second and third lines, the host entries, give gpmon access to all Greenplum Database databases.

Note: It might be necessary to edit the lines in the pg_hba.conf file after running the gpperfmon_install utility to limit the gpmon role's access to databases or to change the authentication method. After you edit the file, run gpstop -u to reload the file in Greenplum Database.

- To limit gpmon access to just the gpperfmon database, edit the host entries in the pg_hba.conf file. For the gpmon user change the second field from all to gpperfmon:

<p>| | | | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>local</td>
<td>gpperfmon</td>
<td>gpmon</td>
<td>md5</td>
</tr>
<tr>
<td>host all</td>
<td>gpmon</td>
<td>127.0.0.1/28</td>
<td>md5</td>
</tr>
<tr>
<td>host all</td>
<td>gpmon</td>
<td>::1/128</td>
<td>md5</td>
</tr>
</tbody>
</table>

- The gpperfmon_install utility assumes the default MD5 authentication method. Greenplum Database can optionally be configured to use the SHA-256 hash algorithm to compute the password hashes saved in the system catalog. This is incompatible with the MD5 authentication method, which expects an MD5 hash or clear text password in the system catalog. Because of this, if you have enabled the SHA-256 hash algorithm in the database, you must edit the pg_hba.conf file after running the gpperfmon_install utility. For the host entries, change the authentication method for the gpmon role from md5 to password:

<p>| | | | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>local</td>
<td>gpperfmon</td>
<td>gpmon</td>
<td>md5</td>
</tr>
<tr>
<td>host all</td>
<td>gpmon</td>
<td>127.0.0.1/28</td>
<td>md5</td>
</tr>
<tr>
<td>host all</td>
<td>gpmon</td>
<td>::1/128</td>
<td>password</td>
</tr>
</tbody>
</table>

The password authentication method submits the user's clear text password for authentication and should not be used on an untrusted network. See "Protecting Passwords in Greenplum Database" in the Greenplum Database Administrator Guide for more information about configuring password hashing.

3. Updates the password file (.pgpass). In order to allow the data collection agents to connect as the gpmon role without a password prompt, you must have a password file that has an entry for the gpmon user. The utility adds the following entry to your password file (if the file does not exist, the utility will create it):

*:5432:gpperfmon:gpmon:gpmon_password
If your password file is not located in the default location (~/.pgpass), use the --pgpass option to specify the file location.

4. Sets the server configuration parameters for Greenplum Command Center. The following parameters must be enabled for the data collection agents to begin collecting data. The utility sets the following parameters in the Greenplum Database postgresql.conf configuration files:
   - gp_enable_gpperfmon=on (in all postgresql.conf files)
   - gpperfmon_port=8888 (in all postgresql.conf files)
   - gp_external_enable_exec=on (in the master postgresql.conf file)

Data collection agents can be configured by setting parameters in the gpperfmon.conf configuration file. See Data Collection Agent Configuration for details.

For information about Greenplum Command Center, see the Greenplum Command Center Documentation.

Options
--enable
In addition to creating the gpperfmon database, performs the additional steps required to enable the data collection agents. When --enable is specified the utility will also create and configure the gpmon superuser account and set the Command Center server configuration parameters in the postgresql.conf files.

--password gpmon_password
Required if --enable is specified. Sets the password of the gpmon superuser. Disallowed if --enable is not specified.

--port gpdb_port
Required. Specifies the connection port of the Greenplum Database master.

--pgpass path_to_file
Optional if --enable is specified. If the password file is not in the default location of ~/.pgpass, specifies the location of the password file.

--verbose
Sets the logging level to verbose.

--help | -h | -?
Displays the online help.

Data Collection Agent Configuration

The $MASTER_DATA_DIRECTORY/gpperfmon/conf/gpperfmon.conf file stores configuration parameters for the data collection agents. For configuration changes to these options to take effect, you must save gpperfmon.conf and then restart Greenplum Database server (gpstop -r).

The gpperfmon.conf file contains the following configuration parameters.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>log_location</td>
<td>Specifies a directory location for gpperfmon log files. Default is $MASTER_DATA_DIRECTORY/gpperfmon/logs.</td>
</tr>
<tr>
<td>min_query_time</td>
<td>Specifies the minimum query run time in seconds for statistics collection. All queries that run longer than this value are logged in the queries_history table. For queries with shorter</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
</tr>
<tr>
<td>---------------</td>
<td>-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>run times</td>
<td>run times, no historical data is collected. Defaults to 20 seconds. If you know that you want to collect data for all queries, you can set this parameter to a low value. Setting the minimum query run time to zero, however, collects data even for the numerous queries run by Greenplum Command Center, creating a large amount of data that may not be useful.</td>
</tr>
<tr>
<td>max_log_size</td>
<td>This parameter is not included in gpperfmon.conf, but it may be added to this file. To prevent the log files from growing to excessive size, you can add the max_log_size parameter to gpperfmon.conf. The value of this parameter is measured in bytes. For example: max_log_size = 10485760 With this setting, the log files will grow to 10MB before the system rolls over to a new log file.</td>
</tr>
<tr>
<td>partition_age</td>
<td>The number of months that gpperfmon statistics data will be retained. The default value is 0, which means that partitions are never dropped automatically.</td>
</tr>
<tr>
<td>quantum</td>
<td>Specifies the time in seconds between updates from data collection agents on all segments. Valid values are 10, 15, 20, 30, and 60. Defaults to 15 seconds. If you prefer a less granular view of performance, or want to collect and analyze minimal amounts of data for system metrics, choose a higher quantum. To collect data more frequently, choose a lower value.</td>
</tr>
<tr>
<td>harvest_interval</td>
<td>The time, in seconds, between data harvests. A data harvest moves recent data from the gpperfmon external (_tail) tables to their corresponding history files. The default is 120. The minimum value is 30.</td>
</tr>
<tr>
<td>smdw_aliases</td>
<td>This parameter allows you to specify additional host names for the standby master. For example, if the standby master has two NICs, you can enter: smdw_aliases=smdw-1,smdw-2 This optional fault tolerance parameter is useful if the Greenplum Command Center loses connectivity with the standby master. Instead of continuously retrying to connect to host smdw, it will try to connect to the NIC-based aliases of smdw-1 and/</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
</tr>
<tr>
<td>-----------</td>
<td>-------------</td>
</tr>
<tr>
<td>or smdw-2</td>
<td>This ensures that the Command Center Console can continuously poll and monitor the standby master.</td>
</tr>
</tbody>
</table>

**Notes**

The `gpperfmon` database and Greenplum Command Center require the `gpmon` role. After the `gpperfmon` database and `gpmon` role have been created, you can change the password for the `gpmon` role and update the information that Greenplum Command Center uses to connect to the `gpperfmon` database:

1. Log in to Greenplum Database as a superuser and change the `gpmon` password with the `ALTER ROLE` command.

```bash
# ALTER ROLE gpmon WITH PASSWORD 'new_password' ;
```

2. Update the password in `.pgpass` file that is used by Greenplum Command Center. The default file location is the `gpadmin` home directory (`~/.pgpass`). The `.pgpass` file contains a line with the `gpmon` password.

```plaintext
*:5432:gpperfmon:gpmon:new_password
```

3. Restart the Greenplum Command Center with the Command Center `gpcmdr` utility.

```bash
$ gpcmdr --restart
```

The gpperfmon monitoring system requires some initialization after startup. Monitoring information appears after a few minutes have passed, and not immediately after installation and startup of the gpperfmon system.

**Examples**

Create the `gpperfmon` database only:

```bash
$ su - gpadmin
$ gpperfmon_install --port 5432
```

Create the `gpperfmon` database, create the `gpmon` superuser, and enable the data collection agents:

```bash
$ su - gpadmin
$ gpperfmon_install --enable --password changeme --port 5432
$ gpstop -r
```

**See Also**

`gppkg`

Installs Greenplum Database extensions in `.gppkg` format, such as PL/Java, PL/R, PostGIS, and MADlib, along with their dependencies, across an entire cluster.

**Synopsis**

```
gppkg [-i package | -u package | -r name-version | -c]
       [-d master_data_directory] [-a] [-v]
```
Greenplum Database Utility Guide

Description

The Greenplum Package Manager (gppkg) utility installs Greenplum Database extensions, along with any dependencies, on all hosts across a cluster. It will also automatically install extensions on new hosts in the case of system expansion and segment recovery.

**Note:** After a major upgrade to Greenplum Database, you must download and install all gppkg extensions again.

Examples of database extensions and packages software that are delivered using the Greenplum Package Manager are:

- PL/Java
- PL/R
- PostGIS
- MADlib

Options

- **-a (do not prompt)**
  Do not prompt the user for confirmation.

- **-c | --clean**
  Reconciles the package state of the cluster to match the state of the master host. Running this option after a failed or partial install/uninstall ensures that the package installation state is consistent across the cluster.

- **-d master_data_directory**
  The master data directory. If not specified, the value set for $MASTER_DATA_DIRECTORY will be used.

- **-i package | --install=package**
  Installs the given package. This includes any pre/post installation steps and installation of any dependencies.

- **--migrate GPHOME_old GPHOME_new**
  Migrates packages from a separate $GPHOME. Carries over packages from one version of Greenplum Database to another.

  For example:
  ```
gppkg --migrate /usr/local/greenplum-db-<old-version> /usr/local/greenplum-db-<new-version>
  ```

  When migrating packages, these requirements must be met.
  
  - At least the master instance of the destination Greenplum Database must be started (the instance installed in `GPHOME_new`). Before running the `gppkg` command start the Greenplum Database master with the command `gpstart -m`.
  - Run the `gppkg` utility from the `GPHOME_new` installation. The migration destination installation directory.

- **-q | --query query_option**
Provides information specified by `query_option` about the installed packages. Only one `query_option` can be specified at a time. The following table lists the possible values for `query_option`. `<package_file>` is the name of a package.

Table 79: Query Options for `gppkg`

<table>
<thead>
<tr>
<th><code>query_option</code></th>
<th>Returns</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>&lt;package_file&gt;</code></td>
<td>Whether the specified package is installed.</td>
</tr>
<tr>
<td><code>--info &lt;package_file&gt;</code></td>
<td>The name, version, and other information about the specified package.</td>
</tr>
<tr>
<td><code>--list &lt;package_file&gt;</code></td>
<td>The file contents of the specified package.</td>
</tr>
<tr>
<td><code>--all</code></td>
<td>List of all installed packages.</td>
</tr>
</tbody>
</table>

```
-r name-version | --remove=name-version
Removes the specified package.
-u package | --update=package
Updates the given package.

Warning: The process of updating a package includes removing all previous versions of the system objects related to the package. For example, previous versions of shared libraries are removed. After the update process, a database function will fail when it is called if the function references a package file that has been removed.
```

```
--version (show utility version)
Displays the version of this utility.
-v | --verbose
Sets the logging level to verbose.
-? | -h | --help
Displays the online help.
```

**gprecoverseg**

Recovers a primary or mirror segment instance that has been marked as down (if mirroring is enabled).

**Synopsis**

```bash
gprecoverseg [-p new_recover_host[,...]] | -i recover_config_file | -s filesystem_config_file | -d master_data_directory]
gprecoverseg -r

gprecoverseg -o output_recover_config_file | -S output_filespace_config_file
  [-p new_recover_host[,...]]
gprecoverseg -?
gprecoverseg --version
```
Description

In a system with mirrors enabled, the `gprecoverseg` utility reactivates a failed segment instance and identifies the changed database files that require resynchronization. Once `gprecoverseg` completes this process, the system goes into resynchronization mode until the recovered segment is brought up to date. The system is online and fully operational during resynchronization.

During an incremental recovery (the `-F` option is not specified), if `gprecoverseg` detects a segment instance with mirroring disabled in a system with mirrors enabled, the utility reports that mirroring is disabled for the segment, does not attempt to recover that segment instance, and continues the recovery process.

A segment instance can fail for several reasons, such as a host failure, network failure, or disk failure. When a segment instance fails, its status is marked as `down` in the Greenplum Database system catalog, and its mirror is activated in change tracking mode. In order to bring the failed segment instance back into operation again, you must first correct the problem that made it fail in the first place, and then recover the segment instance in Greenplum Database using `gprecoverseg`.

**Note:** If incremental recovery was not successful and the down segment instance data is not corrupted, contact Pivotal Support.

Segment recovery using `gprecoverseg` requires that you have an active mirror to recover from. For systems that do not have mirroring enabled, or in the event of a double fault (a primary and mirror pair both down at the same time) — you must take manual steps to recover the failed segment instances and then perform a system restart to bring the segments back online. For example, this command restarts a system.

```
gpstop -r
```

By default, a failed segment is recovered in place, meaning that the system brings the segment back online on the same host and data directory location on which it was originally configured. In this case, use the following format for the recovery configuration file (using `-i`).

```
filespaceOrder=[filespace1_fsname[, filespace2_fsname[, ...]]
<failed_host_address>:<port>:<data_directory>
```

In some cases, this may not be possible (for example, if a host was physically damaged and cannot be recovered). In this situation, `gprecoverseg` allows you to recover failed segments to a completely new host (using `-p`), on an alternative data directory location on your remaining live segment hosts (using `-s`), or by supplying a recovery configuration file (using `-i`) in the following format. The word `SPACE` indicates the location of a required space. Do not add additional spaces.

```
filespaceOrder=[filespace1_fsname[, filespace2_fsname[, ...]]
<failed_host_address>:<port>:<data_directory>SPACE
<recovery_host_address>:<port>:<replication_port>:<data_directory>
[:<fselocation>:...]
```

See the `-i` option below for details and examples of a recovery configuration file.

The `gp_segment_configuration`, `pg_filespace`, and `pg_filespace_entry` system catalog tables can help you determine your current segment configuration so that you can plan your mirror recovery configuration. For example, run the following query:

```
=# SELECT dbid, content, address, port,
replication_port, fselocation as datadir
FROM gp_segment_configuration, pg_filespace_entry
WHERE dbid=fsedbid
ORDER BY dbid;
```
The new recovery segment host must be pre-installed with the Greenplum Database software and configured exactly the same as the existing segment hosts. A spare data directory location must exist on all currently configured segment hosts and have enough disk space to accommodate the failed segments.

The recovery process marks the segment as up again in the Greenplum Database system catalog, and then initiates the resynchronization process to bring the transactional state of the segment up-to-date with the latest changes. The system is online and available during resynchronization. To check the status of the resynchronization process run:

```
gpstate -m
```

**Options**

- **-a (do not prompt)**
  Do not prompt the user for confirmation.

- **-B parallel_processes**
  The number of segments to recover in parallel. If not specified, the utility will start up to 16 parallel processes depending on how many segment instances it needs to recover.

- **-d master_data_directory**
  Optional. The master host data directory. If not specified, the value set for $MASTER_DATA_DIRECTORY will be used.

- **-F (full recovery)**
  Optional. Perform a full copy of the active segment instance in order to recover the failed segment. The default is to only copy over the incremental changes that occurred while the segment was down.

  **Warning:** A full recovery deletes the data directory of the down segment instance before copying the data from the active (current primary) segment instance. Before performing a full recovery, ensure that the segment failure did not cause data corruption and that any host segment disk issues have been fixed.

  Also, for a full recovery, the utility does not restore custom files that are stored in the segment instance data directory even if the custom files are also in the active segment instance. You must restore the custom files manually. For example, when using the gpfdists protocol (gpfdist with SSL encryption) to manage external data, client certificate files are required in the segment instance $SPGDATA/gpfdists directory. These files are not restored. For information about configuring gpfdists, see Encrypting gpfdist Connections.

- **-i recover_config_file**
  Specifies the name of a file with the details about failed segments to recover. Each line in the file is in the following format. The word SPACE indicates the location of a required space. Do not add additional spaces.

  ```
  filesystemOrder=[filesystem1_fsnname[, filesystem2_fsnname[, ...]]
  <failed_host_address>:<port>:<data_directory>SPACE
  <recovery_host_address>:<port>:<replication_port>:<data_directory>
  [:<fselocation>:...] ...
  ```

**Comments**

Lines beginning with # are treated as comments and ignored.

**Filespace Order**
The first comment line that is not a comment specifies filespace ordering. This line starts with `filespaceOrder=` and is followed by list of filespace names delimited by a colon. For example:

```
filespaceOrder=raid1:raid2
```

The default `pg_system` filespace should not appear in this list. The list should be left empty on a system with no filespaces other than the default `pg_system` filespace. For example:

```
filespaceOrder=
```

**Segments to Recover**

Each line after the first specifies a segment to recover. This line can have one of two formats. In the event of in-place recovery, enter one group of colon delimited fields in the line. For example:

```
failedAddress:failedPort:failedDataDirectory
```

For recovery to a new location, enter two groups of fields separated by a space in the line. The required space is indicated by `SPACE`. Do not add additional spaces.

```
failedAddress:failedPort:failedDataDirectory SPACE newAddress:
newPort:newReplicationPort:newDataDirectory
```

On a system with additional filespaces, the second group of fields is expected to be followed with a list of the corresponding filespace locations separated by additional colons. For example, on a system with two additional filespaces, enter two additional directories in the second group, as follows. The required space is indicated by `SPACE`. Do not add additional spaces.

```
failedAddress:failedPort:failedDataDirectory SPACE newAddress:
newPort:newReplicationPort:newDataDirectory:location1:location2
```

**Examples**

**In-place recovery of a single mirror**

```
filespaceOrder=
sdw1-1:50001:/data1/mirror/gpseg16
```

**Recovery of a single mirror to a new host**

```
filespaceOrder=
sdw1-1:50001:/data1/mirror/gpseg16 SPACE sdw4-1:
50001:51001:/data1/recover1/gpseg16
```

**Recovery of a single mirror to a new host on a system with an extra filesystem**

```
filespaceOrder=
fs1sdw1-1:50001:/data1/mirror/gpseg16 SPACE sdw4-1:
50001:51001:/data1/recover1/gpseg16:
data1/fs1/gpseg16
```

**Obtaining a Sample File**

You can use the `-o` option to output a sample recovery configuration file to use as a starting point.

```
-1 logfile_directory
```
The directory to write the log file. Defaults to ~/gpAdminLogs.

-o output_recover_config_file
Specifies a file name and location to output a sample recovery configuration file. The output file lists the currently invalid segments and their default recovery location in the format that is required by the -i option. Use together with the -p option to output a sample file for recovering on a different host. This file can be edited to supply alternate recovery locations if needed.

-p new_recovery_host[,...]
Specifies a spare host outside of the currently configured Greenplum Database array on which to recover invalid segments. In the case of multiple failed segment hosts, you can specify a comma-separated list. The spare host must have the Greenplum Database software installed and configured, and have the same hardware and OS configuration as the current segment hosts (same OS version, locales, gpadmin user account, data directory locations created, ssh keys exchanged, number of network interfaces, network interface naming convention, and so on.).

-q (no screen output)
Run in quiet mode. Command output is not displayed on the screen, but is still written to the log file.

-r (rebalance segments)
After a segment recovery, segment instances may not be returned to the preferred role that they were given at system initialization time. This can leave the system in a potentially unbalanced state, as some segment hosts may have more active segments than is optimal for top system performance. This option rebalances primary and mirror segments by returning them to their preferred roles. All segments must be valid and synchronized before running gprecoverseg -r. If there are any in progress queries, they will be cancelled and rolled back.

-s filespace_config_file
Specifies the name of a configuration file that contains file system locations on the currently configured segment hosts where you can recover failed segment instances. The filespace configuration file is in the format of:

```
pg_system=default_fselocation
filespace1_name=filespace1_fselocation
filespace2_name=filespace2_fselocation
...
```

If your system does not have additional filespaces configured, this file will only have one location (for the default filespace, pg_system). These file system locations must exist on all segment hosts in the array and have sufficient disk space to accommodate recovered segments.

Note: The -s and -S options are only used when you recover to existing hosts in the cluster. You cannot use these options when you recover to a new host. To recover to a new host, use the -i and -o options.

-S output_filespace_config_file
Specifies a file name and location to output a sample filespace configuration file in the format that is required by the -s option. This file should be edited to supply the correct alternate filespace locations.

-v (verbose)
Sets logging output to verbose.

--version (version)
Displays the version of this utility.
-? (help)  
Displays the online help.

**Examples**

Recover any failed segment instances in place:

```bash
$ gprecoverseg
```

Rebalance your Greenplum Database system after a recovery by resetting all segments to their preferred role. First check that all segments are up and synchronized.

```bash
$ gpstate -m
$ gprecoverseg -r
```

Recover any failed segment instances to a newly configured spare segment host:

```bash
$ gprecoverseg -i recover_config_file
```

Output the default recovery configuration file:

```bash
$ gprecoverseg -o /home/gpadmin/recover_config_file
```

**See Also**

`gpstart`, `gpstop`

**gpreload**

Reloads Greenplum Database table data sorting the data based on specified columns.

**Synopsis**

```bash
 gpreload -d database [-p port] [-t | --table-file] path_to_file [-a]
gpreload -h
gpreload --version
```

**Description**

The `gpreload` utility reloads table data with column data sorted. For tables that were created with the table storage option `APPENDONLY=TRUE` and compression enabled, reloading the data with sorted data can improve table compression. You specify a list of tables to be reloaded and the table columns to be sorted in a text file.

Compression is improved by sorting data when the data in the column has a relatively low number of distinct values when compared to the total number of rows.

For a table being reloaded, the order of the columns to be sorted might affect compression. The columns with the fewest distinct values should be listed first. For example, listing state then city would generally result in better compression than listing city then state.

```
public.cust_table: state, city
public.cust_table: city, state
```

For information about the format of the file used with `gpreload`, see the `--table-file` option.
Notes
To improve reload performance, indexes on tables being reloaded should be removed before reloading the
data.

Running the ANALYZE command after reloading table data might query performance because of a change
in the data distribution of the reloaded data.

For each table, the utility copies table data to a temporary table, truncates the existing table data, and
inserts data from the temporary table to the table in the specified sort order. Each table reload is performed
in a single transaction.

For a partitioned table, you can reload the data of a leaf child partition. However, data is inserted from the
root partition table, which acquires a ROW EXCLUSIVE lock on the entire table.

Options
-a (do not prompt)
Optional. If specified, the gpreload utility does not prompt the user for confirmation.

-d database
The database that contains the tables to be reloaded. The gpreload utility connects to
the database as the user running the utility.

-p port
The Greenplum Database master port. If not specified, the value of the PGPORT
environment variable is used. If the value is not available, an error is returned.

{-t | --table-file } path_to_file
The location and name of file containing list of schema qualified table names to reload and
the column names to reorder from the Greenplum Database. Only user defined tables are
supported. Views or system catalog tables are not supported.

If indexes are defined on table listed in the file, gpreload prompts to continue.

Each line specifies a table name and the list of columns to sort. This is the format of each
line in the file:

    schema.table_name: column [desc] [, column2 [desc] ... ]

The table name is followed by a colon (:) and then at least one column name. If you
specify more than one column, separate the column names with a comma. The columns
are sorted in ascending order. Specify the keyword desc after the column name to sort the
column in descending order.

Wildcard characters are not supported.

If there are errors in the file, gpreload reports the first error and exits. No data is
reloaded.

The following example reloads three tables:

    public.clients: region, state, rep_id desc
    public.merchants: region, state
    test.lineitem: group, assy, whse

In the first table public.clients, the data in the rep_id column is sorted in
descending order. The data in the other columns are sorted in ascending order.

--version (show utility version)
Displays the version of this utility.

-? (help)
Displays the online help.
Example
This example command reloads the tables in the database mytest that are listed in the file data-tables.txt.

```
gpreload -d mytest --table-file data-tables.txt
```

CREATE TABLE in the Greenplum Database Reference Guide

gprestore
Restore a Greenplum Database backup that was created using the gpbackup utility. By default gprestore uses backed up metadata files and DDL files located in the Greenplum Database master host data directory, with table data stored locally on segment hosts in CSV data files.

Synopsis
```
gprestore --timestamp YYYYMMDDHHMMSS
    [--backup-dir directory]
    [--create-db]
    [--debug]
    [--exclude-schema schema_name]
    [--exclude-table schema.table]
    [--exclude-table-file file_name]
    [--include-schema schema_name]
    [--include-table schema.table]
    [--include-table-file file_name]
    [--data-only | --metadata-only]
    [--jobs int]
    [--on-error-continue]
    [--plugin-config config_file_location]
    [--quiet]
    [--redirect-db database_name]
    [--verbose]
    [--version]
    [--with-globals]
    [--with-stats]
```

gprestore --help

Description
To use gprestore to restore from a backup set, you must include the --timestamp option to specify the exact timestamp value (YYYYMMDDHHMMSS) of the backup set to restore. If you specified a custom --backup-dir to consolidate the backup files, include the same --backup-dir option with gprestore to locate the backup files.

If the backup you specify is an incremental backup, you need a complete set of backup files (a full backup and any required incremental backups). gprestore ensures that the complete backup set is available before attempting to restore a backup.

Important: For incremental backup sets, the backups must be on a single device. For example, a backup set must all be on a Data Domain system.

For information about incremental backups, see Creating Incremental Backups with gpbackup and gprestore.
When restoring from a backup set, `gprestore` restores to a database with the same name as the name specified when creating the backup set. If the target database exists and a table being restored exists in the database, the restore operation fails. Include the `--create-db` option if the target database does not exist in the cluster. You can optionally restore a backup set to a different database by using the `--redirect-db` option.

When restoring a backup set that contains data from some leaf partitions of a partitioned tables, the partitioned table is restored along with the data for the leaf partitions. For example, you create a backup with the `gpbackup` option `--include-table-file` and the text file lists some leaf partitions of a partitioned table. Restoring the backup creates the partitioned table and restores the data only for the leaf partitions listed in the file.

Greenplum Database system objects are automatically included in a `gpbackup` backup set, but these objects are only restored if you include the `--with-globals` option to `gprestore`. Similarly, if you backed up query plan statistics using the `--with-stats` option, you can restore those statistics by providing `--with-stats` to `gprestore`. By default, only database objects in the backup set are restored.

Performance of restore operations can be improved by creating multiple parallel connections to restore table data and metadata. By default, `gprestore` uses 1 connection, but you can increase this number with the `--jobs` option for large restore operations.

When a restore operation completes, `gprestore` returns a status code. See `Return Codes`.

`gprestore` can send status email notifications after a backup operation completes. You specify when the utility sends the mail and the email recipients in a configuration file. See `Configuring Email Notifications`.

**Note:** This utility uses secure shell (SSH) connections between systems to perform its tasks. In large Greenplum Database deployments, cloud deployments, or deployments with a large number of segments per host, this utility may exceed the host’s maximum threshold for unauthenticated connections. Consider updating the SSH `MaxStartups` and `MaxSessions` configuration parameters to increase this threshold. For more information about SSH configuration options, refer to the SSH documentation for your Linux distribution.

### Options

**--timestamp YYYYMMDDHHMMSS**

Required. Specifies the timestamp of the `gpbackup` backup set to restore. By default, `gprestore` tries to locate metadata files for the timestamp on the Greenplum Database master host in the `$MASTER_DATA_DIRECTORY/backups/YYYYMMDD/YYYYMMDDhhmmss`/ directory, and CSV data files in the `<seg_dir>/backups/YYYYMMDD/YYYYMMDDhhmmss`/ directory of each segment host.

**--backup-dir directory**

Optional. Sources all backup files (metadata files and data files) from the specified directory. You must specify `directory` as an absolute path (not relative). If you do not supply this option, `gprestore` tries to locate metadata files for the timestamp on the Greenplum Database master host in the `$MASTER_DATA_DIRECTORY/backups/YYYYMMDD/YYYYMMDDhhmmss`/ directory. CSV data files must be available on each segment in the `<seg_dir>/backups/YYYYMMDD/YYYYMMDDhhmmss`/ directory. Include this option when you specify a custom backup directory with `gpbackup`.

You cannot combine this option with the option `--plugin-config`.

**--create-db**

Optional. Creates the database before restoring the database object metadata.

The database is created by cloning the empty standard system database `template0`.

**--data-only**

Optional. Restores table data from a backup created with the `gpbackup` utility, without creating the database tables. This option assumes the tables exist in the target database. To restore data for a specific set of tables from a backup set, you can specify an option
to include tables or schemas or exclude tables or schemas. Specify the `--with-stats` option to restore table statistics from the backup.

The backup set must contain the table data to be restored. For example, a backup created with the `gpbackup` option `--metadata-only` does not contain table data.

To restore only database tables, without restoring the table data, see the option `--metadata-only`.

`--debug`
Optional. Displays verbose and debug log messages during a restore operation.

`--exclude-schema schema_name`
Optional. Specifies a database schema to exclude from the restore operation. You can specify this option multiple times to exclude multiple schemas. You cannot combine this option with the option `--include-schema`, or a table filtering option such as `--include-table`.

`--exclude-table schema.table`
Optional. Specifies a table to exclude from the restore operation. The table must be in the format `<schema-name>.<table-name>`. If a table or schema name uses any character other than a lowercase letter, number, or an underscore character, then you must include that name in double quotes. You can specify this option multiple times. If the table is not in the backup set, the restore operation fails. You cannot specify a leaf partition of a partitioned table.

You cannot combine this option with the option `--exclude-schema`, or another a table filtering option such as `--include-table`.

`--exclude-table-file file_name`
Optional. Specifies a text file containing a list of tables to exclude from the restore operation. Each line in the text file must define a single table using the format `<schema-name>.<table-name>`. The file must not include trailing lines. If a table or schema name uses any character other than a lowercase letter, number, or an underscore character, then you must include that name in double quotes. If a table is not in the backup set, the restore operation fails. You cannot specify a leaf partition of a partitioned table.

You cannot combine this option with the option `--exclude-schema`, or another a table filtering option such as `--include-table`.

`--include-schema schema_name`
Optional. Specifies a database schema to restore. You can specify this option multiple times to include multiple schemas. If you specify this option, any schemas that you specify must be available in the backup set. Any schemas that are not included in subsequent `--include-schema` options are omitted from the restore operation.

If a schema that you specify for inclusion exists in the database, the utility issues an error and continues the operation. The utility fails if a table being restored exists in the database.

You cannot use this option if objects in the backup set have dependencies on multiple schemas.

See Filtering the Contents of a Backup or Restore for more information.

`--include-table schema.table`
Optional. Specifies a table to restore. The table must be in the format `<schema-name>.<table-name>`. If a table or schema name uses any character other than a lowercase letter, number, or an underscore character, then you must include that name in double quotes. You can specify this option multiple times. You cannot specify a leaf partition of a partitioned table.

You can also specify the qualified name of a sequence or a view.
If you specify this option, the utility does not automatically restore dependent objects. You must also explicitly specify the dependent objects that are required. For example if you restore a view, you must also restore the tables that the view uses. If you restore a table that uses a sequence, you must also restore the sequence. The dependent objects must exist in the backup set.

You cannot combine this option with a schema filtering option such as --include-schema, or another table filtering option such as --exclude-table-file.

--include-table-file file_name
Optional. Specifies a text file containing a list of tables to restore. Each line in the text file must define a single table using the format <schema-name>.<table-name>. The file must not include trailing lines. If a table or schema name uses any character other than a lowercase letter, number, or an underscore character, then you must include that name in double quotes. Any tables not listed in this file are omitted from the restore operation. You cannot specify a leaf partition of a partitioned table.

You can also specify the qualified name of a sequence or a view.

If you specify this option, the utility does not automatically restore dependent objects. You must also explicitly specify dependent objects that are required. For example if you restore a view, you must also specify the tables that the view uses. If you specify a table that uses a sequence, you must also specify the sequence. The dependent objects must exist in the backup set.

If you use the --include-table-file option, gprestore does not create roles or set the owner of the tables. The utility restores table indexes and rules. Triggers are also restored but are not supported in Greenplum Database.

See Filtering the Contents of a Backup or Restore for more information.

--jobs int
Optional. Specifies the number of parallel connections to use when restoring table data and metadata. By default, gprestore uses 1 connection. Increasing this number can improve the speed of restoring data.

Note: If you used the gpbackup --single-data-file option to combine table backups into a single file per segment, you cannot set --jobs to a value higher than 1 to perform a parallel restore operation.

--metadata-only
Optional. Creates database tables from a backup created with the gpbackup utility, but does not restore the table data. This option assumes the tables do not exist in the target database. To create a specific set of tables from a backup set, you can specify an option to include tables or schemas or exclude tables or schemas. Specify the option --with-globals to restore the Greenplum Database system objects.

The backup set must contain the DDL for tables to be restored. For example, a backup created with the gpbackup option --data-only does not contain the DDL for tables.

To restore table data after you create the database tables, see the option --data-only.

--on-error-continue
Optional. Specify this option to continue the restore operation if an SQL error occurs when creating database metadata (such as tables, roles, or functions) or restoring data. If another type of error occurs, the utility exits. The utility displays an error summary and writes error information to the gprestore log file and continues the restore operation.

The default is to exit on the first error.

--plugin-config config-file_location
Specify the location of the gpbackup plugin configuration file, a YAML-formatted text file. The file contains configuration information for the plugin application that gprestore uses during the restore operation.

If you specify the --plugin-config option when you back up a database, you must specify this option with configuration information for a corresponding plugin application when you restore the database from the backup.

You cannot combine this option with the option --backup-dir.

For information about using storage plugin applications, see Using gpbackup Storage Plugins.

--quiet
Optional. Suppress all non-warning, non-error log messages.

--redirect-db database_name
Optional. Restore to the specified database_name instead of to the database that was backed up.

--verbose
Optional. Displays verbose log messages during a restore operation.

--version
Optional. Print the version number and exit.

--with-globals
Optional. Restores Greenplum Database system objects in the backup set, in addition to database objects. See Objects Included in a Backup or Restore.

--with-stats
Optional. Restore query plan statistics from the backup set.

--help
Displays the online help.

Return Codes
One of these codes is returned after gprestore completes.

- 0 – Restore completed with no problems.
- 1 – Restore completed with non-fatal errors. See log file for more information.
- 2 – Restore failed with a fatal error. See log file for more information.

Examples
Create the demo database and restore all schemas and tables in the backup set for the indicated timestamp:

```bash
$ dropdb demo
$ gprestore --timestamp 20171103152558 --create-db
```

Restore the backup set to the "demo2" database instead of the "demo" database that was backed up:

```bash
$ createdb demo2
$ gprestore --timestamp 20171103152558 --redirect-db demo2
```
Restore global Greenplum Database metadata and query plan statistics in addition to the database objects:

$ gprestore --timestamp 20171103152558 --create-db --with-globals --with-stats

Restore, using backup files that were created in the /home/gpadmin/backup directory, creating 8 parallel connections:

$ gprestore --backup-dir /home/gpadmin/backups/ --timestamp 20171103153156 --create-db --jobs 8

Restore only the "wikipedia" schema included in the backup set:

$ dropdb demo
$ gprestore --include-schema wikipedia --backup-dir /home/gpadmin/backups/ --timestamp 20171103153156 --create-db

If you restore from an incremental backup set, all the required files in the backup set must be available to gprestore. For example, the following timestamp keys specify an incremental backup set. 20170514054532 is the full backup and the others are incremental backups.

20170514054532 (full backup)
20170714095512
20170914081205
20171114064330
20180114051246

The following gprestore command specifies the timestamp 20121114064330. The incremental backup with the timestamps 20120714095512 and 20120914081205 and the full backup must be available to perform a restore.

gprestore --timestamp 20121114064330 --redirect-db mystest --create-db

gpbackup, Parallel Backup with gpbackup and gprestore and Using the S3 Storage Plugin with gpbackup and gprestore

gpscpcopies files between multiple hosts at once.

Synopsis
gpscpc { -f hostfile/gplssh | -h hostname [-h hostname ...] } [-J character] [-v] [user@]hostname:file_to_copy [...] [user@]hostname:copy_to_path

Description
The gpscpc utility allows you to copy one or more files from the specified hosts to other specified hosts in one command using SCP (secure copy). For example, you can copy a file from the Greenplum Database master host to all of the segment hosts at the same time.
To specify the hosts involved in the SCP session, use the `-f` option to specify a file containing a list of host names, or use the `-h` option to name single host names on the command-line. At least one host name (-h) or a host file (-f) is required. The `-J` option allows you to specify a single character to substitute for the `hostname` in the copy from and copy to destination strings. If `-J` is not specified, the default substitution character is an equal sign (=). For example, the following command will copy `.bashrc` from the local host to `/home/gpadmin` on all hosts named in `hostfile_gpssh`:

```
gpscp -f hostfile_gpssh .bashrc =:/home/gpadmin
```

If a user name is not specified in the host list or with `user@` in the file path, `gpscp` will copy files as the currently logged in user. To determine the currently logged in user, do a `whoami` command. By default, `gpscp` goes to `$HOME` of the session user on the remote hosts after login. To ensure the file is copied to the correct location on the remote hosts, it is recommended that you use absolute paths.

Before using `gpscp`, you must have a trusted host setup between the hosts involved in the SCP session. You can use the utility `gpssh-exkeys` to update the known host files and exchange public keys between hosts if you have not done so already.

**Options**

- `-f hostfile_gpssh`
  Specifies the name of a file that contains a list of hosts that will participate in this SCP session. The syntax of the host file is one host per line as follows:

  ```
  <hostname>
  ```

- `-h hostname`
  Specifies a single host name that will participate in this SCP session. You can use the `-h` option multiple times to specify multiple host names.

- `-J character`
  The `-J` option allows you to specify a single character to substitute for the `hostname` in the copy from and copy to destination strings. If `-J` is not specified, the default substitution character is an equal sign (=).

- `-v (verbose mode)`
  Optional. Reports additional messages in addition to the SCP command output.

- `file_to_copy`
  Required. The file name (or absolute path) of a file that you want to copy to other hosts (or file locations). This can be either a file on the local host or on another named host.

- `copy_to_path`
  Required. The path where you want the file(s) to be copied on the named hosts. If an absolute path is not used, the file will be copied relative to `$HOME` of the session user. You can also use the equal sign `=` (or another character that you specify with the `-J` option) in place of a `hostname`. This will then substitute in each host name as specified in the supplied host file (-f) or with the `-h` option.

- `--version`
  Displays the version of this utility.
Examples

Copy the file named installer.tar to / on all the hosts in the file hostfile_gpssh.

```
gpscp -f hostfile_gpssh installer.tar =:/
```

Copy the file named myfuncs.so to the specified location on the hosts named sdw1 and sdw2:

```
gpscp -h sdw1 -h sdw2 myfuncs.so =:/usr/local/greenplum-db/lib
```

gpssh, gpssh-exkeys

**gpseginstall**

Installs Greenplum Database on segment hosts.

**Synopsis**

```
gpseginstall -f hostfile [-u gpdb_admin_user] [-p password]
 [-c u|p|c|s|E|e|l|v]
gpseginstall --help
```

**Description**

The gpseginstall utility provides a simple way to quickly install Greenplum Database on segment hosts that you specify in a host list file. The utility does not install or update Greenplum Database on the master host. You can run gpseginstall as root or as a non-root user. gpseginstall does not perform database initialization. See gpinitsystem for more information about initializing Greenplum Database.

When run as root, gpseginstall default actions are to add a system user (default is gpadmin), create a password (default is changeme), and deploy and install Greenplum Database on segment hosts. To do this, gpseginstall locates the current Greenplum Database binaries on the master from the installation path in the current user's environment variables ($GPHOME). It compresses Greenplum Database software into a tar.gz file and performs an MD5 checksum to verify file integrity.

Then, it copies Greenplum Database to the segment hosts, installs (decompresses) Greenplum Database, and changes the ownership of the Greenplum Database installation to the system user you specify with the -u option. Lastly, it exchanges keys between all Greenplum Database hosts as both root and as the system user you specify with the -u option. gpseginstall also perform a user limit check and verifies the version number of Greenplum Database on all the segments.

If you run gpseginstall as a non-root user, gpseginstall only compresses, copies, and installs Greenplum Database on segment hosts. It can also exchanges keys between Greenplum Database hosts for the current system user, and verifies the version number of Greenplum Database on all the segments.

**Options**

- **-c** | **--commands option_list**

  Optional. This allows you to customize gpseginstall actions. Note that these command options are executed by default if you do not specify the -c option in the gpseginstall syntax.

  - **u**: Adds a system user. (root only)
  - **p**: Changes the password for a system user. (root only)
  - **s**: Compresses, copies, decompresses (installs) Greenplum Database on all segments.
- c: Changes the ownership of the Greenplum Database installation directory on the segment hosts. (root only)
- E: Exchange keys between Greenplum Database master and segment hosts for the root user. (root only)
- e: Exchange keys between Greenplum Database master and segment hosts for the non-root system user.
- l: (Linux only) Checks and modifies the user limits configuration file (/etc/security/limits.conf file) when adding a new user to segment hosts. (root only)
- v: Verifies the version of Greenplum Database running on all segments.

-gpseginstall checks the version number of the Greenplum Database installation referenced by the $GPHOME environment variable and symbolic link to the installation directory. An error occurs if there is a version number mismatch or the Greenplum Database installation directory cannot be found.

- `-f | --file hostfile`
  Required. This specifies the file that lists the segment hosts onto which you want to install Greenplum Database.

  The host list file must have one host name per line and includes a host name for each segment host in your Greenplum system. Make sure there are no blank lines or extra spaces. If a host has multiple configured host names, use only one host name per host.

  For example:

  ```
  sdw1-1
  sdw2-1
  sdw3-1
  sdw4-1
  ```

  If available, you can use the same `gpssh-exkeys` host list file you used to exchange keys between Greenplum Database hosts.

- `-p | --password password`
  Optional. Sets the password for the user you specify with the `-u` option. The default password is `changeme`. This option is only available when you run `gpseginstall` as `root`.

  Recommended security best practices:
  - Always use passwords.
  - Do not use default passwords.
  - Change default passwords immediately after installation.

- `-u | --user user`
  Optional. This specifies the system user. This user is also the Greenplum Database administrative user. This user owns Greenplum Database installation and administers the database. This is also the user under which Greenplum Database is started/initialized. This option is only available when you run `gpseginstall` as `root`. The default is `gpadmin`.

- `--help (help)`
  Displays the online help.

Examples
As `root`, install a Greenplum Database on all segments, leave the system user as the default (`gpadmin`) and set the `gpadmin` password to `secret123`:

```bash
# gpseginstall -f my_host_list_file -p secret123
```
As a non-root user, compress and copy Greenplum Database binaries to all segments (as `gpadmin`):

```
$ gpseinstall -f host_file
```

As root, add a user (`gpadmin2`), set the password for the user (`secret1234`), exchange keys between hosts as the new user, check user limits, and verify version numbers, but do not change ownership of Greenplum binaries, compress/copy/install Greenplum Database on segments, or exchange keys as root.

```
$ gpseinstall -f host_file -u gpadmin2 -p secret1234 -c upelv
```

---

**gpssh**

Provides SSH access to multiple hosts at once.

**Synopsis**

```
gpssh { -f hostfile_gpssh | - h hostname [-h hostname ...] } [-s] [-e] [-d seconds] [-t multiplier] [-v] 
[bash_command]
gpssh -?
gpssh --version
```

**Description**

The `gpssh` utility allows you to run bash shell commands on multiple hosts at once using SSH (secure shell). You can execute a single command by specifying it on the command-line, or omit the command to enter into an interactive command-line session.

To specify the hosts involved in the SSH session, use the `-f` option to specify a file containing a list of host names, or use the `-h` option to name single host names on the command-line. At least one host name (`-h`) or a host file (`-f`) is required. Note that the current host is **not** included in the session by default — to include the local host, you must explicitly declare it in the list of hosts involved in the session.

Before using `gpssh`, you must have a trusted host setup between the hosts involved in the SSH session. You can use the utility `gpssh-exkeys` to update the known host files and exchange public keys between hosts if you have not done so already.

If you do not specify a command on the command-line, `gpssh` will go into interactive mode. At the `gpssh` command prompt (`=>`), you can enter a command as you would in a regular bash terminal command-line, and the command will be executed on all hosts involved in the session. To end an interactive session, press CTRL+D on the keyboard or type `exit` or `quit`.

If a user name is not specified in the host file, `gpssh` will execute commands as the currently logged in user. To determine the currently logged in user, do a `whoami` command. By default, `gpssh` goes to `$HOME` of the session user on the remote hosts after login. To ensure commands are executed correctly on all remote hosts, you should always enter absolute paths.

If you encounter network timeout problems when using `gpssh`, you can use `-d` and `-t` options or set parameters in the `gpssh.conf` file to control the timing that `gpssh` uses when validating the initial `ssh` connection. For information about the configuration file, see `gpssh Configuration File`. 854
Options

**bash_command**

A bash shell command to execute on all hosts involved in this session (optionally enclosed in quotes). If not specified, gpssh starts an interactive session.

**-d (delay) seconds**

Optional. Specifies the time, in seconds, to wait at the start of a gpssh interaction with ssh. Default is 0.05. This option overrides the delaybeforeexecute value that is specified in the gpssh.conf configuration file.

Increasing this value can cause a long wait time during gpssh startup.

**-e (echo)**

Optional. Echoes the commands passed to each host and their resulting output while running in non-interactive mode.

**-f hostfile_gpssh**

Specifies the name of a file that contains a list of hosts that will participate in this SSH session. The syntax of the host file is one host per line.

**-h hostname**

Specifies a single host name that will participate in this SSH session. You can use the -h option multiple times to specify multiple host names.

**-s**

Optional. If specified, before executing any commands on the target host, gpssh sources the file greenplum_path.sh in the directory specified by the $GP HOME environment variable.

This option is valid for both interactive mode and single command mode.

**-t multiplier**

Optional. A decimal number greater than 0 (zero) that is the multiplier for the timeout that gpssh uses when validating the ssh prompt. Default is 1. This option overrides the promptvalidation_timeout value that is specified in the gpssh.conf configuration file.

Increasing this value has a small impact during gpssh startup.

**-v (verbose mode)**

Optional. Reports additional messages in addition to the command output when running in non-interactive mode.

**--version**

Displays the version of this utility.

**-? (help)**

Displays the online help.

**gpssh Configuration File**

The gpssh.conf file contains parameters that let you adjust the timing that gpssh uses when validating the initial ssh connection. These parameters affect the network connection before the gpssh session executes commands with ssh. The location of the file is specified by the environment variable MASTER_DATA_DIRECTORY. If the environment variable is not defined or the gpssh.conf file does not exist, gpssh uses the default values or the values set with the -d and -t options. For information about the environment variable, see the Greenplum Database Reference Guide.
The `gpssh.conf` file is a text file that consists of a `[gpssh]` section and parameters. On a line, the `#` (pound sign) indicates the start of a comment. This is an example `gpssh.conf` file.

```
[gpssh]
delaybeforesend = 0.05
prompt_validation_timeout = 1.0
sync_retries = 5
```

These are the `gpssh.conf` parameters.

**delaybeforesend = seconds**

Specifies the time, in seconds, to wait at the start of a `gpssh` interaction with `ssh`. Default is 0.05. Increasing this value can cause a long wait time during `gpssh` startup. The `-d` option overrides this parameter.

**prompt_validation_timeout = multiplier**

A decimal number greater than 0 (zero) that is the multiplier for the timeout that `gpssh` uses when validating the `ssh` prompt. Increasing this value has a small impact during `gpssh` startup. Default is 1. The `-t` option overrides this parameter.

**sync_retries = attempts**

A non-negative integer that specifies the maximum number of times that `gpssh` attempts to connect to a remote Greenplum Database host. The default is 3. If the value is 0, `gpssh` returns an error if the initial connection attempt fails. Increasing the number of attempts also increases the time between retry attempts. This parameter cannot be configured with a command-line option.

The `-t` option also affects the time between retry attempts.

Increasing this value can compensate for slow network performance or segment host performance issues such as heavy CPU or I/O load. However, when a connection cannot be established, an increased value also increases the delay when an error is returned.

**Examples**

Start an interactive group SSH session with all hosts listed in the file `hostfile_gpssh`:

```
$ gpssh -f hostfile_gpssh
```

At the `gpssh` interactive command prompt, run a shell command on all the hosts involved in this session.

```
=> ls -a /data/primary/*
```

Exit an interactive session:

```
=> exit
=> quit
```

Start a non-interactive group SSH session with the hosts named `sdw1` and `sdw2` and pass a file containing several commands named `command_file` to `gpssh`:

```
$ gpssh -h sdw1 -h sdw2 -v -e < command_file
```

Execute single commands in non-interactive mode on hosts `sdw2` and `localhost`:

```
$ gpssh -h sdw2 -h localhost -v -e 'ls -a /data/primary/*'
$ gpssh -h sdw2 -h localhost -v -e 'echo $GPHOME'
$ gpssh -h sdw2 -h localhost -v -e 'ls -l | wc -l'
```
gpssh-exkeys

Exchanges SSH public keys between hosts.

Synopsis

```
gpssh-exkeys -f hostfile_exkeys | - h hostname [-h hostname ...]
gpssh-exkeys -e hostfile_exkeys -x hostfile_gpexpand
gpssh-exkeys -?
gpssh-exkeys --version
```

Description

The `gpssh-exkeys` utility exchanges SSH keys between the specified host names (or host addresses). This allows SSH connections between Greenplum hosts and network interfaces without a password prompt. The utility is used to initially prepare a Greenplum Database system for password-free SSH access, and also to add additional ssh keys when expanding a Greenplum Database system.

To specify the hosts involved in an initial SSH key exchange, use the `-f` option to specify a file containing a list of host names (recommended), or use the `-h` option to name single host names on the command-line. At least one host name (`-h`) or a host file is required. Note that the local host is included in the key exchange by default.

To specify new expansion hosts to be added to an existing Greenplum Database system, use the `-e` and `-x` options. The `-e` option specifies a file containing a list of existing hosts in the system that already have SSH keys. The `-x` option specifies a file containing a list of new hosts that need to participate in the SSH key exchange.

Keys are exchanged as the currently logged in user. You should perform the key exchange process twice: once as `root` and once as the `gpadmin` user (the user designated to own your Greenplum Database installation). The Greenplum Database management utilities require that the same non-root user be created on all hosts in the Greenplum Database system, and the utilities must be able to connect as that user to all hosts without a password prompt.

The `gpssh-exkeys` utility performs key exchange using the following steps:

- Creates an RSA identification key pair for the current user if one does not already exist. The public key of this pair is added to the `authorized_keys` file of the current user.
- Updates the `known_hosts` file of the current user with the host key of each host specified using the `-h`, `-f`, `-e`, and `-x` options.
- Connects to each host using `ssh` and obtains the `authorized_keys`, `known_hosts`, and `id_rsa.pub` files to set up password-free access.
- Adds keys from the `id_rsa.pub` files obtained from each host to the `authorized_keys` file of the current user.
- Updates the `authorized_keys`, `known_hosts`, and `id_rsa.pub` files on all hosts with new host information (if any).

Options

```
-e hostfile_exkeys
```

When doing a system expansion, this is the name and location of a file containing all configured host names and host addresses (interface names) for each host in your `current`
Greenplum system (master, standby master and segments), one name per line without blank lines or extra spaces. Hosts specified in this file cannot be specified in the host file used with \(-x\).

\(-f\) `hostfile_exkeys`

Specifies the name and location of a file containing all configured host names and host addresses (interface names) for each host in your Greenplum system (master, standby master and segments), one name per line without blank lines or extra spaces.

\(-h\) `hostname`

Specifies a single host name (or host address) that will participate in the SSH key exchange. You can use the \(-h\) option multiple times to specify multiple host names and host addresses.

\(--version\)

Displays the version of this utility.

\(-x\) `hostfile_gpexpand`

When doing a system expansion, this is the name and location of a file containing all configured host names and host addresses (interface names) for each new segment host you are adding to your Greenplum system, one name per line without blank lines or extra spaces. Hosts specified in this file cannot be specified in the host file used with \(-e\).

\(-?\) (help)

Displays the online help.

**Examples**

Exchange SSH keys between all host names and addresses listed in the file `hostfile_exkeys`:

```
$ gpssh-exkeys -f hostfile_exkeys
```

Exchange SSH keys between the hosts `sdw1`, `sdw2`, and `sdw3`:

```
$ gpssh-exkeys -h sdw1 -h sdw2 -h sdw3
```

Exchange SSH keys between existing hosts `sdw1`, `sdw2`, and `sdw3`, and new hosts `sdw4` and `sdw5` as part of a system expansion operation:

```
$ cat hostfile_exkeys
mdw
mdw-1
mdw-2
smdw
smdw-1
smdw-2
sdw1
sdw1-1
sdw1-2
sdw2
sdw2-1
sdw2-2
sdw3
sdw3-1
sdw3-2
$ cat hostfile_gpexpand
sdw4
sdw4-1
sdw4-2
sdw5
sdw5-1
```
See Also

gpssh, gpscp

gpstart

Starts a Greenplum Database system.

Synopsis

```
gpstart [-d master_data_directory] [-B parallel_processes] [-R]
[-m] [-y] [-a] [-t timeout_seconds] [-l logfile_directory]
[--skip-heap-checksum-validation] [-v | -q]
gpstart -? | -h | --help

gpstart --version
```

Description

The `gpstart` utility is used to start the Greenplum Database server processes. When you start a Greenplum Database system, you are actually starting several `postgres` database server listener processes at once (the master and all of the segment instances). The `gpstart` utility handles the startup of the individual instances. Each instance is started in parallel.

The first time an administrator runs `gpstart`, the utility creates a hosts cache file named `.gphostcache` in the user's home directory. Subsequently, the utility uses this list of hosts to start the system more efficiently. If new hosts are added to the system, you must manually remove this file from the `gpadmin` user's home directory. The utility will create a new hosts cache file at the next startup.

As part of the startup process, the utility checks the consistency of heap checksum setting among the Greenplum Database master and segment instances, either enabled or disabled on all instances. If the heap checksum setting is different among the instances, an error is returned and Greenplum Database does not start. The validation can be disabled by specifying the option `--skip-heap-checksum-validation`. For more information about heap checksums, see *Enabling High Availability and Data Consistency Features* in the *Greenplum Database Administrator Guide*.

**Note:** Before you can start a Greenplum Database system, you must have initialized the system using `gpinitsystem`. Enabling or disabling heap checksums is set when you initialize the system and cannot be changed after initialization.

If the Greenplum Database system is configured with a standby master, and `gpstart` does not detect it during startup, `gpstart` displays a warning and lets you cancel the startup operation.

- If the `-a` option (disable interactive mode prompts) is not specified, `gpstart` displays and logs these messages:

  Standby host is unreachable, cannot determine whether the standby is currently acting as the master. Received error: <error>

  Continue only if you are certain that the standby is not acting as the master.

It also displays this prompt to continue startup:

```
Continue with startup Yy|Nn (default=N):
```
• If the `-a` option is specified, the utility does not start the system. The messages are only logged, and `gpstart` adds this log message:

```
Non interactive mode detected. Not starting the cluster. Start the cluster in interactive mode.
```

If the standby master is not accessible, you can start the system and troubleshoot standby master issues while the system is available.

**Options**

- `--a`
  Do not prompt the user for confirmation. Disables interactive mode.

- `--B parallel_processes`
  The number of segments to start in parallel. If not specified, the utility will start up to 64 parallel processes depending on how many segment instances it needs to start.

- `--d master_data_directory`
  Optional. The master host data directory. If not specified, the value set for `$MASTER_DATA_DIRECTORY` will be used.

- `--l logfile_directory`
  The directory to write the log file. Defaults to `~/gpAdminLogs`.

- `--m`
  Optional. Starts the master instance only, which may be useful for maintenance tasks. This mode only allows connections to the master in utility mode. For example:

  ```bash
  PGOPTIONS='--gp_session_role=utility' psql
  ```

  The consistency of the heap checksum setting on master and segment instances is not checked.

- `--q`
  Run in quiet mode. Command output is not displayed on the screen, but is still written to the log file.

- `--R`
  Starts Greenplum Database in restricted mode (only database superusers are allowed to connect).

- `--skip-heap-checksum-validation`
  During startup, the utility does not validate the consistency of the heap checksum setting among the Greenplum Database master and segment instances. The default is to ensure that the heap checksum setting is the same on all instances, either enabled or disabled.

  **Warning:** Starting Greenplum Database without this validation could lead to data loss. Use this option to start Greenplum Database only when it is necessary to ignore the heap checksum verification errors to recover data or to troubleshoot the errors.

- `--t timeout_seconds`
  Specifies a timeout in seconds to wait for a segment instance to start up. If a segment instance was shutdown abnormally (due to power failure or killing its `postgres` database listener process, for example), it may take longer to start up due to the database recovery and validation process. If not specified, the default timeout is 60 seconds.

- `--v`
  Displays detailed status, progress and error messages output by the utility.
-y
Optional. Do not start the standby master host. The default is to start the standby master host and synchronization process.

-? | -h | --help
Displays the online help.

--version
Displays the version of this utility.

Examples
Start a Greenplum Database system:

    gpstart

Start a Greenplum Database system in restricted mode (only allow superuser connections):

    gpstart -R

Start the Greenplum master instance only and connect in utility mode:

    gpstart -m PGOPTIONS='-c gp_session_role=utility' psql

gpstop, gpinitdb

gpstate

Shows the status of a running Greenplum Database system.

Synopsis

    gpstate [-d master_data_directory] [-B parallel_processes]
    
    [-l log_directory]

    gpstate -? | -h | --help

Description

The gpstate utility displays information about a running Greenplum Database instance. There is additional information you may want to know about a Greenplum Database system, since it is comprised of multiple PostgreSQL database instances (segments) spanning multiple machines. The gpstate utility provides additional status information for a Greenplum Database system, such as:

- Which segments are down.
- Master and segment configuration information (hosts, data directories, etc.).
- The ports used by the system.
- A mapping of primary segments to their corresponding mirror segments.

Options

- b (brief status)
Optional. Display a brief summary of the state of the Greenplum Database system. This is the default option.
-B parallel_processes  
The number of segments to check in parallel. If not specified, the utility will start up to 60 parallel processes depending on how many segment instances it needs to check.

-c (show primary to mirror mappings)  
Optional. Display mapping of primary segments to their corresponding mirror segments.

-d master_data_directory  
Optional. The master data directory. If not specified, the value set for $MASTER_DATA_DIRECTORY will be used.

-e (show segments with mirror status issues)  
Show details on primary/mirror segment pairs that have potential issues such as 1) the active segment is running in change tracking mode, meaning a segment is down 2) the active segment is in resynchronization mode, meaning it is catching up changes to the mirror 3) a segment is not in its preferred role, for example a segment that was a primary at system initialization time is now acting as a mirror, meaning you may have one or more segment hosts with unbalanced processing load.

-f (show standby master details)  
Display details of the standby master host if configured.

-i (show Greenplum Database version)  
Display the Greenplum Database software version information for each instance.

-l logfile_directory  
The directory to write the log file. Defaults to ~/gpAdminLogs.

-m (list mirrors)  
Optional. List the mirror segment instances in the system, their current role, and synchronization status.

-p (show ports)  
List the port numbers used throughout the Greenplum Database system.

-q (no screen output)  
Optional. Run in quiet mode. Except for warning messages, command output is not displayed on the screen. However, this information is still written to the log file.

-Q (quick status)  
Optional. Checks segment status in the system catalog on the master host. Does not poll the segments for status.

-s (detailed status)  
Optional. Displays detailed status information for the Greenplum Database system.

-v (verbose output)  
Optional. Displays error messages and outputs detailed status and progress information.

-? | -h | --help (help)  
Displays the online help.

### Output Field Definitions

**gpstop**

Stops or restarts a Greenplum Database system.

### Synopsis

```
gpstop -m [-d master_data_directory] [-y] [-l logfile_directory] [-v | -q]
gpstop -u [-d master_data_directory] [-l logfile_directory] [-v | -q]
gpstop --host host_name [-d master_data_directory] [-l logfile_directory] [-t timeout_seconds] [-a] [-v | -q]
gpstop --version
```

### Description

The `gpstop` utility is used to stop the database servers that comprise a Greenplum Database system. When you stop a Greenplum Database system, you are actually stopping several `postgres` database server processes at once (the master and all of the segment instances). The `gpstop` utility handles the shutdown of the individual instances. Each instance is shutdown in parallel.

By default, you are not allowed to shut down Greenplum Database if there are any client connections to the database. Use the `-M fast` option to roll back all in progress transactions and terminate any connections before shutting down. If there are any transactions in progress, the default behavior is to wait for them to commit before shutting down.
With the `-u` option, the utility uploads changes made to the master `pg_hba.conf` file or to runtime configuration parameters in the master `postgresql.conf` file without interruption of service. Note that any active sessions will not pickup the changes until they reconnect to the database.

**Options**

`-a`

- Do not prompt the user for confirmation.

`-B parallel_processes`

- The number of segments to stop in parallel. If not specified, the utility will start up to 64 parallel processes depending on how many segment instances it needs to stop.

`-d master_data_directory`

- Optional. The master host data directory. If not specified, the value set for `$MASTER_DATA_DIRECTORY` will be used.

`--host host_name`

- The utility shuts down the Greenplum Database segment instances on the specified host to allow maintenance on the host. Each primary segment instance on the host is shut down and the associated mirror segment instance is promoted to a primary segment if the mirror segment is on another host. Mirror segment instances on the host are shut down.

- The segment instances are not shut down and the utility returns an error in these cases:
  - Segment mirroring is not enabled for the system.
  - The master or standby master is on the host.
  - Both a primary segment instance and its mirror are on the host.

- This option cannot be specified with the `-m`, `-r`, `-u`, or `-y` options.

  **Note:** The `gprecoverseg` utility restores segment instances. Run `gprecoverseg` commands to start the segments as mirrors and then to return the segments to their preferred role (primary segments).

`-l logfile_directory`

- The directory to write the log file. Defaults to `~/gpAdminLogs`.

`-m`

- Optional. Shuts down a Greenplum master instance that was started in maintenance mode.

`-M fast`

- Fast shut down. Any transactions in progress are interrupted and rolled back.

`-M immediate`

- Immediate shut down. Any transactions in progress are aborted.

- This mode kills all `postgres` processes without allowing the database server to complete transaction processing or clean up any temporary or in-process work files.

`-M smart`

- Smart shut down. If there are active connections, this command fails with a warning. This is the default shutdown mode.

`-q`

- Run in quiet mode. Command output is not displayed on the screen, but is still written to the log file.

`-r`

- Restart after shutdown is complete.

`-t timeout_seconds`
Specifies a timeout threshold (in seconds) to wait for a segment instance to shut down. If a segment instance does not shut down in the specified number of seconds, `gpstop` displays a message indicating that one or more segments are still in the process of shutting down and that you cannot restart Greenplum Database until the segment instance(s) are stopped. This option is useful in situations where `gpstop` is executed and there are very large transactions that need to rollback. These large transactions can take over a minute to rollback and surpass the default timeout period of 600 seconds.

```
-u
```

This option reloads the `pg_hba.conf` files of the master and segments and the runtime parameters of the `postgresql.conf` files but does not shutdown the Greenplum Database array. Use this option to make new configuration settings active after editing `postgresql.conf` or `pg_hba.conf`. Note that this only applies to configuration parameters that are designated as *runtime* parameters.

```
-v
```

Displays detailed status, progress and error messages output by the utility.

```
-y
```

Do not stop the standby master process. The default is to stop the standby master.

```
?- | -h | --help
```

Displays the online help.

```
--version
```

Displays the version of this utility.

### Examples

**Stop a Greenplum Database system in smart mode:**

```
gpstop
```

**Stop a Greenplum Database system in fast mode:**

```
gpstop -M fast
```

**Stop all segment instances and then restart the system:**

```
gpstop -r
```

**Stop a master instance that was started in maintenance mode:**

```
gpstop -m
```

**Reload the `postgresql.conf` and `pg_hba.conf` files after making configuration changes but do not shutdown the Greenplum Database array:**

```
gpstop -u
```

gptransfer

The gptransfer utility copies objects from databases in a source Greenplum Database system to databases in a destination Greenplum Database system.

Note: Greenplum Database provides two utilities for migrating data between Greenplum Database installations, gpcopy and gptransfer. Use gpcopy to migrate data to a Greenplum Database cluster version 5.9.0 and later. Use the gptransfer utility to migrate data between Greenplum Database installations running software version 5.8.0 or earlier.

The gptransfer utility is deprecated and will be removed in the next major release of Greenplum Database. For information about migrating data with gpcopy, see Migrating Data with gpcopy.

Synopsis

gptransfer
  { --full | 
  [ -d database1 [ -d database2 ... ] ] |
gptransfer utility copies database objects from a source Greenplum Database system to a destination system. You can perform one of the following types of operations:

- **Copy a Greenplum Database system with the **--full** option.**
  
  This option copies all user created databases in a source system to a different destination system. If you specify the **--full** option, you must specify both a source and destination system. The destination system cannot contain any user-defined databases, only the default databases **postgres**, **template0**, and **template1**.

- **Copy a set of user defined database tables to a destination system.** The **-f** and **-t** options copy a specified set of user defined tables, table data, and re-creates the table indexes. The **-d** option copies all user defined tables, table data, and re-creates the table indexes from a specified database.
  
  If the destination system is the same as the source system, you must also specify a destination database with the **--dest-database** option. When you specify a destination database, the source database tables are copied into the specified destination database.

  For partitioned tables, you can specify the **--partition-transfer** or the **--partition-transfer-non-partition-target** option with **-f** option to copy specific leaf child partitions of partitioned tables from a source database. The leaf child partitions are the lowest level partitions of a partitioned database. For the **--partition-transfer** option, the destination tables are leaf child partitions. For the **--partition-transfer-non-partition-target** option, the destination tables are non-partitioned tables.

  If an invalid set of gptransfer options are specified, or if a specified source table or database does not exist, gptransfer returns an error and quits. No data is copied.

  To copy database objects between Greenplum Database systems gptransfer utility uses:
• The Greenplum Database utility `gpfdist` on the source database system. The `gpfdists` protocol is not supported.

• Writable external tables on the source database system and readable external tables on the destination database system. Note that `gptransfer` creates external tables with the `execute` protocol, so the `--source_user` account must have superuser privileges (the default is `gpadmin`).

• Named pipes that transfer the data between a writable external table and a readable external table.

When copying data into the destination system, it is redistributed on the Greenplum Database segments of the destination system. This is the flow of data when `gptransfer` copies database data:

writable external table > `gpfdist` > named pipe > `gpfdist` > readable external table

For information about transferring data with `gptransfer`, see "Migrating Data with Gptransfer" in the Greenplum Database Administrator Guide.

About Database, Schema, and Table Names

When you transfer an entire database, schema and table names in the database can contain only alphanumeric characters and the underscore character (_). Also, Unicode characters are not supported. The same naming restrictions apply when you specify a database, schema, or table as an option or in a file.

Notes

The `gptransfer` utility efficiently transfers tables with large amounts of data. Because of the overhead required to set up parallel transfers, the utility is not recommended for transferring tables with small amounts of data. It might be more efficient to copy the schema and smaller tables to the destination database using other methods, such as the SQL `COPY` command, and then use `gptransfer` to transfer large tables in batches.

The maximum length of a data row that the `gptransfer` utility can copy is 256 MB.

When transferring data between databases, you can run only one instance of `gptransfer` at a time. Running multiple, concurrent instances of `gptransfer` is not supported.

When copying database data between different Greenplum Database systems, `gptransfer` requires a text file that lists all the source segment host names and IP addresses. Specify the name and location of the file with the `--source-map-file` option. If the file is missing or not all segment hosts are listed, `gptransfer` returns an error and quits. See the description of the option for file format information.

The source and destination Greenplum Database segment hosts need to be able to communicate with each other. To ensure that the segment hosts can communicate, you can use a tool such as the Linux `netperf` utility.

If a filespace has been created for a source Greenplum Database system, a corresponding filespace must exist on the target system.

SSH keys must be exchanged between the two systems before using `gptransfer`. The `gptransfer` utility connects to the source system with SSH to create the named pipes and start the `gpfdist` instances. You can use the Greenplum Database `gpssh-exkeys` utility with a list of all the source and destination primary hosts to exchange keys between Greenplum Database hosts.

Source and destination systems must be able to access the `gptransfer` work directory. The default directory is the user's home directory. You can specify a different directory with the `--work-base-dir` option.

The `gptransfer` utility logs messages in the `~/.gpAdminLogs` directory on the master host. `gptransfer` creates a log file with the name `gptransfer_date.log` and appends messages to it each time it runs on that day. You can specify a different directory for the log file using the `--log_directory` option.
Work directories named `~/gptransfer_process_id` are created on segment hosts in the source cluster. Log files for the `gpfdist` instances that `gptransfer` creates are in these directories. Adding the `--gpfdist-verbose` or `--gpfdist-very-verbose` options to the `gptransfer` command line increases the `gpfdist` logging level.

The `gptransfer` utility does not move configuration files such as `postgresql.conf` and `pg_hba.conf`. You must set up the destination system configuration separately.

The `gptransfer` utility does not move external objects such as Greenplum Database extensions, third party jar files, and shared object files. You must install the external objects separately.

The `gptransfer` utility does not move dependent database objects unless you specify the `--full` option. For example, if a table has a default value on a column that is a user-defined function, that function must exist in the destination system database when using the `--t`, `--d`, or `--f` options.

If you move a set of database tables with the `--d`, `--t`, or `--f` option, and the destination table or database does not exist, `gptransfer` creates it. The utility re-creates any indexes on tables before copying data.

If a table exists on the destination system and one of the options `--skip-existing`, `--truncate`, or `--drop` is not specified, `gptransfer` returns an error and quits.

If an error occurs when during the process of copying a table, or table validation fails, `gptransfer` continues copying the other specified tables. After `gptransfer` finishes, it displays a list of tables where an error occurred, writes the names of tables that failed into a text file, and then prints the name of the file. You can use this file with the `gptransfer -f` option to retry copying tables.

The name of the file that contains the list of tables where errors occurred is `failed_migrated_tables_yyyymmdd_hhmmss.txt`. The `yyyymmdd_hhmmss` is a timestamp when the `gptransfer` process was started. The file is created in the directory were `gptransfer` is executed.

After `gptransfer` completes copying database objects, the utility compares the row count of each table copied to the destination databases with the table in the source database. The utility returns the validation results for each table. You can disable the table row count validation by specifying the `--no-final-count` option.

**Note:** If the number of rows do not match, the table is not added to the file that lists the tables where transfer errors occurred.

The `gp_external_max_segs` server configuration parameter controls the number of segment instances that can access a single `gpfdist` instance simultaneously. Setting a low value might affect `gptransfer` performance. For information about the parameter, see the Greenplum Database Reference Guide.

**Limitation for the Source and Destination Systems**

If you are copying data from a system with a larger number of segments to a system with a fewer number of segment hosts, then the total number of primary segments on the destination system must be greater than or equal to the total number of segment hosts on the source system.

For example, assume a destination system has a total of 24 primary segments. This means that the source system cannot have more than 24 segment hosts.

When you copy data from a source Greenplum Database system with a larger number of primary segment instances than on the destination system, the data transfer might be slower when compared to a transfer where the source system has fewer segment instances than the destination system. The `gptransfer` utility uses a different configuration of named pipes and `gpfdist` instances in the two situations.

**Validating Table Data with SHA-256**

Validating table data with SHA-256 (specifying the option `--validate=sha256`) requires the Greenplum Database `pgcrypto` extension. The extension is included with Pivotal Greenplum 5.x. When copying data from a supported Pivotal Greenplum 4.3.x system, the extension package must be installed on the 4.3.x system. You do not need to run `pgcrypto.sql` to install the `pgcrypto` functions in a Greenplum 4.3.x database.
Options

-a
Quiet mode, do not prompt the user for confirmation.

--analyze
Run the ANALYZE command on non-system tables. The default is to not run the ANALYZE command.

--base-port=base_gpfdist_port
Base port for gpfdist on source segment systems. If not specified, the default is 8000.

--batch-size=batch_size
Sets the maximum number of tables that gptransfer concurrently copies to the destination database. If not specified, the default is 2. The maximum is 10.

Note: If the order of the transfer is important, specify a value of 1. The tables are transferred sequentially based on the order specified in the -t and -f options.

-d database
A source database to copy. This option can be specified multiple times to copy multiple databases to the destination system. All the user defined tables and table data are copied to the destination system.

A set of databases can be specified using the Python regular expression syntax. The regular expression pattern must be enclosed in slashes (/RE_pattern/). If you use a regular expression, the name must be enclosed in double quotes ("). This example -d "demo/.*" specifies all databases in the Greenplum Database installation that begin with demo.

Note: Note the following two examples for the -d option are equivalent. They both specify a set of databases that begins with demo and ends with zero or more digits.

-d "demo/[0-9]*/"
d -d "/demo[0-9]*/"

If the source database does not exist, gptransfer returns an error and quits. If a destination database does not exist a database is created.

Not valid with the --full, -f, -t, --partition-transfer, or --partition-transfer-non-partition-target options.

Alternatively, specify the -t or -f option to copy a specified set of tables.

--delimiter=delim
Delimiter to use for writable external tables created by gptransfer. Specify a single ASCII character that separates columns within each row of data. The default value is a comma (.). If delim is a comma (,) or if this option is not specified, gptransfer uses the CSV format for writable external tables. Otherwise, gptransfer uses the TEXT format.

If --delimiter, --format, and --quote options are not specified, these are settings for writable external tables:

FORMAT 'CSV' ( DELIMITER ',' QUOTE E'\001' )

You can specify a delimiter character such as a non-printing character with the format \digits (octal). A backslash followed by the octal value for the character. The octal format must be enclosed in double quotes. This example specifies the octal character \001, the SOH character:

--delimiter="\001"
--dest-database=dest_database_name

The database in the destination Greenplum Database system. If not specified, the source tables are copied into a destination system database with the same name as the source system database.

This option is required if the source and destination Greenplum Database systems are the same.

If destination database does not exist, it is created.

Not valid with the --full, --partition-transfer, or --partition-transfer-non-partition-target options.

--dest-host=dest_host

Destination Greenplum Database hostname or IP address. If not specified, the default is the host the system running gptransfer (127.0.0.1)

--dest-port=dest_port

Destination Greenplum Database port number, If not specified, the default is 5432.

--dest-user=dest_user

User ID that is used to connect to the destination Greenplum Database system. If not specified, the default is the user gpadmin.

--drop

Specify this option to drop the table that is in the destination database if it already exists. Before copying table data, gptransfer drops the table and creates it again.

At most, only one of the options can be specified --skip-existing, --truncate, or --drop. If one of them is not specified and the table exists in the destination system, gptransfer returns an error and quits.

Not valid with the --full, --partition-transfer, or --partition-transfer-non-partition-target options.

--dry-run

When you specify this option, gptransfer generates a list of the migration operations that would have been performed with the specified options. The data is not migrated.

The information is displayed at the command line and written to the log file.

-f table-file

The location and name of file containing list of fully qualified table names to copy from the Greenplum Database source system. In the text file, you specify a single fully qualified table per line (database.schema.table).

A set of tables can be specified using the Python regular expression syntax. See the -d option for information about using regular expressions.

If the source table does not exist, gptransfer returns an error and quits. If the destination database or table does not exist, it is created.

Only the table and table data are copied and indexes are re-created. Dependent objects are not copied.

You cannot specify views, or system catalog tables. The --full option copies user defined views.

If you specify the -d option to copy all the tables from a database, you cannot specify individual tables from the database.

Not valid with the --full, -d, or -t options.

--partition-transfer (partitioned destination table)
Specify this option with the \(-f\) option to copy data from leaf child partition tables of partitioned tables from a source database to the leaf child partition tables in a destination database. The text file specified by the \(-f\) option contains a list of fully qualified leaf child partition table names with this syntax.

\[ src_db.src_schema.src_prt_tbl[, dst_db.dst_schema.dst_prt_tbl] \]

Wildcard characters are not supported in the fully qualified table names. The destination partitioned table must exist. If the destination leaf child partition table is not specified in the file, \(gptransfer\) copies the data to the same fully qualified table name \((db_name.schema.table)\) in the destination Greenplum Database system. If the source and destination Greenplum Database systems are the same, you must specify a destination table where at least one of the following must be different between the source and destination table: \(db_name, schema, or table\).

If either the source or destination table is not a leaf child partition, the utility returns an error and no data are transferred.

These characteristics must be the same for the partitioned table in the source and destination database.

- Number of table columns and the order of the column data types (the source and destination table names and table column names can be different)
- Partition level of the specified source and destination tables
- Partitioning criteria of the specified source and destination leaf child partitions and child partitions above them in the hierarchy (partition type and partition column)

This option is not valid with these options: \(-d, --dest-database, --drop, -F, --full, --schema-only, -T, -t\).

**Note:** If a destination table is not empty or the data in the source or destination table changes during a transfer operation (rows are inserted or deleted), the table row count validation fails due to row count mismatch.

If the destination table is not empty, you can specify the \(-\text{truncate}\) option to truncate the table before the transfer operation.

You can specify the \(-x\) option to acquire exclusive locks on the tables during a transfer operation.

\(--\text{partition-transfer-non-partition-target} \ (\text{non-partitioned destination table})\) \n
Specify this option with the \(-f\) option to copy data from leaf child partition tables of partitioned tables in a source database to non-partitioned tables in a destination database. The text file specified by the \(-f\) option contains a list of fully qualified leaf child partition table names in the source database and non-partitioned tables names in the destination database with this syntax.

\[ src_db.src_schema.src_part_tbl, dest_db.dest_schema.dest_tbl \]

Wildcard characters are not supported in the fully qualified table names. The destination tables must exist, and both source and destination table names are required in the file.

If a source table is not a leaf child partition table or a destination table is not a normal (non-partitioned) table, the utility returns an error and no data are transferred.

If the source and destination Greenplum Database systems are the same, you must specify a destination table where at least one of the following must be different between the source and destination table: \(db_name, schema, or table\).
For the partitioned table in the source database and the table in the destination database, the number of table columns and the order of the column data types must be the same (the source and destination table column names can be different).

The same destination table can be specified in the file for multiple source leaf child partition tables that belong to a single partitioned table. Transferring data from source leaf child partition tables that belong to different partitioned tables to a single non-partitioned table is not supported.

This option is not valid with these options: -d, --dest-database, --drop, -F, --full, --schema-only, -T, -t, --truncate, --validate.

**Note:** If the data in the source or destination table changes during a transfer operation (rows are inserted or deleted), the table row count validation fails due to row count mismatch.

You can specify the -x option to acquire exclusive locks on the tables during a transfer operation.

**-F table-file**

The location and name of file containing list of fully qualified table names to exclude from transferring to the destination system. In the text file, you specify a single fully qualified table per line.

A set of tables can be specified using the Python regular expression syntax. See the -d option for information about using regular expressions.

The utility removes the excluded tables from the list of tables that are being transferred to the destination database before starting the transfer. If excluding tables results in no tables being transferred, the database or schema is not created in the destination system.

If a source table does not exist, gptransfer displays a warning. Only the specified tables are excluded. To exclude dependent objects, you must explicitly specify them.

You cannot specify views, or system catalog tables.

Not valid with the --full, --partition-transfer, or --partition-transfer-non-partition-target options.

You can specify the --dry-run option to test the command. The -v option, displays and logs the excluded tables.

**--format=[CSV | TEXT]**

Specify the format of the writable external tables that are created by gptransfer to transfer data. Values are CSV for comma separated values, or TEXT for plain text. The default value is CSV.

If the options --delimiter, --format, and --quote are not specified, these are default settings for writable external tables:

```
FORMAT 'CSV' ( DELIMITER ',' QUOTE E'\001' )
```

If you specify TEXT, you must also specify a non-comma delimiter with the --delimiter=delim option. These are settings for writable external tables:

```
FORMAT 'TEXT' ( DELIMITER delim ESCAPE 'off' )
```

**--full**

Full migration of a Greenplum Database source system to a destination system. You must specify the options for the destination system, the --source-map-file option, the --dest-host option, and if necessary, the other destination system options.

The --full option cannot be specified with the -t, -d, -f, --partition-transfer, or --partition-transfer-non-partition-target options.
A full migration copies all database objects including, tables, indexes, views, users, roles, functions, and resource queues for all user defined databases. The default databases, postgres, template0 and template1 are not moved.

If a database exists in the destination system, besides the default postgres, template0 and template1 databases, gptransfer returns an error and quits.

Note: The --full option is recommended only when the databases contain a large number of tables with large amounts of data. Because of the overhead required to set up parallel transfers, the utility is not recommended when the databases contain tables with small amounts of data. For more information, see Notes.

--gpfdist-verbose
Set the logging level for gpfdist processes to verbose (--v). Cannot be specified with --gpfdist-very-verbose.

The output is recorded in gpfdist log files in the ~/gptransfer_process_id directory on segment hosts in the source Greenplum Database cluster.

--gpfdist-very-verbose
Set the logging level for gpfdist processes to very verbose (--V). Cannot be specified with --gpfdist-verbose.

The output is recorded in gpfdist log files in the ~/gptransfer_process_id directory on segment hosts in the source Greenplum Database cluster.

-l log_dir
Specify the gptransfer log file directory. If not specified, the default is ~/gpAdminLogs. This directory is created on the master host in the source Greenplum cluster.

--max-line-length= length
Sets the maximum allowed data row length in bytes for the gpfdist utility. If not specified, the default is 10485760. Valid range is 32768 (32K) to 268435456 (256MB).

Should be used when user data includes very wide rows (or when line too long error message occurs). Should not be used otherwise as it increases resource allocation.

--no-final-count
Disable table row count validation that is performed after gptransfer completes copying database objects to the target database. The default is to compare the row count of tables copied to the destination databases with the tables in the source database.

-q | --quiet
If specified, suppress status messages. Messages are only sent to the log file.

--quote=character
The quotation character when gptransfer creates writable external tables with the CSV format. Specify a single ASCII character that is used to enclose column data. The default value is the octal character \001, the SOH character.

You can specify a delimiter character such as a non-printing character with the format "\digits" (octal). A backslash followed by the octal value for the character. The octal value must be enclosed in double quotes.

--schema-only
Create only the schemas specified by the command. Data is not transferred.

If specified with the --full option, gptransfer replicates the complete database schema, including all tables, indexes, views, user defined types (UDT), and user defined functions (UDF) for the source databases. No data is transferred.
If you specify databases with the `-d` option or tables with the `-t` or `-f` options, `gptransfer` creates only the tables and indexes. No data is transferred.

**Not valid with the `--partition-transfer`, `--partition-transfer-non-partition-target`, or `--truncate` options.**

**Note:** Because of the overhead required to set up parallel transfers, the `--schema-only` option is not recommended when transferring information for a large number of tables. For more information, see *Notes.*

---

**--skip-existing**

Specify this option to skip copying a table from the source database if the table already exists in the destination database.

At most, only one of the options can be specified `--skip-existing`, `--truncate`, or `--drop`. If one of them is not specified and the table exists in the destination system, `gptransfer` returns an error and quits.

**Not valid with the `--full` option.**

---

**--source-host=** *source_host*

Source Greenplum Database host name or IP address. If not specified, the default host is the system running `gptransfer` (127.0.0.1).

---

**--source-map-file=** *host_map_file*

File that lists source segment host name and IP addresses. If the file is missing or not all segment hosts are listed, `gptransfer` returns an error and quits.

Each line of the file contains a source host name and the host IP address separated by a comma: `hostname,IPaddress`. This example lists four Greenplum Database hosts and their IP addresses.

```
sdw1,192.0.2.1
sdw2,192.0.2.2
sdw3,192.0.2.3
sdw4,192.0.2.4
```

This option is required if the `--full` option is specified or if the source Greenplum Database system is different than the destination system. This option is not required if source and destination systems are the same.

---

**--source-port=** *source_port*

Source Greenplum Database port number. If not specified, the default is 5432.

---

**--source-user=** *source_user*

User ID that is used to connect to the source Greenplum Database system. If not specified, the default is the user `gpadmin`.

**Note:** `gptransfer` creates external tables with the `execute` protocol, so the `--source-user` that you specify must have superuser privileges.

---

**--sub-batch-size=** *sub_batch_size*

Specifies the maximum degree of parallelism of the operations performed when migrating a table such as starting `gpfdist` instances, creating named pipes for the move operations. If not specified, the default is 25. The maximum is 50.

Specify the `--batch-size` option to control the maximum number of tables that `gptransfer` concurrently processes.

---

**-t db.schema.table**

A table from the source database system to copy. The fully qualified table name must be specified.
A set of tables can be specified using the Python regular expression syntax. See the \-d option for information about using regular expressions.

If the destination table or database does not exist, it is created. This option can be specified multiple times to include multiple tables. Only the table and table data are copied and indexes are re-created. Dependent objects are not copied.

If the source table does not exist, \texttt{gptransfer} returns an error and quits.

If you specify the \-d option to copy all the tables from a database, you do not need to specify individual tables from the database.

\textbf{Not valid with the \texttt{--full}, \texttt{--partition-transfer}, or \texttt{--partition-transfer-non-partition-target} options.}

\texttt{-T db.schema.table}

A table from the source database system to exclude from transfer. The fully qualified table name must be specified.

A set of tables can be specified using the Python regular expression syntax. See the \-d option for information about using regular expressions.

This option can be specified multiple times to include multiple tables. Only the specified tables are excluded. To exclude dependent objects, you must explicitly specify them.

The utility removes the excluded tables from the list of tables that are being transferred to the destination database before starting the transfer. If excluding tables results in no tables being transferred, the database or schema is not created in the destination system.

If a source table does not exist, \texttt{gptransfer} displays a warning.

\textbf{Not valid with the \texttt{--full}, \texttt{--partition-transfer}, or \texttt{--partition-transfer-non-partition-target} options.}

You can specify the \texttt{--dry-run} option to test the command. The \texttt{-v} option displays and logs the excluded tables.

\texttt{--timeout seconds}

Specify the time out value in seconds that \texttt{gptransfer} passes the \texttt{gpfdist} processes that \texttt{gptransfer} uses. The value is the time allowed for Greenplum Database to establish a connection to a \texttt{gpfdist} process. You might need to increase this value when operating on high-traffic networks.

The default value is 300 seconds (5 minutes). The minimum value is 2 seconds, the maximum value is 600 seconds.

\texttt{--truncate}

Specify this option to truncate the table that is in the destination database if it already exists.

At most, only one of the options can be specified \texttt{--skip-existing}, \texttt{--truncate}, or \texttt{--drop}. If one of them is not specified and the table exists in the destination system, \texttt{gptransfer} returns an error and quits.

\textbf{Not valid with the \texttt{--full} option.}

\texttt{--validate=type}

Perform data validation on table data. These are the supported types of validation.

\texttt{count} - Specify this value to compare row counts between source and destination table data.

\texttt{MD5} - Specify this value to compare MD5 values between source and destination table data.

If validation for a table fails, \texttt{gptransfer} displays the name of the table and writes the file name to the text file \texttt{failed_migrated_tables_yyyymmdd_hhmss.txt}. The
### Examples

This command copies the table `public.t1` from the database `db1` and all tables in the database `db2` to the system `mytest2`.

```
  gptransfer -t db1.public.t1 -d db2 --dest-host=mytest2 \
    --source-map-file=gp-source-hosts --truncate
```

If the databases `db1` and `db2` do not exist on the system `mytest2`, they are created. If any of the source tables exist on the destination system, `gptransfer` truncates the table and copies the data from the source to the destination table.

This command copies leaf child partition tables from a source system to a destination system.

```
  gptransfer -f input_file --partition-transfer --source-host=source_host \
    --source-user=source_user --source-port=source_port --dest-host=dest_host \
    --dest-user=dest_user --dest-port=dest_port --source-map-file=host_map_file
```

This line in `input_file` copies a leaf child partition from the source system to the destination system.

```
  srcdb.people.person_1_prt_experienced, destdb.public.employee_1_prt_seniors
```

The line assumes partitioned tables in the source and destination systems similar to the following tables.
In the `people` schema of the `srcdb` database of the source system, a partitioned table with a leaf child partition table `person_1_prt_experienced`. This `CREATE TABLE` command creates a partitioned table with the leaf child partition table.

```sql
CREATE TABLE person(id int, title char(1))
    DISTRIBUTED BY (id)
    PARTITION BY list (title)
    (PARTITION experienced VALUES ('S'),
     PARTITION entry_level VALUES ('J'),
     DEFAULT PARTITION other);
```

In the `public` schema of the `destdb` database of the source system, a partitioned table with a leaf child partition table `public.employee_1_prt_seniors`. This `CREATE TABLE` command creates a partitioned table with the leaf child partition table.

```sql
CREATE TABLE employee(id int, level char(1))
    DISTRIBUTED BY (id)
    PARTITION BY list (level)
    (PARTITION seniors VALUES ('S'),
     PARTITION juniors VALUES ('J'),
     DEFAULT PARTITION other);
```

This example uses Python regular expressions in a filter file to specify the set of tables to transfer. This command specifies the `-f` option with the filter file `/tmp/filter_file` to limit the tables that are transferred.

```bash
gptransfer -f /tmp/filter_file --source-port 5432 --source-host test4 --source-user gpadmin --dest-user gpadmin --dest-port 5432 --dest-host test1 --source-map-file /home/gpadmin/source_map_file
```

This is the contents of `/tmp/filter_file`.

```text
"test1.arc/.*/.*/"  
"test1.c/(..)/y/.*/"
```

In the first line, the regular expressions for the schemas, `arc/.*`, and for the tables, `/.*/`, limit the transfer to all tables with the schema names that start with `arc`.

In the second line, the regular expressions for the schemas, `c/(..)/y`, and for the tables, `/.*/`, limit the transfer to all tables with the schema names that are four characters long and that start with `c` and end with `y`, for example, `crty`.

When the command is run, tables in the database `test1` that satisfy either condition are transferred to the destination database.

`gpfdist`

For information about loading and unloading data, see the *Greenplum Database Administrator Guide*.

`pgbouncer`

Manages database connection pools.

**Synopsis**

```bash
pgbouncer [OPTION ...] pgbouncer.ini
```
 PgBouncer is a light-weight connection pool manager for Greenplum and PostgreSQL databases. PgBouncer maintains a pool of connections for each database user and database combination. PgBouncer either creates a new database connection for the client or reuses an existing pooled connection for the same user and database. When the client disconnects, PgBouncer returns the connection to the pool for re-use.

PgBouncer supports the standard connection interface shared by PostgreSQL and Greenplum Database. The Greenplum Database client application (for example, psql) should connect to the host and port on which PgBouncer is running rather than directly to the Greenplum Database master host and port.

You configure PgBouncer and its access to Greenplum Database via a configuration file. You provide the configuration file name, usually pgbouncer.ini, when you run the pgbouncer command. This file provides location information for Greenplum databases. The pgbouncer.ini file also specifies process, connection pool, authorized users, and authentication configuration for PgBouncer, among other configuration options.

By default, the pgbouncer process runs as a foreground process. You can optionally start pgbouncer as a background (daemon) process with the -d option.

The pgbouncer process is owned by the operating system user that starts the process. You can optionally specify a different user name under which to start pgbouncer.

PgBouncer includes a psql-like administration console. Authorized users can connect to a virtual database to monitor and manage PgBouncer. You can manage a PgBouncer daemon process via the admin console. You can also use the console to update and reload the PgBouncer configuration at runtime without stopping and restarting the process.

For additional information about PgBouncer, refer to the PgBouncer FAQ.

**Options**

- **d | --daemon**
  
  Run PgBouncer as a daemon (a background process). The default start-up mode is to run as a foreground process.

  When run as a daemon, PgBouncer displays start-up messages to stdout. To suppress the display of these messages, include the -q option when you start PgBouncer.

  To stop a PgBouncer process that was started as a daemon, issue the SHUTDOWN command from the PgBouncer administration console.

- **R | --restart**
  
  Restart PgBouncer using the specified command line arguments. Non-TLS connections to databases are maintained during restart; TLS connections are dropped.

  To restart PgBouncer as a daemon, specify the options -Rd.

  **Note:** Restart is available only if the operating system supports Unix sockets and the PgBouncer unix_socket_dir configuration is not disabled.

- **q | --quiet**
  
  Run quietly. Do not display messages to stdout.
-v | --verbose
    Increase message verbosity. Can be specified multiple times.

{-u | --user}=username
    Assume the identity of username on PgBouncer process start-up.

-V | --version
    Show the version and exit.

-h | --help
    Show the command help message and exit.

See Also

pgbouncer.ini, pgbouncer-admin

**pgbouncer.ini**

PgBouncer configuration file.

**Synopsys**

```ini
[DATABASES]
    db = ...

[pgbouncer]
    ...

[users]
    ...
```

**Description**

You specify PgBouncer configuration parameters and identify user-specific configuration parameters in the pgbouncer.ini configuration file.

The PgBouncer configuration file (typically named pgbouncer.ini) is specified in .ini format. Files in .ini format are composed of sections, parameters, and values. Section names are enclosed in square brackets, for example, [section_name]. Parameters and values are specified in key=value format. Lines beginning with a semicolon (;) or pound sign (#) are considered comment lines and are ignored.

The PgBouncer configuration file can contain %include directives, which specify another file to read and process. This enables you to split the configuration file into separate parts. For example:

```
%include filename
```

If the filename provided is not an absolute path, the file system location is taken as relative to the current working directory.

The PgBouncer configuration file includes the following sections, described in detail below:

- [databases] Section
- [pgbouncer] Section
- [users] Section

**[databases] Section**

The [databases] section contains key=value pairs, where the key is a database name and the value is a libpq connect-string list of key=value pairs.
A database name can contain characters [0-9A-Za-z_.-] without quoting. Names that contain other characters must be quoted with standard SQL identifier quoting:

- Enclose names in double quotes (" ").
- Represent a double-quote within an identifier with two consecutive double quote characters.

The database name * is the fallback database. PgBouncer uses the value for this key as a connect string for the requested database. Automatically-created database entries such as these are cleaned up if they remain idle longer than the time specified in `autodb_idle_timeout` parameter.

**Database Connection Parameters**

The following parameters may be included in the `value` to specify the location of the database.

`dbname`
- The destination database name.
  - Default: the client-specified database name

`host`
- The name or IP address of the Greenplum master host. Host names are resolved at connect time. If DNS returns several results, they are used in a round-robin manner. The DNS result is cached and the `dns_max_ttl` parameter determines when the cache entry expires.
  - Default: not set; the connection is made through a Unix socket

`port`
- The Greenplum Database master port.
  - Default: 5432

`user, password`
- If `user=` is set, all connections to the destination database are initiated as the specified user, resulting in a single connection pool for the database.
- If the `user=` parameter is not set, PgBouncer attempts to log in to the destination database with the user name passed by the client. In this situation, there will be one pool for each user who connects to the database.

`auth_user`
- If `auth_user` is set, any user who is not specified in `auth_file` is authenticated by querying the `pg_shadow` database view. PgBouncer performs this query as the `auth_user` Greenplum Database user. `auth_user`'s password must be set in the `auth_file`.

`client_encoding`
- Ask for specific `client_encoding` from server.

`datestyle`
- Ask for specific `datestyle` from server.

`timezone`
- Ask for specific `timezone` from server.

**Pool Configuration**

You can use the following parameters for database-specific pool configuration.

`pool_size`
- Set the maximum size of pools for this database. If not set, the `default_pool_size` is used.
connect_query
Query to be executed after a connection is established, but before allowing the connection to be used by any clients. If the query raises errors, they are logged but ignored otherwise.

pool_mode
Set the pool mode for this database. If not set, the default pool_mode is used.

max_db_connections
Set a database-wide maximum number of PgBouncer connections for this database. The total number of connections for all pools for this database will not exceed this value.

[pgbouncer] Section

Generic Settings

logfile
The location of the log file. The log file is kept open. After log rotation, execute kill -HUP pgbouncer or run the RELOAD; command in the PgBouncer Administration Console.
Default: not set

pidfile
The name of the pid file. Without a pidfile, you cannot run PgBouncer as a background (daemon) process.
Default: not set

listen_addr
A list of interface addresses where PgBouncer listens for TCP connections. You may also use *, which means to listen on all interfaces. If not set, only Unix socket connections are allowed.
Specify addresses numerically (IPv4/IPv6) or by name.
Default: not set

listen_port
The port PgBouncer listens on. Applies to both TCP and Unix sockets.
Default: 6432

unix_socket_dir
Specifies the location for the Unix sockets. Applies to both listening socket and server connections. If set to an empty string, Unix sockets are disabled. Required for online restart (-R option) to work.
Default: /tmp

unix_socket_mode
Filesystem mode for the Unix socket.
Default: 0777

unix_socket_group
Group name to use for Unix socket.
Default: not set

user
If set, specifies the Unix user to change to after startup. This works only if PgBouncer is started as root or if user is the same as the current user.
Default: not set
auth_file

The name of the file containing the user names and passwords to load. The file format is the same as the Greenplum Database pg_auth file.

Default: not set

auth_hba_file

HBA configuration file to use when auth_type is hba. Refer to the HBA file format discussion in the PgBouncer documentation for information about PgBouncer support of the HBA authentication file format.

Default: not set

auth_type

How to authenticate users.

pam

Use PAM to authenticate users. auth_file is ignored. This method is not compatible with databases using the auth_user option. The service name reported to PAM is “pgbouncer”. PAM is not supported in the HBA configuration file.

hba

The actual authentication type is loaded from the auth_hba_file. This setting allows different authentication methods different access paths.

cert

Clients must connect with TLS using a valid client certificate. The client's username is taken from CommonName field in the certificate.

md5

Use MD5-based password check. auth_file may contain both MD5-encrypted or plain-text passwords. This is the default authentication method.

plain

Clear-text password is sent over wire. Deprecated.

trust

No authentication is performed. The username must still exist in the auth_file.

any

Like the trust method, but the username supplied is ignored. Requires that all databases are configured to log in with a specific user. Additionally, the console database allows any user to log in as admin.

auth_query

Query to load a user's password from the database. If a user does not exist in the auth_file and the database entry includes an auth_user, this query is run in the database as auth_user to lookup up the user.

Note that the query is run inside target database, so if a function is used it needs to be installed into each database.

Default: SELECT usename, passwd FROM pg_shadow WHERE usename=$1

auth_user

If auth_user is set, any user who is not specified in auth_file is authenticated through the auth_query query from the pg_shadow database view. PgBouncer performs this query as the auth_user Greenplum Database user. auth_user's password must be set in the auth_file.

Direct access to pg_shadow requires Greenplum Database administrative privileges. It is preferable to use a non-admin user that calls SECURITY DEFINER function instead.
**pool_mode**

Specifies when a server connection can be reused by other clients.

- **session**
  Connection is returned to the pool when the client disconnects. Default.

- **transaction**
  Connection is returned to the pool when the transaction finishes.

- **statement**
  Connection is returned to the pool when the current query finishes. Long transactions with multiple statements are disallowed in this mode.

**max_client_conn**

Maximum number of client connections allowed. When increased, you should also increase the file descriptor limits. The actual number of file descriptors used is more than max_client_conn. The theoretical maximum used, when each user connects with its own username to the server is:

\[
\text{max_client_conn} \, + \, (\text{max_pool_size} \, \times \, \text{total_databases} \, \times \, \text{total_users})
\]

If a database user is specified in the connect string, all users connect using the same username. Then the theoretical maximum connections is:

\[
\text{max_client_conn} \, + \, (\text{max_pool_size} \, \times \, \text{total_databases})
\]

(The theoretical maximum should be never reached, unless someone deliberately crafts a load for it. Still, it means you should set the number of file descriptors to a safely high number. Search for ulimit in your operating system documentation.)

Default: 100

**default_pool_size**

The number of server connections to allow per user/database pair. This can be overridden in the per-database configuration.

Default: 20

**min_pool_size**

Add more server connections to the pool when it is lower than this number. This improves behavior when the usual load drops and then returns suddenly after a period of total inactivity.

Default: 0 (disabled)

**reserve_pool_size**

The number of additional connections to allow for a pool. 0 disables.

Default: 0 (disabled)

**reserve_pool_timeout**

If a client has not been serviced in this many seconds, PgBouncer enables use of additional connections from the reserve pool. 0 disables.

Default: 5.0

**max_db_connections**

The maximum number of connections per database. If you hit the limit, closing a client connection to one pool does not immediately allow a server connection to be established for another pool, because the server connection for the first pool is still open. Once the server connection closes (due to idle timeout), a new server connection will be opened for the waiting pool.
Default: unlimited

**max_user_connections**

The maximum number of connections per-user. When you hit the limit, closing a client connection to one pool does not immediately allow a connection to be established for another pool, because the connection for the first pool is still open. After the connection for the first pool has closed (due to idle timeout), a new server connection is opened for the waiting pool.

**server_round_robin**

By default, PgBouncer reuses server connections in LIFO (last-in, first-out) order, so that a few connections get the most load. This provides the best performance when a single server serves a database. But if there is TCP round-robin behind a database IP, then it is better if PgBouncer also uses connections in that manner to achieve uniform load.

Default: 0

**ignore_startup_parameters**

By default, PgBouncer allows only parameters it can keep track of in startup packets: `client_encoding`, `datestyle`, `timezone`, and `standard_conforming_strings`. All others parameters raise an error. To allow other parameters, specify them here so that PgBouncer can ignore them.

Default: empty

**disable_pqexec**

Disable Simple Query protocol (PQexec). Unlike Extended Query protocol, Simple Query protocol allows multiple queries in one packet, which allows some classes of SQL-injection attacks. Disabling it can improve security. This means that only clients that exclusively use Extended Query protocol will work.

Default: 0

**application_name_add_host**

Add the client host address and port to the application name setting set on connection start. This helps in identifying the source of bad queries. The setting is overwritten without detection if the application executes `SET application_name` after connecting.

Default: 0

**conffile**

Show location of the current configuration file. Changing this parameter will result in PgBouncer using another config file for next RELOAD / SIGHUP.

Default: file from command line

**service_name**

Used during win32 service registration.

Default: pgbouncer

**job_name**

Alias for `service_name`.

**Log Settings**

**syslog**

Toggles syslog on and off.

Default: 0

**syslog_ident**
Under what name to send logs to syslog.
Default: `pgbouncer`

**syslog_facility**

Under what facility to send logs to syslog. Some possibilities are: `auth`, `authpriv`, `daemon`, `user`, `local0-7`
Default: `daemon`

**log_connections**

Log successful logins.
Default: 1

**log_disconnections**

Log disconnections, with reasons.
Default: 1

**log_pooler_errors**

Log error messages that the pooler sends to clients.
Default: 1

**stats_period**

How often to write aggregated statistics to the log.
Default: 60

**Console Access Control**

**admin_users**

Comma-separated list of database users that are allowed to connect and run all commands on the PgBouncer Administration Console. Ignored when `auth_type=any`, in which case any username is allowed in as admin.
Default: empty

**stats_users**

Comma-separated list of database users that are allowed to connect and run read-only queries on the console. This includes all `SHOW` commands except `SHOW FDS`.
Default: empty

**Connection Sanity Checks, Timeouts**

**server_reset_query**

Query sent to server on connection release, before making it available to other clients. At that moment no transaction is in progress so it should not include `ABORT` or `ROLLBACK`.

The query should clean any changes made to a database session so that the next client gets a connection in a well-defined state. Default is `DISCARD ALL` which cleans everything, but that leaves the next client no pre-cached state.

**Note:** Greenplum Database does not support `DISCARD ALL`.

You can use other commands to clean up the session state. For example, `DEALLOCATE ALL` drops prepared statements, and `DISCARD TEMP` drops temporary tables.

When transaction pooling is used, the `server_reset_query` should be empty, as clients should not use any session features. If clients do use session features, they will be broken because transaction pooling does not guarantee that the next query will run on the same connection.
Default: `DISCARD ALL`; (Not supported by Greenplum Database.)

**server_reset_query_always**
Whether `server_reset_query` should be run in all pooling modes. When this setting is off (default), the `server_reset_query` will be run only in pools that are in sessions pooling mode. Connections in transaction pooling mode should not have any need for reset query.
Default: 0

**server_check_delay**
How long to keep released connections available for re-use without running sanity-check queries on it. If 0, then the query is run always.
Default: 30.0

**server_check_query**
A simple do-nothing query to test the server connection.
If an empty string, then sanity checking is disabled.
Default: `SELECT 1;`

**server_lifetime**
The pooler tries to close server connections that have been connected longer than this number of seconds. Setting it to 0 means the connection is to be used only once, then closed.
Default: 3600.0

**server_idle_timeout**
If a server connection has been idle more than this many seconds it is dropped. If this parameter is set to 0, timeout is disabled. [seconds]
Default: 600.0

**server_connect_timeout**
If connection and login will not finish in this number of seconds, the connection will be closed.
Default: 15.0

**server_login_retry**
If a login fails due to failure from `connect()` or authentication, the pooler waits this many seconds before retrying to connect.
Default: 15.0

**client_login_timeout**
If a client connects but does not manage to login in this number of seconds, it is disconnected. This is needed to avoid dead connections stalling `SUSPEND` and thus online restart.
Default: 60.0

**autodb_idle_timeout**
If database pools created automatically (via `*`) have been unused this many seconds, they are freed. Their statistics are also forgotten.
Default: 3600.0

**dns_max_ttl**
How long to cache DNS lookups, in seconds. If a DNS lookup returns several answers, PgBouncer round-robins between them in the meantime. The actual DNS TTL is ignored.

Default: 15.0

dns_nxdomain_ttl
How long error and NXDOMAIN DNS lookups can be cached, in seconds.

Default: 15.0

dns_zone_check_period
Period to check if zone serial numbers have changed.
PgBouncer can collect DNS zones from hostnames (everything after first dot) and then periodically check if the zone serial numbers change. If changes are detected, all hostnames in that zone are looked up again. If any host IP changes, its connections are invalidated.

Works only with UDNS and c-ares backend (--with-udns or --with-cares to configure).

Default: 0.0 (disabled)

TLS settings

client_tls_sslmode
TLS mode to use for connections from clients. TLS connections are disabled by default. When enabled, client_tls_key_file and client_tls_cert_file must be also configured to set up the key and certificate PgBouncer uses to accept client connections.

• disable: Plain TCP. If client requests TLS, it’s ignored. Default.
• allow: If client requests TLS, it is used. If not, plain TCP is used. If client uses client-certificate, it is not validated.
• prefer: Same as allow.
• require: Client must use TLS. If not, client connection is rejected. If client uses client-certificate, it is not validated.
• verify-ca: Client must use TLS with valid client certificate.
• verify-full: Same as verify-ca.

client_tls_key_file
Private key for PgBouncer to accept client connections.

Default: not set

client_tls_cert_file
Root certificate file to validate client certificates.

Default: unset

client_tls_ca_file
Root certificate to validate client certificates.

Default: unset

client_tls_protocols
Which TLS protocol versions are allowed.
Valid values: are tlsv1.0, tlsv1.1, tlsv1.2.
Shortcuts: all (tlsv1.0,tlsv1.1,tlsv1.2), secure (tlsv1.2), legacy (all).

Default: all

client_tls_ciphers
**client_tls_ecdhcurve**
Elliptic Curve name to use for ECDH key exchanges.
*Allowed values:* none (DH is disabled), auto (256-bit ECDH), curve name.
*Default:* auto

**client_tls_dheparams**
DHE key exchange type.
*Allowed values:* none (DH is disabled), auto (2048-bit DH), legacy (1024-bit DH).
*Default:* auto

**server_tls_sslmode**
TLS mode to use for connections to Greenplum Database and PostgreSQL servers. TLS connections are disabled by default.

- **disabled:** Plain TCP. TLS is not requested from the server. Default.
- **allow:** If server rejects plain, try TLS. *(PgBouncer Documentation is speculative on this..)*
- **prefer:** TLS connection is always requested first. When connection is refused, plain TCP is used. Server certificate is not validated.
- **require:** Connection must use TLS. If server rejects it, plain TCP is not attempted. Server certificate is not validated.
- **verify-ca:** Connection must use TLS and server certificate must be valid according to `server_tls_ca_file`. The server hostname is not verified against the certificate.
- **verify-full:** Connection must use TLS and the server certificate must be valid according to `server_tls_ca_file`. The server hostname must match the hostname in the certificate.

**server_tls_ca_file**
Path to the root certificate file used to validate Greenplum Database and PostgreSQL server certificates.
*Default:* unset

**server_tls_key_file**
The private key for PgBouncer to authenticate against Greenplum Database or PostgreSQL server.
*Default:* not set

**server_tls_cert_file**
Certificate for private key. Greenplum Database or PostgreSQL servers can validate it.
*Default:* not set

**server_tls_protocols**
Which TLS protocol versions are allowed.
*Valid values are:* tlsv1.0, tlsv1.1, tlsv1.2.
*Shortcuts:* all (tlsv1.0, tlsv1.1, tlsv1.2); secure (tlsv1.2); legacy (all).
*Default:* all

**server_tls_ciphers**
*Default:* fast
**Dangerous Timeouts**

Setting the following timeouts can cause unexpected errors.

**query_timeout**

Queries running longer than this (seconds) are canceled. This parameter should be used only with a slightly smaller server-side `statement_timeout`, to trap queries with network problems. [seconds]

Default: 0.0 (disabled)

**query_wait_timeout**

The maximum time, in seconds, queries are allowed to wait for execution. If the query is not assigned a connection during that time, the client is disconnected. This is used to prevent unresponsive servers from grabbing up connections.

Default: 120

**client_idle_timeout**

Client connections idling longer than this many seconds are closed. This should be larger than the client-side connection lifetime settings, and only used for network problems.

Default: 0.0 (disabled)

**idle_transaction_timeout**

If client has been in "idle in transaction" state longer than this (seconds), it is disconnected.

Default: 0.0 (disabled)

**Low-level Network Settings**

**pkt_buf**

Internal buffer size for packets. Affects the size of TCP packets sent and general memory usage. Actual `libpq` packets can be larger than this so there is no need to set it large.

Default: 4096

**max_packet_size**

Maximum size for packets that PgBouncer accepts. One packet is either one query or one result set row. A full result set can be larger.

Default: 2147483647

**listen_backlog**

Backlog argument for the `listen(2)` system call. It determines how many new unanswered connection attempts are kept in queue. When the queue is full, further new connection attempts are dropped.

Default: 128

**sbuf_loopcnt**

How many times to process data on one connection, before proceeding. Without this limit, one connection with a big result set can stall PgBouncer for a long time. One loop processes one `pkt_buf` amount of data. 0 means no limit.

Default: 5

**suspend_timeout**

How many seconds to wait for buffer flush during `SUSPEND` or restart (-R). Connection is dropped if flush does not succeed.

Default: 10

**tcp_defer_accept**
For details on this and other TCP options, please see the tcp(7) man page.
Default: 45 on Linux, otherwise 0

tcp_socket_buffer
Default: not set

tcp_keepalive
Turns on basic keepalive with OS defaults.
On Linux, the system defaults are tcp_keepidle=7200, tcp_keepintvl=75,
tcp_keepcnt=9.
Default: 1

tcp_keepcnt
Default: not set

tcp_keepidle
Default: not set

tcp_keepintvl
Default: not set

[users] Section
This section contains key=value pairs, where the key is a user name and the value is a libpq
connect-string list of key=value pairs.

Pool configuration

pool_mode
Set the pool mode for all connections from this user. If not set, the database or default
pool_mode is used.

Example Configuration Files

Minimal Configuration

[databases]
postgres = host=127.0.0.1 dbname=postgres auth_user=gpadmin

[pgbouncer]
pool_mode = session
listen_port = 6543
listen_addr = 127.0.0.1
auth_type = md5
auth_file = users.txt
logfile = pgbouncer.log
pidfile = pgbouncer.pid
admin_users = someuser
stats_users = stat_collector

Use connection parameters passed by the client:

[databases]
* =

[pgbouncer]
listen_port = 6543
listen_addr = 0.0.0.0
auth_type = trust
auth_file = bouncer/users.txt
logfile = pgbouncer.log
pidfile = pgbouncer.pid
ignore_startup_parameters=options

Database Defaults

[databases]
; foodb over unix socket
foodb =

; redirect bardb to bazdb on localhost
bardb = host=127.0.0.1 dbname=bazdb

; access to destination database will go with single user
forcedb = host=127.0.0.1 port=300 user=baz password=foo
client_encoding=UNICODE datestyle=ISO

See Also

pgbouncer, pgbouncer-admin, PgBouncer Configuration Page

pgbouncer-admin

PgBouncer Administration Console.

Synopsis

psql -p port pgbouncer

Description

The PgBouncer Administration Console is available via psql. Connect to the PgBouncer port and the virtual database named pgbouncer to log in to the console.

Users listed in the pgbouncer.ini configuration parameters admin_users and stats_users have privileges to log in to the PgBouncer Administration Console.

You can control connections between PgBouncer and Greenplum Database from the console. You can also set PgBouncer configuration parameters.

Options

-p port

The PgBouncer port number.

Command Syntax

pgbouncer=# SHOW help;
NOTICE:  Console usage
DETAIL:
SHOW HELP|CONFIG|DATABASES|POOLS|CLIENTS|SERVERS|VERSION
SHOW FDS|SOCKETS|ACTIVE_SOCKETS|LISTS|MEM
SHOW DNS_HOSTS|DNS_ZONES
SHOW STATS|STATS_TOTALS|STATS_AVERAGES
SET key = arg
RELOAD
Administration Commands

The following PgBouncer administration commands control the running `pgbouncer` process.

**PAUSE [db]**
If no database is specified, PgBouncer tries to disconnect from all servers, first waiting for all queries to complete. The command will not return before all queries are finished. This command is to be used to prepare to restart the database.

If a database name is specified, PgBouncer pauses only that database.

If you run a `PAUSE db` command, and then a `PAUSE` command to pause all databases, you must execute two `RESUME` commands, one for all databases, and one for the named database.

**SUSPEND**
All socket buffers are flushed and PgBouncer stops listening for data on them. The command will not return before all buffers are empty. To be used when rebooting PgBouncer online.

**RESUME [db]**
Resume work from a previous `PAUSE` or `SUSPEND` command.

If a database was specified for the `PAUSE` command, the database must also be specified with the `RESUME` command.

After pausing all databases with the `PAUSE` command, resuming a single database with the `RESUME db` command is not supported.

**DISABLE db**
Reject all new client connections on the database.

**ENABLE db**
Allow new client connections on the database.

**KILL db**
Immediately drop all client and server connections to the named database.

**SHUTDOWN**
Stop PgBouncer process. To exit from the `psql` command line session, enter `\q`.

**RELOAD**
The PgBouncer process reloads the current configuration file and updates the changeable settings.

**SET key = value**
Override specified configuration setting. See the `SHOW CONFIG;` command.

**SHOW Command**
The `SHOW category` command displays different types of PgBouncer information. You can specify one of the following categories:

- **ACTIVE_SOCKETS**
### ACTIVE_SOCKETS

Table 83: Active Socket Information

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>type</td>
<td>S, for server, C for client.</td>
</tr>
<tr>
<td>user</td>
<td>Username <code>pgbouncer</code> uses to connect to server.</td>
</tr>
<tr>
<td>database</td>
<td>Database name.</td>
</tr>
<tr>
<td>state</td>
<td>State of the server connection, one of active, used or idle.</td>
</tr>
<tr>
<td>addr</td>
<td>IP address of PostgreSQL server.</td>
</tr>
<tr>
<td>port</td>
<td>Port of PostgreSQL server.</td>
</tr>
<tr>
<td>local_addr</td>
<td>Connection start address on local machine.</td>
</tr>
<tr>
<td>local_port</td>
<td>Connection start port on local machine.</td>
</tr>
<tr>
<td>connect_time</td>
<td>When the connection was made.</td>
</tr>
<tr>
<td>request_time</td>
<td>When last request was issued.</td>
</tr>
<tr>
<td>wait</td>
<td>Time waiting.</td>
</tr>
<tr>
<td>wait_us</td>
<td>Time waiting (microseconds).</td>
</tr>
<tr>
<td>ptr</td>
<td>Address of internal object for this connection. Used as unique ID.</td>
</tr>
<tr>
<td>link</td>
<td>Address of client connection the server is paired with.</td>
</tr>
<tr>
<td>remote_pid</td>
<td>Process identifier of backend server process.</td>
</tr>
<tr>
<td>tls</td>
<td>TLS context.</td>
</tr>
<tr>
<td>recv_pos</td>
<td>Receive position in the I/O buffer.</td>
</tr>
<tr>
<td>pkt_pos</td>
<td>Parse position in the I/O buffer.</td>
</tr>
<tr>
<td>pkt_remain</td>
<td>Number of packets remaining on the socket.</td>
</tr>
<tr>
<td>send_pos</td>
<td>Send position in the packet.</td>
</tr>
</tbody>
</table>
### Column Description

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>send_remain</td>
<td>Total packet length remaining to send.</td>
</tr>
<tr>
<td>pkt_avail</td>
<td>Amount of I/O buffer left to parse.</td>
</tr>
<tr>
<td>send_avail</td>
<td>Amount of I/O buffer left to send.</td>
</tr>
</tbody>
</table>

**CLIENTS**

Table 84: Clients

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>type</td>
<td>C, for client.</td>
</tr>
<tr>
<td>user</td>
<td>Client connected user.</td>
</tr>
<tr>
<td>database</td>
<td>Database name.</td>
</tr>
<tr>
<td>state</td>
<td>State of the client connection, one of active, used, waiting or idle.</td>
</tr>
<tr>
<td>addr</td>
<td>IP address of client, or unix for a socket connection.</td>
</tr>
<tr>
<td>port</td>
<td>Port client is connected to.</td>
</tr>
<tr>
<td>local_addr</td>
<td>Connection end address on local machine.</td>
</tr>
<tr>
<td>local_port</td>
<td>Connection end port on local machine.</td>
</tr>
<tr>
<td>connect_time</td>
<td>Timestamp of connect time.</td>
</tr>
<tr>
<td>request_time</td>
<td>Timestamp of latest client request.</td>
</tr>
<tr>
<td>wait</td>
<td>Time waiting.</td>
</tr>
<tr>
<td>wait_us</td>
<td>Time waiting (microseconds).</td>
</tr>
<tr>
<td>ptr</td>
<td>Address of internal object for this connection. Used as unique ID.</td>
</tr>
<tr>
<td>link</td>
<td>Address of server connection the client is paired with.</td>
</tr>
<tr>
<td>remote_pid</td>
<td>Process ID, if client connects with Unix socket and the OS supports getting it.</td>
</tr>
<tr>
<td>tls</td>
<td>Client TLS context.</td>
</tr>
</tbody>
</table>

**CONFIG**

List of current PgBouncer parameter settings

Table 85: Config

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>key</td>
<td>Configuration variable name</td>
</tr>
<tr>
<td>value</td>
<td>Configuration value</td>
</tr>
<tr>
<td>changeable</td>
<td>Either yes or no. Shows whether the variable can be changed while running. If no, the variable can be changed only at boot time.</td>
</tr>
</tbody>
</table>
**DATABASES**

Table 86: Databases

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>Name of configured database entry.</td>
</tr>
<tr>
<td>host</td>
<td>Host pgbouncer connects to.</td>
</tr>
<tr>
<td>port</td>
<td>Port pgbouncer connects to.</td>
</tr>
<tr>
<td>database</td>
<td>Actual database name pgbouncer connects to.</td>
</tr>
<tr>
<td>force_user</td>
<td>When user is part of the connection string, the connection between pgbouncer and the database server is forced to the given user, whatever the client user.</td>
</tr>
<tr>
<td>pool_size</td>
<td>Maximum number of server connections.</td>
</tr>
<tr>
<td>reserve_pool</td>
<td>The number of additional connections that can be created if the pool reaches pool_size.</td>
</tr>
<tr>
<td>pool_mode</td>
<td>The database's override pool_mode or NULL if the default will be used instead.</td>
</tr>
<tr>
<td>max_connections</td>
<td>Maximum number of connections for all pools for this database.</td>
</tr>
<tr>
<td>current_connections</td>
<td>The total count of connections for all pools for this database.</td>
</tr>
<tr>
<td>paused</td>
<td>Paused/unpaused state of the database.</td>
</tr>
<tr>
<td>disabled</td>
<td>Enabled/disabled state of the database.</td>
</tr>
</tbody>
</table>

**DNS_HOSTS**

Table 87: DNS Zones in Cache

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>hostname</td>
<td>Host name</td>
</tr>
<tr>
<td>ttl</td>
<td>How many seconds until next lookup.</td>
</tr>
<tr>
<td>addrs</td>
<td>Comma-separated list of addresses.</td>
</tr>
</tbody>
</table>

**DNS_ZONES**

Table 88: DNS Zones in Cache

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>zonename</td>
<td>Zone name</td>
</tr>
<tr>
<td>serial</td>
<td>Current DNS serial number</td>
</tr>
<tr>
<td>count</td>
<td>Hostnames belonging to this zone</td>
</tr>
</tbody>
</table>
**FDS**

`SHOW FDS` is an internal command used for an online restart, for example when upgrading to a new PgBouncer version. It displays a list of file descriptors in use with the internal state attached to them. This command blocks the internal event loop, so it should not be used while PgBouncer is in use.

When the connected user has username "pgbouncer", connects through a Unix socket, and has the same UID as the running process, the actual file descriptors are passed over the connection.

**Table 89: FDS**

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>fd</td>
<td>File descriptor numeric value.</td>
</tr>
<tr>
<td>task</td>
<td>One of <code>pooler</code>, <code>client</code>, or <code>server</code>.</td>
</tr>
<tr>
<td>user</td>
<td>User of the connection using the file descriptor.</td>
</tr>
<tr>
<td>database</td>
<td>Database of the connection using the file descriptor.</td>
</tr>
<tr>
<td>addr</td>
<td>IP address of the connection using the file descriptor, &quot;unix&quot; if a Unix socket is used.</td>
</tr>
<tr>
<td>port</td>
<td>Port used by the connection using the file descriptor.</td>
</tr>
<tr>
<td>cancel</td>
<td>Cancel key for this connection.</td>
</tr>
<tr>
<td>link</td>
<td>File descriptor for corresponding server/client. NULL if idle.</td>
</tr>
<tr>
<td>client_encoding</td>
<td>Character set used for the database.</td>
</tr>
<tr>
<td>std_strings</td>
<td>This controls whether ordinary string literals (&quot;...&quot;) treat backslashes literally, as specified in the SQL standard.</td>
</tr>
<tr>
<td>datestyle</td>
<td>Display format for date and time values.</td>
</tr>
<tr>
<td>timezone</td>
<td>The timezone for interpreting and displaying time stamps.</td>
</tr>
<tr>
<td>password</td>
<td><code>auth_user's password</code>.</td>
</tr>
</tbody>
</table>

**LISTS**

Shows the following PgBouncer statistics in two columns: the item label and value.

**Table 90: Count of PgBouncer Items**

<table>
<thead>
<tr>
<th>Item</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>databases</td>
<td>Count of databases.</td>
</tr>
<tr>
<td>users</td>
<td>Count of users.</td>
</tr>
<tr>
<td>pools</td>
<td>Count of pools.</td>
</tr>
<tr>
<td>free_clients</td>
<td>Count of free clients.</td>
</tr>
<tr>
<td>used_clients</td>
<td>Count of used clients.</td>
</tr>
<tr>
<td>login_clients</td>
<td>Count of clients in login state.</td>
</tr>
<tr>
<td>free_servers</td>
<td>Count of free servers.</td>
</tr>
<tr>
<td>used_servers</td>
<td>Count of used servers.</td>
</tr>
<tr>
<td>Item</td>
<td>Description</td>
</tr>
<tr>
<td>-------------</td>
<td>---------------------------------</td>
</tr>
<tr>
<td>dns_names</td>
<td>Count of DNS names.</td>
</tr>
<tr>
<td>dns_zones</td>
<td>Count of DNS zones.</td>
</tr>
<tr>
<td>dns_queries</td>
<td>Count of DNS queries.</td>
</tr>
<tr>
<td>dns_pending</td>
<td>Count of in-flight DNS queries.</td>
</tr>
</tbody>
</table>

**MEM**

Shows cache memory information for these PgBouncer caches:

- user_cache
- db_cache
- pool_cache
- server_cache
- client_cache
- iobuf_cache

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>Name of cache.</td>
</tr>
<tr>
<td>size</td>
<td>The size of a single slot in the cache.</td>
</tr>
<tr>
<td>used</td>
<td>Number of used slots in the cache.</td>
</tr>
<tr>
<td>free</td>
<td>The number of available slots in the cache.</td>
</tr>
<tr>
<td>memtotal</td>
<td>Total bytes used by the cache.</td>
</tr>
</tbody>
</table>

**POOLS**

A new pool entry is made for each pair of (database, user).

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>database</td>
<td>Database name.</td>
</tr>
<tr>
<td>user</td>
<td>User name.</td>
</tr>
<tr>
<td>cl_active</td>
<td>Client connections that are linked to server connection and can process queries.</td>
</tr>
<tr>
<td>cl_waiting</td>
<td>Client connections have sent queries but have not yet got a server connection.</td>
</tr>
<tr>
<td>sv_active</td>
<td>Server connections that linked to client.</td>
</tr>
<tr>
<td>sv_idle</td>
<td>Server connections that are unused and immediately usable for client queries.</td>
</tr>
<tr>
<td>sv_used</td>
<td>Server connections that have been idle more than server_check_delay. The server_check_query query must be run on them before they can be used.</td>
</tr>
</tbody>
</table>
Greenplum Database Utility Guide

**Column** | **Description**
---|---
sv_tested | Server connections that are currently running either `server_reset_query` or `server_check_query`.
sv_login | Server connections currently in process of logging in.
maxwait | How long the first (oldest) client in the queue has waited, in seconds. If this begins to increase, the current pool of servers does not handle requests fast enough. The cause may be either an overloaded server or the `pool_size` setting is too small.
maxwait_us | `max_wait` (microseconds).
pool_mode | The pooling mode in use.

**SERVERS**

Table 93: Servers

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>type</td>
<td>S, for server.</td>
</tr>
<tr>
<td>user</td>
<td>User ID that <code>pgbouncer</code> uses to connect to server.</td>
</tr>
<tr>
<td>database</td>
<td>Database name.</td>
</tr>
<tr>
<td>state</td>
<td>State of the <code>pgbouncer</code> server connection, one of active, used, or idle.</td>
</tr>
<tr>
<td>addr</td>
<td>IP address of the Greenplum or PostgreSQL server.</td>
</tr>
<tr>
<td>port</td>
<td>Port of the Greenplum or PostgreSQL server.</td>
</tr>
<tr>
<td>local_addr</td>
<td>Connection start address on local machine.</td>
</tr>
<tr>
<td>local_port</td>
<td>Connection start port on local machine.</td>
</tr>
<tr>
<td>connect_time</td>
<td>When the connection was made.</td>
</tr>
<tr>
<td>request_time</td>
<td>When the last request was issued.</td>
</tr>
<tr>
<td>wait</td>
<td>Time waiting.</td>
</tr>
<tr>
<td>wait_us</td>
<td>Time waiting (microseconds).</td>
</tr>
<tr>
<td>ptr</td>
<td>Address of the internal object for this connection. Used as unique ID.</td>
</tr>
<tr>
<td>link</td>
<td>Address of the client connection the server is paired with.</td>
</tr>
<tr>
<td>remote_pid</td>
<td>Pid of backend server process. If the connection is made over Unix socket and the OS supports getting process ID info, it is the OS pid. Otherwise it is extracted from the cancel packet the server sent, which should be PID in case server is PostgreSQL, but it is a random number in case server is another PgBouncer.</td>
</tr>
<tr>
<td>tls</td>
<td>TLS context.</td>
</tr>
</tbody>
</table>

**STATS**

Shows statistics.
Table 94: Stats

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>database</td>
<td>Statistics are presented per database.</td>
</tr>
<tr>
<td>total_xact_count</td>
<td>Total number of SQL transactions pooled by PgBouncer.</td>
</tr>
<tr>
<td>total_query_count</td>
<td>Total number of SQL queries pooled by PgBouncer.</td>
</tr>
<tr>
<td>total_received</td>
<td>Total volume in bytes of network traffic received by pgbouncer.</td>
</tr>
<tr>
<td>total_sent</td>
<td>Total volume in bytes of network traffic sent by pgbouncer.</td>
</tr>
<tr>
<td>total_xact_time</td>
<td>Total number of microseconds spent by PgBouncer when connected to Greenplum Database in a transaction, either idle in transaction or executing queries.</td>
</tr>
<tr>
<td>total_query_time</td>
<td>Total number of microseconds spent by pgbouncer when actively connected to the database server.</td>
</tr>
<tr>
<td>total_wait_time</td>
<td>Time spent (in microseconds) by clients waiting for a server.</td>
</tr>
<tr>
<td>avg_xact_count</td>
<td>Average number of SQL transactions pooled by PgBouncer.</td>
</tr>
<tr>
<td>avg_query_count</td>
<td>Average queries per second in last stats period.</td>
</tr>
<tr>
<td>avg_recv</td>
<td>Average received (from clients) bytes per second.</td>
</tr>
<tr>
<td>avg_sent</td>
<td>Average sent (to clients) bytes per second.</td>
</tr>
<tr>
<td>avg_xact_time</td>
<td>Average transaction duration in microseconds.</td>
</tr>
<tr>
<td>avg_query_time</td>
<td>Average query duration in microseconds.</td>
</tr>
<tr>
<td>avg_wait_time</td>
<td>Time spent by clients waiting for a server in microseconds (average per second).</td>
</tr>
</tbody>
</table>

**STATS_AVERAGES**
Subset of `SHOW STATS` showing the average values for selected statistics.

**STATS_TOTALS**
Subset of `SHOW STATS` showing the total values for selected statistics.

**USERS**
Table 95: Users

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>The user name</td>
</tr>
<tr>
<td>pool_mode</td>
<td>The user’s override pool_mode, or NULL if the default will be used instead.</td>
</tr>
</tbody>
</table>

**VERSION**
Display PgBouncer version information.

**Note:** This reference documentation is based on the PgBouncer 1.8.1 documentation.
plcontainer

The `plcontainer` utility installs Docker images and manages the PL/Container configuration. The utility consists of two sets of commands.

- `image-*` commands manage Docker images on the Greenplum Database system hosts.
- `runtime-*` commands manage the PL/Container configuration file on the Greenplum Database instances. You can add Docker image information to the PL/Container configuration file including the image name, location, and shared folder information. You can also edit the configuration file.

To configure PL/Container to use a Docker image, you install the Docker image on all the Greenplum Database hosts and then add configuration information to the PL/Container configuration.

PL/Container configuration values, such as image names, runtime IDs, and parameter values and names are case sensitive.

**plcontainer Syntax**

```
plcontainer [command] [-h | --help] [--verbose]
```

Where `command` is one of the following.

- `image-add`:
  - `{-f | --file} image_file`
  - `{-u | --URL} image_URL`

- `image-delete`:
  - `-i | --image image_name`

- `image-list`

- `runtime-add`:
  - `{-r | --runtime} runtime_id`
  - `{-i | --image} image_name {-l | --language} {python | python3 | r}`
  - `{{-v | --volume} shared_volume,[-v | --volume] shared_volume...}`
  - `{{-s | --setting} param=value,[-s | --setting] param=value...}`

- `runtime-replace`:
  - `{-r | --runtime} runtime_id`
  - `{-i | --image} image_name {-l | --language} {python | python3 | r}`
  - `{{-v | --volume} shared_volume,[-v | --volume] shared_volume...}`
  - `{{-s | --setting} param=value,[-s | --setting] param=value...}`

- `runtime-show`:
  - `{-r | --runtime} runtime_id`

- `runtime-delete`:
  - `{-r | --runtime} runtime_id`

- `runtime-edit`:
  - `{-e | --editor} editor`

- `runtime-backup`:
  - `{-f | --file} config_file`

- `runtime-restore`:
  - `{-f | --file} config_file`

- `runtime-verify`

**plcontainer Commands and Options**

**image-add location**

Install a Docker image on the Greenplum Database hosts. Specify either the location of the Docker image file on the host or the URL to the Docker image. These are the supported location options.

- `{-f | --file} image_file` Specify the tar archive file on the host that contains the Docker image. This example points to an image file in the gpadmin home directory `/home/gpadmin/test_image.tar.gz`
- `{-u | --URL} image_URL` Specify the URL of the Docker repository and image. This example URL points to a local Docker repository `192.168.0.1:5000/images/mytest_plc_r:devel`
After installing the Docker image, use the `runtime-add` command to configure PL/Container to use the Docker image.

```
image-delete (-i | --image) image_name
```

Remove an installed Docker image from all Greenplum Database hosts. Specify the full Docker image name including the tag for example `pivotaldata/plcontainer_python_shared:1.0.0`

```
image-list
```

List the Docker images installed on the host. The command list only the images on the local host, not remote hosts. The command lists all installed Docker images, including images installed with Docker commands.

```
runtime-add options
```

Add configuration information to the PL/Container configuration file on all Greenplum Database hosts. If the specified `runtime_id` exists, the utility returns an error and the configuration information is not added.

These are the supported options:

```
{-i | --image} docker-image
```

Required. Specify the full Docker image name, including the tag, that is installed on the Greenplum Database hosts. For example `pivotaldata/plcontainer_python:1.0.0`.

The utility returns a warning if the specified Docker image is not installed.

The `plcontainer image-list` command displays installed image information including the name and tag (the Repository and Tag columns).

```
{-l | --language} python | python3 | r
```

Required. Specify the PL/Container language type, supported values are `python` (PL/Python using Python 2), `python3` (PL/Python using Python 3) and `r` (PL/R). When adding configuration information for a new runtime, the utility adds a startup command to the configuration based on the language you specify.

Startup command for the Python 2 language.

```
/clientdir/pyclient.sh
```

Startup command for the Python 3 language.

```
/clientdir/pyclient3.sh
```

Startup command for the R language.

```
/clientdir/rclient.sh
```

```
{-r | --runtime} runtime_id
```

Required. Add the runtime ID. When adding a `runtime` element in the PL/Container configuration file, this is the value of the `id` element in the PL/Container configuration file. Maximum length is 63 Bytes.

You specify the name in the Greenplum Database UDF on the `# container` line.

```
{-s | --setting} param=value
```

Optional. Specify a setting to add to the runtime configuration information. You can specify this option multiple times. The setting applies to the runtime configuration specified by the `runtime_id`. The parameter is the XML attribute of the `settings` element in the PL/Container configuration file. These are valid parameters.
• **cpu_share** - Set the CPU limit for each container in the runtime configuration. The default value is 1024. The value is a relative weighting of CPU usage compared to other containers.

• **memory_mb** - Set the memory limit for each container in the runtime configuration. The default value is 1024. The value is an integer that specifies the amount of memory in MB.

• **resource_group_id** - Assign the specified resource group to the runtime configuration. The resource group limits the total CPU and memory resource usage for all containers that share this runtime configuration. You must specify the `groupid` of the resource group. For information about managing PL/Container resources, see About PL/Container Resource Management.

• **roles** - Specify the Greenplum Database roles that are allowed to run a container for the runtime configuration. You can specify a single role name or comma separated lists of role names. The default is no restriction.

• **use_container_logging** - Enable or disable Docker logging for the container. The value is either `yes` (enable logging) or `no` (disable logging, the default).

  The Greenplum Database server configuration parameter `log_min_messages` controls the log level. The default log level is `warning`. For information about PL/Container log information, see Notes.

  {--v | --volume} **shared-volume**

  Optional. Specify a Docker volume to bind mount. You can specify this option multiple times to define multiple volumes.

  The format for a shared volume: `host-dir:container-dir:[rw|ro]`. The information is stored as attributes in the `shared_directory` element of the `runtime` element in the PL/Container configuration file.

  • **host-dir** - absolute path to a directory on the host system. The Greenplum Database administrator user (gpadmin) must have appropriate access to the directory.

  • **container-dir** - absolute path to a directory in the Docker container.

  • **[rw|ro]** - read-write or read-only access to the host directory from the container.

  When adding configuration information for a new runtime, the utility adds this read-only shared volume information.

  ```
  greenplum-home/bin/plcontainer_clients:/clientdir:ro
  ```

  If needed, you can specify other shared directories. The utility returns an error if the specified `container-dir` is the same as the one that is added by the utility, or if you specify multiple shared volumes with the same `container-dir`.

  **Warning:** Allowing read-write access to a host directory requires special considerations.

  • When specifying read-write access to host directory, ensure that the specified host directory has the correct permissions.

  • When running PL/Container user-defined functions, multiple concurrent Docker containers that are running on a host could change data in the host directory. Ensure that the functions support multiple concurrent access to the data in the host directory.

  **runtime-backup { -f | --file } config_file**

  Copies the PL/Container configuration file to the specified file on the local host.

  **runtime-delete { -r | --runtime } runtime_id**
Removes runtime configuration information in the PL/Container configuration file on all Greenplum Database instances. The utility returns a message if the specified `runtime_id` does not exist in the file.

`runtime-edit [-e | --editor] editor`  
Edit the XML file `plcontainer_configuration.xml` with the specified editor. The default editor is `vi`.  
Saving the file updates the configuration file on all Greenplum Database hosts. If errors exist in the updated file, the utility returns an error and does not update the file.

`runtime-replace options`  
Replaces runtime configuration information in the PL/Container configuration file on all Greenplum Database instances. If the `runtime_id` does not exist, the information is added to the configuration file. The utility adds a startup command and shared directory to the configuration.  
See `runtime-add` for command options and information added to the configuration.

`runtime-restore {-f | --file} config_file`  
Replaces information in the PL/Container configuration file `plcontainer_configuration.xml` on all Greenplum Database instances with the information from the specified file on the local host.

`runtime-show [{-r | --runtime} runtime_id]`  
Displays formatted PL/Container runtime configuration information. If a `runtime_id` is not specified, the configuration for all runtime IDs are displayed.

`runtime-verify`  
Checks the PL/Container configuration information on the Greenplum Database instances with the configuration information on the master. If the utility finds inconsistencies, you are prompted to replace the remote copy with the local copy. The utility also performs XML validation.

`-h | --help`  
Display help text. If specified without a command, displays help for all `plcontainer` commands. If specified with a command, displays help for the command.

`--verbose`  
Enable verbose logging for the command.

**Examples**

These are examples of common commands to manage PL/Container:

- Install a Docker image on all Greenplum Database hosts. This example loads a Docker image from a file. The utility displays progress information on the command line as the utility installs the Docker image on all the hosts.

  ```bash
  plcontainer image-add -f plc_newr.tar.gz
  ```

  After installing the Docker image, you add or update a runtime entry in the PL/Container configuration file to give PL/Container access to the Docker image to start Docker containers.

- Add a container entry to the PL/Container configuration file. This example adds configuration information for a PL/R runtime, and specifies a shared volume and settings for memory and logging.

  ```bash
  plcontainer runtime-add -r runtime2 -i test_image2:0.1 -l r \
  -v /host_dir2/shared2:/container_dir2/shared2:ro \
  ```
-s memory_mb=512 -s use_container_logging=yes

The utility displays progress information on the command line as it adds the runtime configuration to the configuration file and distributes the updated configuration to all instances.

- Show specific runtime with given runtime id in configuration file

plcontainer runtime-show -r plc_python_shared

The utility displays the configuration information similar to this output.

PL/Container Runtime Configuration:
----------------------------------
Runtime ID: plc_python_shared
Linked Docker Image: test1:latest
Runtime Setting(s):
Shared Directory:
---- Shared Directory From HOST '/usr/local/greenplum-db/bin/plcontainer_clients' to Container '/clientdir', access mode is 'ro'
---- Shared Directory From HOST '/home/gpadmin/share/' to Container '/opt/share', access mode is 'rw'
----------------------------------

- Edit the configuration in an interactive editor of your choice. This example edits the configuration file with the vim editor.

plcontainer runtime-edit -e vim

When you save the file, the utility displays progress information on the command line as it distributes the file to the Greenplum Database hosts.

- Save the current PL/Container configuration to a file. This example saves the file to the local file /home/gpadmin/saved_plc_config.xml

plcontainer runtime-backup -f /home/gpadmin/saved_plc_config.xml

- Overwrite PL/Container configuration file with an XML file. This example replaces the information in the configuration file with the information from the file in the /home/gpadmin directory.

plcontainer runtime-restore -f /home/gpadmin/new_plcontainer_configuration.xml

The utility displays progress information on the command line as it distributes the updated file to the Greenplum Database instances.

**plcontainer Configuration File**

The Greenplum Database utility plcontainer manages the PL/Container configuration files in a Greenplum Database system. The utility ensures that the configuration files are consistent across the Greenplum Database master and segment instances.

**Warning:** Modifying the configuration files on the segment instances without using the utility might create different, incompatible configurations on different Greenplum Database segments that could cause unexpected behavior.

**PL/Container Configuration File**

PL/Container maintains a configuration file plcontainer_configuration.xml in the data directory of all Greenplum Database segments. This query lists the Greenplum Database system data directories:

```
SELECT hostname, datadir FROM gp_segment_configuration;
```
A sample PL/Container configuration file is in $GPHOME/share/postgresql/plcontainer.

In an XML file, names, such as element and attribute names, and values are case sensitive.

In this XML file, the root element configuration contains one or more runtime elements. You specify the id of the runtime element in the # container: line of a PL/Container function definition.

This is an example file. Note that all XML elements, names, and attributes are case sensitive.

```xml
<?xml version="1.0" ?>
<configuration>
  <runtime>
    <id>plc_python_example1</id>
    <image>pivotaldata/plcontainer_python_with_clients:0.1</image>
    <command>/pyclient</command>
  </runtime>
  <runtime>
    <id>plc_python_example2</id>
    <image>pivotaldata/plcontainer_python_without_clients:0.1</image>
    <command>/clientdir/pyclient.sh</command>
    <shared_directory access="ro" container="/clientdir" host="/usr/local/greenplum-db/bin/plcontainer_clients"/>
    <setting memory_mb="512"/>
    <setting use_container_logging="yes"/>
    <setting cpu_share="1024"/>
    <setting resource_group_id="16391"/>
  </runtime>
  <runtime>
    <id>plc_r_example</id>
    <image>pivotaldata/plcontainer_r_without_clients:0.2</image>
    <command>/clientdir/rclient.sh</command>
    <shared_directory access="ro" container="/clientdir" host="/usr/local/greenplum-db/bin/plcontainer_clients"/>
    <setting use_container_logging="yes"/>
    <setting roles="gpadmin,user1"/>
  </runtime>
  <runtime>
    <id>plc_r_example</id>
    <image>pivotaldata/plcontainer_r_with_clients:0.1</image>
    <command>/rclient</command>
    <shared_directory access="ro" container="/clientdir" host="/usr/local/greenplum-db/bin/plcontainer_clients"/>
    <setting use_container_logging="yes"/>
    <setting roles="gpadmin,user1"/>
  </runtime>
</configuration>
```

These are the XML elements and attributes in a PL/Container configuration file.

**configuration**

Root element for the XML file.

**runtime**

One element for each specific container available in the system. These are child elements of the configuration element.

**id**

Required. The value is used to reference a Docker container from a PL/Container user-defined function. The id value must be unique in the configuration. The id must start with a character or digit (a-z, A-Z, or 0-9) and can contain characters, digits, or the characters _ (underscore), . (period), or - (dash). Maximum length is 63 Bytes.

The id specifies which Docker image to use when PL/Container creates a Docker container to execute a user-defined function.

**image**

Required. The value is the full Docker image name, including image tag. The same way you specify them for starting this container in Docker. Configuration allows to have many container objects referencing the same image name, this way in Docker they would be represented by identical containers.
For example, you might have two runtime elements, with different id elements, plc_python_128 and plc_python_256, both referencing the Docker image pivotaldata/plcontainer_python:1.0.0. The first runtime specifies a 128MB RAM limit and the second one specifies a 256MB limit that is specified by the memory_mb attribute of a setting element.

command

Required. The value is the command to be run inside of container to start the client process inside in the container. When creating a runtime element, the plcontainer utility adds a command element based on the language (the -l option).

command element for the Python 2 language.

<command>/clientdir/pyclient.sh</command>

command element for the Python 3 language.

<command>/clientdir/pyclient3.sh</command>

command element for the R language.

<command>/clientdir/rclient.sh</command>

You should modify the value only if you build a custom container and want to implement some additional initialization logic before the container starts.

Note: This element cannot be set with the plcontainer utility. You can update the configuration file with the plcontainer runtime-edit command.

shared_directory

Optional. This element specifies a shared Docker shared volume for a container with access information. Multiple shared_directory elements are allowed. Each shared_directory element specifies a single shared volume. XML attributes for the shared_directory element:

- host - a directory location on the host system.
- container - a directory location inside of container.
- access - access level to the host directory, which can be either ro (read-only) or rw (read-write).

When creating a runtime element, the plcontainer utility adds a shared_directory element.

<shared_directory access="ro" container="/clientdir" host="/usr/local/greenplum-db/bin/plcontainer_clients"/>

For each runtime element, the container attribute of the shared_directory elements must be unique. For example, a runtime element cannot have two shared_directory elements with attribute container="/clientdir".

Warning: Allowing read-write access to a host directory requires special consideration.

- When specifying read-write access to host directory, ensure that the specified host directory has the correct permissions.
- When running PL/Container user-defined functions, multiple concurrent Docker containers that are running on a host could change data in the host directory. Ensure that the functions support multiple concurrent access to the data in the host directory.
settings

Optional. This element specifies Docker container configuration information. Each setting element contains one attribute. The element attribute specifies logging, memory, or networking information. For example, this element enables logging.

```
<setting use_container_logging="yes"/>
```

These are the valid attributes.

cpu_share

Optional. Specify the CPU usage for each PL/Container container in the runtime. The value of the element is a positive integer. The default value is 1024. The value is a relative weighting of CPU usage compared to other containers.

For example, a container with a cpu_share of 2048 is allocated double the CPU slice time compared with container with the default value of 1024.

memory_mb="size"

Optional. The value specifies the amount of memory, in MB, that each container is allowed to use. Each container starts with this amount of RAM and twice the amount of swap space. The container memory consumption is limited by the host system cgroups configuration, which means in case of memory overcommit, the container is terminated by the system.

resource_group_id="rg_groupid"

Optional. The value specifies the groupid of the resource group to assign to the PL/Container runtime. The resource group limits the total CPU and memory resource usage for all running containers that share this runtime configuration. You must specify the groupid of the resource group. If you do not assign a resource group to a PL/Container runtime configuration, its container instances are limited only by system resources. For information about managing PL/Container resources, see About PL/Container Resource Management.

roles="list_of_roles"

Optional. The value is a Greenplum Database role name or a comma-separated list of roles. PL/Container runs a container that uses the PL/Container runtime configuration only for the listed roles. If the attribute is not specified, any Greenplum Database role can run an instance of this container runtime configuration. For example, you create a UDF that specifies the plcontainer language and identifies a # container: runtime configuration that has the roles attribute set. When a role (user) runs the UDF, PL/Container checks the list of roles and runs the container only if the role is on the list.

use_container_logging="{yes | no}"

Optional. Enables or disables Docker logging for the container. The attribute value yes enables logging. The attribute value no disables logging (the default).

The Greenplum Database server configuration parameter log_min_messages controls the PL/Container log level. The default log level is warning. For information about PL/Container log information, see Notes.

By default, the PL/Container log information is sent to a system service. On Red Hat 7 or CentOS 7 systems, the log information is sent to the journald service. On Red Hat 6 or CentOS 6 systems, the log is sent to the syslogd service.

### Update the PL/Container Configuration

You can add a runtime element to the PL/Container configuration file with the `plcontainer runtime-add` command. The command options specify information such as the runtime ID, Docker image, and language. You can use the `plcontainer runtime-replace` command to update an existing runtime element. The utility updates the configuration file on the master and all segment instances.
The PL/Container configuration file can contain multiple runtime elements that reference the same Docker image specified by the XML element image. In the example configuration file, the runtime elements contain id elements named plc_python_128 and plc_python_256, both referencing the Docker container pivotaldata/plcontainer_python:1.0.0. The first runtime element is defined with a 128MB RAM limit and the second one with a 256MB RAM limit.

```xml
<configuration>
  <runtime>
    <id>plc_python_128</id>
    <image>pivotaldata/plcontainer_python:1.0.0</image>
    <command>./client</command>
    <shared_directory access="ro" container="/clientdir" host="/usr/local/gpdb/bin/plcontainer_clients"/>
    <setting memory_mb="128"/>
  </runtime>
  <runtime>
    <id>plc_python_256</id>
    <image>pivotaldata/plcontainer_python:1.0.0</image>
    <command>./client</command>
    <shared_directory access="ro" container="/clientdir" host="/usr/local/gpdb/bin/plcontainer_clients"/>
    <setting memory_mb="256"/>
    <setting resource_group_id="16391"/>
  </runtime>
</configuration>
```

Configuration changes that are made with the utility are applied to the XML files on all Greenplum Database segments. However, PL/Container configurations of currently running sessions use the configuration that existed during session start up. To update the PL/Container configuration in a running session, execute this command in the session.

```
SELECT * FROM plcontainer_refresh_config;
```

Running the command executes a PL/Container function that updates the session configuration on the master and segment instances.
Client Utility Reference

Describes the command-line client utilities provided with Greenplum Database.

Greenplum Database uses the standard PostgreSQL client programs and provides additional client utilities for administering a distributed Greenplum Database DBMS. Greenplum Database client utilities reside in $GPHOME/bin.

Greenplum Database provides the following client utility programs:

**clusterdb**

Reclusters tables that were previously clustered with CLUSTER.

**Synopsis**

```
clusterdb [connection-option ...] [-v] [-t table] [[-d] dbname]
```

```
clusterdb [connection-option ...] [-a] [-v]
```

```
clusterdb --help
```

```
clusterdb --version
```

**Description**

To cluster a table means to physically reorder a table on disk according to an index so that index scan operations can access data on disk in a somewhat sequential order, thereby improving index seek performance for queries that use that index.

The clusterdb utility will find any tables in a database that have previously been clustered with the CLUSTER SQL command, and clusters them again on the same index that was last used. Tables that have never been clustered are not affected.

Clusterdb is a wrapper around the SQL command CLUSTER. Although clustering a table in this way is supported in Greenplum Database, it is not recommended because the CLUSTER operation itself is extremely slow.

If you do need to order a table in this way to improve your query performance, Greenplum recommends using a CREATE TABLE AS statement to reorder the table on disk rather than using CLUSTER. If you do 'cluster' a table in this way, then clusterdb would not be relevant.

**Options**

```
-a | --all
```

Cluster all databases.

```
[-d] dbname | [--dbname] dbname
```

Specifies the name of the database to be clustered. If this is not specified, the database name is read from the environment variable PGDATABASE. If that is not set, the user name specified for the connection is used.

```
-e | --echo
```

Echo the commands that clusterdb generates and sends to the server.

```
-q | --quiet
```

Do not display a response.

```
-t table | --table table
```

Cluster the named table only.

-\(v\) | --verbose
Print detailed information during processing.

Connection Options

-\(h\) host | --host host
The host name of the machine on which the Greenplum master database server is running. If not specified, reads from the environment variable PGHOST or defaults to localhost.

-\(p\) port | --port port
The TCP port on which the Greenplum master database server is listening for connections. If not specified, reads from the environment variable PGPORT or defaults to 5432.

-\(U\) username | --username username
The database role name to connect as. If not specified, reads from the environment variable PGUSER or defaults to the current system role name.

-\(w\) | --no-password
Never issue a password prompt. If the server requires password authentication and a password is not available by other means such as a .pgpass file, the connection attempt will fail. This option can be useful in batch jobs and scripts where no user is present to enter a password.

-\(W\) | --password
Force a password prompt.

Examples

To cluster the database test:

```
clusterdb test
```

To cluster a single table foo in a database named xyzzy:

```
clusterdb --table foo xyzzy
```

See Also

CLUSTER in the Greenplum Database Reference Guide

createdb

Creates a new database.

Synopsis

```
createdb [connection_option ...] [-D tablespace] [-E encoding]
[-O owner] [-T template] [-e] [dbname ['description']]    
createdb --help
createdb --version
```

Description

createdb creates a new database in a Greenplum Database system.
Normally, the database user who executes this command becomes the owner of the new database. However a different owner can be specified via the \(-o\) option, if the executing user has appropriate privileges.

\texttt{createdb} is a wrapper around the SQL command \texttt{CREATE DATABASE}.

**Options**

\texttt{dbname}

The name of the database to be created. The name must be unique among all other databases in the Greenplum system. If not specified, reads from the environment variable \texttt{PGDATABASE}, then \texttt{PGUSER} or defaults to the current system user.

\texttt{description}

A comment to be associated with the newly created database. Descriptions containing white space must be enclosed in quotes.

\texttt{-D tablespace} | \texttt{--tablespace tablespace}

The default tablespace for the database.

\texttt{-e echo}

Echo the commands that \texttt{createdb} generates and sends to the server.

\texttt{-E encoding} | \texttt{--encoding encoding}

Character set encoding to use in the new database. Specify a string constant (such as 'UTF8'), an integer encoding number, or \texttt{DEFAULT} to use the default encoding. See the Greenplum Database Reference Guide for information about supported character sets.

\texttt{-O owner} | \texttt{--owner owner}

The name of the database user who will own the new database. Defaults to the user executing this command.

\texttt{-T template} | \texttt{--template template}

The name of the template from which to create the new database. Defaults to \texttt{template1}.

**Connection Options**

\texttt{-h host} | \texttt{--host host}

The host name of the machine on which the Greenplum master database server is running. If not specified, reads from the environment variable \texttt{PGHOST} or defaults to localhost.

\texttt{-p port} | \texttt{--port port}

The TCP port on which the Greenplum master database server is listening for connections. If not specified, reads from the environment variable \texttt{PGPORT} or defaults to 5432.

\texttt{-U username} | \texttt{--username username}

The database role name to connect as. If not specified, reads from the environment variable \texttt{PGUSER} or defaults to the current system role name.

\texttt{-w} | \texttt{--no-password}

Never issue a password prompt. If the server requires password authentication and a password is not available by other means such as a \texttt{.pgpass} file, the connection attempt will fail. This option can be useful in batch jobs and scripts where no user is present to enter a password.

\texttt{-W} | \texttt{--password}

Force a password prompt.
Examples
To create the database test using the default options:

```
createdb test
```

To create the database demo using the Greenplum master on host gpmaster, port 54321, using the LATIN1 encoding scheme:

```
createdb -p 54321 -h gpmaster -E LATIN1 demo
```

See Also
CREATE DATABASE in the Greenplum Database Reference Guide

createlang
Defines a new procedural language for a database.

Synopsis
```
createlang [connection_option ...] [-e] langname [[-d] dbname]
createlang [connection-option ...] -l dbname
createlang --help
createlang --version
```

Description
The createlang utility adds a new programming language to a database. createlang is a wrapper around the SQL command CREATE EXTENSION.

Note: createlang is deprecated and may be removed in a future release. Direct use of the CREATE EXTENSION command is recommended instead.

The procedural language packages included in the standard Greenplum Database distribution are:

- PL/pgSQL
- PL/Perl
- PL/Python

The PL/pgSQL language is registered in all databases by default.

Greenplum Database also has language handlers for PL/Java and PL/R, but those languages are not pre-installed with Greenplum Database. See the Procedural Languages section in the PostgreSQL documentation for more information.

Options

langname

Specifies the name of the procedural programming language to be defined.

`[-d] dbname | [--dbname] dbname`

Specifies to which database the language should be added. The default is to use the PGDATABASE environment variable setting, or the same name as the current system user.

`-e | --echo`

Echo the commands that createlang generates and sends to the server.
-l dbname | --list dbname
Show a list of already installed languages in the target database.

Connection Options
-h host | --host host
The host name of the machine on which the Greenplum master database server is running. If not specified, reads from the environment variable PGHOST or defaults to localhost.

-p port | --port port
The TCP port on which the Greenplum master database server is listening for connections. If not specified, reads from the environment variable PGPORT or defaults to 5432.

-U username | --username username
The database role name to connect as. If not specified, reads from the environment variable PGUSER or defaults to the current system role name.

-w | --no-password
Never issue a password prompt. If the server requires password authentication and a password is not available by other means such as a .pgpass file, the connection attempt will fail. This option can be useful in batch jobs and scripts where no user is present to enter a password.

-W | --password
Force a password prompt.

Examples
To install the language plperl into the database mytestdb:

```
createlang plperl mytestdb
```

See Also
CREATE LANGUAGE and DROP LANGUAGE in the Greenplum Database Reference Guide

createuser
Creates a new database role.

Synopsis
```
createuser [connection_option ...] [role_attribute ...] [-e] role_name
createuser --help
createuser --version
```

Description
createuser creates a new Greenplum Database role. You must be a superuser or have the CREATEROLE privilege to create new roles. You must connect to the database as a superuser to create new superusers.

Superusers can bypass all access permission checks within the database, so superuser privileges should not be granted lightly.

createuser is a wrapper around the SQL command CREATE ROLE.
Options

role_name

The name of the role to be created. This name must be different from all existing roles in
this Greenplum Database installation.

-c number | --connection-limit number

Set a maximum number of connections for the new role. The default is to set no limit.

-D | --no-createdb

The new role will not be allowed to create databases. This is the default.

-d | --createdb

The new role will be allowed to create databases.

-e | --echo

Echo the commands that createuser generates and sends to the server.

-E | --encrypted

Encrypts the role's password stored in the database. If not specified, the default password
behavior is used.

-i | --inherit

The new role will automatically inherit privileges of roles it is a member of. This is the
default.

-I | --no-inherit

The new role will not automatically inherit privileges of roles it is a member of.

-l | --login

The new role will be allowed to log in to Greenplum Database. This is the default.

-L | --no-login

The new role will not be allowed to log in (a group-level role).

-N | --unencrypted

Does not encrypt the role's password stored in the database. If not specified, the default
password behavior is used.

-P | --pwprompt

If given, createuser will issue a prompt for the password of the new role. This is not
necessary if you do not plan on using password authentication.

-r | --createrole

The new role will be allowed to create new roles (CREATEROLE privilege).

-R | --no-createrole

The new role will not be allowed to create new roles. This is the default.

-s | --superuser

The new role will be a superuser.

-S | --no-superuser

The new role will not be a superuser. This is the default.

Connection Options

-h host | --host host

The host name of the machine on which the Greenplum master database server is
running. If not specified, reads from the environment variable PGHOST or defaults to
localhost.

-p port | --port port
The TCP port on which the Greenplum master database server is listening for connections. If not specified, reads from the environment variable `PGPORT` or defaults to 5432.

```
-U username | --username username
```

The database role name to connect as. If not specified, reads from the environment variable `PGUSER` or defaults to the current system role name.

```
-w | --no-password
```

Never issue a password prompt. If the server requires password authentication and a password is not available by other means such as a `.pgpass` file, the connection attempt will fail. This option can be useful in batch jobs and scripts where no user is present to enter a password.

```
-W | --password
```

Force a password prompt.

### Examples

Create a role named `joe` using the default options:

```
createuser joe
```

Shall the new role be a superuser? (y/n) n
Shall the new role be allowed to create databases? (y/n) n
Shall the new role be allowed to create more new roles? (y/n) n

```
CREATE ROLE
```

To create the same role `joe` using connection options and avoiding the prompts and taking a look at the underlying command:

```
createuser -h masterhost -p 54321 -S -D -R -e joe
```

CREATE ROLE `joe` NOSUPERUSER NOCREATEDB NOCREATEROLE INHERIT LOGIN;

```
CREATE ROLE
```

To create the role `joe` as a superuser, and assign password `admin123` immediately:

```
createuser -P -s -e joe
```

Enter password for new role: *admin123*

Enter it again: *admin123*

```
CREATE ROLE joe PASSWORD 'admin123' SUPERUSER CREATEDB CREATEROLE INHERIT LOGIN;
```

```
CREATE ROLE
```

In the above example, the new password is not actually echoed when typed, but we show what was typed for clarity. However the password will appear in the echoed command, as illustrated if the `-e` option is used.

### See Also

`createuser` in the Greenplum Database Reference Guide

**dropdb**

Removes a database.

### Synopsis

```
dropdb [connection_option ...] [-e] [-i] dbname
```
dropdb --help
dropdb --version

Description

dropdb destroys an existing database. The user who executes this command must be a superuser or the owner of the database being dropped.

dropdb is a wrapper around the SQL command DROP DATABASE. See the Greenplum Database Reference Guide for information about DROP DATABASE.

Options

dbname

The name of the database to be removed.

-e | --echo

Echo the commands that dropdb generates and sends to the server.

-i | --interactive

Issues a verification prompt before doing anything destructive.

Connection Options

-h host | --host host

The host name of the machine on which the Greenplum master database server is running. If not specified, reads from the environment variable PGHOST or defaults to localhost.

-p port | --port port

The TCP port on which the Greenplum master database server is listening for connections. If not specified, reads from the environment variable PGPORT or defaults to 5432.

-U username | --username username

The database role name to connect as. If not specified, reads from the environment variable PGUSER or defaults to the current system role name.

-w | --no-password

Never issue a password prompt. If the server requires password authentication and a password is not available by other means such as a .pgpass file, the connection attempt will fail. This option can be useful in batch jobs and scripts where no user is present to enter a password.

-W | --password

Force a password prompt.

Examples

To destroy the database named demo using default connection parameters:

dropdb demo

To destroy the database named demo using connection options, with verification, and a peek at the underlying command:

dropdb -p 54321 -h masterhost -i -e demo

Database "demo" will be permanently deleted.
Are you sure? (y/n) y
DROP DATABASE "demo"
DROP DATABASE

DROP DATABASE in the *Greenplum Database Reference Guide*

**droplang**

Removes a procedural language.

**Synopsis**

```plaintext
droplang [connection-option ...] [-e] langname [[-d] dbname]
droplang [connection-option ...] [-e] -l dbname
droplang --help
droplang --version
```

**Description**

`droplang` removes an existing programming language from a database. `droplang` can drop any procedural language, even those not supplied by the Greenplum Database distribution.

Although programming languages can be removed directly using several SQL commands, it is recommended to use `droplang` because it performs a number of checks and is much easier to use.

`droplang` is a wrapper for the SQL command `DROP LANGUAGE`.

**Options**

**langname**

Specifies the name of the programming language to be removed.

**[-d] dbname | [--dbname] dbname**

Specifies from which database the language should be removed. The default is to use the `PGDATABASE` environment variable setting, or the same name as the current system user.

**-e | --echo**

Echo the commands that `droplang` generates and sends to the server.

**-l | --list**

Show a list of already installed languages in the target database.

**Connection Options**

**-h host | --host host**

The host name of the machine on which the Greenplum master database server is running. If not specified, reads from the environment variable `PGHOST` or defaults to localhost.

**-p port | --port port**

The TCP port on which the Greenplum master database server is listening for connections. If not specified, reads from the environment variable `PGPORT` or defaults to 5432.

**-U username | --username username**

The database role name to connect as. If not specified, reads from the environment variable `PGUSER` or defaults to the current system role name.

**-w | --no-password**

Never issue a password prompt. If the server requires password authentication and a password is not available by other means such as a `.pgpass` file, the connection attempt...
will fail. This option can be useful in batch jobs and scripts where no user is present to enter a password.

-w | --password
    Force a password prompt.

Examples
To remove the language pltcl from the mydatabase database:

droplang pltcl mydatabase

See Also
DROP LANGUAGE in the Greenplum Database Reference Guide

dropuser
Removes a database role.

Synopsis

dropuser [connection_option ...] [-e] [-i] role_name

dropuser --help

dropuser --version

Description
dropuser removes an existing role from Greenplum Database. Only superusers and users with the CREATEROLE privilege can remove roles. To remove a superuser role, you must yourself be a superuser.
dropuser is a wrapper around the SQL command DROP ROLE.

Options

role_name
    The name of the role to be removed. You will be prompted for a name if not specified on the command line.

-e | --echo
    Echo the commands that dropuser generates and sends to the server.

-i | --interactive
    Prompt for confirmation before actually removing the role.

Connection Options

-h host | --host host
    The host name of the machine on which the Greenplum master database server is running. If not specified, reads from the environment variable PGHOST or defaults to localhost.

-p port | --port port
    The TCP port on which the Greenplum master database server is listening for connections. If not specified, reads from the environment variable PGPORT or defaults to 5432.

-U username | --username username
The database role name to connect as. If not specified, reads from the environment variable `PGUSER` or defaults to the current system role name.

```
-w | --no-password
```

Never issue a password prompt. If the server requires password authentication and a password is not available by other means such as a `.pgpass` file, the connection attempt will fail. This option can be useful in batch jobs and scripts where no user is present to enter a password.

```
-W | --password
```

Force a password prompt.

**Examples**

To remove the role `joe` using default connection options:

```
dropuser joe
DROP ROLE
```

To remove the role `joe` using connection options, with verification, and a peek at the underlying command:

```
dropuser -p 54321 -h masterhost -i -e joe
Role "joe" will be permanently removed.
Are you sure? (y/n) y
DROP ROLE "joe"
DROP ROLE
```

**See Also**

DROP ROLE in the *Greenplum Database Reference Guide*

**pg_config**

Retrieves information about the installed version of Greenplum Database.

**Synopsis**

```
pg_config [option ...]
```

**Description**

The `pg_config` utility prints configuration parameters of the currently installed version of Greenplum Database. It is intended, for example, to be used by software packages that want to interface to Greenplum Database to facilitate finding the required header files and libraries. Note that information printed out by `pg_config` is for the Greenplum Database master only.

If more than one option is given, the information is printed in that order, one item per line. If no options are given, all available information is printed, with labels.

**Options**

```
--bindir
```

Print the location of user executables. Use this, for example, to find the `psql` program. This is normally also the location where the `pg_config` program resides.

```
--docdir
```

Print the location of documentation files.

```
--includedir
```

...
Print the location of C header files of the client interfaces.

--pkgincludedir
Print the location of other C header files.

--includedir-server
Print the location of C header files for server programming.

--libdir
Print the location of object code libraries.

--pkglibdir
Print the location of dynamically loadable modules, or where the server would search for them. (Other architecture-dependent data files may also be installed in this directory.)

--localedir
Print the location of locale support files.

--mandir
Print the location of manual pages.

--sharedir
Print the location of architecture-independent support files.

--sysconfdir
Print the location of system-wide configuration files.

--pgxs
Print the location of extension makefiles.

--configure
Print the options that were given to the configure script when Greenplum Database was configured for building.

--cc
Print the value of the CC variable that was used for building Greenplum Database. This shows the C compiler used.

--cppflags
Print the value of the CPPFLAGS variable that was used for building Greenplum Database. This shows C compiler switches needed at preprocessing time.

--cflags
Print the value of the CFLAGS variable that was used for building Greenplum Database. This shows C compiler switches.

--cflags_sl
Print the value of the CFLAGS_SL variable that was used for building Greenplum Database. This shows extra C compiler switches used for building shared libraries.

--ldflags
Print the value of the LDFLAGS variable that was used for building Greenplum Database. This shows linker switches.

--ldflags_sl
Print the value of the LDFLAGS_SL variable that was used for building Greenplum Database. This shows linker switches used for building shared libraries.

--libs
Print the value of the LIBS variable that was used for building Greenplum Database. This normally contains `-l` switches for external libraries linked into Greenplum Database.
--version

Print the version of Greenplum Database.

Examples
To reproduce the build configuration of the current Greenplum Database installation, run the following command:

```bash
eval ./configure 'pg_config --configure'
```

The output of `pg_config --configure` contains shell quotation marks so arguments with spaces are represented correctly. Therefore, using `eval` is required for proper results.

**pg_dump**

Extracts a database into a single script file or other archive file.

**Synopsis**

```bash
pg_dump [connection_option ...] [dump_option ...] dbname
```

**Description**

`pg_dump` is a standard PostgreSQL utility for backing up a database, and is also supported in Greenplum Database. It creates a single (non-parallel) dump file. For routine backups of Greenplum Database, it is better to use the Greenplum Database backup utility, `gpcrondump`, for the best performance.

Use `pg_dump` if you are migrating your data to another database vendor's system, or to another Greenplum Database system with a different segment configuration (for example, if the system you are migrating to has greater or fewer segment instances). To restore, you must use the corresponding `pg_restore` utility (if the dump file is in archive format), or you can use a client program such as `psql` (if the dump file is in plain text format).

Since `pg_dump` is compatible with regular PostgreSQL, it can be used to migrate data into Greenplum Database. The `pg_dump` utility in Greenplum Database is very similar to the PostgreSQL `pg_dump` utility, with the following exceptions and limitations:

- If using `pg_dump` to backup a Greenplum Database database, keep in mind that the dump operation can take a long time (several hours) for very large databases. Also, you must make sure you have sufficient disk space to create the dump file.
- If you are migrating data from one Greenplum Database system to another, use the `--gp-syntax` command-line option to include the `DISTRIBUTED BY` clause in `CREATE TABLE` statements. This ensures that Greenplum Database table data is distributed with the correct distribution key columns upon restore.

`pg_dump` makes consistent backups even if the database is being used concurrently. `pg_dump` does not block other users accessing the database (readers or writers).

When used with one of the archive file formats and combined with `pg_restore`, `pg_dump` provides a flexible archival and transfer mechanism. `pg_dump` can be used to backup an entire database, then `pg_restore` can be used to examine the archive and/or select which parts of the database are to be restored. The most flexible output file format is the `custom` format (`-Fc`). It allows for selection and reordering of all archived items, and is compressed by default. The tar format (`-Ft`) is not compressed and it is not possible to reorder data when loading, but it is otherwise quite flexible. It can be manipulated with standard UNIX tools such as `tar`.

**Note:** The `--ignore-version` option is deprecated and will be removed in a future release.
Options

dbname
Specifications the name of the database to be dumped. If this is not specified, the environment variable PGDATABASE is used. If that is not set, the user name specified for the connection is used.

Dump Options

-a | --data-only
Dump only the data, not the schema (data definitions). This option is only meaningful for the plain-text format. For the archive formats, you may specify the option when you call pg_restore.

-b | --blobs
Include large objects in the dump. This is the default behavior except when --schema, --table, or --schema-only is specified, so the -b switch is only useful to add large objects to selective dumps.

-c | --clean
Adds commands to the text output file to clean (drop) database objects prior to (the commands for) creating them. Note that objects are not dropped before the dump operation begins, but DROP commands are added to the DDL dump output files so that when you use those files to do a restore, the DROP commands are run prior to the CREATE commands. This option is only meaningful for the plain-text format. For the archive formats, you may specify the option when you call pg_restore.

-C | --create
Begin the output with a command to create the database itself and reconnect to the created database. (With a script of this form, it doesn't matter which database you connect to before running the script.) This option is only meaningful for the plain-text format. For the archive formats, you may specify the option when you call pg_restore.

-d | --inserts
Dump data as INSERT commands (rather than COPY). This will make restoration very slow; it is mainly useful for making dumps that can be loaded into non-PostgreSQL-based databases. Also, since this option generates a separate command for each row, an error in reloading a row causes only that row to be lost rather than the entire table contents. Note that the restore may fail altogether if you have rearranged column order. The -D option is safe against column order changes, though even slower.

-D | --column-inserts | --attribute-inserts
Dump data as INSERT commands with explicit column names (INSERT INTO table(column, ...) VALUES ...). This will make restoration very slow; it is mainly useful for making dumps that can be loaded into non-PostgreSQL-based databases. Also, since this option generates a separate command for each row, an error in reloading a row causes only that row to be lost rather than the entire table contents.

-E encoding | --encoding=encoding
Create the dump in the specified character set encoding. By default, the dump is created in the database encoding. (Another way to get the same result is to set the PGCLIENTENCODING environment variable to the desired dump encoding.)

-f file | --file=file
Send output to the specified file. If this is omitted, the standard output is used.

-F p|c|t | --format=plain|custom|tar
Selects the format of the output. format can be one of the following:
p | plain — Output a plain-text SQL script file (the default).
c | custom — Output a custom archive suitable for input into `pg_restore`. This is the most flexible format in that it allows reordering of loading data as well as object definitions. This format is also compressed by default.

t | tar — Output a tar archive suitable for input into `pg_restore`. Using this archive format allows reordering and/or exclusion of database objects at the time the database is restored. It is also possible to limit which data is reloaded at restore time.

-i | --ignore-version

Note: This option is deprecated and will be removed in a future release.

Ignore version mismatch between `pg_dump` and the database server. `pg_dump` can dump from servers running previous releases of Greenplum Database (or PostgreSQL), but very old versions may not be supported anymore. Use this option if you need to override the version check.

-n schema | --schema=schema

Dump only schemas matching the schema pattern; this selects both the schema itself, and all its contained objects. When this option is not specified, all non-system schemas in the target database will be dumped. Multiple schemas can be selected by writing multiple `-n` switches. Also, the schema parameter is interpreted as a pattern according to the same rules used by `psql`'s `\d` commands, so multiple schemas can also be selected by writing wildcard characters in the pattern. When using wildcards, be careful to quote the pattern if needed to prevent the shell from expanding the wildcards.

Note: When `-n` is specified, `pg_dump` makes no attempt to dump any other database objects that the selected schema(s) may depend upon. Therefore, there is no guarantee that the results of a specific-schema dump can be successfully restored by themselves into a clean database.

Note: Non-schema objects such as blobs are not dumped when `-n` is specified. You can add blobs back to the dump with the `--blobs` switch.

-N schema | --exclude-schema=schema

Do not dump any schemas matching the schema pattern. The pattern is interpreted according to the same rules as for `-n`. `-N` can be given more than once to exclude schemas matching any of several patterns. When both `-n` and `-N` are given, the behavior is to dump just the schemas that match at least one `-n` switch but no `-N` switches. If `-N` appears without `-n`, then schemas matching `-N` are excluded from what is otherwise a normal dump.

-o | --oids

Dump object identifiers (OIDs) as part of the data for every table. Use of this option is not recommended for files that are intended to be restored into Greenplum Database.

-o | --no-owner

Do not output commands to set ownership of objects to match the original database. By default, `pg_dump` issues `ALTER OWNER` or `SET SESSION AUTHORIZATION` statements to set ownership of created database objects. These statements will fail when the script is run unless it is started by a superuser (or the same user that owns all of the objects in the script). To make a script that can be restored by any user, but will give that user ownership of all the objects, specify `-o`. This option is only meaningful for the plain-text format. For the archive formats, you may specify the option when you call `pg_restore`.

-s | --schema-only

Dump only the object definitions (schema), not data.

-S username | --superuser=username
Specify the superuser user name to use when disabling triggers. This is only relevant if `--disable-triggers` is used. It is better to leave this out, and instead start the resulting script as a superuser.

**Note:** Greenplum Database does not support user-defined triggers.

```
-t table | --table=table
```

Dump only tables (or views or sequences) matching the table pattern. Specify the table in the format `schema.table`.

Multiple tables can be selected by writing multiple `-t` switches. Also, the table parameter is interpreted as a pattern according to the same rules used by `psql`'s `\d` commands, so multiple tables can also be selected by writing wildcard characters in the pattern. When using wildcards, be careful to quote the pattern if needed to prevent the shell from expanding the wildcards. The `-n` and `-N` switches have no effect when `-t` is used, because tables selected by `-t` will be dumped regardless of those switches, and non-table objects will not be dumped.

**Note:** When `-t` is specified, `pg_dump` makes no attempt to dump any other database objects that the selected table(s) may depend upon. Therefore, there is no guarantee that the results of a specific-table dump can be successfully restored by themselves into a clean database.

Also, `-t` cannot be used to specify a child table partition. To dump a partitioned table, you must specify the parent table name.

```
-T table | --exclude-table=table
```

Do not dump any tables matching the table pattern. The pattern is interpreted according to the same rules as for `-t`. `-T` can be given more than once to exclude tables matching any of several patterns. When both `-t` and `-T` are given, the behavior is to dump just the tables that match at least one `-t` switch but no `-T` switches. If `-T` appears without `-t`, then tables matching `-T` are excluded from what is otherwise a normal dump.

```
-v | --verbose
```

Specifies verbose mode. This will cause `pg_dump` to output detailed object comments and start/stop times to the dump file, and progress messages to standard error.

```
-x | --no-privileges | --no-acl
```

Prevent dumping of access privileges (GRANT/REVOKE commands).

```
--disable-dollar-quoting
```

This option disables the use of dollar quoting for function bodies, and forces them to be quoted using SQL standard string syntax.

```
--disable-triggers
```

This option is only relevant when creating a data-only dump. It instructs `pg_dump` to include commands to temporarily disable triggers on the target tables while the data is reloaded. Use this if you have triggers on the tables that you do not want to invoke during data reload. The commands emitted for `--disable-triggers` must be done as superuser. So, you should also specify a superuser name with `-S`, or preferably be careful to start the resulting script as a superuser. This option is only meaningful for the plain-text format. For the archive formats, you may specify the option when you call `pg_restore`.

**Note:** Greenplum Database does not support user-defined triggers.

```
--use-set-session-authorization
```

Output SQL-standard `SET SESSION AUTHORIZATION` commands instead of `ALTER OWNER` commands to determine object ownership. This makes the dump more standards compatible, but depending on the history of the objects in the dump, may not restore properly. A dump using `SET SESSION AUTHORIZATION` will require superuser privileges to restore correctly, whereas `ALTER OWNER` requires lesser privileges.
**--gp-syntax | --no-gp-syntax**

Use **--gp-syntax** to dump Greenplum Database syntax in the *CREATE TABLE* statements. This allows the distribution policy (Distributed by or Distributed Randomly clauses) of a Greenplum Database table to be dumped, which is useful for restoring into other Greenplum Database systems. The default is to include Greenplum Database syntax when connected to a Greenplum Database system, and to exclude it when connected to a regular PostgreSQL system.

**--function-oids oids**

Dump the function(s) specified in the *oids* list of object identifiers.

**Note:** This option is provided solely for use by other administration utilities; its use for any other purpose is not recommended or supported. The behaviour of the option may change in future releases without notice.

**--relation-oids oids**

Dump the relation(s) specified in the *oids* list of object identifiers.

**Note:** This option is provided solely for use by other administration utilities; its use for any other purpose is not recommended or supported. The behaviour of the option may change in future releases without notice.

**-Z 0..9 | --compress=0..9**

Specify the compression level to use in archive formats that support compression. Currently only the custom archive format supports compression.

**Connection Options**

**-h host | --host host**

The host name of the machine on which the Greenplum Database master database server is running. If not specified, reads from the environment variable PGHOST or defaults to localhost.

**-p port | --port port**

The TCP port on which the Greenplum Database master database server is listening for connections. If not specified, reads from the environment variable PGPORT or defaults to 5432.

**-U username | --username username**

The database role name to connect as. If not specified, reads from the environment variable PGUSER or defaults to the current system role name.

**-W | --password**

Force a password prompt.

**Notes**

When a data-only dump is chosen and the option **--disable-triggers** is used, *pg_dump* emits commands to disable triggers on user tables before inserting the data and commands to re-enable them after the data has been inserted. If the restore is stopped in the middle, the system catalogs may be left in the wrong state.

Members of tar archives are limited to a size less than 8 GB. (This is an inherent limitation of the tar file format.) Therefore this format cannot be used if the textual representation of any one table exceeds that size. The total size of a tar archive and any of the other output formats is not limited, except possibly by the operating system.

The dump file produced by *pg_dump* does not contain the statistics used by the optimizer to make query planning decisions. Therefore, it is wise to run **ANALYZE** after restoring from a dump file to ensure good performance.
Examples

Dump a database called mydb into a SQL-script file:

```
pg_dump mydb > db.sql
```

To reload such a script into a (freshly created) database named newdb:

```
psql -d newdb -f db.sql
```

Dump a Greenplum Database in tar file format and include distribution policy information:

```
pg_dump -Ft --gp-syntax mydb > db.tar
```

To dump a database into a custom-format archive file:

```
pg_dump -Fc mydb > db.dump
```

To reload an archive file into a (freshly created) database named newdb:

```
pg_restore -d newdb db.dump
```

To dump a single table named mytab:

```
pg_dump -t mytab mydb > db.sql
```

To specify an upper-case or mixed-case name in -t and related switches, you need to double-quote the name; else it will be folded to lower case. But double quotes are special to the shell, so in turn they must be quoted. Thus, to dump a single table with a mixed-case name, you need something like:

```
pg_dump -t ""MixedCaseName"" mydb > mytab.sql
```

See Also

`pg_dumpall`, `pg_restore`, `psql`

**pg_dumpall**

Extracts all databases in a Greenplum Database system to a single script file or other archive file.

**Synopsis**

```
pg_dumpall [connection_option ...] [dump_option ...]
```

**Description**

`pg_dumpall` is a standard PostgreSQL utility for backing up all databases in a Greenplum Database (or PostgreSQL) instance, and is also supported in Greenplum Database. It creates a single (non-parallel) dump file. For routine backups of Greenplum Database it is better to use the Greenplum Database backup utility, `gpcrondump`, for the best performance.

`pg_dumpall` creates a single script file that contains SQL commands that can be used as input to `psql` to restore the databases. It does this by calling `pg_dump` for each database. `pg_dumpall` also dumps global objects that are common to all databases. (`pg_dump` does not save these objects.) This currently includes information about database users and groups, and access permissions that apply to databases as a whole.
Since `pg_dumpall` reads tables from all databases you will most likely have to connect as a database superuser in order to produce a complete dump. Also you will need superuser privileges to execute the saved script in order to be allowed to add users and groups, and to create databases.

The SQL script will be written to the standard output. Shell operators should be used to redirect it into a file. `pg_dumpall` needs to connect several times to the Greenplum Database master server (once per database). If you use password authentication it is likely to ask for a password each time. It is convenient to have a `~/.pgpass` file in such cases.

**Note:** The `--ignore-version` option is deprecated and will be removed in a future release.

---

**Options**

**Dump Options**

- **-a | --data-only**
  Dump only the data, not the schema (data definitions). This option is only meaningful for the plain-text format. For the archive formats, you may specify the option when you call `pg_restore`.

- **-c | --clean**
  Output commands to clean (drop) database objects prior to (the commands for) creating them. This option is only meaningful for the plain-text format. For the archive formats, you may specify the option when you call `pg_restore`.

- **-d | --inserts**
  Dump data as `INSERT` commands (rather than `COPY`). This will make restoration very slow; it is mainly useful for making dumps that can be loaded into non-PostgreSQL-based databases. Also, since this option generates a separate command for each row, an error in reloading a row causes only that row to be lost rather than the entire table contents. Note that the restore may fail altogether if you have rearranged column order. The `-D` option is safe against column order changes, though even slower.

- **-D | --column-inserts | --attribute-inserts**
  Dump data as `INSERT` commands with explicit column names (`INSERT INTO table (column, ...) VALUES ...`). This will make restoration very slow; it is mainly useful for making dumps that can be loaded into non-PostgreSQL-based databases. Also, since this option generates a separate command for each row, an error in reloading a row causes only that row to be lost rather than the entire table contents.

- **-F | --filespaces**
  Dump filespace definitions.

- **-f filename | --file=filename**
  Send output to the specified file.

- **-g | --globals-only**
  Dump only global objects (roles and tablespaces), no databases.

- **-i | --ignore-version**
  **Note:** This option is deprecated and will be removed in a future release.
  Ignore version mismatch between `pg_dump` and the database server. `pg_dump` can dump from servers running previous releases of Greenplum Database (or PostgreSQL), but very old versions may not be supported anymore. Use this option if you need to override the version check.

- **-o | --oids**
  Dump object identifiers (OIDs) as part of the data for every table. Use of this option is not recommended for files that are intended to be restored into Greenplum Database.

- **-O | --no-owner**
Do not output commands to set ownership of objects to match the original database. By default, `pg_dump` issues `ALTER OWNER` or `SET SESSION AUTHORIZATION` statements to set ownership of created database objects. These statements will fail when the script is run unless it is started by a superuser (or the same user that owns all of the objects in the script). To make a script that can be restored by any user, but will give that user ownership of all the objects, specify `-O`. This option is only meaningful for the plain-text format. For the archive formats, you may specify the option when you call `pg_restore`.

```
-s | --schema-only
```

Dump only the object definitions (schema), not data.

```
-S username | --superuser=username
```

Specify the superuser user name to use when disabling triggers. This is only relevant if `--disable-triggers` is used. It is better to leave this out, and instead start the resulting script as a superuser.

**Note:** Greenplum Database does not support user-defined triggers.

```
-t | --tablespaces-only
```

Dump only tablespaces, not databases or roles.

```
-v | --verbose
```

Specifies verbose mode. This will cause `pg_dump` to output detailed object comments and start/stop times to the dump file, and progress messages to standard error.

```
-x | --no-privileges | --no-acl
```

Prevent dumping of access privileges (`GRANT/REVOKE` commands).

```
--disable-dollar-quoting
```

This option disables the use of dollar quoting for function bodies, and forces them to be quoted using SQL standard string syntax.

```
--disable-triggers
```

This option is only relevant when creating a data-only dump. It instructs `pg_dumpall` to include commands to temporarily disable triggers on the target tables while the data is reloaded. Use this if you have triggers on the tables that you do not want to invoke during data reload. The commands emitted for `--disable-triggers` must be done as superuser. So, you should also specify a superuser name with `-S`, or preferably be careful to start the resulting script as a superuser.

**Note:** Greenplum Database does not support user-defined triggers.

```
--resource-queues
```

Dump resource queue definitions.

```
--resource-groups
```

Dump resource group definitions.

```
--roles-only
```

Dump only roles, not databases, tablespaces, or filespaces.

```
--use-set-session-authorization
```

Output SQL-standard `SET SESSION AUTHORIZATION` commands instead of `ALTER OWNER` commands to determine object ownership. This makes the dump more standards compatible, but depending on the history of the objects in the dump, may not restore properly. A dump using `SET SESSION AUTHORIZATION` will require superuser privileges to restore correctly, whereas `ALTER OWNER` requires lesser privileges.

```
--gp-syntax
```

Output Greenplum Database syntax in the `CREATE TABLE` statements. This allows the distribution policy (`DISTRIBUTED BY` or `DISTRIBUTED RANDOMLY` clauses) of
a Greenplum Database table to be dumped, which is useful for restoring into other
Greenplum Database systems.

--no-gp-syntax
Do not output the table distribution clauses in the CREATE TABLE statements.

Connection Options
-\( h \) host | --host=host
The host name of the machine on which the Greenplum master database server is
running. If not specified, reads from the environment variable PGHOST or defaults to
localhost.

-\( l \) dbname | --database=dbname
Specifies the name of the database in which to connect to dump global objects. If not
specified, the postgres database is used. If the postgres database does not exist, the
template1 database is used.

-\( p \) port | --port=port
The TCP port on which the Greenplum master database server is listening for connections.
If not specified, reads from the environment variable PGPORT or defaults to 5432.

-\( U \) username | --username= username
The database role name to connect as. If not specified, reads from the environment
variable PGUSER or defaults to the current system role name.

-w
Never prompt for a password.

-W | --password
Force a password prompt.

Notes
Since pg_dumpall calls pg_dump internally, some diagnostic messages will refer to pg_dump.
Once restored, it is wise to run ANALYZE on each database so the query planner has useful statistics. You
can also run vacuumdb -a -z to analyze all databases.

pg_dumpall requires all needed tablespace (filespace) directories to exist before the restore or database
creation will fail for databases in non-default locations.

Examples
To dump all databases:

```
pg_dumpall > db.out
```

To reload this file:

```
psql template1 -f db.out
```

To dump only global objects (including filespaces and resource queues):

```
pg_dumpall -g -F --resource-queues
```

pg_dump
**pg_restore**

Restores a database from an archive file created by `pg_dump`.

**Synopsis**

```
pg_restore [connection_option ...] [restore_option ...] filename
```

**Description**

`pg_restore` is a utility for restoring a database from an archive created by `pg_dump` in one of the non-plain-text formats. It will issue the commands necessary to reconstruct the database to the state it was in at the time it was saved. The archive files also allow `pg_restore` to be selective about what is restored, or even to reorder the items prior to being restored.

`pg_restore` can operate in two modes. If a database name is specified, the archive is restored directly into the database. Otherwise, a script containing the SQL commands necessary to rebuild the database is created and written to a file or standard output. The script output is equivalent to the plain text output format of `pg_dump`. Some of the options controlling the output are therefore analogous to `pg_dump` options.

`pg_restore` cannot restore information that is not present in the archive file. For instance, if the archive was made using the “dump data as `INSERT` commands” option, `pg_restore` will not be able to load the data using `COPY` statements.

**Note:** The `--ignore-version` option is deprecated and will be removed in a future release.

**Options**

`filename`

Specifies the location of the archive file to be restored. If not specified, the standard input is used.

**Restore Options**

- `-a` | `--data-only`
  
  Restore only the data, not the schema (data definitions).

- `-c` | `--clean`
  
  Clean (drop) database objects before recreating them.

- `-C` | `--create`
  
  Create the database before restoring into it. (When this option is used, the database named with `-d` is used only to issue the initial `CREATE DATABASE` command. All data is restored into the database name that appears in the archive.)

- `-d dbname` | `--dbname=dbname`
  
  Connect to this database and restore directly into this database. The default is to use the `PGDATABASE` environment variable setting, or the same name as the current system user.

- `-e` | `--exit-on-error`
  
  Exit if an error is encountered while sending SQL commands to the database. The default is to continue and to display a count of errors at the end of the restoration.

- `-f outfilename` | `--file=outfilename`
  
  Specify output file for generated script, or for the listing when used with `-l`. Default is the standard output.

- `-F t | c` | `--format=tar | custom`
  
  Choose the archive format. If `--format=tar`, use a tar file. Otherwise, use a custom format.
The format of the archive produced by `pg_dump`. It is not necessary to specify the format, since `pg_restore` will determine the format automatically. Format can be either `tar` or `custom`.

- `-i` | `--ignore-version`
  
  Note: This option is deprecated and will be removed in a future release.

  Ignore database version checks.

- `-I index` | `--index=index`

  Restore definition of named index only.

- `-l` | `--list`

  List the contents of the archive. The output of this operation can be used with the `-L` option to restrict and reorder the items that are restored.

- `-L list-file` | `--use-list=list-file`

  Restore elements in the `list-file` only, and in the order they appear in the file. Lines can be moved and may also be commented out by placing a `;` at the start of the line.

- `-n schema` | `--schema=schema`

  Restore only objects that are in the named schema. This can be combined with the `-t` option to restore just a specific table.

- `-O` | `--no-owner`

  Do not output commands to set ownership of objects to match the original database. By default, `pg_restore` issues `ALTER OWNER` or `SET SESSION AUTHORIZATION` statements to set ownership of created schema elements. These statements will fail unless the initial connection to the database is made by a superuser (or the same user that owns all of the objects in the script). With `-O`, any user name can be used for the initial connection, and this user will own all the created objects.

- `-P 'function-name(argtype [, ...])'` | `--function='function-name(argtype [, ...])'`

  Restore the named function only. The function name must be enclosed in quotes. Be careful to spell the function name and arguments exactly as they appear in the dump file's table of contents (as shown by the `--list` option).

- `-s` | `--schema-only`

  Restore only the schema (data definitions), not the data (table contents). Sequence current values will not be restored, either. (Do not confuse this with the `--schema` option, which uses the word schema in a different meaning.)

- `-S username` | `--superuser=username`

  Specify the superuser user name to use when disabling triggers. This is only relevant if `--disable-triggers` is used.

  Note: Greenplum Database does not support user-defined triggers.

- `-t table` | `--table=table`

  Restore definition and/or data of named table only.

- `-T trigger` | `--trigger=trigger`

  Restore named trigger only.

  Note: Greenplum Database does not support user-defined triggers.

- `-v` | `--verbose`

  Specifies verbose mode.

- `-x` | `--no-privileges` | `--no-acl`
Prevent restoration of access privileges (GRANT/REVOKE commands).

--disable-triggers
This option is only relevant when performing a data-only restore. It instructs pg_restore to execute commands to temporarily disable triggers on the target tables while the data is reloaded. Use this if you have triggers on the tables that you do not want to invoke during data reload. The commands emitted for --disable-triggers must be done as superuser. So, you should also specify a superuser name with -S, or preferably run pg_restore as a superuser.

Note: Greenplum Database does not support user-defined triggers.

--no-data-for-failed-tables
By default, table data is restored even if the creation command for the table failed (e.g., because it already exists). With this option, data for such a table is skipped. This behavior is useful when the target database may already contain the desired table contents. Specifying this option prevents duplicate or obsolete data from being loaded. This option is effective only when restoring directly into a database, not when producing SQL script output.

Connection Options
-h host | --host host
The host name of the machine on which the Greenplum master database server is running. If not specified, reads from the environment variable PGHOST or defaults to localhost.

-p port | --port port
The TCP port on which the Greenplum Database master database server is listening for connections. If not specified, reads from the environment variable PGPORT or defaults to 5432.

-U username | --username username
The database role name to connect as. If not specified, reads from the environment variable PGUSER or defaults to the current system role name.

-W | --password
Force a password prompt.

-l | --single-transaction
Execute the restore as a single transaction. This ensures that either all the commands complete successfully, or no changes are applied.

Notes
If your installation has any local additions to the template1 database, be careful to load the output of pg_restore into a truly empty database; otherwise you are likely to get errors due to duplicate definitions of the added objects. To make an empty database without any local additions, copy from template0 not template1, for example:

```
CREATE DATABASE foo WITH TEMPLATE template0;
```

When restoring data to a pre-existing table and the option --disable-triggers is used, pg_restore emits commands to disable triggers on user tables before inserting the data then emits commands to re-enable them after the data has been inserted. If the restore is stopped in the middle, the system catalogs may be left in the wrong state.

pg_restore will not restore large objects for a single table. If an archive contains large objects, then all large objects will be restored.

See also the pg_dump documentation for details on limitations of pg_dump.
Once restored, it is wise to run `ANALYZE` on each restored table so the query planner has useful statistics.

**Examples**

Assume we have dumped a database called `mydb` into a custom-format dump file:

```
pg_dump -Fc mydb > db.dump
```

To drop the database and recreate it from the dump:

```
dropdb mydb
pg_restore -C -d template1 db.dump
```

To reload the dump into a new database called `newdb`. Notice there is no `-C`, we instead connect directly to the database to be restored into. Also note that we clone the new database from `template0` not `template1`, to ensure it is initially empty:

```
createdb -T template0 newdb
pg_restore -d newdb db.dump
```

To reorder database items, it is first necessary to dump the table of contents of the archive:

```
pg_restore -l db.dump > db.list
```

The listing file consists of a header and one line for each item, for example,

```
; Archive created at Fri Jul 28 22:28:36 2006
;   dbname: mydb
;   TOC Entries: 74
;   Compression: 0
;   Dump Version: 1.4-0
;   Format: CUSTOM
;
; Selected TOC Entries:
;
2; 145344 TABLE species postgres
3; 145344 ACL species
4; 145359 TABLE nt_header postgres
5; 145359 ACL nt_header
6; 145402 TABLE species_records postgres
7; 145402 ACL species_records
8; 145416 TABLE ss_old postgres
9; 145416 ACL ss_old
10; 145433 TABLE map_resolutions postgres
11; 145433 ACL map_resolutions
12; 145443 TABLE hs_old postgres
13; 145443 ACL hs_old
```

Semicolons start a comment, and the numbers at the start of lines refer to the internal archive ID assigned to each item. Lines in the file can be commented out, deleted, and reordered. For example,

```
10; 145433 TABLE map_resolutions postgres
;2; 145344 TABLE species postgres
;4; 145359 TABLE nt_header postgres
6; 145402 TABLE species_records postgres
;8; 145416 TABLE ss_old postgres
```

Could be used as input to `pg_restore` and would only restore items 10 and 6, in that order:

```
pg_restore -L db.list db.dump
```

*pg_dump*

**psql**

Interactive command-line interface for Greenplum Database

**Synopsis**

```
psql [option ...] [dbname [username]]
```

**Description**

`psql` is a terminal-based front-end to Greenplum Database. It enables you to type in queries interactively, issue them to Greenplum Database, and see the query results. Alternatively, input can be from a file. In addition, it provides a number of meta-commands and various shell-like features to facilitate writing scripts and automating a wide variety of tasks.

**Options**

- `-a` | `--echo-all`
  
  Print all input lines to standard output as they are read. This is more useful for script processing rather than interactive mode.

- `-A` | `--no-align`
  
  Switches to unaligned output mode. (The default output mode is aligned.)

- `-c 'command'` | `--command 'command'`
  
  Specifies that `psql` is to execute the specified command string, and then exit. This is useful in shell scripts. `command` must be either a command string that is completely parseable by the server, or a single backslash command. Thus you cannot mix SQL and `psql` meta-commands with this option. To achieve that, you could pipe the string into `psql`, like this:

  ```
  echo '\x20 SELECT * FROM foo;' | psql
  ```

  (`\` is the separator meta-command.)

  If the command string contains multiple SQL commands, they are processed in a single transaction, unless there are explicit `BEGIN/COMMIT` commands included in the string to divide it into multiple transactions. This is different from the behavior when the same string is fed to `psql`'s standard input.

- `-d dbname` | `--dbname dbname`
  
  Specifies the name of the database to connect to. This is equivalent to specifying `dbname` as the first non-option argument on the command line.

  If this parameter contains an equals sign, it is treated as a `conninfo` string; for example you can pass `'dbname=postgres user=username password=mypass'` as `dbname`.

- `-e` | `--echo-queries`
  
  Copy all SQL commands sent to the server to standard output as well.

- `-E` | `--echo-hidden`
  
  Echo the actual queries generated by `\d` and other backslash commands. You can use this to study `psql`'s internal operations.

- `-f filename` | `--file filename`
Use a file as the source of commands instead of reading commands interactively. After the file is processed, `psql` terminates. If `filename` is `-` (hyphen), then standard input is read. Using this option is subtly different from writing `psql < filename`. In general, both will do what you expect, but using `-f` enables some nice features such as error messages with line numbers.

`-F separator | --field-separator separator`

Use the specified separator as the field separator for unaligned output.

`-H | --html`

Turn on HTML tabular output.

`-l | --list`

List all available databases, then exit. Other non-connection options are ignored.

`-L filename | --log-file filename`

Write all query output into the specified log file, in addition to the normal output destination.

`-o filename | --output filename`

Put all query output into the specified file.

`-P assignment | --pset assignment`

Allows you to specify printing options in the style of `
\pset` on the command line. Note that here you have to separate name and value with an equal sign instead of a space. Thus to set the output format to LaTeX, you could write `-P format=latex`.

`-q | --quiet`

Specifies that `psql` should do its work quietly. By default, it prints welcome messages and various informational output. If this option is used, none of this happens. This is useful with the `-c` option.

`-R separator | --record-separator separator`

Use `separator` as the record separator for unaligned output.

`-s | --single-step`

Run in single-step mode. That means the user is prompted before each command is sent to the server, with the option to cancel execution as well. Use this to debug scripts.

`-S | --single-line`

Runs in single-line mode where a new line terminates an SQL command, as a semicolon does.

`-t | --tuples-only`

Turn off printing of column names and result row count footers, etc. This command is equivalent to `
\pset tuples_only` and is provided for convenience.

`-T table_options | --table-attr table_options`

Allows you to specify options to be placed within the HTML table tag. See `
\pset` for details.

`-v assignment | --set assignment | --variable assignment`

Perform a variable assignment, like the `
\set` internal command. Note that you must separate name and value, if any, by an equal sign on the command line. To unset a variable, leave off the equal sign. To just set a variable without a value, use the equal sign but leave off the value. These assignments are done during a very early stage of start-up, so variables reserved for internal purposes might get overwritten later.

`-V | --version`

Print the `psql` version and exit.

`-x | --expanded`
Turn on the expanded table formatting mode.

-x | --no-psqlrc
Do not read the start-up file (neither the system-wide psqlrc file nor the user's
~/psqlrc file).

-1 | --single-transaction
When psql executes a script with the -f option, adding this option wraps BEGIN/COMMIT
around the script to execute it as a single transaction. This ensures that either all the
commands complete successfully, or no changes are applied.

If the script itself uses BEGIN, COMMIT, or ROLLBACK, this option will not have the
desired effects. Also, if the script contains any command that cannot be executed inside
a transaction block, specifying this option will cause that command (and hence the whole
transaction) to fail.

-? | --help
Show help about psql command line arguments, and exit.

Connection Options
-h host | --host host
The host name of the machine on which the Greenplum master database server is
running. If not specified, reads from the environment variable PGHOST or defaults to
localhost.

When starting psql on the master host, if the host value begins with a slash, it is used as
the directory for the UNIX-domain socket.

-p port | --port port
The TCP port on which the Greenplum master database server is listening for connections.
If not specified, reads from the environment variable PGPORT or defaults to 5432.

-U username | --username username
The database role name to connect as. If not specified, reads from the environment
variable PGUSER or defaults to the current system role name.

-W | --password
Force a password prompt. psql should automatically prompt for a password whenever the
server requests password authentication. However, currently password request detection
is not totally reliable, hence this option to force a prompt. If no password prompt is issued
and the server requires password authentication, the connection attempt will fail.

-w --no-password
Never issue a password prompt. If the server requires password authentication and a
password is not available by other means such as a .pgpass file, the connection attempt
will fail. This option can be useful in batch jobs and scripts where no user is present to
enter a password.

Note: This option remains set for the entire session, and so it affects uses of the meta-
command \connect as well as the initial connection attempt.

Exit Status
psql returns 0 to the shell if it finished normally, 1 if a fatal error of its own (out of memory, file not found)
occurs, 2 if the connection to the server went bad and the session was not interactive, and 3 if an error
occurred in a script and the variable ON_ERROR_STOP was set.

Usage
Connecting to a Database
psql is a client application for Greenplum Database. In order to connect to a database you need to know the name of your target database, the host name and port number of the Greenplum master server and what database user name you want to connect as. psql can be told about those parameters via command line options, namely -d, -h, -p, and -U respectively. If an argument is found that does not belong to any option it will be interpreted as the database name (or the user name, if the database name is already given). Not all these options are required; there are useful defaults. If you omit the host name, psql will connect via a UNIX-domain socket to a master server on the local host, or via TCP/IP to localhost on machines that do not have UNIX-domain sockets. The default master port number is 5432. If you use a different port for the master, you must specify the port. The default database user name is your UNIX user name, as is the default database name. Note that you cannot just connect to any database under any user name. Your database administrator should have informed you about your access rights.

When the defaults are not right, you can save yourself some typing by setting any or all of the environment variables PGAPPNAME, PGDATABASE, PGHOST, PGPORT, and PGUSER to appropriate values.

It is also convenient to have a ~/.pgpass file to avoid regularly having to type in passwords. This file should reside in your home directory and contain lines of the following format:

```
hostname:port:database:username:password
```

The permissions on .pgpass must disallow any access to world or group (for example: chmod 0600 ~/.pgpass). If the permissions are less strict than this, the file will be ignored. (The file permissions are not currently checked on Microsoft Windows clients, however.)

If the connection could not be made for any reason (insufficient privileges, server is not running, etc.), psql will return an error and terminate.

**Entering SQL Commands**

In normal operation, psql provides a prompt with the name of the database to which psql is currently connected, followed by the string => for a regular user or # for a superuser. For example:

```
testdb=>
testdb=
```

At the prompt, the user may type in SQL commands. Ordinarily, input lines are sent to the server when a command-terminating semicolon is reached. An end of line does not terminate a command. Thus commands can be spread over several lines for clarity. If the command was sent and executed without error, the results of the command are displayed on the screen.

**Meta-Commands**

Anything you enter in psql that begins with an unquoted backslash is a psql meta-command that is processed by psql itself. These commands help make psql more useful for administration or scripting. Meta-commands are more commonly called slash or backslash commands.

The format of a psql command is the backslash, followed immediately by a command verb, then any arguments. The arguments are separated from the command verb and each other by any number of whitespace characters.

To include whitespace into an argument you may quote it with a single quote. To include a single quote into such an argument, use two single quotes. Anything contained in single quotes is furthermore subject to C-like substitutions for \n (new line), \t (tab), \digits (octal), and \xdigits (hexadecimal).

If an unquoted argument begins with a colon (:), it is taken as a psql variable and the value of the variable is used as the argument instead.

Arguments that are enclosed in backquotes (` `) are taken as a command line that is passed to the shell. The output of the command (with any trailing newline removed) is taken as the argument value. The above escape sequences also apply in backquotes.
Some commands take an SQL identifier (such as a table name) as argument. These arguments follow the syntax rules of SQL: Unquoted letters are forced to lowercase, while double quotes ("”) protect letters from case conversion and allow incorporation of whitespace into the identifier. Within double quotes, paired double quotes reduce to a single double quote in the resulting name. For example, FOO"BAR"BAZ is interpreted as fooBARbaz, and "A weird"" name" becomes A weird" name.

Parsing for arguments stops when another unquoted backslash occurs. This is taken as the beginning of a new meta-command. The special sequence \ (two backslashes) marks the end of arguments and continues parsing SQL commands, if any. That way SQL and psql commands can be freely mixed on a line. But in any case, the arguments of a meta-command cannot continue beyond the end of the line.

The following meta-commands are defined:

\a  
If the current table output format is unaligned, it is switched to aligned. If it is not unaligned, it is set to unaligned. This command is kept for backwards compatibility. See \pset for a more general solution.

\cd [directory]  
Changes the current working directory. Without argument, changes to the current user’s home directory. To print your current working directory, use \!pwd.

\C [title]  
Sets the title of any tables being printed as the result of a query or unset any such title. This command is equivalent to \pset title.

\c | \connect [dbname [username] [host] [port]]  
Establishes a new connection. If the new connection is successfully made, the previous connection is closed. If any of dbname, username, host or port are omitted, the value of that parameter from the previous connection is used. If the connection attempt failed, the previous connection will only be kept if psql is in interactive mode. When executing a non-interactive script, processing will immediately stop with an error. This distinction was chosen as a user convenience against typos, and a safety mechanism that scripts are not accidentally acting on the wrong database.

\conninfo  
Displays information about the current connection including the database name, the user name, the type of connection (UNIX domain socket, TCP/IP, etc.), the host, and the port.

\copy {table [(column_list)] | (query)} {from | to} {'filename' | stdin | stdout | pstdin | pstdout} [with] [binary] [oids] [delimiter [as] 'character'] [null [as] 'string'] [csv [header] [quote [as] 'character'] [escape [as] 'character'] [force quote column_list] [force not null column_list]}  
Performs a frontend (client) copy. This is an operation that runs an SQL COPY command, but instead of the server reading or writing the specified file, psql reads or writes the file and routes the data between the server and the local file system. This means that file accessibility and privileges are those of the local user, not the server, and no SQL superuser privileges are required.

The syntax of the command is similar to that of the SQL COPY command. Note that, because of this, special parsing rules apply to the \copy command. In particular, the variable substitution rules and backslash escapes do not apply.

\copy ... from stdin | to stdout reads/writes based on the command input and output respectively. All rows are read from the same source that issued the command, continuing until \. is read or the stream reaches EOF. Output is sent to the same place as command output. To read/write from psql’s standard input or output, use pstdin or pstdout. This option is useful for populating tables in-line within a SQL script file.
This operation is not as efficient as the SQL \texttt{COPY} command because all data must pass through the client/server connection.

\texttt{copyright}

Shows the copyright and distribution terms of PostgreSQL on which Greenplum Database is based.

\texttt{d [relation_pattern] | \texttt{d}+ [relation_pattern] | \texttt{dS} [relation_pattern]}

For each relation (table, external table, view, index, or sequence) matching the relation pattern, show all columns, their types, the tablespace (if not the default) and any special attributes such as \texttt{NOT NULL} or defaults, if any. Associated indexes, constraints, rules, and triggers are also shown, as is the view definition if the relation is a view.

- The command form \texttt{d}+ is identical, except that more information is displayed: any comments associated with the columns of the table are shown, as is the presence of OIDs in the table.

For partitioned tables, the command \texttt{d} or \texttt{d}+ specified with the root partition table or child partition table displays information about the table including partition keys on the current level of the partition table. The command \texttt{d}+ also displays the immediate child partitions of the table and whether the child partition is an external table or regular table.

For append-optimized tables and column-oriented tables, \texttt{d}+ displays the storage options for a table. For append-optimized tables, the options are displayed for the table. For column-oriented tables, storage options are displayed for each column.

- The command form \texttt{dS} is identical, except that system information is displayed as well as user information. For example, \texttt{dt} displays user tables, but not system tables; \texttt{dtS} displays both user and system tables. Both these commands can take the + parameter to display additional information, as in \texttt{dt}+ and \texttt{dtS}+.

If \texttt{d} is used without a pattern argument, it is equivalent to \texttt{dtvs} which will show a list of all tables, views, and sequences.

\texttt{da [aggregate_pattern]}

Lists all available aggregate functions, together with the data types they operate on. If a pattern is specified, only aggregates whose names match the pattern are shown.

\texttt{db [tablespace_pattern] | \texttt{db}+ [tablespace_pattern]}

Lists all available tablespaces and their corresponding filespace locations. If pattern is specified, only tablespaces whose names match the pattern are shown. If + is appended to the command name, each object is listed with its associated permissions.

\texttt{dc [conversion_pattern]}

Lists all available conversions between character-set encodings. If pattern is specified, only conversions whose names match the pattern are listed.

\texttt{dC}

Lists all available type casts.

\texttt{dd [object_pattern]}

Lists all available objects. If pattern is specified, only matching objects are shown.

\texttt{dD [domain_pattern]}

Lists all available domains. If pattern is specified, only matching domains are shown.

\texttt{dE [relation_pattern]}

Lists all external tables, or only those that match the pattern.

\texttt{df [function_pattern] | \texttt{df}+ [function_pattern] }
Lists available functions, together with their argument and return types. If pattern is specified, only functions whose names match the pattern are shown. If the form \df+ is used, additional information about each function, including language and description, is shown. To reduce clutter, \df does not show data type I/O functions. This is implemented by ignoring functions that accept or return type cstring.

\dg [role_pattern]
Lists all database roles. If pattern is specified, only those roles whose names match the pattern are listed.

\distPvES [index | sequence | table | parent table | view | external_table | system_object]
This is not the actual command name: the letters i, s, t, P, v, E, S stand for index, sequence, table, parent table, view, external table, and system table, respectively. You can specify any or all of these letters, in any order, to obtain a listing of all the matching objects. The letter S restricts the listing to system objects; without S, only non-system objects are shown. If + is appended to the command name, each object is listed with its associated description, if any. If a pattern is specified, only objects whose names match the pattern are listed.

\dl
This is an alias for \lo_list, which shows a list of large objects.

\dn [schema_pattern] | \dn+ [schema_pattern]
Lists all available schemas (namespaces). If pattern is specified, only schemas whose names match the pattern are listed. Non-local temporary schemas are suppressed. If + is appended to the command name, each object is listed with its associated permissions and description, if any.

\do [operator_pattern]
Lists available operators with their operand and return types. If pattern is specified, only operators whose names match the pattern are listed.

\dp [relation_pattern_to_show_privileges]
Produces a list of all available tables, views and sequences with their associated access privileges. If pattern is specified, only tables, views and sequences whose names match the pattern are listed. The GRANT and REVOKE commands are used to set access privileges.

\dT [datatype_pattern] | \dT+ [datatype_pattern]
Lists all data types or only those that match pattern. The command form \dT+ shows extra information.

\du [role_pattern]
Lists all database roles, or only those that match pattern.

\dx [extension_pattern] | \dx+ [extension_pattern]
Lists all installed extensions, or only those that match the pattern. \dx and \dx+ are functionally equivalent.

\e | \edit [filename]
If a file name is specified, the file is edited; after the editor exits, its content is copied back to the query buffer. If no argument is given, the current query buffer is copied to a temporary file which is then edited in the same fashion. The new query buffer is then re-parsed according to the normal rules of psql, where the whole buffer is treated as a single line. (Thus you cannot make scripts this way. Use \i for that.) This means also that if the query ends with (or rather contains) a semicolon, it is immediately executed. In other cases it will merely wait in the query buffer.
psql searches the environment variables PSQL_EDITOR, EDITOR, and VISUAL (in that order) for an editor to use. If all of them are unset, vi is used on UNIX systems, notepad.exe on Windows systems.

`\echo text [ ... ]`
Prints the arguments to the standard output, separated by one space and followed by a newline. This can be useful to intersperse information in the output of scripts.
If you use the `\o` command to redirect your query output you may wish to use `\qecho` instead of this command.

`\encoding [encoding]`
Sets the client character set encoding. Without an argument, this command shows the current encoding.

`\f [field_separator_string]`
Sets the field separator for unaligned query output. The default is the vertical bar (|). See also `\pset` for a generic way of setting output options.

`\g [{{filename | |command }}]`
Sends the current query input buffer to the server and optionally stores the query's output in a file or pipes the output into a separate UNIX shell executing command. A bare `\g` is virtually equivalent to a semicolon. A `\g` with argument is a one-shot alternative to the `\o` command.

`\h | \help [sql_command]`
Gives syntax help on the specified SQL command. If a command is not specified, then psql will list all the commands for which syntax help is available. Use an asterisk (*) to show syntax help on all SQL commands. To simplify typing, commands that consist of several words do not have to be quoted.

`\H`
Turns on HTML query output format. If the HTML format is already on, it is switched back to the default aligned text format. This command is for compatibility and convenience, but see `\pset` about setting other output options.

`\i input_filename`
Reads input from a file and executes it as though it had been typed on the keyboard. If you want to see the lines on the screen as they are read you must set the variable ECHO to all.

`\l | \list | \l+ | \list+`
List the names, owners, and character set encodings of all the databases in the server. If + is appended to the command name, database descriptions are also displayed.

`\lo_export loid filename`
Reads the large object with OID loid from the database and writes it to filename. Note that this is subtly different from the server function lo_export, which acts with the permissions of the user that the database server runs as and on the server's file system. Use `\lo_list` to find out the large object's OID.

`\lo_import large_object_filename [comment]`
Stores the file into a large object. Optionally, it associates the given comment with the object. Example:

```
mydb=> \lo_import '/home/gpadmin/pictures/photo.xcf' 'a picture of me'
lo_import 152801
```

The response indicates that the large object received object ID 152801 which one ought to remember if one wants to access the object ever again. For that reason it is recommended
to always associate a human-readable comment with every object. Those can then be seen with the \lo_list command. Note that this command is subtly different from the server-side lo_import because it acts as the local user on the local file system, rather than the server’s user and file system.

\lo_list

Shows a list of all large objects currently stored in the database, along with any comments provided for them.

\lo_unlink largeobject_oid

Deletes the large object of the specified OID from the database. Use \lo_list to find out the large object’s OID.

\o [ {query_result_filename | |command} ]

Saves future query results to a file or pipes them into a UNIX shell command. If no arguments are specified, the query output will be reset to the standard output. Query results include all tables, command responses, and notices obtained from the database server, as well as output of various backslash commands that query the database (such as \d), but not error messages. To intersperse text output in between query results, use 'echo.

\p

Print the current query buffer to the standard output.

\password [username]

Changes the password of the specified user (by default, the current user). This command prompts for the new password, encrypts it, and sends it to the server as an ALTER ROLE command. This makes sure that the new password does not appear in cleartext in the command history, the server log, or elsewhere.

\prompt [ text ] name

Prompts the user to set a variable name. Optionally, you can specify a prompt. Enclose prompts longer than one word in single quotes.

By default, \prompt uses the terminal for input and output. However, use the -f command line switch to specify standard input and standard output.

\pset print_option [value]

This command sets options affecting the output of query result tables. print_option describes which option is to be set. Adjustable printing options are:

- **format** – Sets the output format to one of unaligned, aligned, html, latex, troff-ms, or wrapped. First letter abbreviations are allowed. Unaligned writes all columns of a row on a line, separated by the currently active field separator. This is intended to create output that might be intended to be read in by other programs. Aligned mode is the standard, human-readable, nicely formatted text output that is default. The HTML and LaTeX modes put out tables that are intended to be included in documents using the respective mark-up language. They are not complete documents! (This might not be so dramatic in HTML, but in LaTeX you must have a complete document wrapper.)

The wrapped option sets the output format like the aligned parameter, but wraps wide data values across lines to make the output fit in the target column width. The target width is set with the columns option. To specify the column width and select the wrapped format, use two \pset commands; for example, to set the with to 72 columns and specify wrapped format, use the commands \pset columns 72 and then \pset format wrapped.
Note: Since `psql` does not attempt to wrap column header titles, the wrapped format behaves the same as aligned if the total width needed for column headers exceeds the target.

- **border** – The second argument must be a number. In general, the higher the number the more borders and lines the tables will have, but this depends on the particular format. In HTML mode, this will translate directly into the `border=...` attribute, in the others only values 0 (no border), 1 (internal dividing lines), and 2 (table frame) make sense.

- **columns** – Sets the target width for the `wrapped` format, and also the width limit for determining whether output is wide enough to require the pager. The default is zero. Zero causes the target width to be controlled by the environment variable `COLUMNS`, or the detected screen width if `COLUMNS` is not set. In addition, if `columns` is zero then the wrapped format affects screen output only. If columns is nonzero then file and pipe output is wrapped to that width as well.

After setting the target width, use the command `\pset format wrapped` to enable the wrapped format.

- **expanded | x** – Toggles between regular and expanded format. When expanded format is enabled, query results are displayed in two columns, with the column name on the left and the data on the right. This mode is useful if the data would not fit on the screen in the normal horizontal mode. Expanded mode is supported by all four output formats.

- **linestyle [unicode | ascii | old-ascii]** – Sets the border line drawing style to one of unicode, ascii, or old-ascii. Unique abbreviations, including one letter, are allowed for the three styles. The default setting is ascii. This option only affects the `aligned` and `wrapped` output formats.

  - **ascii** – uses plain ASCII characters. Newlines in data are shown using a + symbol in the right-hand margin. When the wrapped format wraps data from one line to the next without a newline character, a dot (.) is shown in the right-hand margin of the first line, and again in the left-hand margin of the following line.

  - **old-ascii** – style uses plain ASCII characters, using the formatting style used in PostgreSQL 8.4 and earlier. Newlines in data are shown using a : symbol in place of the left-hand column separator. When the data is wrapped from one line to the next without a newline character, a ; symbol is used in place of the left-hand column separator.

  - **unicode** – style uses Unicode box-drawing characters. Newlines in data are shown using a carriage return symbol in the right-hand margin. When the data is wrapped from one line to the next without a newline character, an ellipsis symbol is shown in the right-hand margin of the first line, and again in the left-hand margin of the following line.

When the `border` setting is greater than zero, this option also determines the characters with which the border lines are drawn. Plain ASCII characters work everywhere, but Unicode characters look nicer on displays that recognize them.

- **null 'string'** – The second argument is a string to print whenever a column is null. The default is not to print anything, which can easily be mistaken for an empty string. For example, the command `\psetnull '(empty)'` displays `(empty)` in null columns.

- **fieldsep** – Specifies the field separator to be used in unaligned output mode. That way one can create, for example, tab- or comma-separated output, which other programs might prefer. To set a tab as field separator, type `\pset fieldsep '\t'`. The default field separator is '|' (a vertical bar).

- **footer** – Toggles the display of the default footer (x rows).
• numericlocale – Toggles the display of a locale-aware character to separate groups of digits to the left of the decimal marker. It also enables a locale-aware decimal marker.

• recordsep – Specifies the record (line) separator to use in unaligned output mode. The default is a newline character.

• title [text] – Sets the table title for any subsequently printed tables. This can be used to give your output descriptive tags. If no argument is given, the title is unset.

• tableattr | T [text] – Allows you to specify any attributes to be placed inside the HTML table tag. This could for example be cellpadding or bgcolor. Note that you probably don't want to specify border here, as that is already taken care of by \pset border.

• tuples_only | t [novalue | on | off] – The \pset tuples_only command by itself toggles between tuples only and full display. The values on and off set the tuples display, regardless of the current setting. Full display may show extra information such as column headers, titles, and various footers. In tuples only mode, only actual table data is shown. The \t command is equivalent to \pset tuples_only and is provided for convenience.

• pager – Controls the use of a pager for query and psql help output. When on, if the environment variable PAGER is set, the output is piped to the specified program. Otherwise a platform-dependent default (such as more) is used. When off, the pager is not used. When on, the pager is used only when appropriate. Pager can also be set to always, which causes the pager to be always used.

\q
Quits the psql program.

\qecho text [ ... ]
This command is identical to \echo except that the output will be written to the query output channel, as set by \o.

\r
Resets (clears) the query buffer.

\s [history_filename]
Print or save the command line history to filename. If filename is omitted, the history is written to the standard output.

\set [name [value [ ... ]]]
Sets the internal variable name to value or, if more than one value is given, to the concatenation of all of them. If no second argument is given, the variable is just set with no value. To unset a variable, use the \unset command.

Valid variable names can contain characters, digits, and underscores. See "Variables" in Advanced Features. Variable names are case-sensitive.

Although you are welcome to set any variable to anything you want, psql treats several variables as special. They are documented in the topic about variables.

This command is totally separate from the SQL command SET.

\t [novalue | on | off]
The \t command by itself toggles a display of output column name headings and row count footer. The values on and off set the tuples display, regardless of the current setting. This command is equivalent to \pset tuples_only and is provided for convenience.

\T table_options
Allows you to specify attributes to be placed within the table tag in HTML tabular output mode.
The \timing command by itself toggles a display of how long each SQL statement takes, in milliseconds. The values on and off set the time display, regardless of the current setting.

\w {filename | |command}

Outputs the current query buffer to a file or pipes it to a UNIX command.

\x

Toggles expanded table formatting mode.

\z [relation_to_show_privileges]

Produces a list of all available tables, views and sequences with their associated access privileges. If a pattern is specified, only tables, views and sequences whose names match the pattern are listed. This is an alias for \dp.

\! [command]

Escapes to a separate UNIX shell or executes the UNIX command. The arguments are not further interpreted, the shell will see them as is.

\?

Shows help information about the psql backslash commands.

Patterns

The various \d commands accept a pattern parameter to specify the object name(s) to be displayed. In the simplest case, a pattern is just the exact name of the object. The characters within a pattern are normally folded to lower case, just as in SQL names; for example, \dt FOO will display the table named foo. As in SQL names, placing double quotes around a pattern stops folding to lower case. Should you need to include an actual double quote character in a pattern, write it as a pair of double quotes within a double-quote sequence; again this is in accord with the rules for SQL quoted identifiers. For example, \dt "FOO""BAR" will display the table named FOO"BAR (not foo"bar). Unlike the normal rules for SQL names, you can put double quotes around just part of a pattern, for instance \dt FOO"FOO"BAR will display the table named fooFOObar.

Within a pattern, * matches any sequence of characters (including no characters) and ? matches any single character. (This notation is comparable to UNIX shell file name patterns.) For example, \dt int* displays all tables whose names begin with int. But within double quotes, * and ? lose these special meanings and are just matched literally.

A pattern that contains a dot (.) is interpreted as a schema name pattern followed by an object name pattern. For example, \dt foo*.bar* displays all tables whose table name starts with bar that are in schemas whose schema name starts with foo. When no dot appears, then the pattern matches only objects that are visible in the current schema search path. Again, a dot within double quotes loses its special meaning and is matched literally.

Advanced users can use regular-expression notations. All regular expression special characters work as specified in the PostgreSQL documentation on regular expressions, except for ., which is taken as a separator as mentioned above, * which is translated to the regular-expression notation .*, and ? which is translated to .. You can emulate these pattern characters at need by writing ., (R+|) for R*, or (R|) for R?. Remember that the pattern must match the whole name, unlike the usual interpretation of regular expressions; write * at the beginning and/or end if you don't wish the pattern to be anchored. Note that within double quotes, all regular expression special characters lose their special meanings and are matched literally. Also, the regular expression special characters are matched literally in operator name patterns (such as the argument of \do).

Whenever the pattern parameter is omitted completely, the \d commands display all objects that are visible in the current schema search path – this is equivalent to using the pattern *. To see all objects in the database, use the pattern *.*.
Advanced Features

Variables

`psql` provides variable substitution features similar to common UNIX command shells. Variables are simply name/value pairs, where the value can be any string of any length. To set variables, use the `psql` meta-command \set:

```
set db=> \set foo bar
```

sets the variable `foo` to the value `bar`. To retrieve the content of the variable, precede the name with a colon and use it as the argument of any slash command:

```
set db=> \echo :foo
```

```
bar
```

**Note:** The arguments of \set are subject to the same substitution rules as with other commands. Thus you can construct interesting references such as \set :foo 'something' and get 'soft links' or 'variable variables' of Perl or PHP fame, respectively. Unfortunately, there is no way to do anything useful with these constructs. On the other hand, \set bar :foo is a perfectly valid way to copy a variable.

If you call \set without a second argument, the variable is set, with an empty string as value. To unset (or delete) a variable, use the command \unset.

`psql`'s internal variable names can consist of letters, numbers, and underscores in any order and any number of them. A number of these variables are treated specially by `psql`. They indicate certain option settings that can be changed at run time by altering the value of the variable or represent some state of the application. Although you can use these variables for any other purpose, this is not recommended, as the program behavior might behave unexpectedly. By convention, all specially treated variables consist of all upper-case letters (and possibly numbers and underscores). To ensure maximum compatibility in the future, avoid using such variable names for your own purposes. A list of all specially treated variables are as follows:

**AUTOCOMMIT**

When on (the default), each SQL command is automatically committed upon successful completion. To postpone commit in this mode, you must enter a `BEGIN` or `START TRANSACTION` SQL command. When off or unset, SQL commands are not committed until you explicitly issue `COMMIT` or `END`. The autocommit-on mode works by issuing an implicit `BEGIN` for you, just before any command that is not already in a transaction block and is not itself a `BEGIN` or other transaction-control command, nor a command that cannot be executed inside a transaction block (such as `VACUUM`).

In autocommit-off mode, you must explicitly abandon any failed transaction by entering `ABORT` or `ROLLBACK`. Also keep in mind that if you exit the session without committing, your work will be lost.

The autocommit-on mode is PostgreSQL's traditional behavior, but autocommit-off is closer to the SQL spec. If you prefer autocommit-off, you may wish to set it in your `~/.psqlrc` file.

**DBNAME**

The name of the database you are currently connected to. This is set every time you connect to a database (including program start-up), but can be unset.

**ECHO**

If set to all, all lines entered from the keyboard or from a script are written to the standard output before they are parsed or executed. To select this behavior on program start-up, use the switch `-a`. If set to queries, `psql` merely prints all queries as they are sent to the server. The switch for this is `-e`.

**ECHO_HIDDEN**
When this variable is set and a backslash command queries the database, the query is first shown. This way you can study the Greenplum Database internals and provide similar functionality in your own programs. (To select this behavior on program start-up, use the switch \-E.) If you set the variable to the value noexec, the queries are just shown but are not actually sent to the server and executed.

**ENCODING**

The current client character set encoding.

**FETCH_COUNT**

If this variable is set to an integer value > 0, the results of `SELECT` queries are fetched and displayed in groups of that many rows, rather than the default behavior of collecting the entire result set before display. Therefore only a limited amount of memory is used, regardless of the size of the result set. Settings of 100 to 1000 are commonly used when enabling this feature. Keep in mind that when using this feature, a query may fail after having already displayed some rows.

Although you can use any output format with this feature, the default aligned format tends to look bad because each group of `FETCH_COUNT` rows will be formatted separately, leading to varying column widths across the row groups. The other output formats work better.

**HISTCONTROL**

If this variable is set to ignorespace, lines which begin with a space are not entered into the history list. If set to a value of ignoredups, lines matching the previous history line are not entered. A value of ignoreboth combines the two options. If unset, or if set to any other value than those above, all lines read in interactive mode are saved on the history list.

**HISTFILE**

The file name that will be used to store the history list. The default value is `~/.psql_history`. For example, putting

```
\set HISTFILE ~/.psql_history- :DBNAME
```

in `~/.psqlrc` will cause `psql` to maintain a separate history for each database.

**HISTSIZE**

The number of commands to store in the command history. The default value is 500.

**HOST**

The database server host you are currently connected to. This is set every time you connect to a database (including program start-up), but can be unset.

**IGNOREEOF**

If unset, sending an EOF character (usually CTRL+D) to an interactive session of `psql` will terminate the application. If set to a numeric value, that many EOF characters are ignored before the application terminates. If the variable is set but has no numeric value, the default is 10.

**LASTOID**

The value of the last affected OID, as returned from an `INSERT` or `lo_insert` command. This variable is only guaranteed to be valid until after the result of the next SQL command has been displayed.

**ON_ERROR_ROLLBACK**

When on, if a statement in a transaction block generates an error, the error is ignored and the transaction continues. When interactive, such errors are only ignored in interactive sessions, and not when reading script files. When off (the default), a statement in a transaction block that generates an error aborts the entire transaction. The
on_error_rollback-on mode works by issuing an implicit `SAVEPOINT` for you, just before each command that is in a transaction block, and rolls back to the savepoint on error.

**ON_ERROR_STOP**
By default, if non-interactive scripts encounter an error, such as a malformed SQL command or internal meta-command, processing continues. This has been the traditional behavior of `psql` but it is sometimes not desirable. If this variable is set, script processing will immediately terminate. If the script was called from another script it will terminate in the same fashion. If the outermost script was not called from an interactive `psql` session but rather using the `-f` option, `psql` will return error code 3, to distinguish this case from fatal error conditions (error code 1).

**PORT**
The database server port to which you are currently connected. This is set every time you connect to a database (including program start-up), but can be unset.

**PROMPT1**
**PROMPT2**
**PROMPT3**
These specify what the prompts `psql` issues should look like. See “Prompting”.

**QUIET**
This variable is equivalent to the command line option `-q`. It is not very useful in interactive mode.

**SINGLELINE**
This variable is equivalent to the command line option `-S`.

**SINGLESTEP**
This variable is equivalent to the command line option `-s`.

**USER**
The database user you are currently connected as. This is set every time you connect to a database (including program start-up), but can be unset.

**VERBOSITY**
This variable can be set to the values `default`, `verbose`, or `terse` to control the verbosity of error reports.

**SQL Interpolation**
An additional useful feature of `psql` variables is that you can substitute (interpolate) them into regular SQL statements. The syntax for this is again to prepend the variable name with a colon (:).

```bash
testdb=> \set foo 'my_table'
testdb=> SELECT * FROM :foo;
```

would then query the table `my_table`. The value of the variable is copied literally, so it can even contain unbalanced quotes or backslash commands. You must make sure that it makes sense where you put it. Variable interpolation will not be performed into quoted SQL entities.

A popular application of this facility is to refer to the last inserted OID in subsequent statements to build a foreign key scenario. Another possible use of this mechanism is to copy the contents of a file into a table column. First load the file into a variable and then proceed as above.

```bash
testdb=> \set content '''' `cat my_file.txt` '''
testdb=> INSERT INTO my_table VALUES (:content);
```
One problem with this approach is that `my_file.txt` might contain single quotes. These need to be escaped so that they don't cause a syntax error when the second line is processed. This could be done with the program `sed`:

```sql
  testdb=> \set content ''' `sed -e "s/'/'/g" < my_file.txt`''
```

If you are using non-standard-conforming strings then you'll also need to double backslashes. This is a bit tricky:

```sql
  testdb=> \set content ''' `sed -e "s/'/'/g" -e 's/\\/\\\\/g' < my_file.txt`''
```

Note the use of different shell quoting conventions so that neither the single quote marks nor the backslashes are special to the shell. Backslashes are still special to `sed`, however, so we need to double them.

Since colons may legally appear in SQL commands, the following rule applies: the character sequence "`:name`" is not changed unless "`name`" is the name of a variable that is currently set. In any case you can escape a colon with a backslash to protect it from substitution. (The colon syntax for variables is standard SQL for embedded query languages, such as ECPG. The colon syntax for array slices and type casts are Greenplum Database extensions, hence the conflict.)

### Prompting

The prompts `psql` issues can be customized to your preference. The three variables `PROMPT1`, `PROMPT2`, and `PROMPT3` contain strings and special escape sequences that describe the appearance of the prompt. Prompt 1 is the normal prompt that is issued when `psql` requests a new command. Prompt 2 is issued when more input is expected during command input because the command was not terminated with a semicolon or a quote was not closed. Prompt 3 is issued when you run an SQL `COPY` command and you are expected to type in the row values on the terminal.

The value of the selected prompt variable is printed literally, except where a percent sign (%) is encountered. Depending on the next character, certain other text is substituted instead. Defined substitutions are:

- `%M` - The full host name (with domain name) of the database server, or `[local]` if the connection is over a UNIX domain socket, or `[local:/dir/name]`, if the UNIX domain socket is not at the compiled in default location.
- `%m` - The host name of the database server, truncated at the first dot, or `[local]` if the connection is over a UNIX domain socket.
- `%> - The port number at which the database server is listening.
- `%n` - The database session user name. (The expansion of this value might change during a database session as the result of the command `SET SESSION AUTHORIZATION`.)
- `%/` - The name of the current database.
- `%~` - Like `/`, but the output is ~ (tilde) if the database is your default database.
- `%#`
If the session user is a database superuser, then a #, otherwise a >. (The expansion of this value might change during a database session as the result of the command SET SESSION AUTHORIZATION.)

%R

In prompt 1 normally =, but ^ if in single-line mode, and ! if the session is disconnected from the database (which can happen if \connect fails). In prompt 2 the sequence is replaced by *, ^, a single quote, a double quote, or a dollar sign, depending on whether psql expects more input because the command wasn't terminated yet, because you are inside a /* ... */ comment, or because you are inside a quoted or dollar-escaped string. In prompt 3 the sequence doesn't produce anything.

%x

Transaction status: an empty string when not in a transaction block, or * when in a transaction block, or ! when in a failed transaction block, or ? when the transaction state is indeterminate (for example, because there is no connection).

%digits

The character with the indicated octal code is substituted.

%:name:

The value of the psql variable name. See “Variables” in Advanced Features for details.

%`command`

The output of command, similar to ordinary back-tick substitution.

%[ ... %]

Prompts may contain terminal control characters which, for example, change the color, background, or style of the prompt text, or change the title of the terminal window. In order for line editing to work properly, these non-printing control characters must be designated as invisible by surrounding them with %[ and %]. Multiple pairs of these may occur within the prompt. For example,

```
testdb=> \set PROMPT1 '%[033[1;33;40m%]%n@%/%R%[^033[0m%]#'
```

results in a boldfaced (1;) yellow-on-black (33;40) prompt on VT100-compatible, color-capable terminals. To insert a percent sign into your prompt, write \%. The default prompts are '""' for prompts 1 and 2, and '>> ' for prompt 3.

Command-Line Editing

psql supports the NetBSD libedit library for convenient line editing and retrieval. The command history is automatically saved when psql exits and is reloaded when psql starts up. Tab-completion is also supported, although the completion logic makes no claim to be an SQL parser. If for some reason you do not like the tab completion, you can turn it off by putting this in a file named .inputrc in your home directory:

```
$if psql
set disable-completion on
$endif
```

Environment

PAGER

If the query results do not fit on the screen, they are piped through this command. Typical values are more or less. The default is platform-dependent. The use of the pager can be disabled by using the \pset command.

PGDATABASE

PGHOST
**Files**

Before starting up, `psql` attempts to read and execute commands from the user's `~/.psqlrc` file. The command-line history is stored in the file `~/.psql_history`.

**Notes**

`psql` only works smoothly with servers of the same version. That does not mean other combinations will fail outright, but subtle and not-so-subtle problems might come up. Backslash commands are particularly likely to fail if the server is of a different version.

**Notes for Windows users**

`psql` is built as a console application. Since the Windows console windows use a different encoding than the rest of the system, you must take special care when using 8-bit characters within `psql`. If `psql` detects a problematic console code page, it will warn you at startup. To change the console code page, two things are necessary:

Set the code page by entering:

```
    cmd.exe /c chcp 1252
```

1252 is a character encoding of the Latin alphabet, used by Microsoft Windows for English and some other Western languages. If you are using Cygwin, you can put this command in `/etc/profile`.

Set the console font to Lucida Console, because the raster font does not work with the ANSI code page.

**Examples**

Start `psql` in interactive mode:

```
    psql -p 54321 -U sally mydatabase
```

In `psql` interactive mode, spread a command over several lines of input. Notice the changing prompt:

```
    testdb=> CREATE TABLE my_table ( 
    testdb(> first integer not null default 0, 
    testdb(> second text) 
    testdb-> ; 
    CREATE TABLE
```
Look at the table definition:

```sql
testdb=> \d my_table
Table "my_table"
 Attribute |  Type   | Modifier
-----------+---------+-------------------
 first     | integer | not null default 0
 second    | text    |
```

Run `psql` in non-interactive mode by passing in a file containing SQL commands:

```
psql -f /home/gpadmin/test/myscript.sql
```

**reindexdb**

Rebuilds indexes in a database.

**Synopsis**

```bash
reindexdb [connection-option ...] [--table | -t table ]
 [---index | -i index ] [dbname]
reindexdb [connection-option ...] [--all | -a]
reindexdb [connection-option ...] [--system | -s] [dbname]
reindexdb --help
reindexdb --version
```

**Description**

`reindexdb` is a utility for rebuilding indexes in Greenplum Database, and is a wrapper around the SQL command `REINDEX`.

**Options**

- `-a | --all`
  Reindex all databases.
- `[-d] dbname | [dbname]`
  Specifies the name of the database to be reindexed. If this is not specified and `-all` is not used, the database name is read from the environment variable `PGDATABASE`. If that is not set, the user name specified for the connection is used.
- `-e | --echo`
  Echo the commands that `reindexdb` generates and sends to the server.
- `-i index | --index index`
  Recreate index only.
- `-q | --quiet`
  Do not display a response.
- `-s | --system`
  Reindex system catalogs.
- `-t table | --table table`
  Reindex table only.
Connection Options

- **h** host | **--host** host
  Specifies the host name of the machine on which the Greenplum master database server is running. If not specified, reads from the environment variable PGHOST or defaults to localhost.

- **p** port | **--port** port
  Specifies the TCP port on which the Greenplum master database server is listening for connections. If not specified, reads from the environment variable PGPORT or defaults to 5432.

- **U** username | **--username** username
  The database role name to connect as. If not specified, reads from the environment variable PGUSER or defaults to the current system user name.

- **w** | **--no-password**
  Never issue a password prompt. If the server requires password authentication and a password is not available by other means such as a .pgpass file, the connection attempt will fail. This option can be useful in batch jobs and scripts where no user is present to enter a password.

- **W** | **--password**
  Force a password prompt.

Notes

reindexdb might need to connect several times to the master server, asking for a password each time. It is convenient to have a ~/.pgpass file in such cases.

Examples

To reindex the database mydb:

reindexdb mydb

To reindex the table foo and the index bar in a database named abcd:

reindexdb --table foo --index bar abcd

REINDEX in the Greenplum Database Reference Guide

vacuumdb

Garbage-collects and analyzes a database.

Synopsis

```
vacuumdb [connection-option...] [--full | -f] [-F] [--verbose | -v]
    [--analyze | -z] [--table | -t table [ [ column [, ... ] ] ] ] [dbname]
vacuumdb [connection-options...] [--all | -a] [--full | -f] [-F]
    [--verbose | -v] [--analyze | -z]
vacuumdb --help
vacuumdb --version
```
Description

vacuumdb is a utility for cleaning a Greenplum Database database. vacuumdb will also generate internal statistics used by the Greenplum Database query optimizer.

vacuumdb is a wrapper around the SQL command VACUUM. There is no effective difference between vacuuming databases via this utility and via other methods for accessing the server.

Options

-a | --all
    Vacuums all databases.

[-d] dbname | [--dbname] dbname
    The name of the database to vacuum. If this is not specified and -all is not used, the database name is read from the environment variable PGDATABASE. If that is not set, the user name specified for the connection is used.

-e | --echo
    Echo the commands that reindexdb generates and sends to the server.

-f | --full
    Selects a full vacuum, which may reclaim more space, but takes much longer and exclusively locks the table.

    Warning: A VACUUM FULL is not recommended in Greenplum Database.

-F | --freeze
    Freeze row transaction information.

-q | --quiet
    Do not display a response.

-t table [(column)] | --table table [(column)]
    Clean or analyze this table only. Column names may be specified only in conjunction with the --analyze option. If you specify columns, you probably have to escape the parentheses from the shell.

-v | --verbose
    Print detailed information during processing.

-z | --analyze
    Collect statistics for use by the query planner.

Connection Options

-h host | --host host
    Specifies the host name of the machine on which the Greenplum master database server is running. If not specified, reads from the environment variable PGHOST or defaults to localhost.

-p port | --port port
    Specifies the TCP port on which the Greenplum master database server is listening for connections. If not specified, reads from the environment variable PGPORT or defaults to 5432.

-U username | --username username
    The database role name to connect as. If not specified, reads from the environment variable PGUSER or defaults to the current system user name.

-w | --no-password
    Never issue a password prompt. If the server requires password authentication and a password is not available by other means such as a .pgpass file, the connection attempt
will fail. This option can be useful in batch jobs and scripts where no user is present to enter a password.

```
-w | --password
    Force a password prompt.
```

### Notes

`vacuumdb` might need to connect several times to the master server, asking for a password each time. It is convenient to have a `~/.pgpass` file in such cases.

### Examples

To clean the database `test`:

```
vacuumdb test
```

To clean and analyze a database named `bigdb`:

```
vacuumdb --analyze bigdb
```

To clean a single table `foo` in a database named `mydb`, and analyze a single column `bar` of the table. Note the quotes around the table and column names to escape the parentheses from the shell:

```
vacuumdb --analyze --verbose --table 'foo(bar)' mydb
```

Additional Supplied Modules

This section describes additional modules available in the Greenplum Database contrib subdirectory.

**citext Data Type**

The citext module provides a case-insensitive character string type, citext. Essentially, it internally calls the lower function when comparing values. Otherwise, it behaves almost exactly like the text data type.

The standard method to perform case-insensitive matches on text values is to use the lower function when comparing values, for example:

```
SELECT * FROM tab WHERE lower(col) = LOWER(?);
```

This method works well, but has drawbacks:

- It makes your SQL statements verbose, and you must remember to use lower on both the column and the query value.
- It does not work with an index, unless you create a functional index using lower.

The citext data type allows you to eliminate calls to lower in SQL queries and you can create case-insensitive indexes on columns of type citext. citext is locale-aware, like the text type, which means comparing uppercase and lowercase characters depends on the rules of the LC_CTYPE locale setting. This behavior is the same as using lower in queries, but it is done transparently by the data type, so you do not have to do anything special in your queries.

**Installing citext**

Before you can use the citext data type, run the installation script `$GPHOME/share/postgresql/contrib/citext.sql` in each database where you want to use the type:

```
$ psql -d testdb -f $GPHOME/share/postgresql/contrib/citext.sql
```

**Using the citext Type**

Here is a simple example defining a citext table column:

```
CREATE TABLE users (  
    id bigint PRIMARY KEY,  
    nick CITEXT NOT NULL,  
    pass TEXT NOT NULL  
) DISTRIBUTED BY (id);

INSERT INTO users VALUES (1, 'larry', md5(random()::text) );
INSERT INTO users VALUES (2, 'Tom', md5(random()::text) );
INSERT INTO users VALUES (3, 'Damian', md5(random()::text) );
INSERT INTO users VALUES (4, 'NEAL', md5(random()::text) );
INSERT INTO users VALUES (5, 'Bjørn', md5(random()::text) );

SELECT * FROM users WHERE nick = 'Larry';
```

The SELECT statement returns one tuple, even though the nick column is set to larry and the query specified Larry.
String Comparison Behavior

citext performs comparisons by converting each string to lower case (as though the lower function were called) and then comparing the results normally. Two strings are considered equal if lower would produce identical results for them.

In order to emulate a case-insensitive collation as closely as possible, there are citext-specific versions of a number of string-processing operators and functions. So, for example, the regular expression operators ~ and ~* exhibit the same behavior when applied to citext: they both match case-insensitively. The same is true for !~ and !~*, as well as for the LIKE operators ~~ and ~~~*, and !~~ and !~~*. If you want to match case-sensitively, you can cast the operator's arguments to text.

The following functions perform matching case-insensitively if their arguments are citext:

- regexp_match()
- regexp_matches()
- regexp_replace()
- regexp_split_to_array()
- regexp_split_to_table()
- replace()
- split_part()
- strpos()
- translate()

For the regexp functions, if you want to match case-sensitively, you can specify the "c" flag to force a case-sensitive match. If you want case-sensitive behavior, you must cast to text before using one of these functions.

Limitations

- A column of type citext cannot be part of a primary key or distribution key in a CREATE TABLE statement.
- The citext type's case-folding behavior depends on the LC_CTYPE setting of your database. How it compares values is therefore determined when the database is created. It is not truly case-insensitive in the terms defined by the Unicode standard. Effectively, what this means is that, as long as you're happy with your collation, you should be happy with citext's comparisons. But if you have data in different languages stored in your database, users of one language may find their query results are not as expected if the collation is for another language.
- citext is not as efficient as text because the operator functions and the B-tree comparison functions must make copies of the data and convert them to lower case for comparisons. It is, however, slightly more efficient than using lower to perform case-insensitive matching.
- citext may not be the best option if you need data to compare case-sensitively in some contexts and case-insensitively in other contexts. The standard recommendation is to use the text type and manually apply the lower function when you need to compare case-insensitively. This works if case-insensitive comparison is needed only infrequently. If you need case-insensitive behavior most of the time and case-sensitive infrequently, consider storing the data as citext and explicitly casting the column to text when you want case-sensitive comparison. In either situation, you will need two indexes if you want both types of searches to be fast.
- The schema containing the citext operators must be in the current search_path (typically public); if it is not, the normal case-sensitive text operators will be invoked instead.
**dblink Functions**

The `dblink` module supports connections to other Greenplum Database databases from within a database session. These databases can reside in the same Greenplum Database system, or in a remote system.

Greenplum Database supports `dblink` connections between databases in Greenplum Database installations with the same major version number. `dblink` may also connect to other Greenplum Database installations that use compatible libpq libraries.

You create a `dblink` connection to a database and execute an SQL command in the database as a Greenplum Database user. The user must have the appropriate access privileges to the database tables referenced in the SQL command. If the database is in a remote system, the user must be defined as a Greenplum Database user in the remote system with the appropriate access privileges.

`dblink` is intended for database users to perform short ad hoc queries in other databases. `dblink` is not intended for use as a replacement for external tables or for administrative tools such as `gpcopy` or `gptransfer` (deprecated).

Refer to `dblink` in the PostgreSQL documentation for more information about individual `dblink` functions.

**Limitations**

In this release of Greenplum Database, statements that modify table data cannot use named or implicit `dblink` connections. Instead, you must provide the connection string directly in the `dblink()` function. For example:

```
$psql -d postgres
psql (8.3.23)
Type "help" for help.
postgres=# CREATE TABLE testdblocal (a int, b text) DISTRIBUTED BY (a);
CREATE TABLE
postgres=# INSERT INTO testdblocal select * FROM dblink('dbname=postgres',
    'SELECT * FROM testdblink') AS dbltab(id int, product text);
INSERT 0 2
```

The Greenplum Database version of `dblink` disables the following asynchronous functions:

- `dblink_send_query()`
- `dblink_is_busy()`
- `dblink_get_result()`

**Using dblink**

The following procedure identifies the basic steps for configuring and using `dblink` in Greenplum Database. The examples use `dblink_connect()` to create a connection to a database and `dblink()` to execute an SQL query.

Only superusers can use `dblink_connect()` to create connections that do not require a password. If non-superusers need this capability, use `dblink_connect_u()` instead. See Using `dblink` as a Non-Superuser.

1. Begin by creating a sample table to query using the `dblink` functions. These commands create a small table in the `postgres` database, which you will later query from the `testdb` database using `dblink`:

```
$ psql -d postgres
psql (8.3.23)
Type "help" for help.
postgres=# CREATE TABLE testdblink (a int, b text) DISTRIBUTED BY (a);
CREATE TABLE
postgres=# INSERT INTO testdblink VALUES (1, 'Cheese'), (2, 'Fish');
INSERT 0 2
```
2. Log into a different database as a superuser. In this example, the superuser `gpadmin` logs into the database `testdb`. If the `dblink` functions are not already available, install them using the `$GPHOME/share/postgresql/contrib/dblink.sql` script:

```
$ psql -d testdb
psql (9.4beta1)
Type "help" for help.

testdb=# \i /usr/local/greenplum-db/share/postgresql/contrib/dblink.sql
SET
CREATE FUNCTION
CREATE FUNCTION ...
```

3. Use the `dblink_connect()` function to create either an implicit or a named connection to another database. The connection string that you provide should be a libpq-style keyword/value string. This example creates a connection named `mylocalconn` to the `postgres` database on the local Greenplum Database system:

```
testdb=# SELECT dblink_connect('mylocalconn', 'dbname=postgres
user=gpadmin');
dblink_connect
-----------------
OK
(1 row)
```

**Note:** If a user is not specified, `dblink_connect()` uses the value of the `PGUSER` environment variable when Greenplum Database was started. If `PGUSER` is not set, the default is the system user that started Greenplum Database.

4. Use the `dblink()` function to query a database using a configured connection. Keep in mind that this function returns a record type, so you must assign the columns returned in the `dblink()` query. For example, the following command uses the named connection to query the table you created earlier:

```
testdb=# SELECT * FROM dblink('mylocalconn', 'SELECT * FROM testdblink')
AS dbltab(id int, product text);
id | product
----+---------
1 | Cheese
2 | Fish
(2 rows)
```

To connect to the local database as another user, specify the user in the connection string. This example connects to the database as the user `test_user`. Using `dblink_connect()`, a superuser can create a connection to another local database without specifying a password.

```
testdb=# SELECT dblink_connect('localconn2', 'dbname=postgres
user=test_user');
```

To make a connection to a remote database system, include host and password information in the connection string. For example, to create an implicit `dblink` connection to a remote system:

```
testdb=# SELECT dblink_connect('host=remotehost port=5432 dbname=postgres
user=gpadmin password=secret');
```
Using dblink as a Non-Superuser

To make a connection to a database with `dblink_connect()`, non-superusers must include host, user, and password information in the connection string. The host, user, and password information must be included even when connecting to a local database. For example, the user `test_user` can create a dblink connection to the local system `mdw` with this command:

```
SELECT dblink_connect('host=mdw port=5432 dbname=postgres
 user=test_user password=secret');
```

If non-superusers need to create dblink connections that do not require a password, they can use the `dblink_connect_u()` function. The `dblink_connect_u()` function is identical to `dblink_connect()`, except that it allows non-superusers to create connections that do not require a password.

In some situations, it may be appropriate to grant EXECUTE permission on `dblink_connect_u()` to specific users who are considered trustworthy, but this should be done with care.

**Warning:** If a Greenplum Database system has configured users with an authentication method that does not involve a password, then impersonation and subsequent escalation of privileges can occur when a non-superuser executes `dblink_connect_u()`. The dblink connection will appear to have originated from the user specified by the function. For example, a non-superuser can execute `dblink_connect_u()` and specify a user that is configured with trust authentication.

Also, even if the dblink connection requires a password, it is possible for the password to be supplied from the server environment, such as a `~/.pgpass` file belonging to the server’s user.

1. **As a superuser, grant the EXECUTE privilege on the dblink_connect_u() functions in the user database.** This example grants the privilege to the non-superuser `test_user` on the functions with the signatures for creating an implicit or a named dblink connection.

```
GRANT EXECUTE ON FUNCTION dblink_connect_u(text) TO test_user;
GRANT EXECUTE ON FUNCTION dblink_connect_u(text, text) TO test_user;
```

2. **Now test_user can create a connection to another local database without a password.** For example, `test_user` can log into the `testdb` database and execute this command to create a connection named `testconn` to the local `postgres` database.

```
SELECT dblink_connect_u('testconn', 'dbname=postgres
 user=test_user');
```

**Note:** If a user is not specified, `dblink_connect_u()` uses the value of the `PGUSER` environment variable when Greenplum Database was started. If `PGUSER` is not set, the default is the system user that started Greenplum Database.

3. **test_user can use the dblink() function to execute a query using a dblink connection.** For example, this command uses the dblink connection named `testconn` created in the previous step. `test_user` must have appropriate access to the table.

```
SELECT * FROM dblink('testconn', 'SELECT * FROM testdblink') AS dbltab(id int, product text);
```
Using dblink with SSL-Encrypted Connections to Greenplum

When you use dblink to connect to Greenplum Database over an encrypted connection, you must specify the sslmode property in the connection string. Set sslmode to at least require to disallow unencrypted transfers. For example:

```sql
SELECT dblink_connect('greenplum_con_sales', 'dbname=sales host=gpmaster user=gpadmin sslmode=require');
```

Refer to SSL Client Authentication for information about configuring Greenplum Database to use SSL.

hstore Functions

The hstore module implements a data type for storing sets of (key,value) pairs within a single Greenplum Database data field. This can be useful in various scenarios, such as rows with many attributes that are rarely examined, or semi-structured data.

In the current implementation, neither the key nor the value string can exceed 65535 bytes in length; an error will be thrown if this limit is exceeded. These maximum lengths may change in future releases.

Installing hstore

Before you can use hstore data type and functions, run the installation script $GPHOME/share/postgresql/contrib/hstore.sql in each database where you want the ability to query other databases:

```
$ psql -d testdb -f $GPHOME/share/postgresql/contrib/hstore.sql
```

hstore External Representation

The text representation of an hstore value includes zero or more key => value items, separated by commas. For example:

```
k => v
foo => bar, baz => whatever
"1-a" => "anything at all"
```

The order of the items is not considered significant (and may not be reproduced on output). Whitespace between items or around the => sign is ignored. Use double quotes if a key or value includes whitespace, comma, = or >. To include a double quote or a backslash in a key or value, precede it with another backslash. (Keep in mind that depending on the setting of standard_conforming_strings, you may need to double backslashes in SQL literal strings.)

A value (but not a key) can be a SQL NULL. This is represented as

```
key => NULL
```

The NULL keyword is not case-sensitive. Again, use double quotes if you want the string null to be treated as an ordinary data value.

Currently, double quotes are always used to surround key and value strings on output, even when this is not strictly necessary.
# hstore Operators and Functions

## Table 96: hstore Operators

<table>
<thead>
<tr>
<th>Operator</th>
<th>Description</th>
<th>Example</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>hstore -&gt; text</td>
<td>get value for key (null if not present)</td>
<td>'a=&gt;x, b=&gt;y'::hstore -&gt; 'a'</td>
<td>x</td>
</tr>
<tr>
<td>text =&gt; text</td>
<td>make single-item hstore</td>
<td>'a' =&gt; 'b'</td>
<td>&quot;a&quot;=&quot;b&quot;</td>
</tr>
<tr>
<td>hstore</td>
<td></td>
<td>hstore</td>
<td>concatenation</td>
</tr>
<tr>
<td>hstore ? text</td>
<td>does hstore contain key?</td>
<td>'a=&gt;1':hstore ? 'a'</td>
<td>t</td>
</tr>
<tr>
<td>hstore @&gt; hstore</td>
<td>does left operand contain right?</td>
<td>'a=&gt;b, b=&gt;1, c=&gt;NULL':hstore @&gt; 'b=&gt;1'</td>
<td>t</td>
</tr>
<tr>
<td>hstore &lt;@ hstore</td>
<td>is left operand contained in right?</td>
<td>'a=&gt;c':hstore &lt;@ 'a=&gt;b, b=&gt;1, c=&gt;NULL'</td>
<td>f</td>
</tr>
</tbody>
</table>

**Note:** The `=>` operator is deprecated and may be removed in a future release. Use the `hstore(text, text)` function instead.

## Table 97: hstore Functions

<table>
<thead>
<tr>
<th>Function</th>
<th>Return Type</th>
<th>Description</th>
<th>Example</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>hstore(text, text)</td>
<td>hstore</td>
<td>make single-item hstore</td>
<td>hstore('a', 'b')</td>
<td>&quot;a&quot;=&quot;b&quot;</td>
</tr>
<tr>
<td>akeys(hstore)</td>
<td>text[]</td>
<td>get hstore's keys as array</td>
<td>akeys('a=&gt;1,b=&gt;2')</td>
<td>(a,b)</td>
</tr>
<tr>
<td>skeys(hstore)</td>
<td>setof text</td>
<td>get hstore's keys as set</td>
<td>skeys('a=&gt;1,b=&gt;2')</td>
<td>a</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td>b</td>
</tr>
<tr>
<td>avals(hstore)</td>
<td>text[]</td>
<td>get hstore's values as array</td>
<td>avals('a=&gt;1,b=&gt;2')</td>
<td>(1,2)</td>
</tr>
<tr>
<td>svals(hstore)</td>
<td>setof text</td>
<td>get hstore's values as set</td>
<td>svals('a=&gt;1,b=&gt;2')</td>
<td>1</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td>2</td>
</tr>
<tr>
<td>each(hstore)</td>
<td>setof (key text, value text)</td>
<td>get hstore's keys and values as set</td>
<td>select * from each('a=&gt;1,b=&gt;2')</td>
<td>key</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td>a</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td>b</td>
</tr>
<tr>
<td>exist(hstore, text)</td>
<td>boolean</td>
<td>does hstore contain key?</td>
<td>exist('a=&gt;1','a')</td>
<td>t</td>
</tr>
<tr>
<td>Function</td>
<td>Return Type</td>
<td>Description</td>
<td>Example</td>
<td>Result</td>
</tr>
<tr>
<td>------------------</td>
<td>-------------</td>
<td>----------------------------------</td>
<td>--------------------------</td>
<td>-----------</td>
</tr>
<tr>
<td>defined(hstore, text)</td>
<td>boolean</td>
<td>does hstore contain non-null value for key?</td>
<td>defined('a=&gt;NULL','a')</td>
<td>f</td>
</tr>
<tr>
<td>delete(hstore, text)</td>
<td>hstore</td>
<td>delete any item matching key</td>
<td>delete('a=&gt;1,b=&gt;2','b')</td>
<td>&quot;a'=&gt;&quot;1&quot;</td>
</tr>
</tbody>
</table>

**Indexes**

`hstore` has index support for `@>` and `?` operators. You can use the GiST index type. For example:

```sql
CREATE INDEX hidx ON testhstore USING GIST(h);
```

**Examples**

Add a key, or update an existing key with a new value:

```sql
UPDATE tab SET h = h || ('c' => '3');
```

Delete a key:

```sql
UPDATE tab SET h = delete(h, 'k1');
```

**Statistics**

The `hstore` type, because of its intrinsic liberality, could contain a lot of different keys. Checking for valid keys is the task of the application. Examples below demonstrate several techniques for checking keys and obtaining statistics.

Simple example:

```sql
SELECT * FROM each('aaa=>bq, b=>NULL, ""=>1');
```

Using a table:

```sql
SELECT (each(h)).key, (each(h)).value INTO stat FROM testhstore;
```

Online statistics:

```sql
SELECT key, count(*) FROM
  (SELECT (each(h)).key FROM testhstore) AS stat
GROUP BY key
ORDER BY count DESC, key;
```

<table>
<thead>
<tr>
<th>key</th>
<th>count</th>
</tr>
</thead>
<tbody>
<tr>
<td>line</td>
<td>883</td>
</tr>
<tr>
<td>query</td>
<td>207</td>
</tr>
<tr>
<td>pos</td>
<td>203</td>
</tr>
<tr>
<td>node</td>
<td>202</td>
</tr>
<tr>
<td>space</td>
<td>197</td>
</tr>
<tr>
<td>status</td>
<td>195</td>
</tr>
<tr>
<td>public</td>
<td>194</td>
</tr>
<tr>
<td>title</td>
<td>190</td>
</tr>
<tr>
<td>org</td>
<td>189</td>
</tr>
<tr>
<td>.................</td>
<td></td>
</tr>
</tbody>
</table>
**Oracle Compatibility Functions**

Describes the Oracle Compatibility SQL functions in Greenplum Database. These functions target PostgreSQL.

**Installing Oracle Compatibility Functions**

Before using any Oracle Compatibility Functions, run the installation script `$GPHOME/share/postgresql/contrib/orafunc.sql` once for each database. For example, to install the functions in database `testdb`, use the following command:

```
$ psql -d testdb -f $GPHOME/share/postgresql/contrib/orafunc.sql
```

To uninstall Oracle Compatibility Functions, run the `uninstall_orafunc.sql` script:

```
$GPHOME/share/postgresql/contrib/uninstall_orafunc.sql
```

The following functions are available by default and do not require running the Oracle Compatibility installer:

- `sinh`
- `tanh`
- `cosh`
- `decode`

**Note:** The Oracle Compatibility Functions reside in the `oracompat` schema. To access them, prefix the schema name (`oracompat`) or alter the database search path to include the schema name. For example:

```
ALTER DATABASE db_name SET search_path = $user, public, oracompat;
```

If you alter the database search path, you must restart the database.

**Oracle and Greenplum Implementation Differences**

There are some differences in the implementation of these compatibility functions in the Greenplum Database from the Oracle implementation. If you use validation scripts, the output may not be exactly the same as in Oracle. Some of the differences are as follows:

- Oracle performs a decimal round off, Greenplum Database does not:
  - 2.00 becomes 2 in Oracle.
  - 2.0.0 remains 2.00 in Greenplum Database.
- The provided Oracle Compatibility functions handle implicit type conversions differently. For example, using the `decode` function:

  ```
  decode(expression, value, return [,value, return]... [, default])
  ```

  Oracle automatically converts `expression` and each `value` to the datatype of the first `value` before comparing. Oracle automatically converts `return` to the same datatype as the first result.

  The Greenplum implementation restricts `return` and `default` to be of the same data type. The `expression` and `value` can be different types if the data type of `value` can be converted into the data type of the `expression`. This is done implicitly. Otherwise, `decode` fails with an `invalid input syntax` error. For example:

  ```
  SELECT decode('M',true,false);
  ```
CASE
------
f
(1 row)
SELECT decode(1,'M',true,false);
ERROR: Invalid input syntax for integer:
"M"
LINE 1: SELECT decode(1,'M',true,false);

- Numbers in bigint format are displayed in scientific notation in Oracle, but not in Greenplum Database:
  - 9223372036854775 displays as 9.2234E+15 in Oracle.
  - 9223372036854775 remains 9223372036854775 in Greenplum Database.
- The default date and timestamp format in Oracle is different than the default format in Greenplum Database. If the following code is executed:

```sql
CREATE TABLE TEST(date1 date, time1 timestamp, time2 timestamp with timezone);
INSERT INTO TEST VALUES ('2001-11-11','2001-12-13 01:51:15','2001-12-13 01:51:15 -08:00');
SELECT DECODE(date1, '2001-11-11', '2001-01-01') FROM TEST;
```

Greenplum Database returns the row, but Oracle does not return any rows.

Note: The correct syntax in Oracle to return the row is:

```sql
SELECT DECODE(to_char(date1, 'YYYY-MM-DD'), '2001-11-11', '2001-01-01') FROM TEST;
```

### Oracle Compatibility Functions Reference

The following are the Oracle Compatibility Functions.

<table>
<thead>
<tr>
<th>add_months</th>
<th>nanvl</th>
</tr>
</thead>
<tbody>
<tr>
<td>bitand</td>
<td>next_day</td>
</tr>
<tr>
<td>concat</td>
<td>next_day (2)</td>
</tr>
<tr>
<td>cosh</td>
<td>nls_sort</td>
</tr>
<tr>
<td>decode</td>
<td>nvl</td>
</tr>
<tr>
<td>dump</td>
<td>nvl2</td>
</tr>
<tr>
<td>instr</td>
<td>oracle_substr</td>

<tr>
<td>listagg (2)</td>
<td>sinh</td>
</tr>
<tr>
<td>lnv1</td>
<td>tanh</td>
</tr>
<tr>
<td>months_between</td>
<td>trunc</td>
</tr>
</tbody>
</table>

### add_months

Oracle-compliant function to add a given number of months to a given date.
Synopsis

`add_months(date_expression, months_to_add)`

Description

This Oracle-compatible function adds `months_to_add` to a `date_expression` and returns a `DATE`.

If the `date_expression` specifies the last day of the month, or if the resulting month has fewer days than the `date_expression`, then the returned value is the last day of the resulting month. Otherwise, the returned value has the same day of the month as the `date_expression`.

Parameters

date_expression

The starting date. This can be any expression that can be implicitly converted to `DATE`.

months_to_add

The number of months to add to the `date_expression`. This is an integer or any value that can be implicitly converted to an integer. This parameter can be positive or negative.

Example

```
SELECT name, phone, nextcalldate FROM clientdb
WHERE nextcalldate >= add_months(CURRENT_DATE, 6);
```

Returns `name`, `phone`, and `nextcalldate` for all records where `nextcalldate` is at least six months in the future.

Compatibility

This command is compatible with Oracle syntax and is provided for convenience.

bitand

Oracle-compliant function that computes a logical AND operation on the bits of two non-negative values.

Synopsis

`bitand(expr1, expr2)`

Description

This Oracle-compatible function returns an integer representing an AND operation on the bits of two non-negative values (`expr1` and `expr2`). 1 is returned when the values are the same. 0 is returned when the values are different. Only significant bits are compared. For example, an AND operation on the integers 5 (binary 101) and 1 (binary 001 or 1) compares only the rightmost bit, and results in a value of 1 (binary 1).

The types of `expr1` and `expr2` are `NUMBER`, and the result is of type `NUMBER`. If either argument is `NULL`, the result is `NULL`.

The arguments must be in the range $-2^{(n-1)} \ldots (2^{(n-1)}-1)$. If an argument is out of this range, the result is undefined.

Note:

- The current implementation of `BITAND` defines $n = 128$.
- PL/SQL supports an overload of `BITAND` for which the types of the inputs and of the result are all `BINARY_INTEGER` and for which $n = 32$. 

Parameters

expr1
A non-negative integer expression.

expr2
A non-negative integer expression.

Example

```
SELECT bitand(expr1, expr2)
FROM ClientDB;
```

Compatibility
This command is compatible with Oracle syntax and is provided for convenience.

concat
Oracle-compliant function to concatenate two strings together.

Synopsis

```
concat (string1, string2)
```

Description
This Oracle-compatible function concatenates two strings (string1 and string2) together.

The string returned is in the same character set as string1. Its datatype depends on the datatypes of the arguments.

In concatenations of two different datatypes, the datatype returned is the one that results in a lossless conversion. Therefore, if one of the arguments is a LOB, then the returned value is a LOB. If one of the arguments is a national datatype, then the returned value is a national datatype. For example:

```
concat(CLOB, NCLOB) returns NCLOB
concat(NCLOB, NCHAR) returns NCLOB
concat(NCLOB, CHAR) returns NCLOB
concat(NCHAR, CLOB) returns NCLOB
```

This function is equivalent to the concatenation operator (||).

Parameters

string1/string2
The two strings to concatenate together.

Both string1 and string2 can be any of the datatypes CHAR, VARCHAR2, NCHAR, NVARCHAR2, CLOB, or NCLOB.

Example

```
SELECT concat(concat(last_name, ''s job category is ''),
job_id)
FROM employees
```

Returns 'Smith's job category is 4B'
**Compatibility**
This command is compatible with Oracle syntax and is provided for convenience.

**cosh**
Oracle-compliant function to return the hyperbolic cosine of a given number.

**Synopsis**
\[
cosh(float8)
\]

**Description**
This Oracle-compatible function returns the hyperbolic cosine of the floating 8 input number (\(float8\)).

**Parameters**
- \(float8\)
  The input number.

**Example**

```sql
SELECT cosh(0.2)
FROM ClientDB;
```

Returns `'1.02006675561908'` (hyperbolic cosine of 0.2)

**Compatibility**
This command is compatible with Oracle syntax and is provided for convenience.

**decode**
Oracle-compliant function to transform a data value to a specified return value. This function is a way to implement a set of `CASE` statements.

**Note:** `decode` is converted into a reserved word in Greenplum Database. If you want to use the Postgres two-argument `decode` function that decodes binary strings previously encoded to ASCII-only representation, you must invoke it by using the full schema-qualified syntax, `pg_catalog.decode()`, or by enclosing the function name in quotes "decode" ()

**Note:** Greenplum's implementation of this function transforms `decode` into `case`.

This results in the following type of output:

```sql
gpctest=# select decode(a, 1, 'A', 2, 'B', 'C') from decodetest;
   case
  ------
     C
    A
    B
    C
(5 rows)
```
This also means that if you deparse your view with `decode`, you will see `case` expression instead.

You should use the `case` function instead of `decode`.

### Synopsis

```sql
decode(expression, value, return [,value, return]... 
[ , default])
```

### Description

The Oracle-compatible function `decode` searches for a value in an expression. If the value is found, the function returns the specified value.

**Note:** This function is available by default and can be accessed without running the Oracle Compatibility installer.

### Parameters

**expression**

The expression to search.

**value**

The value to find in the expression.

**return**

What to return if expression matches value.

**default**

What to return if expression does not match any of the values.

Only one `expression` is passed to the function. Multiple `value/return` pairs can be passed.

The `default` parameter is optional. If `default` is not specified and if `expression` does not match any of the passed `value` parameters, `decode` returns `null`. The Greenplum implementation restricts `return` and `default` to be of the same data type. The `expression` and `value` can be different types if the data type of `value` can be converted into the data type of the `expression`. This is done implicitly. Otherwise, `decode` fails with an `invalid input syntax` error.

### Examples

In the following code, `decode` searches for a value for `company_id` and returns a specified value for that company. If `company_id` not one of the listed values, the default value `Other` is returned.

```sql
SELECT decode(company_id, 1, 'EMC', 
              2, 'Greenplum', 
              'Other')
FROM suppliers;
```

The following code using `CASE` statements to produce the same result as the example using `decode`.

```sql
SELECT CASE company_id
      WHEN IS NOT DISTINCT FROM 1 THEN 'EMC'
      WHEN IS NOT DISTINCT FROM 2 THEN 'Greenplum'
      ELSE 'Other'
      END
FROM suppliers;
```
Notes

To assign a range of values to a single return value, either pass an expression for each value in the range, or pass an expression that evaluates identically for all values in the range. For example, if a fiscal year begins on August 1, the quarters are shown in the following table.

Table 98: Months and Quarters for Fiscal Year Beginning on August 1

<table>
<thead>
<tr>
<th>Range (Alpha)</th>
<th>Range (Numeric)</th>
<th>Quarter</th>
</tr>
</thead>
<tbody>
<tr>
<td>August — October</td>
<td>8 — 10</td>
<td>Q1</td>
</tr>
<tr>
<td>November — January</td>
<td>11 — 1</td>
<td>Q2</td>
</tr>
<tr>
<td>February — April</td>
<td>2 — 4</td>
<td>Q3</td>
</tr>
<tr>
<td>May — July</td>
<td>5 — 7</td>
<td>Q4</td>
</tr>
</tbody>
</table>

The table contains a numeric field `curr_month` that holds the numeric value of a month, 1 – 12. There are two ways to use `decode` to get the quarter:

- **Method 1 - Include 12 values in the `decode` function:**

  ```sql
  SELECT decode(curr_month, 1, 'Q2',
                2, 'Q3',
                3, 'Q3',
                4, 'Q3',
                5, 'Q4',
                6, 'Q4',
                7, 'Q4',
                8, 'Q1',
                9, 'Q1',
               10, 'Q1',
               11, 'Q2',
               12, 'Q2')
  FROM suppliers;
  ```

- **Method 2 - Use an expression that defines a unique value to decode:**

  ```sql
  SELECT decode((1+MOD(curr_month+4,12)/3)::int, 1, 'Q1',
                2, 'Q2',
                3, 'Q3',
                4, 'Q4',
  FROM suppliers;
  ```

Compatibility

This command is compatible with Oracle syntax and is provided for convenience.

See Also

PostgreSQL `decode` (not compatible with Oracle)

dump

Oracle-compliant function that returns a text value that includes the datatype code, the length in bytes, and the internal representation of the expression.
**Synopsis**

\[ \text{dump(expression [,integer])} \]

**Description**

This Oracle-compatible function returns a text value that includes the datatype code, the length in bytes, and the internal representation of the expression.

**Parameters**

- **expression**
  - Any expression
- **integer**
  - The number of characters to return

**Example**

- \( \text{dump('Tech')} \) returns 'Typ=96 Len=4: 84,101,99,104'
- \( \text{dump ('tech')} \) returns 'Typ-96 Len=4: 84,101,99,104'
- \( \text{dump('Tech', 10)} \) returns 'Typ=96 Len=4: 84,101,99,104'
- \( \text{dump('Tech', 16)} \) returns 'Typ=96 Len=4: 54,65,63,68'
- \( \text{dump('Tech', 1016)} \) returns 'Typ=96 Len=4 CharacterSet=US7ASCII: 54,65,63,68'
- \( \text{dump('Tech', 1017)} \) returns 'Typ=96 Len=4 CharacterSet=US7ASCII: T,e,c,h'

**Compatibility**

This command is compatible with Oracle syntax and is provided for convenience.

**instr**

Oracle-compliant function to return the location of a substring in a string.

**Synopsis**

\[ \text{instr(string, substring, [position[,occurrence]])} \]

**Description**

This Oracle-compatible function searches for a substring in a string. If found, it returns an integer indicating the position of the substring in the string, if not found, the function returns 0.

Optionally you can specify that the search starts at a given position in the string, and only return the nth occurrence of the substring in the string.

\( \text{instr} \) calculates strings using characters as defined by the input character set.

The value returned is of \text{NUMBER} datatype.

**Parameters**

- **string**
The string to search.

substring

The substring to search for in string.

Both string and substring can be any of the datatypes CHAR, VARCHAR2, NCHAR, NVARCHAR2, CLOB, or NCLOB.

position

The position is a nonzero integer in string where the search will start. If not specified, this defaults to 1. If this value is negative, the function counts backwards from the end of string then searches towards to beginning from the resulting position.

occurrence

Occurrence is an integer indicating which occurrence of the substring should be searched for. The value of occurrence must be positive.

Both position and occurrence must be of datatype NUMBER, or any datatype that can be implicitly converted to NUMBER, and must resolve to an integer. The default values of both position and occurrence are 1, meaning that the search begins at the first character of string for the first occurrence of substring. The return value is relative to the beginning of string, regardless of the value of position, and is expressed in characters.

Examples

SELECT instr('Greenplum', 'e')
FROM ClientDB;

Returns 3; the first occurrence of 'e'

SELECT instr('Greenplum', 'e',1,2)
FROM ClientDB;

Returns 4; the second occurrence of 'e'

Compatibility

This command is compatible with Oracle syntax and is provided for convenience.

last_day

Oracle-compliant function to return the last day in a given month.

Synopsis

last_day(date_expression)

Description

This Oracle-compatible function returns the last day of the month specified by a date_expression. The return type is always DATE, regardless of the datatype of date_expression.

Parameters

date_expression

The date value used to calculate the last day of the month. This can be any expression that can be implicitly converted to DATE.
Example

```
SELECT name, hiredate, last_day(hiredate) "Option Date"
FROM employees;
```

Returns the name, hiredate, and last_day of the month of hiredate labeled "Option Date."

Compatibility

This command is compatible with Oracle syntax and is provided for convenience.

listagg

Oracle-compliant function that aggregates text values into a string.

**Note:** This function is an overloaded function. There are two Oracle-compliant `listagg` functions, one that takes one argument, the text to be aggregated (see below), and one that takes two arguments, the text to be aggregated and a delimiter (see next page).

Synopsis

```
listagg(text)
```

Description

This Oracle-compatible function aggregates text values into a string.

Parameters

- `text`

  The text value to be aggregated into a string.

Example

```
SELECT listagg(t) FROM (VALUES('abc'), ('def')) as l(t)
```

Returns: abcdef

Compatibility

This command is compatible with Oracle syntax and is provided for convenience.

listagg (2)

Oracle-compliant function that aggregates text values into a string, separating each by the separator specified in a second argument.

**Note:** This function is an overloaded function. There are two Oracle-compliant `listagg` functions, one that takes one argument, the text to be aggregated (see previous page), and one that takes two arguments, the text to be aggregated and a delimiter (see below).

Synopsis

```
listagg(text, separator)
```
Description
This Oracle-compatible function aggregates text values into a string, separating each by the separator specified in a second argument (separator).

Parameters
- text
  The text value to be aggregated into a string.
- separator
  The separator by which to delimit the text values.

Example
```
SELECT oracompat.listagg(t, '.') FROM (VALUES('abc'), ('def')) as l(t)
```

Returns: abc.def

Compatibility
This command is compatible with Oracle syntax and is provided for convenience.

Innvl
Oracle-compliant function that returns true if the argument is false or NULL, or false.

Synopsis
```
innvl(condition)
```

Description
This Oracle-compatible function takes as an argument a condition and returns true if the condition is false or NULL and false if the condition is true.

Parameters
- condition
  Any condition that evaluates to true, false, or NULL.

Example
```
SELECT innvl(true)
```

Returns: false

```
SELECT innvl(NULL)
```

Returns: true

```
SELECT innvl(false)
```

Returns: true

```
SELECT (3=5)
```

Returns: false
Returns: true

Compatibility
This command is compatible with Oracle syntax and is provided for convenience.

months_between
Oracle-compliant function to evaluate the number of months between two given dates.

Synopsis

```sql
months_between(date_expression1, date_expression2)
```

Description
This Oracle-compatible function returns the number of months between `date_expression1` and `date_expression2`.

- If `date_expression1` is later than `date_expression2`, then the result is positive.
- If `date_expression1` is earlier than `date_expression2`, then the result is negative.
- If `date_expression1` and `date_expression2` are either the same days of the month or both last days of months, then the result is always an integer. Otherwise the function calculates the fractional portion of the month based on a 31-day month.

Parameters
- `date_expression1`, `date_expression2`
  - The date values used to calculate the number of months. This can be any expression that can be implicitly converted to `DATE`.

Examples

```sql
SELECT months_between(
    to_date ('2003/07/01', 'yyyy/mm/dd'),
    to_date ('2003/03/14', 'yyyy/mm/dd')
);
```

Returns the number of months between July 1, 2003 and March 14, 2014.

```sql
SELECT * FROM employees
where months_between(hire_date, leave_date) <12;
```

Returns the number of months between `hire_date` and `leave_date`.

Compatibility
This command is compatible with Oracle syntax and is provided for convenience.

nanvl
Oracle-compliant function to substitute a value for a floating point number when a non-number value is encountered.

Synopsis

```sql
nanvl(float1, float2)
```
Description
This Oracle-compatible function evaluates a floating point number (float1) such as BINARY_FLOAT or BINARY_DOUBLE. If it is a non-number ('not a number', NaN), the function returns float2. This function is most commonly used to convert non-number values into either NULL or 0.

Parameters
float1
The BINARY_FLOAT or BINARY_NUMBER to evaluate.

float2
The value to return if float1 is not a number.

float1 and float2 can be any numeric datatype or any nonnumeric datatype that can be implicitly converted to a numeric datatype. The function determines the argument with the highest numeric precedence, implicitly converts the remaining arguments to that datatype, and returns that datatype.

Example
```
SELECT nanvl(binary1, 0)
FROM MyDB;
```

Returns 0 if the binary1 field contained a non-number value. Otherwise, it would return the binary1 value.

Compatibility
This command is compatible with Oracle syntax and is provided for convenience.

next_day
Oracle-compliant function to return the date of the next specified weekday after a date.

This section describes using this function with a string argument; see the following page for details about using this function with an integer argument.

Note: This function is an overloaded function. There are two Oracle-compliant next_day functions, one that takes a date and a day of the week as its arguments (see below), and one that takes a date and an integer as its arguments (see next page).

Synopsis
```
next_day(date_expression, day_of_the_week)
```

Description
This Oracle-compatible function returns the first day_of_the_week (Tuesday, Wednesday, etc.) to occur after a date_expression.

The weekday must be specified in English.

The case of the weekday is irrelevant.

The return type is always DATE, regardless of the datatype of date_expression.

Parameters
date_expression
The starting date. This can be any expression that can be implicitly converted to DATE.
**day_of_the_week**

A string containing the name of a day, in English; for example 'Tuesday'. *day_of_the_week* is case-insensitive.

**Example**

```sql
SELECT name, next_day(hiredate,"MONDAY") "Second Week Start"
FROM employees;
```

Returns the name and the date of the next Monday after *hiredate* labeled "Second Week Start".

**Compatibility**

This command is compatible with Oracle syntax and is provided for convenience.

**next_day** (2)

Oracle-compliant function to add a given number of days to a date and returns the date of the following day.

*Note:* This function is an overloaded function. There are two Oracle *next_day* functions, one that takes a date and a day of the week as its arguments (see previous page), and one that takes a date and an integer as its arguments (see below).

**Synopsis**

```sql
next_day(date_expression, days_to_add)
```

**Description**

This Oracle-compatible function adds the number of *days_to_add* to a *date_expression* and returns the date of the following day after the result.

The return type is always *DATE*, regardless of the datatype of *date_expression*.

**Parameters**

- **date_expression**
  The starting date. This can be any expression that can be implicitly converted to *DATE*.

- **days_to_add**
  The number of days to be added to the *date_expression*. This is an integer or any value that can be implicitly converted to an integer. This parameter can be positive or negative.

**Example**

```sql
SELECT name, next_day(hiredate,90) "Benefits Eligibility Date"
FROM EMPLOYEES;
```

Returns the name and the date that is 90 days after *hiredate* labeled "Benefits Eligibility Date".

**Compatibility**

This command is compatible with Oracle syntax and is provided for convenience.
nlssort
Oracle-compliant function that sorts data according to a specific collation.

Synopsis
nlssort (variable, collation)

Description
This Oracle-compatible function sorts data according to a specific collation.

Parameters
variable
The data to sort.
collation
The collation type by which to sort.

Example
CREATE TABLE test (name text);
INSERT INTO test VALUES('Anne'), ('anne'), ('Bob'), ('bob');
SELECT * FROM test ORDER BY nlssort(name, 'en_US.UTF-8');
  anne
  Anne
  bob
  Bob

SELECT * FROM test ORDER BY nlssort(name, 'C');
  Anne
  Bob
  anne
  bob

In the first example, the UTF-8 collation rules are specified. This groups characters together regardless of case.
In the second example, ASCII (C) collation is specified. This sorts according to ASCII order. The result is that upper case characters are sorted ahead of lower case ones.

Compatibility
This command is compatible with Oracle syntax and is provided for convenience.

nvl
Oracle-compliant function to substitute a specified value when an expression evaluates to null.

Note: This function is analogous to the PostgreSQL coalesce function.

Synopsis
nvl(expression_to_evaluate, null_replacement_value)
Description
This Oracle-compatible function evaluates `expression_to_evaluate`. If it is `null`, the function returns `null_replacement_value`; otherwise, it returns `expression_to_evaluate`.

Parameters
- `expression_to_evaluate`
  The expression to evaluate for a null value.
- `null_replacement_value`
  The value to return if `expression_to_evaluate` is `null`.
Both `expression_to_evaluate` and `null_replacement_value` must be the same data type.

Examples
```
SELECT nvl(contact_name,'None')
FROM clients;
SELECT nvl(amount_past_due,0)
FROM txns;
SELECT nvl(nickname,firstname)
FROM contacts;
```

Compatibility
This command is compatible with Oracle syntax and is provided for convenience.

`nvl2`
Oracle-compliant function that returns alternate values for both null and non-null values.

Synopsis
```
nvl2(expression_to_evaluate, non_null_replacement_value, null_replacement_value)
```

Description
This Oracle-compatible function evaluates `expression_to_evaluate`. If it is not `null`, the function returns `non_null_replacement_value`; otherwise, it returns `null_replacement_value`.

Parameters
- `expression_to_evaluate`
  The expression to evaluate for a null value.
- `non_null_replacement_value`
  The value to return if `expression_to_evaluate` is not `null`.
- `null_replacement_value`
  The value to return if `expression_to_evaluate` is `null`.

Example
```
select nvl2(unit_number,'Multi Unit','Single Unit')
from clients;
```
Compatibility
This command is compatible with Oracle syntax and is provided for convenience.

See Also
decode

oracle.substr
This Oracle-compliant function extracts a portion of a string.

Synopsis

```
oracle.substr(string, [start [,char_count]])
```

Description
This Oracle-compatible function extract a portion of a string.
If `start` is 0, it is evaluated as 1.
If `start` is negative, the starting position is negative, the starting position is `start` characters moving backwards from the end of string.
If `char_count` is not passed to the function, all characters from start to the end of string are returned.
If `char_count` is less than 1, null is returned.
If `start` or `char_count` is a number, but not an integer, the values are resolved to integers.

Parameters

- `string`
  The string from which to extract.
- `start`
  An integer specifying the starting position in the string.
- `char_count`
  An integer specifying the number of characters to extract.

Example

```
oracle.substr(name,1,15)
```

Returns the first 15 characters of `name`.

```
oracle.substr("Greenplum",-4,4)
```

Returns "plum".

```
oracle.substr(name,2)
```

Returns all characters of `name`, beginning with the second character.

Compatibility
PostgreSQL `substr` (not compatible with Oracle)
reverse
Oracle-compliant function to return the input string in reverse order.

**Synopsis**

```plaintext
reverse (string)
```

**Description**
This Oracle-compatible function returns the input string (string) in reverse order.

**Parameters**

- `string`
  The input string.

**Example**

```sql
SELECT reverse('gnirts')
FROM ClientDB;
```

Returns 'string'

**Compatibility**
This command is compatible with Oracle syntax and is provided for convenience.

round
Oracle-compliant function to round a date to a specific unit of measure (day, week, etc.).

*Note:* This function is an overloaded function. It shares the same name with the Postgres `round` mathematical function that rounds numeric input to the nearest integer or optionally to the nearest x number of decimal places.

**Synopsis**

```plaintext
round (date_time_expression, [unit_of_measure])
```

**Description**
This Oracle-compatible function rounds a `date_time_expression` to the nearest `unit_of_measure` (day, week, etc.). If a `unit_of_measure` is not specified, the `date_time_expression` is rounded to the nearest day. It operates according to the rules of the Gregorian calendar.

If the `date_time_expression` datatype is `TIMESTAMP`, the value returned is always of datatype `TIMESTAMP`.

If the `date_time_expression` datatype is `DATE`, the value returned is always of datatype `DATE`.

**Parameters**

- `date_time_expression`
  The date to round. This can be any expression that can be implicitly converted to `DATE` or `TIMESTAMP`.

- `unit_of_measure`
  The unit of measure.
The unit of measure to apply for rounding. If not specified, then the `date_time_expression` is rounded to the nearest day. Valid parameters are:

Table 99: Valid Parameters

<table>
<thead>
<tr>
<th>Unit</th>
<th>Valid parameters</th>
<th>Rounding Rule</th>
</tr>
</thead>
<tbody>
<tr>
<td>Year</td>
<td>SYYYY, YYYY, YEAR, SYEAR, YYY, YY, Y</td>
<td>Rounds up on July 1st</td>
</tr>
<tr>
<td>ISO Year</td>
<td>IYYY, IY, I</td>
<td>Rounds up on the 16th day of the second month of the quarter</td>
</tr>
<tr>
<td>Quarter</td>
<td>Q</td>
<td>Rounds up on the 16th day of the second month of the quarter</td>
</tr>
<tr>
<td>Month</td>
<td>MONTH, MON, MM, RM</td>
<td>Rounds up on the 16th day of the month</td>
</tr>
<tr>
<td>Week</td>
<td>WW</td>
<td>Same day of the week as the first day of the year</td>
</tr>
<tr>
<td>IW</td>
<td>IW</td>
<td>Same day of the week as the first day of the ISO year</td>
</tr>
<tr>
<td>W</td>
<td>W</td>
<td>Same day of the week as the first day of the month</td>
</tr>
<tr>
<td>Day</td>
<td>DDD, DD, J</td>
<td>Rounds to the nearest day</td>
</tr>
<tr>
<td>Start day of the week</td>
<td>DAY, DY, D</td>
<td>Rounds to the nearest start (sunday) day of the week</td>
</tr>
<tr>
<td>Hour</td>
<td>HH, HH12, HH24</td>
<td>Rounds to the next hour</td>
</tr>
<tr>
<td>Minute</td>
<td>MI</td>
<td>Rounds to the next minute</td>
</tr>
</tbody>
</table>

Example

```sql
SELECT round(TO_DATE('27-OCT-00','DD-MON-YY'), 'YEAR')
FROM ClientDB;
```

Returns '01-JAN-01' (27 Oct 00 rounded to the first day of the following year (YEAR))

```sql
SELECT round('startdate','Q')
FROM ClientDB;
```

Returns '01-JUL-92' (the `startdate` rounded to the first day of the quarter (Q))

Compatibility

This command is compatible with Oracle syntax and is provided for convenience.

See Also

PostgreSQL `round` (not compatible with Oracle)

**sinh**

Oracle-compliant function to return the hyperbolic sine of a given number.
**Synopsis**

\[
\text{sinh}(\text{float8})
\]

**Description**

This Oracle-compatible function returns the hyperbolic sine of the floating 8 input number \( \text{float8} \).

*Note:* This function is available by default and can be accessed without running the Oracle Compatibility installer.

**Parameters**

\[ \text{float8} \]

The input number.

**Example**

```
SELECT sinh(3)
FROM ClientDB;
```

Returns '10.0178749274099'' (hyperbolic sine of 3)

**Compatibility**

This command is compatible with Oracle syntax and is provided for convenience.

**tanh**

Oracle-compliant function to return the hyperbolic tangent of a given number.

**Synopsis**

\[
\text{tanh}(\text{float8})
\]

**Description**

This Oracle-compatible function returns the hyperbolic tangent of the floating 8 input number \( \text{float8} \).

*Note:* This function is available by default and can be accessed without running the Oracle Compatibility installer.

**Parameters**

\[ \text{float8} \]

The input number.

**Example**

```
SELECT tanh(3)
FROM ClientDB;
```

Returns '0.99505475368673'' (hyperbolic tangent of 3)

**Compatibility**

This command is compatible with Oracle syntax and is provided for convenience.
**trunc**

Oracle-compliant function to truncate a date to a specific unit of measure (day, week, hour, etc.).

**Note:**
This function is an overloaded function. It shares the same name with the Postgres `trunc` and the Oracle `trunc` mathematical functions. Both of these truncate numeric input to the nearest integer or optionally to the nearest x number of decimal places.

**Synopsis**

```sql
trunc(date_time_expression, [unit_of_measure])
```

**Description**

This Oracle-compatible function truncates a `date_time_expression` to the nearest `unit_of_measure` (day, week, etc.). If a `unit_of_measure` is not specified, the `date_time_expression` is truncated to the nearest day. It operates according to the rules of the Gregorian calendar.

If the `date_time_expression` datatype is `TIMESTAMP`, the value returned is always of datatype `TIMESTAMP`, truncated to the hour/min level.

If the `date_time_expression` datatype is `DATE`, the value returned is always of datatype `DATE`.

**Parameters**

- **date_time_expression**
  The date to truncate. This can be any expression that can be implicitly converted to `DATE` or `TIMESTAMP`.

- **unit_of_measure**
  The unit of measure to apply for truncating. If not specified, then `date_time_expression` is truncated to the nearest day. Valid formats are:

**Table 100: Valid Format Parameters**

<table>
<thead>
<tr>
<th>Unit</th>
<th>Valid parameters</th>
</tr>
</thead>
<tbody>
<tr>
<td>Year</td>
<td>SYYYY, YYYY, YEAR, SYEAR, YYY, YY, Y</td>
</tr>
<tr>
<td>ISO Year</td>
<td>IYYY, IY, I</td>
</tr>
<tr>
<td>Quarter</td>
<td>Q</td>
</tr>
<tr>
<td>Month</td>
<td>MONTH, MON, MM, RM</td>
</tr>
<tr>
<td>Week</td>
<td>WW</td>
</tr>
<tr>
<td>IW</td>
<td>IW</td>
</tr>
<tr>
<td>W</td>
<td>W</td>
</tr>
<tr>
<td>Day</td>
<td>DDD, DD, J</td>
</tr>
<tr>
<td>Start day of the week</td>
<td>DAY, DY, D</td>
</tr>
<tr>
<td>Hour</td>
<td>HH, HH12, HH24</td>
</tr>
<tr>
<td>Minute</td>
<td>MI</td>
</tr>
</tbody>
</table>
**Examples**

```sql
SELECT TRUNC(TO_DATE('27-OCT-92','DD-MON-YY'), 'YEAR')
FROM ClientDB;
```

Returns '01-JAN-92' (27 Oct 92 truncated to the first day of the year (YEAR))

```sql
SELECT TRUNC(startdate,'Q')
FROM ClientDB;
```

Returns '1992-07-01' (the startdate truncated to the first day of the quarter (Q), depending on the date_style setting)

**Compatibility**

This command is compatible with Oracle syntax and is provided for convenience.

**See Also**

PostgreSQL `trunc` (not compatible with Oracle)

Greenplum Database Reference Guide

Reference information for Greenplum Database systems including SQL commands, system catalogs, environment variables, server configuration parameters, character set support, datatypes, and Greenplum Database extensions.
SQL Command Reference

The following SQL commands are available in Greenplum Database:

- ABORT
- ALTER AGGREGATE
- ALTER CONVERSION
- ALTER DATABASE
- ALTER DOMAIN
- ALTER EXTERNAL TABLE
- ALTER FILESPACE
- ALTER FOREIGN DATA WRAPPER
- ALTER FOREIGN TABLE
- ALTER FUNCTION
- ALTER GROUP
- ALTER INDEX
- ALTER LANGUAGE
- ALTER OPERATOR
- ALTER OPERATOR CLASS
- ALTER OPERATOR FAMILY
- ALTER PROTOCOL
- ALTER RESOURCE GROUP
- ALTER RESOURCE QUEUE
- ALTER ROLE
- ALTER SCHEMA
- ALTER SEQUENCE
- ALTER SERVER
- ALTER TABLE
- ALTER TABLESPACE
- ALTER TYPE
- ALTER USER
- ALTER USER MAPPING
- ALTER VIEW
- ANALYZE
- BEGIN
- CHECKPOINT
- CLOSE
- CLUSTER
- COMMENT
- COMMIT
- COPY
- CREATE AGGREGATE
- CREATE CAST
- CREATE CONVERSION
- CREATE DATABASE
- CREATE DOMAIN
- CREATE EXTERNAL TABLE
- CREATE FOREIGN DATA WRAPPER
- CREATE FOREIGN TABLE
• CREATE FUNCTION

SQL Syntax Summary

**ABORT**

Aborts the current transaction.

```
ABORT [WORK | TRANSACTION]
```

See `ABORT` for more information.
### ALTER AGGREGATE
Changes the definition of an aggregate function

```
ALTER AGGREGATE name ( type [ , ... ] ) RENAME TO new_name
ALTER AGGREGATE name ( type [ , ... ] ) OWNER TO new_owner
ALTER AGGREGATE name ( type [ , ... ] ) SET SCHEMA new_schema
```

See [ALTER AGGREGATE](#) for more information.

### ALTER CONVERSION
Changes the definition of a conversion.

```
ALTER CONVERSION name RENAME TO newname
ALTER CONVERSION name OWNER TO newowner
```

See [ALTER CONVERSION](#) for more information.

### ALTER DATABASE
Changes the attributes of a database.

```
ALTER DATABASE name [ WITH CONNECTION LIMIT connlimit ]
ALTER DATABASE name SET parameter { TO | = } { value | DEFAULT }
ALTER DATABASE name RESET parameter
ALTER DATABASE name RENAME TO newname
ALTER DATABASE name OWNER TO new_owner
```

See [ALTER DATABASE](#) for more information.

### ALTER DOMAIN
Changes the definition of a domain.

```
ALTER DOMAIN name { SET DEFAULT expression | DROP DEFAULT }
ALTER DOMAIN name SET | DROP NOT NULL
ALTER DOMAIN name ADD domain_constraint
ALTER DOMAIN name DROP CONSTRAINT constraint_name [RESTRICT | CASCADE]
ALTER DOMAIN name OWNER TO new_owner
ALTER DOMAIN name SET SCHEMA new_schema
```

See [ALTER DOMAIN](#) for more information.

### ALTER EXTENSION
Change the definition of an extension that is registered in a Greenplum database.

```
ALTER EXTENSION name UPDATE [ TO new_version ]
```
ALTER EXTENSION name SET SCHEMA new_schema
ALTER EXTENSION name ADD member_object
ALTER EXTENSION name DROP member_object

where member_object is:

ACCESS METHOD object_name | 
AGGREGATE aggregate_name (aggregate_signature) | 
CAST (source_type AS target_type) | 
COLLATION object_name | 
CONVERSION object_name | 
DOMAIN object_name | 
EVENT TRIGGER object_name | 
FOREIGN DATA WRAPPER object_name | 
FOREIGN TABLE object_name | 
FUNCTION function_name ( [ [ argmode ] [ argname ] argtype [, ...] ] ) | 
MATERIALIZED VIEW object_name | 
OPERATOR operator_name (left_type, right_type) | 
OPERATOR CLASS object_name USING index_method | 
OPERATOR FAMILY object_name USING index_method | 
[ PROCEDURAL ] LANGUAGE object_name | 
SCHEMA object_name | 
SEQUENCE object_name | 
SERVER object_name | 
TABLE object_name | 
TEXT SEARCH CONFIGURATION object_name | 
TEXT SEARCH DICTIONARY object_name | 
TEXT SEARCH PARSER object_name | 
TEXT SEARCH TEMPLATE object_name | 
TRANSFORM FOR type_name LANGUAGE lang_name | 
TYPE object_name | 
VIEW object_name

and aggregate_signature is:

* | [ argmode ] [ argname ] argtype [, ... ] | 
[ [ argmode ] [ argname ] argtype [, ... ] ] | 
ORDER BY [ argmode ] [ argname ] argtype [, ... ]

See ALTER EXTENSION for more information.

**ALTER EXTERNAL TABLE**

Changes the definition of an external table.

ALTER EXTERNAL TABLE name action [, ... ]

where action is one of:

ADD [COLUMN] new_column type 
DROP [COLUMN] column [RESTRICT|CASCADE] 
ALTER [COLUMN] column TYPE type [USING expression] 
OWNER TO new_owner

See ALTER EXTERNAL TABLE for more information.

**ALTER FILESPACE**

Changes the definition of a filespace.

ALTER FILESPACE name RENAME TO newname
ALTER FILESPACE name OWNER TO newowner

See ALTER FILESPACE for more information.

**ALTER FUNCTION**

Changes the definition of a function.

```
ALTER FUNCTION name ( [ [argmode] [argname] argtype [, ...] ] )
    action [, ... ] [RESTRICT]
```

```
ALTER FUNCTION name ( [ [argmode] [argname] argtype [, ...] ] )
    RENAME TO new_name
```

```
ALTER FUNCTION name ( [ [argmode] [argname] argtype [, ...] ] )
    OWNER TO new_owner
```

```
ALTER FUNCTION name ( [ [argmode] [argname] argtype [, ...] ] )
    SET SCHEMA new_schema
```

See ALTER FUNCTION for more information.

**ALTER GROUP**

Changes a role name or membership.

```
ALTER GROUP groupname ADD USER username [, ... ]
```

```
ALTER GROUP groupname DROP USER username [, ... ]
```

```
ALTER GROUP groupname RENAME TO newname
```

See ALTER GROUP for more information.

**ALTER INDEX**

Changes the definition of an index.

```
ALTER INDEX name RENAME TO new_name
```

```
ALTER INDEX name SET TABLESPACE tablespace_name
```

```
ALTER INDEX name SET ( FILLFACTOR = value )
```

```
ALTER INDEX name RESET ( FILLFACTOR )
```

See ALTER INDEX for more information.

**ALTER LANGUAGE**

Changes the name of a procedural language.

```
ALTER LANGUAGE name RENAME TO newname
```

```
ALTER LANGUAGE name OWNER TO new_owner
```

See ALTER LANGUAGE for more information.
**ALTER OPERATOR**
Changes the definition of an operator.

```sql
ALTER OPERATOR name ( {lefttype | NONE} , {righttype | NONE} )
OWNER TO newowner
```

See `ALTER OPERATOR` for more information.

**ALTER OPERATOR CLASS**
Changes the definition of an operator class.

```sql
ALTER OPERATOR CLASS name USING index_method RENAME TO newname

ALTER OPERATOR CLASS name USING index_method OWNER TO newowner
```

See `ALTER OPERATOR CLASS` for more information.

**ALTER OPERATOR FAMILY**
Changes the definition of an operator family.

```sql
ALTER OPERATOR FAMILY name USING index_method ADD
 { OPERATOR strategy_number operator_name ( op_type, op_type ) [ RECHECK ]
 | FUNCTION support_number [ ( op_type [, op_type ] ) ] funcname
 ( argument_type [, ...] )
 } [, ... ]

ALTER OPERATOR FAMILY name USING index_method DROP
 { OPERATOR strategy_number ( op_type, op_type )
 | FUNCTION support_number [ ( op_type [, op_type ] )
 } [, ... ]

ALTER OPERATOR FAMILY name USING index_method RENAME TO newname

ALTER OPERATOR FAMILY name USING index_method OWNER TO newowner
```

See `ALTER OPERATOR FAMILY` for more information.

**ALTER PROTOCOL**
Changes the definition of a protocol.

```sql
ALTER PROTOCOL name RENAME TO newname

ALTER PROTOCOL name OWNER TO newowner
```

See `ALTER PROTOCOL` for more information.

**ALTER RESOURCE GROUP**
Changes the limits of a resource group.

```sql
ALTER RESOURCE GROUP name SET group_attribute value
```

See `ALTER RESOURCE GROUP` for more information.
**ALTER RESOURCE QUEUE**
Changes the limits of a resource queue.

```
ALTER RESOURCE QUEUE name WITH ( queue_attribute=value [, ... ] )
```

See **ALTER RESOURCE QUEUE** for more information.

**ALTER ROLE**
Changes a database role (user or group).

```
ALTER ROLE name RENAME TO newname
ALTER ROLE name SET config_parameter {TO | =} {value | DEFAULT}
ALTER ROLE name RESET config_parameter
ALTER ROLE name RESOURCE QUEUE {queue_name | NONE}
ALTER ROLE name RESOURCE GROUP {group_name | NONE}
ALTER ROLE name [ [WITH] option [ ... ] ]
```

See **ALTER ROLE** for more information.

**ALTER SCHEMA**
Changes the definition of a schema.

```
ALTER SCHEMA name RENAME TO newname
ALTER SCHEMA name OWNER TO newowner
```

See **ALTER SCHEMA** for more information.

**ALTER SEQUENCE**
Changes the definition of a sequence generator.

```
ALTER SEQUENCE name [INCREMENT [ BY ] increment]
[MINVALUE minvalue | NO MINVALUE]
[MAXVALUE maxvalue | NO MAXVALUE]
[RESTART [ WITH ] start]
[CACHE cache] [[ NO ] CYCLE]
[OWNED BY \{table.column \| NONE\}]
ALTER SEQUENCE name RENAME TO new_name
ALTER SEQUENCE name SET SCHEMA new_schema
```

See **ALTER SEQUENCE** for more information.

**ALTER TABLE**
Changes the definition of a table.

```
ALTER TABLE [ONLY] name RENAME [COLUMN] column TO new_column
ALTER TABLE name RENAME TO new_name
```
ALTER TABLE name SET SCHEMA new_schema

ALTER TABLE [ONLY] name SET
DISTRIBUTED BY (column, [ ... ] )
DISTRIBUTED RANDOMLY
WITH (REORGANIZE=true|false)

ALTER TABLE [ONLY] name action [, ... ]

ALTER TABLE name
  [ ALTER PARTITION { partition_name | FOR (RANK(number))
  | FOR (value) ) [...] ] partition_action

where action is one of:

  ADD [COLUMN] column_name data_type [ DEFAULT default_expr ]
  [ column_constraint [ ... ] ]
  [ ENCODING ( storage_directive [ , ... ] ) ]
  DROP [COLUMN] column [RESTRICT | CASCADE]
  ALTER [COLUMN] column TYPE type [USING expression]
  ALTER [COLUMN] column SET DEFAULT expression
  ALTER [COLUMN] column DROP DEFAULT
  ALTER [COLUMN] column { SET | DROP } NOT NULL
  ALTER [COLUMN] column SET STATISTICS integer
  ADD table_constraint
  DROP CONSTRAINT constraint_name [RESTRICT | CASCADE]
  DISABLE TRIGGER [trigger_name | ALL | USER]
  ENABLE TRIGGER [trigger_name | ALL | USER]
  CLUSTER ON index_name
  SET WITHOUT CLUSTER
  SET WITHOUT OIDS
  SET (FILLFACTOR = value)
  RESET (FILLFACTOR)
  INHERIT parent_table
  NO INHERIT parent_table
  OWNER TO new_owner
  SET TABLESPACE new_tablespace

See ALTER TABLE for more information.

**ALTER TABLESPACE**

Changes the definition of a tablespace.

ALTER TABLESPACE name RENAME TO newname
ALTER TABLESPACE name OWNER TO newowner

See ALTER TABLESPACE for more information.

**ALTER TYPE**

Changes the definition of a data type.

ALTER TYPE name
  OWNER TO new_owner | SET SCHEMA new_schema

See ALTER TYPE for more information.
ALTER USER
Changes the definition of a database role (user).

ALTER USER name RENAME TO newname
ALTER USER name SET config_parameter {TO | =} {value | DEFAULT}
ALTER USER name RESET config_parameter
ALTER USER name RESOURCE QUEUE {queue_name | NONE}
ALTER USER name RESOURCE GROUP {group_name | NONE}
ALTER USER name [ [WITH] option [ ... ] ]

See ALTER USER for more information.

ALTER VIEW
Changes the definition of a view.

ALTER VIEW name RENAME TO newname

See ALTER VIEW for more information.

ANALYZE
Collects statistics about a database.

ANALYZE [VERBOSE] [table [ (column [, ...] ) ]]
ANALYZE [VERBOSE] {root_partition|leaf_partition} [ (column [, ...] )]
ANALYZE [VERBOSE] ROOTPARTITION {ALL | root_partition [ (column [, ...] )]}

See ANALYZE for more information.

BEGIN
Starts a transaction block.

BEGIN [WORK | TRANSACTION] [transaction_mode]
[READ ONLY | READ WRITE]

See BEGIN for more information.

CHECKPOINT
Forces a transaction log checkpoint.

CHECKPOINT

See CHECKPOINT for more information.

CLOSE
Closes a cursor.

CLOSE cursor_name
See \texttt{CLOSE} for more information.

**CLUSTER**

Physically reorders a heap storage table on disk according to an index. Not a recommended operation in Greenplum Database.

\begin{verbatim}
CLUSTER indexname ON tablename
CLUSTER tablename
CLUSTER
\end{verbatim}

See \texttt{CLUSTER} for more information.

**COMMENT**

Defines or change the comment of an object.

\begin{verbatim}
COMMENT ON
{ TABLE object_name |
  COLUMN table_name.column_name |
  AGGREGATE agg_name (agg_type [, ...]) |
  CAST (sourcetype AS targettype) |
  CONSTRAINT constraint_name ON table_name |
  CONVERSION object_name |
  DATABASE object_name |
  DOMAIN object_name |
  FILESPACE object_name |
  FUNCTION func_name (\[[argmode] [argname] argtype [, ...])\]) |
  INDEX object_name |
  LARGE OBJECT large_object_oid |
  OPERATOR op (leftoperand_type, rightoperand_type) |
  OPERATOR CLASS object_name USING index_method |
  [PROCEDURAL] LANGUAGE object_name |
  RESOURCE QUEUE object_name |
  ROLE object_name |
  RULE rule_name ON table_name |
  SCHEMA object_name |
  SEQUENCE object_name |
  TABLESPACE object_name |
  TRIGGER trigger_name ON table_name |
  TYPE object_name |
  VIEW object_name }
IS 'text'
\end{verbatim}

See \texttt{COMMENT} for more information.

**COMMIT**

Commits the current transaction.

\begin{verbatim}
COMMIT [WORK | TRANSACTION]
\end{verbatim}

See \texttt{COMMIT} for more information.

**COPY**

Copies data between a file and a table.

\begin{verbatim}
COPY table [(column [, ...])] FROM ('file' | PROGRAM 'command' | STDIN)
\end{verbatim}
[ [WITH]
[ON SEGMENT]
[BINARY]
[OIDS]
[HEADER]
[DELIMITER [ AS ] 'delimiter']
[NULL [ AS ] 'null string']
[ESCAPE [ AS ] 'escape' | 'OFF']
[NEWLINE [ AS ] 'LF' | 'CR' | 'CRLF']
[CSV [QUOTE [ AS ] 'quote']
  [FORCE QUOTE column [, ...]]
[FILL MISSING FIELDS]
[[LOG ERRORS]
SEGMENT REJECT LIMIT count [ROWS | PERCENT] ]

COPY {table [(column [, ...])] | (query)) TO {'file' | PROGRAM 'command' | STDOUT}
  [ [WITH]
    [ON SEGMENT]
    [BINARY]
    [OIDS]
    [HEADER]
    [DELIMITER [ AS ] 'delimiter']
    [NULL [ AS ] 'null string']
    [ESCAPE [ AS ] 'escape' | 'OFF']
    [CSV [QUOTE [ AS ] 'quote']
      [FORCE QUOTE column [, ...]]
    ]
    [IGNORE EXTERNAL PARTITIONS ]

See COPY for more information.

CREATE AGGREGATE
Defines a new aggregate function.

CREATE [ORDERED] AGGREGATE name (input_data_type [ , ... ])
  ( SFUNC = sfunc,
    STYPE = state_data_type
    [, PREFUNC = prefunc]
    [, FINALFUNC = ffunc]
    [, INITCOND = initial_condition]
    [, SORTOP = sort_operator] )

See CREATE AGGREGATE for more information.

CREATE CAST
Defines a new cast.

CREATE CAST (sourcetype AS targettype)
  WITH FUNCTION funcname (argtypes)
  [AS ASSIGNMENT | AS IMPLICIT]

CREATE CAST (sourcetype AS targettype) WITHOUT FUNCTION
  [AS ASSIGNMENT | AS IMPLICIT]

See CREATE CAST for more information.
CREATE CONVERSION
Defines a new encoding conversion.

```
CREATE [DEFAULT] CONVERSION name FOR source_encoding TO dest_encoding FROM funcname
```
See `CREATE CONVERSION` for more information.

CREATE DATABASE
Creates a new database.

```
CREATE DATABASE name [ [WITH] [OWNER [=] dbowner] [TEMPLATE [=] template] [ENCODING [=] encoding] [TABLESPACE [=] tablespace] [CONNECTION LIMIT [=] connlimit ] ]
```
See `CREATE DATABASE` for more information.

CREATE DOMAIN
Defines a new domain.

```
CREATE DOMAIN name [AS] data_type [DEFAULT expression] [CONSTRAINT constraint_name [NOT NULL | NULL] CHECK (expression) [...]]
```
See `CREATE DOMAIN` for more information.

CREATE EXTENSION
Registers an extension in a Greenplum database.

```
CREATE EXTENSION [ IF NOT EXISTS ] extension_name [ WITH ] [ SCHEMA schema_name ] [ VERSION version ] [ FROM old_version ] [ CASCADE ]
```
See `CREATE EXTENSION` for more information.

CREATE EXTERNAL TABLE
Defines a new external table.

```
CREATE [READABLE] EXTERNAL [TEMPORARY | TEMP] TABLE table_name
( column_name data_type [, ...] | LIKE other_table ) LOCATION ('file://seghost[:port]/path/file' [, ...])
  | ('gpfdist://filehost[:port]/file_pattern[#transform=trans_name]' [, ...])
  | ('gpdfs://hdfs_host[:port]/path/file')
  | ('pxf://path-to-data?PROFILE[&custom-option=value[...]])
  | ('s3://S3_endpoint[:port]/bucket_name/[S3_prefix] [region=S3-region] [config=config_file]')
[ON MASTER] FORMAT 'TEXT'
```
CREATE [READABLE] EXTERNAL WEB [TEMPORARY | TEMP] TABLE table_name
  (column_name data_type [, ...] | LIKE other_table)
  LOCATION ('http://webhost[:port]/path/file' [, ...])
  | EXECUTE 'command' [ON ALL
  MASTER
  number_of_segments
  HOST ['segment_hostname']
  SEGMENT segment_id ]

FORMAT 'TEXT'

CREATE WRITABLE EXTERNAL [TEMPORARY | TEMP] TABLE table_name
  (column_name data_type [, ...] | LIKE other_table)
  LOCATION ('gpfdist://outputhost[:port]/filename[#transform=trans_name]' [, ...])
  | ('gpfdists://outputhost[:port]/file_pattern[#transform=trans_name]' [, ...])
  | ('gphdfs://hdfs_host[:port]/path')
  FORMAT 'TEXT'
  | 'CSV'
CREATE WRITABLE EXTERNAL \[TEMPORARY | TEMP\] TABLE table_name
( column_name data_type [, ...] | LIKE other_table )
LOCATION('s3://S3_endpoint[:port]/bucket_name/[S3_prefix] [region=S3-region] [config=config_file])
[ON MASTER]
FORMAT 'TEXT'
| ([ DELIMITER [AS] 'delimiter'
    NULL [AS] 'null string'
    ESCAPE [AS] 'escape' | 'OFF' ] )
| 'CSV'
| ([QUOTE [AS] 'quote'
    DELIMITER [AS] 'delimiter'
    NULL [AS] 'null string'
    FORCE QUOTE column [, ...] | * ]
    ESCAPE [AS] 'escape'] )

CREATE WRITABLE EXTERNAL WEB \[TEMPORARY | TEMP\] TABLE table_name
( column_name data_type [, ...] | LIKE other_table )
EXECUTE 'command' [ON ALL]
FORMAT 'TEXT'
| ([ DELIMITER [AS] 'delimiter'
    NULL [AS] 'null string'
    ESCAPE [AS] 'escape' | 'OFF' ] )
| 'CSV'
| ([QUOTE [AS] 'quote'
    DELIMITER [AS] 'delimiter'
    NULL [AS] 'null string'
    FORCE QUOTE column [, ...] | * ]
    ESCAPE [AS] 'escape'] )
| 'CUSTOM' (Formatter=<formatter specifications>)
| ENCODING 'write_encoding'
| DISTRIBUTED BY (column, [ ... ] ) | DISTRIBUTED RANDOMLY ]

See CREATE EXTERNAL TABLE for more information.

CREATE FUNCTION
 Defines a new function.

CREATE [OR REPLACE] FUNCTION name
( [ [ argmode ] [ argname ] argtype [ { DEFAULT | = } defexpr ] [, ... ] ] )
[ RETURNS { { SETOF } rettype
    | TABLE {[ [ argname argtype | LIKE other table ]
      [, ...]]} ]
} ]

| LANGUAGE langname
IMMUTABLE | STABLE | VOLATILE
| CALLED ON NULL INPUT | RETURNS NULL ON NULL INPUT | STRICT
| [EXTERNAL] SECURITY INVOKER | [EXTERNAL] SECURITY DEFINER
| COST execution_cost
SET configuration_parameter { TO value | = value | FROM CURRENT } AS 'definition'
See `CREATE FUNCTION` for more information.

**CREATE GROUP**
Defines a new database role.

`CREATE GROUP name [[WITH] option [ ... ]]`

See `CREATE GROUP` for more information.

**CREATE INDEX**
Defines a new index.

`CREATE [UNIQUE] INDEX name ON table`
`[USING btree|bitmap|gist]`
`{ (column | (expression)) [opclass] [, ... ] }
[ WITH ( FILLFACTOR = value ) ]
[ TABLESPACE tablespace ]
[ WHERE predicate ]`

See `CREATE INDEX` for more information.

**CREATE LANGUAGE**
Defines a new procedural language.

`CREATE [PROCEDURAL] LANGUAGE name`

`CREATE [TRUSTED] [PROCEDURAL] LANGUAGE name`
`HANDLER call_handler [ INLINE inline_handler ]`
`[VALIDATOR valfunction]`

See `CREATE LANGUAGE` for more information.

**CREATE OPERATOR**
Defines a new operator.

`CREATE OPERATOR name (`
`PROCEDURE = funcname`
`[, LEFTARG = lefttype] [, RIGHTARG = righttype]`
`[, COMMUTATOR = com_op] [, NEGATOR = neg_op]`
`[, RESTRICT = res_proc] [, JOIN = join_proc]`
`[, HASHES] [, MERGES] )`

See `CREATE OPERATOR` for more information.

**CREATE OPERATOR CLASS**
Defines a new operator class.

`CREATE OPERATOR CLASS name [DEFAULT] FOR TYPE data_type`
`USING index_method AS`
`{`
`OPERATOR strategy_number op_name [(op_type, op_type)] [RECHECK]`
FUNCTION  support_number funcname (argument_type [, ...] )
STORAGE  storage_type
} [, ...]

See CREATE OPERATOR CLASS for more information.

CREATE OPERATOR FAMILY
Defines a new operator family.

CREATE OPERATOR FAMILY name USING index_method

See CREATE OPERATOR FAMILY for more information.

CREATE PROTOCOL
Registers a custom data access protocol that can be specified when defining a Greenplum Database external table.

CREATE [TRUSTED] PROTOCOL name (  
   [readfunc='read_call_handler'] [, writefunc='write_call_handler'] 
   [, validatorfunc='validate_handler' ])

See CREATE PROTOCOL for more information.

CREATE RESOURCE GROUP
Defines a new resource group.

CREATE RESOURCE GROUP name WITH (group_attribute=value [, ... ])

See CREATE RESOURCE GROUP for more information.

CREATE RESOURCE QUEUE
Defines a new resource queue.

CREATE RESOURCE QUEUE name WITH (queue_attribute=value [, ... ])

See CREATE RESOURCE QUEUE for more information.

CREATE ROLE
Defines a new database role (user or group).

CREATE ROLE name [[WITH] option [ ... ]]

See CREATE ROLE for more information.

CREATE RULE
Defines a new rewrite rule.

CREATE [OR REPLACE] RULE name AS ON event
   TO table [WHERE condition]
   DO [ALSO | INSTEAD] ( NOTHING | command | (command; command ...

See CREATE RULE for more information.
**CREATE SCHEMA**
Defines a new schema.

```
CREATE SCHEMA schema_name [AUTHORIZATION username]
   [schema_element [ ... ]]
```

```
CREATE SCHEMA AUTHORIZATION rolename [schema_element [ ... ]]
```

See **CREATE SCHEMA** for more information.

**CREATE SEQUENCE**
Defines a new sequence generator.

```
CREATE [TEMPORARY | TEMP] SEQUENCE name
   [INCREMENT [BY] value]
   [MINVALUE minvalue | NO MINVALUE]
   [MAXVALUE maxvalue | NO MAXVALUE]
   [START [ WITH ] start]
   [CACHE cache]
   [[NO] CYCLE]
   [OWNED BY { table.column | NONE }]
```

See **CREATE SEQUENCE** for more information.

**CREATE TABLE**
Defines a new table.

```
CREATE [[GLOBAL | LOCAL] {TEMPORARY | TEMP}] TABLE table_name ( 
   [ { column_name data_type [ DEFAULT default_expr ]
   [column_constraint [ ... ]
   [ ENCODING ( storage_directive [, ... ] ) ]
   ]
   | table_constraint
   LIKE other_table [(INCLUDING | EXCLUDING)
   (DEFAULTS | CONSTRAINTS)] ...)
 [, ... ]
 )
 [ INHERITS ( parent_table [, ... ] ) ]
 [ WITH ( storage_parameter=value [, ... ] )
 [ ON COMMIT {PRESERVE ROWS | DELETE ROWS | DROP }]
 [ TABLESPACE tablespace ]
 [ DISTRIBUTED BY (column, [ ... ]) | DISTRIBUTED RANDOMLY ]
 [ PARTITION BY partition_type (column) ]
   [ SUBPARTITION BY partition_type (column) ]
   [ SUBPARTITION TEMPLATE ( template_spec ) ]
   [...] (partition_spec)
   [ SUBPARTITION BY partition_type (column) ]
   [...] (partition_spec
   [ ( subpartition_spec 
   [...])]
 )
)
```

See **CREATE TABLE** for more information.
CREATE TABLE AS
Defines a new table from the results of a query.

```
CREATE [ [GLOBAL | LOCAL] {TEMPORARY | TEMP} ] TABLE table_name
[ (column_name [, ...] ) ]
[ WITH ( storage_parameter=value [, ... ] ) ]
[ ON COMMIT {PRESERVE ROWS | DELETE ROWS | DROP} ]
[ TABLESPACE tablespace ]
AS query
[ DISTRIBUTED BY (column, [ ... ] ) | DISTRIBUTED RANDOMLY ]
```

See `CREATE TABLE AS` for more information.

CREATE TABLESPACE
Defines a new tablespace.

```
CREATE TABLESPACE tablespace_name [OWNER username]
FILESPACE filespace_name
```

See `CREATE TABLESPACE` for more information.

CREATE TYPE
Defines a new data type.

```
CREATE TYPE name AS ( attribute_name data_type [, ... ] )
CREATE TYPE name AS ENUM ( 'label' [, ... ] )
CREATE TYPE name ( INPUT = input_function,
 OUTPUT = output_function
[, RECEIVE = receive_function ]
[, SEND = send_function ]
[, TYPMOD_IN = type_modifier_input_function ]
[, TYPMOD_OUT = type_modifier_output_function ]
[, INTERNALLENGTH = {internallength | VARIABLE}]
[, PASSEDBYVALUE ]
[, ALIGNMENT = alignment ]
[, STORAGE = storage ]
[, DEFAULT = default ]
[, ELEMENT = element ]
[, DELIMITER = delimiter ]
```

CREATE TYPE name

See `CREATE TYPE` for more information.

CREATE USER
Defines a new database role with the LOGIN privilege by default.

```
CREATE USER name [[WITH] option [ ... ]]
```

See `CREATE USER` for more information.
CREATE VIEW
Defines a new view.

```sql
CREATE [OR REPLACE] [TEMP | TEMPORARY] VIEW name
    [ ( column_name [, ...] ) ]
AS query
```

See `CREATE VIEW` for more information.

DEALLOCATE
Deallocates a prepared statement.

```sql
DEALLOCATE [PREPARE] name
```

See `DEALLOCATE` for more information.

DECLARE
Defines a cursor.

```sql
DECLARE name [BINARY] [INSENSITIVE] [NO SCROLL] CURSOR
    [{WITH | WITHOUT} HOLD]
FOR query [FOR READ ONLY]
```

See `DECLARE` for more information.

DELETE
Deletes rows from a table.

```sql
DELETE FROM [ONLY] table [[AS] alias]
    [USING usinglist]
    [WHERE condition | WHERE CURRENT OF cursor_name ]
```

See `DELETE` for more information.

DISCARD
Discards the session state.

```sql
DISCARD { ALL | PLANS | TEMPORARY | TEMP }
```

See `DISCARD` for more information.

DROP AGGREGATE
Removes an aggregate function.

```sql
DROP AGGREGATE [IF EXISTS] name ( type [, ...] ) [CASCADE | RESTRICT]
```

See `DROP AGGREGATE` for more information.

DO
Executes an anonymous code block as a transient anonymous function.

```sql
DO [ LANGUAGE lang_name ] code
```
See **DO** for more information.

**DROP CAST**
Removes a cast.

```
DROP CAST [IF EXISTS] (sourcetype AS targettype) [CASCADE | RESTRICT]
```

See **DROP CAST** for more information.

**DROP CONVERSION**
Removes a conversion.

```
DROP CONVERSION [IF EXISTS] name [CASCADE | RESTRICT]
```

See **DROP CONVERSION** for more information.

**DROP DATABASE**
Removes a database.

```
DROP DATABASE [IF EXISTS] name
```

See **DROP DATABASE** for more information.

**DROP DOMAIN**
Removes a domain.

```
DROP DOMAIN [IF EXISTS] name [, ...] [CASCADE | RESTRICT]
```

See **DROP DOMAIN** for more information.

**DROP EXTENSION**
Removes an extension from a Greenplum database.

```
DROP EXTENSION [ IF EXISTS ] name [, ...] [ CASCADE | RESTRICT ]
```

See **DROP EXTENSION** for more information.

**DROP EXTERNAL TABLE**
Removes an external table definition.

```
DROP EXTERNAL [WEB] TABLE [IF EXISTS] name [CASCADE | RESTRICT]
```

See **DROP EXTERNAL TABLE** for more information.

**DROP FILESPACE**
Removes a filespace.

```
DROP FILESPACE [IF EXISTS] filespacename
```

See **DROP FILESPACE** for more information.
DROP FUNCTION
Removes a function.

```
DROP FUNCTION [IF EXISTS] name ( [ [argmode] [argname] argtype [, ...] ] ) [CASCADE | RESTRICT]
```

See `DROP FUNCTION` for more information.

DROP GROUP
Removes a database role.

```
DROP GROUP [IF EXISTS] name [, ...]
```

See `DROP GROUP` for more information.

DROP INDEX
Removes an index.

```
DROP INDEX [IF EXISTS] name [, ...] [CASCADE | RESTRICT]
```

See `DROP INDEX` for more information.

DROP LANGUAGE
Removes a procedural language.

```
DROP [PROCEDURAL] LANGUAGE [IF EXISTS] name [CASCADE | RESTRICT]
```

See `DROP LANGUAGE` for more information.

DROP OPERATOR
Removes an operator.

```
DROP OPERATOR [IF EXISTS] name ( {lefttype | NONE} , {righttype | NONE} ) [CASCADE | RESTRICT]
```

See `DROP OPERATOR` for more information.

DROP OPERATOR CLASS
Removes an operator class.

```
DROP OPERATOR CLASS [IF EXISTS] name USING index_method [CASCADE | RESTRICT]
```

See `DROP OPERATOR CLASS` for more information.

DROP OPERATOR FAMILY
Removes an operator family.

```
DROP OPERATOR FAMILY [IF EXISTS] name USING index_method [CASCADE | RESTRICT]
```

See `DROP OPERATOR FAMILY` for more information.
**DROP OWNED**
Removes database objects owned by a database role.

```
DROP OWNED BY name [, ...] [CASCADE | RESTRICT]
```

See *DROP OWNED* for more information.

**DROP PROTOCOL**
Removes a external table data access protocol from a database.

```
DROP PROTOCOL [IF EXISTS] name
```

See *DROP PROTOCOL* for more information.

**DROP RESOURCE GROUP**
Removes a resource group.

```
DROP RESOURCE GROUP group_name
```

See *DROP RESOURCE GROUP* for more information.

**DROP RESOURCE QUEUE**
Removes a resource queue.

```
DROP RESOURCE QUEUE queue_name
```

See *DROP RESOURCE QUEUE* for more information.

**DROP ROLE**
Removes a database role.

```
DROP ROLE [IF EXISTS] name [, ...]
```

See *DROP ROLE* for more information.

**DROP RULE**
Removes a rewrite rule.

```
DROP RULE [IF EXISTS] name ON relation [CASCADE | RESTRICT]
```

See *DROP RULE* for more information.

**DROP SCHEMA**
Removes a schema.

```
DROP SCHEMA [IF EXISTS] name [, ...] [CASCADE | RESTRICT]
```

See *DROP SCHEMA* for more information.
**DROP SEQUENCE**
Removes a sequence.

```
DROP SEQUENCE [IF EXISTS] name [, ...] [CASCADE | RESTRICT]
```

See *DROP SEQUENCE* for more information.

**DROP TABLE**
Removes a table.

```
DROP TABLE [IF EXISTS] name [, ...] [CASCADE | RESTRICT]
```

See *DROP TABLE* for more information.

**DROP TABLESPACE**
Removes a tablespace.

```
DROP TABLESPACE [IF EXISTS] tablesapce
```

See *DROP TABLESPACE* for more information.

**DROP TYPE**
Removes a data type.

```
DROP TYPE [IF EXISTS] name [, ...] [CASCADE | RESTRICT]
```

See *DROP TYPE* for more information.

**DROP USER**
Removes a database role.

```
DROP USER [IF EXISTS] name [, ...]
```

See *DROP USER* for more information.

**DROP VIEW**
Removes a view.

```
DROP VIEW [IF EXISTS] name [, ...] [CASCADE | RESTRICT]
```

See *DROP VIEW* for more information.

**END**
Commits the current transaction.

```
END [WORK | TRANSACTION]
```

See *END* for more information.
EXECUTE
Executes a prepared SQL statement.

EXECUTE name [ (parameter [, ...] ) ]

See EXECUTE for more information.

EXPLAIN
Shows the query plan of a statement.

EXPLAIN [ANALYZE] [VERBOSE] statement

See EXPLAIN for more information.

FETCH
Retrieves rows from a query using a cursor.

FETCH [ forward_direction { FROM | IN } ] cursorname

See FETCH for more information.

GRANT
Defines access privileges.

GRANT { {SELECT | INSERT | UPDATE | DELETE | REFERENCES | TRIGGER | TRUNCATE } [, ...] | ALL [PRIVILEGES] } 
ON [TABLE] tablename [, ...] 
TO { rolename | PUBLIC} [, ...] [WITH GRANT OPTION]

GRANT { {USAGE | SELECT | UPDATE} [, ...] | ALL [PRIVILEGES] } 
ON SEQUENCE sequencename [, ...] 
TO { rolename | PUBLIC} [, ...] [WITH GRANT OPTION]

GRANT { {CREATE | CONNECT | TEMPORARY | TEMP} [, ...] | ALL [PRIVILEGES] } 
ON DATABASE dbname [, ...] 
TO { rolename | PUBLIC} [, ...] [WITH GRANT OPTION]

GRANT { USAGE | ALL [ PRIVILEGES ] } 
ON FOREIGN DATA WRAPPER fdwname [, ...] 
TO { [ GROUP ] rolename | PUBLIC} [, ...] [ WITH GRANT OPTION ]

GRANT { USAGE | ALL [ PRIVILEGES ] } 
ON FOREIGN SERVER servername [, ...] 
TO { [ GROUP ] rolename | PUBLIC} [, ...] [ WITH GRANT OPTION ]

GRANT { EXECUTE | ALL [PRIVILEGES] } 
ON FUNCTION funcname ( [ [argmode] [argname] argtype [, ...] ] ) [, ...] 
TO {rolename | PUBLIC} [, ...] [WITH GRANT OPTION]

GRANT { USAGE | ALL [PRIVILEGES] } 
ON LANGUAGE langname [, ...] 
TO { rolename | PUBLIC} [, ...] [WITH GRANT OPTION]

GRANT { {CREATE | USAGE} [, ...] | ALL [PRIVILEGES] } 
ON SCHEMA schemaname [, ...] 
TO { rolename | PUBLIC} [, ...] [WITH GRANT OPTION]
GRANT { CREATE | ALL [PRIVILEGES] } 
   ON TABLESPACE tablespacename [, ...] 
   TO {rolename | PUBLIC} [, ...] [WITH GRANT OPTION]

GRANT parent_role [, ...] 
   TO member_role [, ...] [WITH ADMIN OPTION]

GRANT { SELECT | INSERT | ALL [PRIVILEGES] } 
   ON PROTOCOL protocolname 
   TO username

See [GRANT](#) for more information.

### INSERT

Creates new rows in a table.

```
INSERT INTO table [( column [, ...] )]
   {DEFAULT VALUES | VALUES ( {expression | DEFAULT} [, ...] )
   [, ...] | query}
```

See [INSERT](#) for more information.

### LOAD

Loads or reloads a shared library file.

```
LOAD 'filename'
```

See [LOAD](#) for more information.

### LOCK

Locks a table.

```
LOCK [TABLE] name [, ...] [IN lockmode MODE] [NOWAIT]
```

See [LOCK](#) for more information.

### MOVE

Positions a cursor.

```
MOVE [ forward_direction {FROM | IN} ] cursorname
```

See [MOVE](#) for more information.

### PREPARE

Prepare a statement for execution.

```
PREPARE name [ (datatype [, ...] ) ] AS statement
```

See [PREPARE](#) for more information.
**REASSIGN OWNED**
Changes the ownership of database objects owned by a database role.

REASSIGN OWNED BY old_role [, ...] TO new_role

See `REASSIGN OWNED` for more information.

**REINDEX**
Rebuilds indexes.

REINDEX {INDEX | TABLE | DATABASE | SYSTEM} name

See `REINDEX` for more information.

**RELEASE SAVEPOINT**
Destroys a previously defined savepoint.

RELEASE [SAVEPOINT] savepoint_name

See `RELEASE SAVEPOINT` for more information.

**RESET**
Restores the value of a system configuration parameter to the default value.

RESET configuration_parameter
RESET ALL

See `RESET` for more information.

**REVOKE**
Removes access privileges.

REVOKE [GRANT OPTION FOR] { {SELECT | INSERT | UPDATE | DELETE
| REFERENCES | TRIGGER | TRUNCATE } [, ...] | ALL [PRIVILEGES] }
ON [TABLE] tablename [, ...]
FROM { rolename | PUBLIC } [, ...]
[CASCADE | RESTRICT]

REVOKE [GRANT OPTION FOR] { {USAGE | SELECT | UPDATE} [, ...]
| ALL [PRIVILEGES] }
ON SEQUENCE sequencename [, ...]
FROM { rolename | PUBLIC } [, ...]
[CASCADE | RESTRICT]

REVOKE [GRANT OPTION FOR] { {CREATE | CONNECT
| TEMPORARY | TEMP} [, ...] | ALL [PRIVILEGES] }
ON DATABASE dbname [, ...]
FROM { rolename | PUBLIC } [, ...]
[CASCADE | RESTRICT]

REVOKE [GRANT OPTION FOR] {EXECUTE | ALL [PRIVILEGES]}
ON FUNCTION funcname ( [[argmode] argname argtype
[, ...]] ) [, ...]
FROM { rolename | PUBLIC } [, ...]
[CASCADE | RESTRICT]
REVOKE [GRANT OPTION FOR] {USAGE | ALL [PRIVILEGES]}
ON LANGUAGE langname [, ...]
FROM {rolename | PUBLIC} [, ...]
[ CASCADE | RESTRICT ]

REVOKE [GRANT OPTION FOR] {CREATE | USAGE} [, ...]
| ALL [PRIVILEGES] }
ON SCHEMA schemaname [, ...]
FROM {rolename | PUBLIC} [, ...]
[CASCADE | RESTRICT]

REVOKE [GRANT OPTION FOR] {CREATE | ALL [PRIVILEGES] }
ON TABLESPACE tablespacename [, ...]
FROM {rolename | PUBLIC} [, ...]
[CASCADE | RESTRICT]

REVOKE [ADMIN OPTION FOR] parent_role [, ...]
FROM member_role [, ...]
[CASCADE | RESTRICT]

See REVOKE for more information.

ROLLBACK
Aborts the current transaction.

ROLLBACK [WORK | TRANSACTION]

See ROLLBACK for more information.

ROLLBACK TO SAVEPOINT
Rolls back the current transaction to a savepoint.

ROLLBACK [WORK | TRANSACTION] TO [SAVEPOINT] savepoint_name

See ROLLBACK TO SAVEPOINT for more information.

SAVEPOINT
Defines a new savepoint within the current transaction.

SAVEPOINT savepoint_name

See SAVEPOINT for more information.

SELECT
Retrieves rows from a table or view.

[ WITH [ RECURSIVE¹ ] with_query [, ...] ]
SELECT [ALL | DISTINCT [ON {expression [, ...]}]]
* | expression [[AS] output_name] [, ...]
[FROM from_item [, ...]]
[WHERE condition]
[GROUP BY grouping_element [, ...]]
[HAVING condition [, ...]]
[WINDOW window_name AS (window_specification)]
[UNION | INTERSECT | EXCEPT] [ALL] select]
[ORDER BY expression [ASC | DESC | USING operator] [NULLS {FIRST | LAST}]
[, ...]]
[LIMIT {count | ALL}]
[OFFSET start]
[FOR {UPDATE | SHARE} [OF table_name [, ...]]] [NOWAIT] [...]]

See SELECT for more information.

**SELECT INTO**

Defines a new table from the results of a query.

[ WITH [ RECURSIVE^1 ] with_query [, ...] ]
SELECT [ALL | DISTINCT [ON ( expression [, ...] )]]
 * | expression [AS output_name] [, ...]
INTO [TEMPORARY | TEMP] [TABLE] new_table
[FROM from_item [, ...]]
[WHERE condition]
[GROUP BY expression [, ...]]
[HAVING condition [, ...]]
[(UNION | INTERSECT | EXCEPT) [ALL] select]
[ORDER BY expression [ASC | DESC | USING operator] [NULLS {FIRST | LAST}]
[, ...]]
[LIMIT {count | ALL}]
[OFFSET start]
[FOR {UPDATE | SHARE} [OF table_name [, ...]]] [NOWAIT] [...]]

See SELECT INTO for more information.

**SET**

Changes the value of a Greenplum Database configuration parameter.

SET [SESSION | LOCAL] configuration_parameter {TO | =} value | 'value' | DEFAULT

SET [SESSION | LOCAL] TIME_ZONE {timezone | LOCAL | DEFAULT}

See SET for more information.

**SET ROLE**

Sets the current role identifier of the current session.

SET [SESSION | LOCAL] ROLE rolename

SET [SESSION | LOCAL] ROLE NONE

RESET ROLE

See SET ROLE for more information.

**SET SESSION AUTHORIZATION**

Sets the session role identifier and the current role identifier of the current session.

SET [SESSION | LOCAL] SESSION AUTHORIZATION rolename

SET [SESSION | LOCAL] SESSION AUTHORIZATION DEFAULT
RESET SESSION AUTHORIZATION

See SET SESSION AUTHORIZATION for more information.

SET TRANSACTION

Sets the characteristics of the current transaction.

```
SET TRANSACTION [transaction_mode] [READ ONLY | READ WRITE]
SET SESSION CHARACTERISTICS AS TRANSACTION transaction_mode
[READ ONLY | READ WRITE]
```

See SET TRANSACTION for more information.

SHOW

Shows the value of a system configuration parameter.

```
SHOW configuration_parameter
SHOW ALL
```

See SHOW for more information.

START TRANSACTION

Starts a transaction block.

```
START TRANSACTION [SERIALIZABLE | READ COMMITTED | READ UNCOMMITTED]
[READ WRITE | READ ONLY]
```

See START TRANSACTION for more information.

TRUNCATE

Empties a table of all rows.

```
TRUNCATE [TABLE] name [, ...] [CASCADE | RESTRICT]
```

See TRUNCATE for more information.

UPDATE

Updates rows of a table.

```
UPDATE [ONLY] table [[[AS] alias]
SET {column = {expression | DEFAULT} |
(column [, ...]) = ({expression | DEFAULT} [, ...])} [, ...]
[FROM fromlist]
[WHERE condition | WHERE CURRENT OF cursor_name ]
```

See UPDATE for more information.

VACUUM

Garbage-collects and optionally analyzes a database.

```
VACUUM [FULL] [FREEZE] [VERBOSE] [table]
```
VACUUM [FULL] [FREEZE] [VERBOSE] ANALYZE
   [table [(column [, ...] )]]

See VACUUM for more information.

VALUES
Computes a set of rows.

VALUES ( expression [, ...] ) [, ...]
   [ORDER BY sort_expression [ASC | DESC | USING operator] [, ...]]
   [LIMIT {count | ALL}] [OFFSET start]

See VALUES for more information.

ABORT
Aborts the current transaction.

Synopsis
ABORT [WORK | TRANSACTION]

Description
ABORT rolls back the current transaction and causes all the updates made by the transaction to be discarded. This command is identical in behavior to the standard SQL command ROLLBACK, and is present only for historical reasons.

Parameters
WORK
TRANSACTION
   Optional key words. They have no effect.

Notes
Use COMMIT to successfully terminate a transaction.

Issuing ABORT when not inside a transaction does no harm, but it will provoke a warning message.

Compatibility
This command is a Greenplum Database extension present for historical reasons. ROLLBACK is the equivalent standard SQL command.

See Also
BEGIN, COMMIT, ROLLBACK

ALTER AGGREGATE
Changes the definition of an aggregate function

Synopsis
ALTER AGGREGATE name ( type [, ... ] ) RENAME TO new_name
ALTER AGGREGATE name ( type [ , ... ] ) OWNER TO new_owner
ALTER AGGREGATE name ( type [ , ... ] ) SET SCHEMA new_schema

Description
ALTER AGGREGATE changes the definition of an aggregate function.

You must own the aggregate function to use ALTER AGGREGATE. To change the schema of an aggregate
function, you must also have CREATE privilege on the new schema. To alter the owner, you must also
be a direct or indirect member of the new owning role, and that role must have CREATE privilege on the
aggregate function's schema. (These restrictions enforce that altering the owner does not do anything you
could not do by dropping and recreating the aggregate function. However, a superuser can alter ownership
of any aggregate function anyway.)

Parameters
name
The name (optionally schema-qualified) of an existing aggregate function.

type
An input data type on which the aggregate function operates. To reference a zero-
argument aggregate function, write * in place of the list of input data types.

new_name
The new name of the aggregate function.

new_owner
The new owner of the aggregate function.

new_schema
The new schema for the aggregate function.

Examples
To rename the aggregate function myavg for type integer to my_average:

ALTER AGGREGATE myavg(integer) RENAME TO my_average;

To change the owner of the aggregate function myavg for type integer to joe:

ALTER AGGREGATE myavg(integer) OWNER TO joe;

To move the aggregate function myavg for type integer into schema myschema:

ALTER AGGREGATE myavg(integer) SET SCHEMA myschema;

Compatibility
There is no ALTER AGGREGATE statement in the SQL standard.

See Also
CREATE AGGREGATE, DROP AGGREGATE

ALTER CONVERSION
Changes the definition of a conversion.
Synopsis

ALTER CONVERSION name RENAME TO newname
ALTER CONVERSION name OWNER TO newowner

Description

ALTER CONVERSION changes the definition of a conversion.

You must own the conversion to use ALTER CONVERSION. To alter the owner, you must also be a direct or indirect member of the new owning role, and that role must have CREATE privilege on the conversion’s schema. (These restrictions enforce that altering the owner does not do anything you could not do by dropping and recreating the conversion. However, a superuser can alter ownership of any conversion anyway.)

Parameters

name
The name (optionally schema-qualified) of an existing conversion.

newname
The new name of the conversion.

newowner
The new owner of the conversion.

Examples

To rename the conversion iso_8859_1_to_utf8 to latin1_to_unicode:

ALTER CONVERSION iso_8859_1_to_utf8 RENAME TO latin1_to_unicode;

To change the owner of the conversion iso_8859_1_to_utf8 to joe:

ALTER CONVERSION iso_8859_1_to_utf8 OWNER TO joe;

Compatibility

There is no ALTER CONVERSION statement in the SQL standard.

See Also

CREATE CONVERSION, DROP CONVERSION

ALTER DATABASE

Changes the attributes of a database.

Synopsis

ALTER DATABASE name [ WITH CONNECTION LIMIT connlimit ]
ALTER DATABASE name SET parameter { TO | = } { value | DEFAULT }
ALTER DATABASE name RESET parameter
ALTER DATABASE name RENAME TO newname
ALTER DATABASE \textit{name} OWNER TO \textit{new_owner}

\section*{Description}

\texttt{ALTER DATABASE} changes the attributes of a database.

The first form changes the allowed connection limit for a database. Only the database owner or a superuser can change this setting.

The second and third forms change the session default for a configuration parameter for a Greenplum database. Whenever a new session is subsequently started in that database, the specified value becomes the session default value. The database-specific default overrides whatever setting is present in the server configuration file (\texttt{postgresql.conf}). Only the database owner or a superuser can change the session defaults for a database. Certain parameters cannot be set this way, or can only be set by a superuser.

The fourth form changes the name of the database. Only the database owner or a superuser can rename a database; non-superuser owners must also have the \texttt{CREATEDB} privilege. You cannot rename the current database. Connect to a different database first.

The fifth form changes the owner of the database. To alter the owner, you must own the database and also be a direct or indirect member of the new owning role, and you must have the \texttt{CREATEDB} privilege. (Note that superusers have all these privileges automatically.)

\section*{Parameters}

\textit{name}

The name of the database whose attributes are to be altered.

\textit{connlimit}

The maximum number of concurrent connections possible. The default of -1 means there is no limitation.

\textit{parameter value}

Set this database’s session default for the specified configuration parameter to the given value. If value is \texttt{DEFAULT} or, equivalently, \texttt{RESET} is used, the database-specific setting is removed, so the system-wide default setting will be inherited in new sessions. Use \texttt{RESET ALL} to clear all database-specific settings. See \texttt{Server Configuration Parameters} for information about server parameters. for information about all user-settable configuration parameters.

\textit{newname}

The new name of the database.

\textit{new_owner}

The new owner of the database.

\section*{Notes}

It is also possible to set a configuration parameter session default for a specific role (user) rather than to a database. Role-specific settings override database-specific ones if there is a conflict. See \texttt{ALTER ROLE}.

\section*{Examples}

To set the default schema search path for the \texttt{mydatabase} database:

\begin{verbatim}
ALTER DATABASE mydatabase SET search_path TO myschema, public, pg_catalog;
\end{verbatim}
Compatibility

The ALTER DATABASE statement is a Greenplum Database extension.

See Also

CREATE DATABASE, DROP DATABASE, SET

ALTER DOMAIN

Changes the definition of a domain.

Synopsis

```
ALTER DOMAIN name { SET DEFAULT expression | DROP DEFAULT }
ALTER DOMAIN name { SET | DROP } NOT NULL
ALTER DOMAIN name ADD domain_constraint
ALTER DOMAIN name DROP CONSTRAINT constraint_name [RESTRICT | CASCADE]
ALTER DOMAIN name OWNER TO new_owner
ALTER DOMAIN name SET SCHEMA new_schema
```

Description

ALTER DOMAIN changes the definition of an existing domain. There are several sub-forms:

- **SET/DROP DEFAULT** — These forms set or remove the default value for a domain. Note that defaults only apply to subsequent INSERT commands. They do not affect rows already in a table using the domain.
- **SET/DROP NOT NULL** — These forms change whether a domain is marked to allow NULL values or to reject NULL values. You may only SET NOT NULL when the columns using the domain contain no null values.
- **ADD domain_constraint** — This form adds a new constraint to a domain using the same syntax as CREATE DOMAIN. This will only succeed if all columns using the domain satisfy the new constraint.
- **DROP CONSTRAINT** — This form drops constraints on a domain.
- **OWNER** — This form changes the owner of the domain to the specified user.
- **SET SCHEMA** — This form changes the schema of the domain. Any constraints associated with the domain are moved into the new schema as well.

You must own the domain to use ALTER DOMAIN. To change the schema of a domain, you must also have CREATE privilege on the new schema. To alter the owner, you must also be a direct or indirect member of the new owning role, and that role must have CREATE privilege on the domain's schema. (These restrictions enforce that altering the owner does not do anything you could not do by dropping and recreating the domain. However, a superuser can alter ownership of any domain anyway.)

Parameters

- **name**
  
  The name (optionally schema-qualified) of an existing domain to alter.

- **domain_constraint**
  
  New domain constraint for the domain.

- **constraint_name**
  
  Name of an existing constraint to drop.
**CASCADE**

Automatically drop objects that depend on the constraint.

**RESTRICT**

Refuse to drop the constraint if there are any dependent objects. This is the default behavior.

**new_owner**

The user name of the new owner of the domain.

**new_schema**

The new schema for the domain.

### Examples

To add a **NOT NULL** constraint to a domain:

```
ALTER DOMAIN zipcode SET NOT NULL;
```

To remove a **NOT NULL** constraint from a domain:

```
ALTER DOMAIN zipcode DROP NOT NULL;
```

To add a check constraint to a domain:

```
ALTER DOMAIN zipcode ADD CONSTRAINT zipchk CHECK (char_length(VALUE) = 5);
```

To remove a check constraint from a domain:

```
ALTER DOMAIN zipcode DROP CONSTRAINT zipchk;
```

To move the domain into a different schema:

```
ALTER DOMAIN zipcode SET SCHEMA customers;
```

### Compatibility

**ALTER DOMAIN** conforms to the SQL standard, except for the **OWNER** and **SET SCHEMA** variants, which are Greenplum Database extensions.

### See Also

`CREATE DOMAIN`, `DROP DOMAIN`

---

**ALTER EXTENSION**

Change the definition of an extension that is registered in a Greenplum database.

### Synopsis

```
ALTER EXTENSION name UPDATE [ TO new_version ]
ALTER EXTENSION name SET SCHEMA new_schema
ALTER EXTENSION name ADD member_object
ALTER EXTENSION name DROP member_object
```

where `member_object` is:
ACCESS METHOD object_name |
AGGREGATE aggregate_name ( aggregate_signature ) |
CAST (source_type AS target_type) |
COLLATION object_name |
CONVERSION object_name |
DOMAIN object_name |
EVENT TRIGGER object_name |
FOREIGN DATA WRAPPER object_name |
FOREIGN TABLE object_name |
FUNCTION function_name ( [ [ argmode ] [ argname ] argtype [, ...] ] ) |
MATERIALIZED VIEW object_name |
OPERATOR operator_name (left_type, right_type) |
OPERATOR CLASS object_name USING index_method |
OPERATOR FAMILY object_name USING index_method |
[ PROCEDURAL ] LANGUAGE object_name |
SCHEMA object_name |
SEQUENCE object_name |
SERVER object_name |
TABLE object_name |
TEXT SEARCH CONFIGURATION object_name |
TEXT SEARCH DICTIONARY object_name |
TEXT SEARCH PARSER object_name |
TEXT SEARCH TEMPLATE object_name |
TRANSFORM FOR type_name LANGUAGE lang_name |
VIEW object_name |

and aggregate_signature is:

* | [ argmode ] [ argname ] argtype [, ... ] |
[ [ argmode ] [ argname ] argtype [, ... ] ]
ORDER BY [ argmode ] [ argname ] argtype [, ... ]

Description

ALTER EXTENSION changes the definition of an installed extension. These are the subforms:

UPDATE

This form updates the extension to a newer version. The extension must supply a suitable update script (or series of scripts) that can modify the currently-installed version into the requested version.

SET SCHEMA

This form moves the extension member objects into another schema. The extension must be relocatable.

ADD member_object

This form adds an existing object to the extension. This is useful in extension update scripts. The added object is treated as a member of the extension. The object can only be dropped by dropping the extension.

DROP member_object

This form removes a member object from the extension. This is mainly useful in extension update scripts. The object is not dropped, only disassociated from the extension.

See Packaging Related Objects into an Extension for more information about these operations.

You must own the extension to use ALTER EXTENSION. The ADD and DROP forms also require ownership of the object that is being added or dropped.
Parameters

name
The name of an installed extension.

new_version
The new version of the extension. The new_version can be either an identifier or a string literal. If not specified, the command attempts to update to the default version in the extension control file.

new_schema
The new schema for the extension.

object_name
aggregate_name
function_name
operator_name
The name of an object to be added to or removed from the extension. Names of tables, aggregates, domains, foreign tables, functions, operators, operator classes, operator families, sequences, text search objects, types, and views can be schema-qualified.

source_type
The name of the source data type of the cast.

target_type
The name of the target data type of the cast.

argmode
The mode of a function or aggregate argument: IN, OUT, INOUT, or VARIADIC. The default is IN.

The command ignores the OUT arguments. Only the input arguments are required to determine the function identity. It is sufficient to list the IN, INOUT, and VARIADIC arguments.

argname
The name of a function or aggregate argument.

The command ignores argument names, since only the argument data types are required to determine the function identity.

argtype
The data type of a function or aggregate argument.

left_type
right_type
The data types (optionally schema-qualified) of the operator arguments. Specify NONE for the missing argument of a prefix or postfix operator.

PROCEDURAL
This is a noise word.

type_name
The name of the data type of the transform.

lang_name
The name of the language of the transform.
Examples
To update the hstore extension to version 2.0:

```
ALTER EXTENSION hstore UPDATE TO '2.0';
```

To change the schema of the hstore extension to utils:

```
ALTER EXTENSION hstore SET SCHEMA utils;
```

To add an existing function to the hstore extension:

```
ALTER EXTENSION hstore ADD FUNCTION populate_record(anyelement, hstore);
```

Compatibility
ALTER EXTENSION is a Greenplum Database extension.

See Also
CREATE EXTENSION, DROP EXTENSION

**ALTER EXTERNAL TABLE**
Changes the definition of an existing external table.

Synopsis

```
ALTER EXTERNAL TABLE name action [, ... ]
```

where action is one of:

```
ADD [COLUMN] new_column type
DROP [COLUMN] column [RESTRICT|CASCADE]
ALTER [COLUMN] column TYPE type [USING expression]
OWNER TO new_owner
```

Description

ALTER EXTERNAL TABLE changes the definition of an existing external table. These are the supported
ALTER EXTERNAL TABLE actions:

- **ADD COLUMN** — Adds a new column to the external table definition.
- **DROP COLUMN** — Drops a column from the external table definition. If you drop readable external
table columns, it only changes the table definition in Greenplum Database. The CASCADE keyword
is required if anything outside the table depends on the column, such as a view that references the
column.
- **ALTER COLUMN TYPE** — Changes the data type of a table column.
- **OWNER** — Changes the owner of the external table to the specified user.

Use the ALTER TABLE command to perform these actions on an external table.

- Set (change) the table schema.
- Rename the table.
- Rename a table column.

You must own the external table to use ALTER EXTERNAL TABLE or ALTER TABLE. To change the
schema of an external table, you must also have CREATE privilege on the new schema. To alter the owner,
you must also be a direct or indirect member of the new owning role, and that role must have CREATE privilege on the external table's schema. A superuser has these privileges automatically.

Changes to the external table definition with either `ALTER EXTERNAL TABLE` or `ALTER TABLE` do not affect the external data.

The `ALTER EXTERNAL TABLE` and `ALTER TABLE` commands cannot modify the type external table (read, write, web), the table `FORMAT` information, or the location of the external data. To modify this information, you must drop and recreate the external table definition.

**Parameters**

*name*

The name (possibly schema-qualified) of an existing external table definition to alter.

*column*

Name of an existing column.

*new_column*

Name of a new column.

*USING expression*

Optional if an implicit or assignment cast exists from the old column data type to new data type. The clause is required if there is no implicit or assignment cast.

The `USING` clause does not affect the external data.

*type*

Data type of the new column, or new data type for an existing column.

*new_owner*

The role name of the new owner of the external table.

*CASCADE*

Automatically drop objects that depend on the dropped column, such as a view that references the column.

*RESTRICT*

Refuse to drop the column or constraint if there are any dependent objects. This is the default behavior.

**Examples**

Add a new column to an external table definition:

```sql
ALTER EXTERNAL TABLE ext_expenses ADD COLUMN manager text;
```

Change the owner of an external table:

```sql
ALTER EXTERNAL TABLE ext_data OWNER TO jojo;
```

Change the data type of an external table:

```sql
ALTER EXTERNAL TABLE ext_leads ALTER COLUMN acct_code TYPE integer USING acct_code::integer
```

When altering the column data type from `text` to `integer`, the `USING` clause is required but does not affect the external data.
**Compatibility**

ALTER EXTERNAL TABLE is a Greenplum Database extension. There is no ALTER EXTERNAL TABLE statement in the SQL standard or regular PostgreSQL.

**See Also**

CREATE EXTERNAL TABLE, DROP EXTERNAL TABLE, ALTER TABLE

---

**ALTER FILESPACE**

Changes the definition of a filespace.

**Synopsis**

```
ALTER FILESPACE name RENAME TO newname
ALTER FILESPACE name OWNER TO newowner
```

**Description**

ALTER FILESPACE changes the definition of a filespace.

You must own the filespace to use ALTER FILESPACE. To alter the owner, you must also be a direct or indirect member of the new owning role (note that superusers have these privileges automatically).

**Parameters**

`name`

The name of an existing filespace.

`newname`

The new name of the filespace. The new name cannot begin with `pg_` or `gp_` (reserved for system filespaces).

`newowner`

The new owner of the filespace.

**Examples**

Rename filespace `myfs` to `fast_ssd`:

```
ALTER FILESPACE myfs RENAME TO fast_ssd;
```

Change the owner of tablespace `myfs`:

```
ALTER FILESPACE myfs OWNER TO dba;
```

**Compatibility**

There is no ALTER FILESPACE statement in the SQL standard or in PostgreSQL.

**See Also**

DROP FILESPACE, gpfilespace in the Greenplum Database Utility Guide

---

**ALTER FUNCTION**

Changes the definition of a function.
Synopsis

ALTER FUNCTION name ( [ [argmode] argname argtype [, ...] ] )
    action [, ... ] [RESTRICT]

ALTER FUNCTION name ( [ [argmode] argname argtype [, ...] ] )
    RENAME TO new_name

ALTER FUNCTION name ( [ [argmode] argname argtype [, ...] ] )
    OWNER TO new_owner

ALTER FUNCTION name ( [ [argmode] argname argtype [, ...] ] )
    SET SCHEMA new_schema

where action is one of:

{CALLED ON NULL INPUT | RETURNS NULL ON NULL INPUT | STRICT}
{IMMUTABLE | STABLE | VOLATILE}
{[EXTERNAL] SECURITY INVOKER | [EXTERNAL] SECURITY DEFINER}
COST execution_cost
SET configuration_parameter { TO | = } { value | DEFAULT }
SET configuration_parameter FROM CURRENT
RESET configuration_parameter
RESET ALL

Description

ALTER FUNCTION changes the definition of a function.

You must own the function to use ALTER FUNCTION. To change a function's schema, you must also have CREATE privilege on the new schema. To alter the owner, you must also be a direct or indirect member of the new owning role, and that role must have CREATE privilege on the function's schema. (These restrictions enforce that altering the owner does not do anything you could not do by dropping and recreating the function. However, a superuser can alter ownership of any function anyway.)

Parameters

name

The name (optionally schema-qualified) of an existing function.

argmode

The mode of an argument: either IN, OUT, INOUT, or VARIADIC. If omitted, the default is IN. Note that ALTER FUNCTION does not actually pay any attention to OUT arguments, since only the input arguments are needed to determine the function's identity. So it is sufficient to list the IN, INOUT, and VARIADIC arguments.

argname

The name of an argument. Note that ALTER FUNCTION does not actually pay any attention to argument names, since only the argument data types are needed to determine the function's identity.

argtype

The data type(s) of the function's arguments (optionally schema-qualified), if any.

new_name

The new name of the function.

new_owner

The new owner of the function. Note that if the function is marked SECURITY DEFINER, it will subsequently execute as the new owner.
new_schema

The new schema for the function.

CALLED ON NULL INPUT
RETURNS NULL ON NULL INPUT
STRICT

CALLED ON NULL INPUT changes the function so that it will be invoked when some or all of its arguments are null. RETURNS NULL ON NULL INPUT or STRICT changes the function so that it is not invoked if any of its arguments are null; instead, a null result is assumed automatically. See CREATE FUNCTION for more information.

IMMUTABLE
STABLE
VOLATILE

Change the volatility of the function to the specified setting. See CREATE FUNCTION for details.

[ EXTERNAL ] SECURITY INVOKER
[ EXTERNAL ] SECURITY DEFINER

Change whether the function is a security definer or not. The key word EXTERNAL is ignored for SQL conformance. See CREATE FUNCTION for more information about this capability.

COST execution_cost

Change the estimated execution cost of the function. See CREATE FUNCTION for more information.

configuration_parameter
value

Set or change the value of a configuration parameter when the function is called. If value is DEFAULT or, equivalently, RESET is used, the function-local setting is removed, and the function executes with the value present in its environment. Use RESET ALL to clear all function-local settings. SET FROM CURRENT applies the session’s current value of the parameter when the function is entered.

RESTRICT

Ignored for conformance with the SQL standard.

Notes

Greenplum Database has limitations on the use of functions defined as STABLE or VOLATILE. See CREATE FUNCTION for more information.

Examples

To rename the function sqrt for type integer to square_root:

```sql
ALTER FUNCTION sqrt(integer) RENAME TO square_root;
```

To change the owner of the function sqrt for type integer to joe:

```sql
ALTER FUNCTION sqrt(integer) OWNER TO joe;
```

To change the schema of the function sqrt for type integer to math:

```sql
ALTER FUNCTION sqrt(integer) SET SCHEMA math;
```
To adjust the search path that is automatically set for a function:

```sql
ALTER FUNCTION check_password(text) RESET search_path;
```

**Compatibility**

This statement is partially compatible with the `ALTER FUNCTION` statement in the SQL standard. The standard allows more properties of a function to be modified, but does not provide the ability to rename a function, make a function a security definer, or change the owner, schema, or volatility of a function. The standard also requires the `RESTRICT` key word, which is optional in Greenplum Database.

**See Also**

`CREATE FUNCTION`, `DROP FUNCTION`

---

**ALTER GROUP**

Changes a role name or membership.

**Synopsis**

```
ALTER GROUP groupname ADD USER username [, ... ]
ALTER GROUP groupname DROP USER username [, ... ]
ALTER GROUP groupname RENAME TO newname
```

**Description**

`ALTER GROUP` changes the attributes of a user group. This is an obsolete command, though still accepted for backwards compatibility, because users and groups are superseded by the more general concept of roles. See `ALTER ROLE` for more information.

The first two variants add users to a group or remove them from a group. Any role can play the part of `groupname` or `username`. The preferred method for accomplishing these tasks is to use `GRANT` and `REVOKE`.

**Parameters**

- `groupname`
  - The name of the group (role) to modify.

- `username`
  - Users (roles) that are to be added to or removed from the group. The users (roles) must already exist.

- `newname`
  - The new name of the group (role).

**Examples**

To add users to a group:

```sql
ALTER GROUP staff ADD USER karl, john;
```

To remove a user from a group:

```sql
ALTER GROUP workers DROP USER beth;
```
Compatibility
There is no `ALTER GROUP` statement in the SQL standard.

See Also
`ALTER ROLE, GRANT, REVOKE`

**ALTER INDEX**
Changes the definition of an index.

**Synopsis**

```
ALTER INDEX name RENAME TO new_name

ALTER INDEX name SET TABLESPACE tablespace_name

ALTER INDEX name SET ( FILLFACTOR = value )

ALTER INDEX name RESET ( FILLFACTOR )
```

**Description**
`ALTER INDEX` changes the definition of an existing index. There are several subforms:

- **RENAME** — Changes the name of the index. There is no effect on the stored data.
- **SET TABLESPACE** — Changes the index's tablespace to the specified tablespace and moves the data file(s) associated with the index to the new tablespace. See also `CREATE TABLESPACE`.
- **SET FILLFACTOR** — Changes the index-method-specific storage parameters for the index. The built-in index methods all accept a single parameter: `FILLFACTOR`. The fillfactor for an index is a percentage that determines how full the index method will try to pack index pages. Index contents will not be modified immediately by this command. Use `REINDEX` to rebuild the index to get the desired effects.
- **RESET FILLFACTOR** — Resets `FILLFACTOR` to the default. As with `SET`, a `REINDEX` may be needed to update the index entirely.

**Parameters**

- **name**
  The name (optionally schema-qualified) of an existing index to alter.

- **new_name**
  New name for the index.

- **tablespace_name**
  The tablespace to which the index will be moved.

- **FILLFACTOR**
  The fillfactor for an index is a percentage that determines how full the index method will try to pack index pages. For B-trees, leaf pages are filled to this percentage during initial index build, and also when extending the index at the right (largest key values). If pages subsequently become completely full, they will be split, leading to gradual degradation in the index's efficiency.

  B-trees use a default fillfactor of 90, but any value from 10 to 100 can be selected. If the table is static then fillfactor 100 is best to minimize the index's physical size, but for heavily updated tables a smaller fillfactor is better to minimize the need for page splits. The other index methods use fillfactor in different but roughly analogous ways; the default fillfactor varies between methods.
Notes
These operations are also possible using ALTER TABLE.
Changing any part of a system catalog index is not permitted.

Examples
To rename an existing index:

```sql
ALTER INDEX distributors RENAME TO suppliers;
```

To move an index to a different tablespace:

```sql
ALTER INDEX distributors SET TABLESPACE fasttablespace;
```

To change an index's fill factor (assuming that the index method supports it):

```sql
ALTER INDEX distributors SET (fillfactor = 75);
REINDEX INDEX distributors;
```

Compatibility
ALTER INDEX is a Greenplum Database extension.

See Also
CREATE INDEX, REINDEX, ALTER TABLE

**ALTER LANGUAGE**
Changes the name of a procedural language.

Synopsis

```sql
ALTER LANGUAGE name RENAME TO newname
ALTER LANGUAGE name OWNER TO new_owner
```

Description
ALTER LANGUAGE changes the definition of a procedural language for a specific database. Definition changes supported include renaming the language or assigning a new owner. You must be superuser or the owner of the language to use ALTER LANGUAGE.

Parameters

- `name`
  Name of a language.

- `newname`
  The new name of the language.

- `new_owner`
  The new owner of the language.

Compatibility
There is no ALTER LANGUAGE statement in the SQL standard.
ALTER OPERATOR

Changes the definition of an operator.

Synopsis

```
ALTER OPERATOR name ( {lefttype | NONE} , {righttype | NONE} )
OWNER TO newowner
```

Description

ALTER OPERATOR changes the definition of an operator. The only currently available functionality is to change the owner of the operator.

You must own the operator to use ALTER OPERATOR. To alter the owner, you must also be a direct or indirect member of the new owning role, and that role must have CREATE privilege on the operator's schema. (These restrictions enforce that altering the owner does not do anything you could not do by dropping and recreating the operator. However, a superuser can alter ownership of any operator anyway.)

Parameters

- **name**
  The name (optionally schema-qualified) of an existing operator.

- **lefttype**
  The data type of the operator's left operand; write NONE if the operator has no left operand.

- **righttype**
  The data type of the operator's right operand; write NONE if the operator has no right operand.

- **newowner**
  The new owner of the operator.

Examples

Change the owner of a custom operator `a @@ b` for type `text`:

```
ALTER OPERATOR @@ (text, text) OWNER TO joe;
```

Compatibility

There is no ALTEROPERATOR statement in the SQL standard.

See Also

- CREATE OPERATOR, DROP OPERATOR
- ALTER OPERATOR CLASS

ALTER OPERATOR CLASS

Changes the definition of an operator class.
Synopsis

ALTER OPERATOR CLASS name USING index_method RENAME TO newname

ALTER OPERATOR CLASS name USING index_method OWNER TO newowner

Description

ALTER OPERATOR CLASS changes the definition of an operator class. You must own the operator class to use ALTER OPERATOR CLASS. To alter the owner, you must also be a direct or indirect member of the new owning role, and that role must have CREATE privilege on the operator class’s schema. (These restrictions enforce that altering the owner does not do anything you could not do by dropping and recreating the operator class. However, a superuser can alter ownership of any operator class anyway.)

Parameters

name
   The name (optionally schema-qualified) of an existing operator class.

index_method
   The name of the index method this operator class is for.

newname
   The new name of the operator class.

newowner
   The new owner of the operator class

Compatibility

There is no ALTER OPERATOR CLASS statement in the SQL standard.

See Also

CREATE OPERATOR CLASS, DROP OPERATOR CLASS

ALTER OPERATOR FAMILY

Changes the definition of an operator family.

Synopsis

ALTER OPERATOR FAMILY name USING index_method ADD
   {  OPERATOR strategy_number operator_name ( op_type , op_type ) [ RECHECK ]
   | FUNCTION support_number [ ( op_type [ , op_type ] ) ] funcname
   ( argument_type [ , ... ] )
   } [, ... ]

ALTER OPERATOR FAMILY name USING index_method DROP
   {  OPERATOR strategy_number ( op_type , op_type )
   | FUNCTION support_number [ ( op_type [ , op_type ] ) ]
   } [, ... ]

ALTER OPERATOR FAMILY name USING index_method RENAME TO newname

ALTER OPERATOR FAMILY name USING index_method OWNER TO newowner
Description

`ALTER OPERATOR FAMILY` changes the definition of an operator family. You can add operators and support functions to the family, remove them from the family, or change the family's name or owner.

When operators and support functions are added to a family with `ALTER OPERATOR FAMILY`, they are not part of any specific operator class within the family, but are just "loose" within the family. This indicates that these operators and functions are compatible with the family's semantics, but are not required for correct functioning of any specific index. (Operators and functions that are so required should be declared as part of an operator class, instead; see `CREATE OPERATOR CLASS`.) You can drop loose members of a family from the family at any time, but members of an operator class cannot be dropped without dropping the whole class and any indexes that depend on it. Typically, single-data-type operators and functions are part of operator classes because they are needed to support an index on that specific data type, while cross-data-type operators and functions are made loose members of the family.

You must be a superuser to use `ALTER OPERATOR FAMILY`. (This restriction is made because an erroneous operator family definition could confuse or even crash the server.)

`ALTER OPERATOR FAMILY` does not presently check whether the operator family definition includes all the operators and functions required by the index method, nor whether the operators and functions form a self-consistent set. It is the user's responsibility to define a valid operator family.

`OPERATOR` and `FUNCTION` clauses can appear in any order.

Parameters

- `name`
  The name (optionally schema-qualified) of an existing operator family.

- `index_method`
  The name of the index method this operator family is for.

- `strategy_number`
  The index method's strategy number for an operator associated with the operator family.

- `operator_name`
  The name (optionally schema-qualified) of an operator associated with the operator family.

- `op_type`
  In an `OPERATOR` clause, the operand data type(s) of the operator, or `NONE` to signify a left-unary or right-unary operator. Unlike the comparable syntax in `CREATE OPERATOR CLASS`, the operand data types must always be specified. In an `ADD FUNCTION` clause, the operand data type(s) the function is intended to support, if different from the input data type(s) of the function. For B-tree and hash indexes it is not necessary to specify `op_type` since the function's input data type(s) are always the correct ones to use. For `GIN` indexes it is necessary to specify the input data type the function is to be used with. In a `DROP FUNCTION` clause, the operand data type(s) the function is intended to support must be specified.

- `RECHECK`
  If present, the index is "lossy" for this operator, and so the rows retrieved using the index must be rechecked to verify that they actually satisfy the qualification clause involving this operator.

- `support_number`
  The index method's support procedure number for a function associated with the operator family.

- `funcname`
  The name (optionally schema-qualified) of a function that is an index method support procedure for the operator family.
argument_types
The parameter data type(s) of the function.

casename
The new name of the operator family.

caseowner
The new owner of the operator family.

Compatibility
There is no ALTER OPERATOR FAMILY statement in the SQL standard.

Notes
Notice that the DROP syntax only specifies the "slot" in the operator family, by strategy or support number and input data type(s). The name of the operator or function occupying the slot is not mentioned. Also, for DROP FUNCTION the type(s) to specify are the input data type(s) the function is intended to support; for GiST indexes this might have nothing to do with the actual input argument types of the function.

Because the index machinery does not check access permissions on functions before using them, including a function or operator in an operator family is tantamount to granting public execute permission on it. This is usually not an issue for the sorts of functions that are useful in an operator family.

The operators should not be defined by SQL functions. A SQL function is likely to be inlined into the calling query, which will prevent the optimizer from recognizing that the query matches an index.

Examples
The following example command adds cross-data-type operators and support functions to an operator family that already contains B-tree operator classes for data types int4 and int2.:

ALTER OPERATOR FAMILY integer_ops USING btree ADD

-- int4 vs int2
OPERATOR 1 < (int4, int2),
OPERATOR 2 <= (int4, int2),
OPERATOR 3 = (int4, int2),
OPERATOR 4 >= (int4, int2),
OPERATOR 5 > (int4, int2),
FUNCTION 1 btint42cmp(int4, int2),

-- int2 vs int4
OPERATOR 1 < (int2, int4),
OPERATOR 2 <= (int2, int4),
OPERATOR 3 = (int2, int4),
OPERATOR 4 >= (int2, int4),
OPERATOR 5 > (int2, int4),
FUNCTION 1 btint24cmp(int2, int4);

To remove these entries:

ALTER OPERATOR FAMILY integer_ops USING btree DROP

-- int4 vs int2
OPERATOR 1 (int4, int2),
OPERATOR 2 (int4, int2),
OPERATOR 3 (int4, int2),
OPERATOR 4 (int4, int2),
OPERATOR 5 (int4, int2),
FUNCTION 1 (int4, int2),
ALTER PROTOCOL

Changes the definition of a protocol.

Synopsis

```
ALTER PROTOCOL name RENAME TO newname
ALTER PROTOCOL name OWNER TO newowner
```

Description

ALTER PROTOCOL changes the definition of a protocol. Only the protocol name or owner can be altered.

You must own the protocol to use ALTER PROTOCOL. To alter the owner, you must also be a direct or indirect member of the new owning role, and that role must have CREATE privilege on schema of the conversion.

These restrictions are in place to ensure that altering the owner only makes changes that could by made by dropping and recreating the protocol. Note that a superuser can alter ownership of any protocol.

Parameters

- **name**
  - The name (optionally schema-qualified) of an existing protocol.

- **newname**
  - The new name of the protocol.

- **newowner**
  - The new owner of the protocol.

Examples

To rename the conversion GPDBauth to GPDB_authentication:

```
ALTER PROTOCOL GPDBauth RENAME TO GPDB_authentication;
```

To change the owner of the conversion GPDB_authentication to joe:

```
ALTER PROTOCOL GPDB_authentication OWNER TO joe;
```

Compatibility

There is no ALTER PROTOCOL statement in the SQL standard.
ALTER RESOURCE GROUP

Changes the limits of a resource group.

Synopsis

```
ALTER RESOURCE GROUP name SET group_attribute value
```

where `group_attribute` is one of:

- `CONCURRENCY integer`
- `CPU_RATE_LIMIT integer`
- `CPUSET tuple`
- `MEMORY_LIMIT integer`
- `MEMORY_SHARED_QUOTA integer`
- `MEMORY_SPILL_RATIO integer`

Description

`ALTER RESOURCE GROUP` changes the limits of a resource group. Only a superuser can alter a resource group.

You can set or reset the concurrency limit of a resource group that you create for roles to control the maximum number of active concurrent statements in that group. You can also reset the memory or CPU resources of a resource group to control the amount of memory or CPU resources that all queries submitted through the group can consume on each segment host.

When you alter the CPU resource management mode or limit of a resource group, the new mode or limit is immediately applied.

When you alter a memory limit of a resource group that you create for roles, the new resource limit is immediately applied if current resource usage is less than or equal to the new value and there are no running transactions in the resource group. If the current resource usage exceeds the new memory limit value, or if there are running transactions in other resource groups that hold some of the resource, then Greenplum Database defers assigning the new limit until resource usage falls within the range of the new value.

When you increase the memory limit of a resource group that you create for external components, the new resource limit is phased in as system memory resources become available. If you decrease the memory limit of a resource group that you create for external components, the behavior is component-specific. For example, if you decrease the memory limit of a resource group that you create for a PL/Container runtime, queries in a running container may fail with an out of memory error.

You can alter one limit type in a single `ALTER RESOURCE GROUP` call.

Parameters

- `name`
  The name of the resource group to alter.
- `CONCURRENCY integer`
  The maximum number of concurrent transactions, including active and idle transactions, that are permitted for resource groups that you assign to roles. Any transactions submitted after the `CONCURRENCY` value limit is reached are queued. When a running transaction completes, the earliest queued transaction is executed.
The `CONCURRENCY` value must be an integer in the range \([0..\text{max\_connections}]\). The default `CONCURRENCY` value for a resource group that you create for roles is 20.

**Note:** You cannot set the `CONCURRENCY` value for the `admin_group` to zero (0).

**CPU_RATE_LIMIT** `integer`

The percentage of CPU resources to allocate to this resource group. The minimum CPU percentage for a resource group is 1. The maximum is 100. The sum of the `CPU_RATE_LIMIITS` of all resource groups defined in the Greenplum Database cluster must not exceed 100.

If you alter the `CPU_RATE_LIMIT` of a resource group in which you previously configured a `CPUSET`, `CPUSET` is disabled, the reserved CPU cores are returned to Greenplum Database, and `CPUSET` is set to -1.

**CPUSET** `tuple`

The CPU cores to reserve for this resource group. The CPU cores that you specify in `tuple` must be available in the system and cannot overlap with any CPU cores that you specify for other resource groups.

`tuple` is a comma-separated list of single core numbers or core intervals. You must enclose `tuple` in single quotes, for example, ‘1,3-4’.

If you alter the `CPUSET` value of a resource group for which you previously configured a `CPU_RATE_LIMIT`, `CPU_RATE_LIMIT` is disabled, the reserved CPU resources are returned to Greenplum Database, and `CPU_RATE_LIMIT` is set to -1.

You can alter `CPUSET` for a resource group only after you have enabled resource group-based resource management for your Greenplum Database cluster.

**MEMORY_LIMIT** `integer`

The percentage of Greenplum Database memory resources to reserve for this resource group. The minimum memory percentage for a resource group is 0. The maximum is 100.

When `MEMORY_LIMIT` is 0, Greenplum Database reserves no memory for the resource group, but uses global shared memory to fulfill all memory requests in the group. If `MEMORY_LIMIT` is 0, `MEMORY_SPILL_RATIO` must also be 0.

The sum of the `MEMORY_LIMIT`s of all resource groups defined in the Greenplum Database cluster must not exceed 100. If this sum is less than 100, Greenplum Database allocates any unreserved memory to a resource group global shared memory pool.

**MEMORY_SHARED_QUOTA** `integer`

The percentage of memory resources to share among transactions in the resource group. The minimum memory shared quota percentage for a resource group is 0. The maximum is 100. The default `MEMORY_SHARED_QUOTA` value is 20.

**MEMORY_SPILL_RATIO** `integer`

The memory usage threshold for memory-intensive operators in a transaction. You can specify an integer percentage value from 0 to 100 inclusive. The default `MEMORY_SPILL_RATIO` value is 20. When `MEMORY_SPILL_RATIO` is 0, Greenplum Database uses the `statement_mem` server configuration parameter value to control initial query operator memory.

**Notes**

Use `CREATE ROLE` or `ALTER ROLE` to assign a specific resource group to a role (user).

You cannot submit an `ALTER RESOURCE GROUP` command in an explicit transaction or sub-transaction.
**Examples**

Change the active transaction limit for a resource group:

```
ALTER RESOURCE GROUP rgroup1 SET CONCURRENCY 13;
```

Update the CPU limit for a resource group:

```
ALTER RESOURCE GROUP rgroup2 SET CPU_RATE_LIMIT 45;
```

Update the memory limit for a resource group:

```
ALTER RESOURCE GROUP rgroup3 SET MEMORY_LIMIT 30;
```

Update the memory spill ratio for a resource group:

```
ALTER RESOURCE GROUP rgroup4 SET MEMORY_SPILL_RATIO 25;
```

Reserve CPU core 1 for a resource group:

```
ALTER RESOURCE GROUP rgroup5 SET CPUSET '1';
```

**Compatibility**

The `ALTER RESOURCE GROUP` statement is a Greenplum Database extension. This command does not exist in standard PostgreSQL.

**See Also**

`CREATE RESOURCE GROUP`, `DROP RESOURCE GROUP`, `CREATE ROLE`, `ALTER ROLE`

---

**ALTER RESOURCE QUEUE**

Changes the limits of a resource queue.

**Synopsis**

```
ALTER RESOURCE QUEUE name WITH ( queue_attribute=value [, ... ] )
```

where `queue_attribute` is:

- `ACTIVE_STATEMENTS`\(=\)integer
- `MEMORY_LIMIT`\(=\)'memory_units'
- `MAX_COST`\(=\)float
- `COST_OVERCOMMIT`\(=\){TRUE|FALSE}
- `MIN_COST`\(=\)float
- `PRIORITY`\(=\){MIN|LOW|MEDIUM|HIGH|MAX}

```
ALTER RESOURCE QUEUE name WITHOUT ( queue_attribute [, ... ] )
```

where `queue_attribute` is:

- `ACTIVE_STATEMENTS`
- `MEMORY_LIMIT`
- `MAX_COST`
- `COST_OVERCOMMIT`
- `MIN_COST`
**Note:** A resource queue must have either an `ACTIVE_STATEMENTS` or a `MAX_COST` value. Do not remove both these `queue_attributes` from a resource queue.

**Description**

`ALTER RESOURCE QUEUE` changes the limits of a resource queue. Only a superuser can alter a resource queue. A resource queue must have either an `ACTIVE_STATEMENTS` or a `MAX_COST` value (or it can have both). You can also set or reset priority for a resource queue to control the relative share of available CPU resources used by queries associated with the queue, or memory limit of a resource queue to control the amount of memory that all queries submitted through the queue can consume on a segment host.

`ALTER RESOURCE QUEUE WITHOUT` removes the specified limits on a resource that were previously set. A resource queue must have either an `ACTIVE_STATEMENTS` or a `MAX_COST` value. Do not remove both these `queue_attributes` from a resource queue.

**Parameters**

`name`

The name of the resource queue whose limits are to be altered.

`ACTIVE_STATEMENTS integer`  
The number of active statements submitted from users in this resource queue allowed on the system at any one time. The value for `ACTIVE_STATEMENTS` should be an integer greater than 0. To reset `ACTIVE_STATEMENTS` to have no limit, enter a value of `-1`.

`MEMORY_LIMIT 'memory_units'`  
Sets the total memory quota for all statements submitted from users in this resource queue. Memory units can be specified in kB, MB or GB. The minimum memory quota for a resource queue is 10MB. There is no maximum; however the upper boundary at query execution time is limited by the physical memory of a segment host. The default value is no limit (`-1`).

`MAX_COST float`  
The total query optimizer cost of statements submitted from users in this resource queue allowed on the system at any one time. The value for `MAX_COST` is specified as a floating point number (for example 100.0) or can also be specified as an exponent (for example 1e+2). To reset `MAX_COST` to have no limit, enter a value of `-1.0`.

`COST_OVERCOMMIT boolean`  
If a resource queue is limited based on query cost, then the administrator can allow cost overcommit (`COST_OVERCOMMIT=True`, the default). This means that a query that exceeds the allowed cost threshold will be allowed to run but only when the system is idle. If `COST_OVERCOMMIT=False` is specified, queries that exceed the cost limit will always be rejected and never allowed to run.

`MIN_COST float`  
Queries with a cost under this limit will not be queued and run immediately. Cost is measured in units of disk page fetches; 1.0 equals one sequential disk page read. The value for `MIN_COST` is specified as a floating point number (for example 100.0) or can also be specified as an exponent (for example 1e+2). To reset `MIN_COST` to have no limit, enter a value of `-1.0`.

`PRIORITY={MIN|LOW|MEDIUM|HIGH|MAX}`  
Sets the priority of queries associated with a resource queue. Queries or statements in queues with higher priority levels will receive a larger share of available CPU resources in case of contention. Queries in low-priority queues may be delayed while higher priority queries are executed.
Notes

GPORCA and the legacy Greenplum Database query optimizer utilize different query costing models and may compute different costs for the same query. The Greenplum Database resource queue resource management scheme neither differentiates nor aligns costs between GPORCA and the legacy optimizer; it uses the literal cost value returned from the optimizer to throttle queries.

When resource queue-based resource management is active, use the `MEMORY_LIMIT` and `ACTIVE_STATEMENTS` limits for resource queues rather than configuring cost-based limits. Even when using GPORCA, Greenplum Database may fall back to using the legacy query optimizer for certain queries, so using cost-based limits can lead to unexpected results.

Examples

Change the active query limit for a resource queue:

```
ALTER RESOURCE QUEUE myqueue WITH (ACTIVE_STATEMENTS=20);
```

Change the memory limit for a resource queue:

```
ALTER RESOURCE QUEUE myqueue WITH (MEMORY_LIMIT='2GB');
```

Reset the maximum and minimum query cost limit for a resource queue to no limit:

```
ALTER RESOURCE QUEUE myqueue WITH (MAX_COST=-1.0, MIN_COST= -1.0);
```

Reset the query cost limit for a resource queue to $3^{10}$ (or 30000000000.0) and do not allow overcommit:

```
ALTER RESOURCE QUEUE myqueue WITH (MAX_COST=3e+10, COST_OVERCOMMIT=FALSE);
```

Reset the priority of queries associated with a resource queue to the minimum level:

```
ALTER RESOURCE QUEUE myqueue WITH (PRIORITY=MIN);
```

Remove the `MAX_COST` and `MEMORY_LIMIT` limits from a resource queue:

```
ALTER RESOURCE QUEUE myqueue WITHOUT (MAX_COST, MEMORY_LIMIT);
```

Compatibility

The `ALTER RESOURCE QUEUE` statement is a Greenplum Database extension. This command does not exist in standard PostgreSQL.

See Also

`CREATE RESOURCE QUEUE`, `DROP RESOURCE QUEUE`, `CREATE ROLE`, `ALTER ROLE`

**ALTER ROLE**

Changes a database role (user or group).

Synopsis

```
ALTER ROLE name RENAME TO newname

ALTER ROLE name SET config_parameter {TO | =} (value | DEFAULT)
```
ALTER ROLE name RESET config_parameter
ALTER ROLE name RESOURCE QUEUE {queue_name | NONE}
ALTER ROLE name RESOURCE GROUP {group_name | NONE}
ALTER ROLE name [ [WITH] option [ ... ] ]

where option can be:

SUPERUSER | NOSUPERUSER
CREATEDB | NOCREATEDB
CREATEROLE | NOCREATEROLE
CREATEUSER | NOCREATEUSER
CREATEEXTABLE | NOCREATEEXTABLE
[ ( attribute='value', [ , ... ] ) ]
  where attributes and value are:
type='readable' | 'writable'
protocol='gpfdist' | 'http'
INHERIT | NOINHERIT
LOGIN | NOLOGIN
CONNECTION LIMIT connlimit
[ ENCRYPTED | UNENCRYPTED] PASSWORD 'password'
VALID UNTIL 'timestamp'
[ DENY deny_point ]
[ DENY BETWEEN deny_point AND deny_point]
[ DROP DENY FOR deny_point ]

Description
ALTER ROLE changes the attributes of a Greenplum Database role. There are several variants of this command:

- **RENAME** — Changes the name of the role. Database superusers can rename any role. Roles having CREATEROLE privilege can rename non-superuser roles. The current session user cannot be renamed (connect as a different user to rename a role). Because MD5-encrypted passwords use the role name as cryptographic salt, renaming a role clears its password if the password is MD5-encrypted.

- **SET | RESET** — changes a role’s session default for a specified configuration parameter. Whenever the role subsequently starts a new session, the specified value becomes the session default, overriding whatever setting is present in server configuration file (postgresql.conf). For a role without LOGIN privilege, session defaults have no effect. Ordinary roles can change their own session defaults. Superusers can change anyone’s session defaults. Roles having CREATEROLE privilege can change defaults for non-superuser roles. See the Greenplum Database Administrator Guide for information about all user-settable configuration parameters.

- **RESOURCE QUEUE** — Assigns the role to a resource queue. The role would then be subject to the limits assigned to the resource queue when issuing queries. Specify NONE to assign the role to the default resource queue. A role can only belong to one resource queue. For a role without LOGIN privilege, resource queues have no effect. See CREATE RESOURCE QUEUE for more information.

- **RESOURCE GROUP** — Assigns a resource group to the role. The role would then be subject to the concurrent transaction, memory, and CPU limits configured for the resource group. You can assign a single resource group to one or more roles. You cannot assign a resource group that you create for an external component to a role. See CREATE RESOURCE GROUP for additional information.

- **WITH option** — Changes many of the role attributes that can be specified in CREATE ROLE. Attributes not mentioned in the command retain their previous settings. Database superusers can change any of these settings for any role. Roles having CREATEROLE privilege can change any of these settings, but only for non-superuser roles. Ordinary roles can only change their own password.
Parameters

name
The name of the role whose attributes are to be altered.

newname
The new name of the role.

config_parameter=value
Set this role's session default for the specified configuration parameter to the given value.
If value is DEFAULT or if RESET is used, the role-specific variable setting is removed,
so the role will inherit the system-wide default setting in new sessions. Use RESET ALL
to clear all role-specific settings. See SET and Server Configuration Parameters for
information about user-settable configuration parameters.

group_name
The name of the resource group to assign to this role. Specifying the group_name NONE
removes the role's current resource group assignment and assigns a default resource
group based on the role's capability. SUPERUSER roles are assigned the admin_group
resource group, while the default_group resource group is assigned to non-admin
roles.

You cannot assign a resource group that you create for an external component to a role.

queue_name
The name of the resource queue to which the user-level role is to be assigned. Only roles
with LOGIN privilege can be assigned to a resource queue. To unassign a role from a
resource queue and put it in the default resource queue, specify NONE. A role can only
belong to one resource queue.

SUPERUSER | NOSUPERUSER
CREATEDB | NOCREATEDB
CREATEROLE | NOCREATEROLE
CREATEUSER | NOCREATEUSER

CREATEUSER and NOCREATEUSER are obsolete, but still accepted, spellings of
SUPERUSER and NOSUPERUSER. Note that they are not equivalent to the CREATEROLE
and NOCREATEROLE clauses.

CREATEEXTTABLE | NOCREATEEXTTABLE [(attribute='value')]
If CREATEEXTTABLE is specified, the role being defined is allowed to create external
tables. The default type is readable and the default protocol is gpfdist if not
specified. NOCREATEEXTTABLE (the default) denies the role the ability to create external
tables. Note that external tables that use the file or execute protocols can only be
created by superusers.

INHERIT | NOINHERIT
LOGIN | NOLOGIN
CONNECTION LIMIT conlimit
PASSWORD password
ENCRYPTED | UNENCRYPTED
VALID UNTIL 'timestamp'

These clauses alter role attributes originally set by CREATE ROLE.

DENY deny_point
DENY BETWEEN deny_point AND deny_point

The DENY and DENY BETWEEN keywords set time-based constraints that are enforced at
login. DENY sets a day or a day and time to deny access. DENY BETWEEN sets an interval
during which access is denied. Both use the parameter `deny_point` that has following format:

```
DAY day [ TIME 'time' ]
```

The two parts of the `deny_point` parameter use the following formats:

For day:

```
{'Sunday' | 'Monday' | 'Tuesday' | 'Wednesday' | 'Thursday' | 'Friday' | 'Saturday' | 0-6 }
```

For time:

```
{ 00-23 : 00-59 | 01-12 : 00-59 { AM | PM }}
```

The `DENY BETWEEN` clause uses two `deny_point` parameters.

```
DENY BETWEEN deny_point AND deny_point
```

For more information about time-based constraints and examples, see "Managing Roles and Privileges" in the Greenplum Database Administrator Guide.

**DROP DENY FOR deny_point**

```
DROP DENY FOR deny_point
```

The `DROP DENY FOR` clause removes a time-based constraint from the role. It uses the `deny_point` parameter described above.

For more information about time-based constraints and examples, see "Managing Roles and Privileges" in the Greenplum Database Administrator Guide.

**Notes**

Use `GRANT` and `REVOKE` for adding and removing role memberships.

Caution must be exercised when specifying an unencrypted password with this command. The password will be transmitted to the server in clear text, and it might also be logged in the client's command history or the server log. The `psql` command-line client contains a meta-command `\password` that can be used to safely change a role's password.

It is also possible to tie a session default to a specific database rather than to a role. Role-specific settings override database-specific ones if there is a conflict. See `ALTER DATABASE`.

**Examples**

Change the password for a role:

```
ALTER ROLE daria WITH PASSWORD 'passwd123';
```

Change a password expiration date:

```
ALTER ROLE scott VALID UNTIL 'May 4 12:00:00 2015 +1';
```

Make a password valid forever:

```
ALTER ROLE luke VALID UNTIL 'infinity';
```

Give a role the ability to create other roles and new databases:

```
ALTER ROLE joelle CREATEROLE CREATEDB;
```
Give a role a non-default setting of the `maintenance_work_mem` parameter:

```
ALTER ROLE admin SET maintenance_work_mem = 100000;
```

Assign a role to a resource queue:

```
ALTER ROLE sammy RESOURCE QUEUE poweruser;
```

Give a role permission to create writable external tables:

```
ALTER ROLE load CREATEEXTTABLE (type='writable');
```

Alter a role so it does not allow login access on Sundays:

```
ALTER ROLE user3 DENY DAY 'Sunday';
```

Alter a role to remove the constraint that does not allow login access on Sundays:

```
ALTER ROLE user3 DROP DENY FOR DAY 'Sunday';
```

Assign a new resource group to a role:

```
ALTER ROLE parttime_user RESOURCE GROUP rg_light;
```

**Compatibility**

The `ALTER ROLE` statement is a Greenplum Database extension.

`CREATE ROLE`, `DROP ROLE`, `SET`, `CREATE RESOURCE GROUP`, `CREATE RESOURCE QUEUE`, `GRANT`, `REVOKE`

### ALTER SCHEMA

Changes the definition of a schema.

**Synopsis**

```
ALTER SCHEMA name RENAME TO newname
```

```
ALTER SCHEMA name OWNER TO newowner
```

**Description**

`ALTER SCHEMA` changes the definition of a schema.

You must own the schema to use `ALTER SCHEMA`. To rename a schema you must also have the `CREATE` privilege for the database. To alter the owner, you must also be a direct or indirect member of the new owning role, and you must have the `CREATE` privilege for the database. Note that superusers have all these privileges automatically.

**Parameters**

`name`

The name of an existing schema.

`newname`
The new name of the schema. The new name cannot begin with `pg_`, as such names are reserved for system schemas.

`newowner`

The new owner of the schema.

**Compatibility**

There is no `ALTER SCHEMA` statement in the SQL standard.

**See Also**

`CREATE SCHEMA`, `DROP SCHEMA`

**ALTER SEQUENCE**

Changes the definition of a sequence generator.

**Synopsis**

```
ALTER SEQUENCE name [INCREMENT [ BY ] increment]
[MINVALUE minvalue | NO MINVALUE]
[MAXVALUE maxvalue | NO MAXVALUE]
[RESTART [ WITH ] start]
[CACHE cache] [[ NO ] CYCLE]
[OWNED BY {table.column | NONE}]
```

```
ALTER SEQUENCE name RENAME TO new_name

ALTER SEQUENCE name SET SCHEMA new_schema
```

**Description**

`ALTER SEQUENCE` changes the parameters of an existing sequence generator. Any parameters not specifically set in the `ALTER SEQUENCE` command retain their prior settings.

You must own the sequence to use `ALTER SEQUENCE`. To change a sequence's schema, you must also have `CREATE` privilege on the new schema. Note that superusers have all these privileges automatically.

**Parameters**

`name`

The name (optionally schema-qualified) of a sequence to be altered.

`increment`

The clause `INCREMENT BY increment` is optional. A positive value will make an ascending sequence, a negative one a descending sequence. If unspecified, the old increment value will be maintained.

`minvalue`

`NO MINVALUE`

The optional clause `MINVALUE minvalue` determines the minimum value a sequence can generate. If `NO MINVALUE` is specified, the defaults of 1 and -263-1 for ascending and descending sequences, respectively, will be used. If neither option is specified, the current minimum value will be maintained.

`maxvalue`

`NO MAXVALUE`
The optional clause `MAXVALUE maxvalue` determines the maximum value for the sequence. If `NO MAXVALUE` is specified, the defaults are 263-1 and -1 for ascending and descending sequences, respectively, will be used. If neither option is specified, the current maximum value will be maintained.

`start`

The optional clause `RESTART WITH start` changes the current value of the sequence. Altering the sequence in this manner is equivalent to calling the `setval(sequence, start_val, is_called) function with is_called = false`. The first `nextval()` call after you alter the sequence start value does not increment the sequence and returns `start`.

`cache`

The clause `CACHE cache` enables sequence numbers to be preallocated and stored in memory for faster access. The minimum value is 1 (only one value can be generated at a time, i.e., no cache). If unspecified, the old cache value will be maintained.

`CYCLE`

The optional `CYCLE` key word may be used to enable the sequence to wrap around when the `maxvalue` or `minvalue` has been reached by an ascending or descending sequence. If the limit is reached, the next number generated will be the respective `minvalue` or `maxvalue`.

`NO CYCLE`

If the optional `NO CYCLE` key word is specified, any calls to `nextval()` after the sequence has reached its maximum value will return an error. If neither `CYCLE` or `NO CYCLE` are specified, the old cycle behavior will be maintained.

`OWNED BY table.column`

`OWNED BY NONE`

The `OWNED BY` option causes the sequence to be associated with a specific table column, such that if that column (or its whole table) is dropped, the sequence will be automatically dropped as well. If specified, this association replaces any previously specified association for the sequence. The specified table must have the same owner and be in the same schema as the sequence. Specifying `OWNED BY NONE` removes any existing table column association.

`new_name`

The new name for the sequence.

`new_schema`

The new schema for the sequence.

**Notes**

To avoid blocking of concurrent transactions that obtain numbers from the same sequence, `ALTER SEQUENCE`'s effects on the sequence generation parameters are never rolled back; those changes take effect immediately and are not reversible. However, the `OWNED BY`, `RENAME TO`, and `SET SCHEMA` clauses are ordinary catalog updates and can be rolled back.

`ALTER SEQUENCE` will not immediately affect `nextval()` results in sessions, other than the current one, that have preallocated (cached) sequence values. They will use up all cached values prior to noticing the changed sequence generation parameters. The current session will be affected immediately.

Some variants of `ALTER TABLE` can be used with sequences as well. For example, to rename a sequence use `ALTER TABLE RENAME`. 
Examples

Restart a sequence called `serial` at 105:

```
ALTER SEQUENCE serial RESTART WITH 105;
```

Compatibility

`ALTER SEQUENCE` conforms to the SQL standard, except for the `OWNED BY`, `RENAME TO`, and `SET SCHEMA` clauses, which are Greenplum Database extensions.

COMPRESSTYPE={ZLIB|QUICKLZ|RLE_TYPE|NONE}
COMPRESSLEVEL={0-9}
FILLFACTOR={10-100}
OIDS={TRUE|FALSE}
```

### Description

`ALTER TABLE` changes the definition of an existing table. There are several subforms:

- **ADD COLUMN** — Adds a new column to the table, using the same syntax as `CREATE TABLE`. The `ENCODING` clause is valid only for append-optimized, column-oriented tables.
- **DROP COLUMN** — Drops a column from a table. Note that if you drop table columns that are being used as the Greenplum Database distribution key, the distribution policy for the table will be changed to `DISTRIBUTED RANDOMLY`. Indexes and table constraints involving the column will be automatically dropped as well. You will need to say `CASCADE` if anything outside the table depends on the column (such as views).
- **ALTER COLUMN TYPE** — Changes the data type of a column of a table. Note that you cannot alter column data types that are being used as distribution or partitioning keys. Indexes and simple table constraints involving the column will be automatically converted to use the new column type by reparsing the originally supplied expression. The optional `USING` clause specifies how to compute the new column value from the old. If omitted, the default conversion is the same as an assignment cast from old data type to new. A `USING` clause must be provided if there is no implicit or assignment cast from old to new type.
- **SET/DROP DEFAULT** — Sets or removes the default value for a column. The default values only apply to subsequent `INSERT` commands. They do not cause rows already in the table to change. Defaults may also be created for views, in which case they are inserted into statements on the view before the view’s `ON INSERT` rule is applied.
- **SET/DROP NOT NULL** — Changes whether a column is marked to allow null values or to reject null values. You can only use `SET NOT NULL` when the column contains no null values.
- **SET STATISTICS** — Sets the per-column statistics-gathering target for subsequent `ANALYZE` operations. The target can be set in the range 1 to 1000, or set to -1 to revert to using the system default statistics target (`default_statistics_target`).
- **ADD table_constraint** — Adds a new constraint to a table (not just a partition) using the same syntax as `CREATE TABLE`.
- **DROP CONSTRAINT** — Drops the specified constraint on a table.
- **DISABLE/ENABLE TRIGGER** — Disables or enables trigger(s) belonging to the table. A disabled trigger is still known to the system, but is not executed when its triggering event occurs. For a deferred trigger, the enable status is checked when the event occurs, not when the trigger function is actually executed. One may disable or enable a single trigger specified by name, or all triggers on the table, or only user-created triggers. Disabling or enabling constraint triggers requires superuser privileges.

**Note:** Triggers are not supported in Greenplum Database. Triggers in general have very limited functionality due to the parallelism of Greenplum Database.

- **CLUSTER ON/SET WITHOUT CLUSTER** — Selects or removes the default index for future `CLUSTER` operations. It does not actually re-cluster the table. Note that `CLUSTER` is not the recommended way to physically reorder a table in Greenplum Database because it takes so long. It is better to recreate the table with `CREATE TABLE AS` and order it by the index column(s).

**Note:** `CLUSTER ON` is not supported on append-optimized tables.

- **SET WITHOUT OIDS** — Removes the OID system column from the table. Note that there is no variant of `ALTER TABLE` that allows OIDs to be restored to a table once they have been removed.
• **SET (FILLFACTOR = value) / RESET (FILLFACTOR)** — Changes the fillfactor for the table. The fillfactor for a table is a percentage between 10 and 100. 100 (complete packing) is the default. When a smaller fillfactor is specified, **INSERT** operations pack table pages only to the indicated percentage; the remaining space on each page is reserved for updating rows on that page. This gives **UPDATE** a chance to place the updated copy of a row on the same page as the original, which is more efficient than placing it on a different page. For a table whose entries are never updated, complete packing is the best choice, but in heavily updated tables smaller fillfactors are appropriate. Note that the table contents will not be modified immediately by this command. You will need to rewrite the table to get the desired effects.

• **SET DISTRIBUTED** — Changes the distribution policy of a table. Changes to a hash distribution policy will cause the table data to be physically redistributed on disk, which can be resource intensive.

• **INHERIT parent_table / NO INHERIT parent_table** — Adds or removes the target table as a child of the specified parent table. Queries against the parent will include records of its child table. To be added as a child, the target table must already contain all the same columns as the parent (it could have additional columns, too). The columns must have matching data types, and if they have **NOT NULL** constraints in the parent then they must also have **NOT NULL** constraints in the child. There must also be matching child-table constraints for all **CHECK** constraints of the parent.

• **OWNER** — Changes the owner of the table, sequence, or view to the specified user.

• **SET TABLESPACE** — Changes the table’s tablespace to the specified tablespace and moves the data file(s) associated with the table to the new tablespace. Indexes on the table, if any, are not moved; but they can be moved separately with additional **SET TABLESPACE** commands. See also **CREATE TABLESPACE**. If changing the tablespace of a partitioned table, all child table partitions will also be moved to the new tablespace.

• **RENAME** — Changes the name of a table (or an index, sequence, or view) or the name of an individual column in a table. There is no effect on the stored data. Note that Greenplum Database distribution key columns cannot be renamed.

• **SET SCHEMA** — Moves the table into another schema. Associated indexes, constraints, and sequences owned by table columns are moved as well.

• **ALTER PARTITION | DROP PARTITION | RENAME PARTITION | TRUNCATE PARTITION | ADD PARTITION | SPLIT PARTITION | EXCHANGE PARTITION | SET SUBPARTITION TEMPLATE** — Changes the structure of a partitioned table. In most cases, you must go through the parent table to alter one of its child table partitions.

  **Note:** If you add a partition to a table that has subpartition encodings, the new partition inherits the storage directives for the subpartitions. For more information about the precedence of compression settings, see “Using Compression” in the *Greenplum Database Administrator Guide*.

You must own the table to use **ALTER TABLE**. To change the schema of a table, you must also have **CREATE** privilege on the new schema. To add the table as a new child of a parent table, you must own the parent table as well. To alter the owner, you must also be a direct or indirect member of the new owning role, and that role must have **CREATE** privilege on the table’s schema. A superuser has these privileges automatically.

  **Note:** Memory usage increases significantly when a table has many partitions, if a table has compression, or if the blocksize for a table is large. If the number of relations associated with the table is large, this condition can force an operation on the table to use more memory. For example, if the table is a **CO** table and has a large number of columns, each column is a relation. An operation like **ALTER TABLE** ALTER COLUMN opens all the columns in the table allocates associated buffers. If a **CO** table has 40 columns and 100 partitions, and the columns are compressed and the blocksize is 2 MB (with a system factor of 3), the system attempts to allocate 24 GB, that is (40 × 100) × (2 × 3) MB or 24 GB.

**Parameters**

**ONLY**
Only perform the operation on the table name specified. If the ONLY keyword is not used, the operation will be performed on the named table and any child table partitions associated with that table.

**name**

The name (possibly schema-qualified) of an existing table to alter. If ONLY is specified, only that table is altered. If ONLY is not specified, the table and all its descendant tables (if any) are updated.

**Note:** Constraints can only be added to an entire table, not to a partition. Because of that restriction, the name parameter can only contain a table name, not a partition name.

**column**

Name of a new or existing column. Note that Greenplum Database distribution key columns must be treated with special care. Altering or dropping these columns can change the distribution policy for the table.

**new_column**

New name for an existing column.

**new_name**

New name for the table.

**type**

Data type of the new column, or new data type for an existing column. If changing the data type of a Greenplum distribution key column, you are only allowed to change it to a compatible type (for example, `text` to `varchar` is OK, but `text` to `int` is not).

**table_constraint**

New table constraint for the table. Note that foreign key constraints are currently not supported in Greenplum Database. Also a table is only allowed one unique constraint and the uniqueness must be within the Greenplum Database distribution key.

**constraint_name**

Name of an existing constraint to drop.

**CASCADE**

Automatically drop objects that depend on the dropped column or constraint (for example, views referencing the column).

**RESTRICT**

Refuse to drop the column or constraint if there are any dependent objects. This is the default behavior.

**trigger_name**

Name of a single trigger to disable or enable. Note that Greenplum Database does not support triggers.

**ALL**

Disable or enable all triggers belonging to the table including constraint related triggers. This requires superuser privilege.

**USER**

Disable or enable all user-created triggers belonging to the table.

**index_name**

The index name on which the table should be marked for clustering. Note that CLUSTER is not the recommended way to physically reorder a table in Greenplum Database because it takes so long. It is better to recreate the table with `CREATE TABLE AS` and order it by the index column(s).
**FILLFACTOR**
Set the fillfactor percentage for a table.

**value**
The new value for the FILLFACTOR parameter, which is a percentage between 10 and 100. 100 is the default.

**DISTRIBUTED BY (column) | DISTRIBUTED RANDOMLY**
Specifies the distribution policy for a table. Changing a hash distribution policy will cause the table data to be physically redistributed on disk, which can be resource intensive. If you declare the same hash distribution policy or change from hash to random distribution, data will not be redistributed unless you declare SET WITH (REORGANIZE=true).

**REORGANIZE=true|false**
Use REORGANIZE=true when the hash distribution policy has not changed or when you have changed from a hash to a random distribution, and you want to redistribute the data anyways.

**parent_table**
A parent table to associate or de-associate with this table.

**new_owner**
The role name of the new owner of the table.

**new_tablespace**
The name of the tablespace to which the table will be moved.

**new_schema**
The name of the schema to which the table will be moved.

**parent_table_name**
When altering a partitioned table, the name of the top-level parent table.

**ALTER [DEFAULT] PARTITION**
If altering a partition deeper than the first level of partitions, use ALTER PARTITION clauses to specify which subpartition in the hierarchy you want to alter. For each partition level in the table hierarchy that is above the target partition, specify the partition that is related to the target partition in an ALTER PARTITION clause.

**DROP [DEFAULT] PARTITION**
Drops the specified partition. If the partition has subpartitions, the subpartitions are automatically dropped as well.

**TRUNCATE [DEFAULT] PARTITION**
Truncates the specified partition. If the partition has subpartitions, the subpartitions are automatically truncated as well.

**RENAME [DEFAULT] PARTITION**
Changes the partition name of a partition (not the relation name). Partitioned tables are created using the naming convention: `<parentname>_<level>_prt_<partition_name>`.

**ADD DEFAULT PARTITION**
Adds a default partition to an existing partition design. When data does not match to an existing partition, it is inserted into the default partition. Partition designs that do not have a default partition will reject incoming rows that do not match to an existing partition. Default partitions must be given a name.

**ADD PARTITION**
*partition_element* - Using the existing partition type of the table (range or list), defines the boundaries of new partition you are adding.
name - A name for this new partition.

VALUES - For list partitions, defines the value(s) that the partition will contain.

START - For range partitions, defines the starting range value for the partition. By default, start values are INCLUSIVE. For example, if you declared a start date of '2016-01-01', then the partition would contain all dates greater than or equal to '2016-01-01'. Typically the data type of the START expression is the same type as the partition key column. If that is not the case, then you must explicitly cast to the intended data type.

END - For range partitions, defines the ending range value for the partition. By default, end values are EXCLUSIVE. For example, if you declared an end date of '2016-02-01', then the partition would contain all dates less than but not equal to '2016-02-01'. Typically the data type of the END expression is the same type as the partition key column. If that is not the case, then you must explicitly cast to the intended data type.

WITH - Sets the table storage options for a partition. For example, you may want older partitions to be append-optimized tables and newer partitions to be regular heap tables. See CREATE TABLE for a description of the storage options.

TABLESPACE - The name of the tablespace in which the partition is to be created.

subpartition_spec - Only allowed on partition designs that were created without a subpartition template. Declares a subpartition specification for the new partition you are adding. If the partitioned table was originally defined using a subpartition template, then the template will be used to generate the subpartitions automatically.

EXCHANGE [DEFAULT] PARTITION

Exchanges another table into the partition hierarchy into the place of an existing partition. In a multi-level partition design, you can only exchange the lowest level partitions (those that contain data).

The Greenplum Database server configuration parameter gp_enable_exchange_default_partition controls availability of the EXCHANGE DEFAULT PARTITION clause. The default value for the parameter is off. The clause is not available and Greenplum Database returns an error if the clause is specified in an ALTER TABLE command.

For information about the parameter, see Server Configuration Parameters.

Warning: Before you exchange the default partition, you must ensure the data in the table to be exchanged, the new default partition, is valid for the default partition. For example, the data in the new default partition must not contain data that would be valid in other leaf child partitions of the partitioned table. Otherwise, queries against the partitioned table with the exchanged default partition that are executed by GPORCA might return incorrect results.

WITH TABLE table_name - The name of the table you are swapping into the partition design. You can exchange a table where the table data is stored in the database. For example, the table is created with the CREATE TABLE command.

With the EXCHANGE PARTITION clause, you can also exchange a readable external table (created with the CREATE EXTERNAL TABLE command) into the partition hierarchy in the place of an existing leaf child partition. If you specify a readable external table, you must also specify the WITHOUT VALIDATION clause to skip table validation against the CHECK constraint of the partition you are exchanging.

Exchanging a leaf child partition with an external table is not supported if the partitioned table contains a column with a check constraint or a NOT NULL constraint.

Exchanging a partition with a partitioned table or a child partition of a partitioned table is not supported.
**WITH | WITHOUT VALIDATION** - Validates that the data in the table matches the `CHECK` constraint of the partition you are exchanging. The default is to validate the data against the `CHECK` constraint.

**Warning:** If you specify the `WITHOUT VALIDATION` clause, you must ensure that the data in table that you are exchanging for an existing child leaf partition is valid against the `CHECK` constraints on the partition. Otherwise, queries against the partitioned table might return incorrect results.

**SET SUBPARTITION TEMPLATE**
Modifies the subpartition template for an existing partition. After a new subpartition template is set, all new partitions added will have the new subpartition design (existing partitions are not modified).

**SPLIT DEFAULT PARTITION**
Splits a default partition. In a multi-level partition, only a range partition can be split, not a list partition, and you can only split the lowest level default partitions (those that contain data). Splitting a default partition creates a new partition containing the values specified and leaves the default partition containing any values that do not match to an existing partition.

**AT** - For list partitioned tables, specifies a single list value that should be used as the criteria for the split.

**START** - For range partitioned tables, specifies a starting value for the new partition.

**END** - For range partitioned tables, specifies an ending value for the new partition.

**INTO** - Allows you to specify a name for the new partition. When using the `INTO` clause to split a default partition, the second partition name specified should always be that of the existing default partition. If you do not know the name of the default partition, you can look it up using the `pg_partitions` view.

**SPLIT PARTITION**
Splits an existing partition into two partitions. In a multi-level partition, only a range partition can be split, not a list partition, and you can only split the lowest level partitions (those that contain data).

**AT** - Specifies a single value that should be used as the criteria for the split. The partition will be divided into two new partitions with the split value specified being the starting range for the *latter* partition.

**INTO** - Allows you to specify names for the two new partitions created by the split.

**partition_name**
The given name of a partition. The given partition name is the `partitionname` column value in the `pg_partitions` system view.

**FOR (RANK(number))**
For range partitions, the rank of the partition in the range.

**FOR ('value')**
Specifies a partition by declaring a value that falls within the partition boundary specification. If the value declared with `FOR` matches to both a partition and one of its subpartitions (for example, if the value is a date and the table is partitioned by month and then by day), then `FOR` will operate on the first level where a match is found (for example, the monthly partition). If your intent is to operate on a subpartition, you must declare so as follows: `ALTER TABLE name ALTER PARTITION FOR ('2016-10-01') DROP PARTITION FOR ('2016-10-01');`
Notes

The table name specified in the ALTER TABLE command cannot be the name of a partition within a table.

Take special care when altering or dropping columns that are part of the Greenplum Database distribution key as this can change the distribution policy for the table.

Greenplum Database does not currently support foreign key constraints. For a unique constraint to be enforced in Greenplum Database, the table must be hash-distributed (not DISTRIBUTED RANDOMLY), and all of the distribution key columns must be the same as the initial columns of the unique constraint columns.

Adding a CHECK or NOT NULL constraint requires scanning the table to verify that existing rows meet the constraint.

When a column is added with ADD COLUMN, all existing rows in the table are initialized with the column's default value, or NULL if no DEFAULT clause is specified. Adding a column with a non-null default or changing the type of an existing column will require the entire table to be rewritten. This may take a significant amount of time for a large table; and it will temporarily require double the disk space.

You can specify multiple changes in a single ALTER TABLE command, which will be done in a single pass over the table.

The DROP COLUMN form does not physically remove the column, but simply makes it invisible to SQL operations. Subsequent insert and update operations in the table will store a null value for the column. Thus, dropping a column is quick but it will not immediately reduce the on-disk size of your table, as the space occupied by the dropped column is not reclaimed. The space will be reclaimed over time as existing rows are updated.

The fact that ALTER TYPE requires rewriting the whole table is sometimes an advantage, because the rewriting process eliminates any dead space in the table. For example, to reclaim the space occupied by a dropped column immediately, the fastest way is: ALTER TABLE table ALTER COLUMN anycol TYPE sametype; where anycol is any remaining table column and sametype is the same type that column already has. This results in no semantically-visible change in the table, but the command forces rewriting, which gets rid of no-longer-useful data.

If a table is partitioned or has any descendant tables, it is not permitted to add, rename, or change the type of a column in the parent table without doing the same to the descendants. This ensures that the descendants always have columns matching the parent.

To see the structure of a partitioned table, you can use the view pg_partitions. This view can help identify the particular partitions you may want to alter.

A recursive DROP COLUMN operation will remove a descendant table's column only if the descendant does not inherit that column from any other parents and never had an independent definition of the column. A nonrecursive DROP COLUMN (ALTER TABLE ONLY ... DROP COLUMN) never removes any descendant columns, but instead marks them as independently defined rather than inherited.

The TRIGGER, CLUSTER, OWNER, and TABLESPACE actions never recurse to descendant tables; that is, they always act as though ONLY were specified. Adding a constraint can recurse only for CHECK constraints.

These ALTER PARTITION operations are supported if no data is changed on a partitioned table that contains a leaf child partition that has been exchanged to use an external table Otherwise, an error is returned:

• Adding or dropping a column.
• Changing the data type of column.

These ALTER PARTITION operations are not supported for a partitioned table that contains a leaf child partition that has been exchanged to use an external table:

• Setting a subpartition template.
• Altering the partition properties.
• Creating a default partition.
• Setting a distribution policy.
• Setting or dropping a NOT NULL constraint of column.
• Adding or dropping constraints.
• Splitting an external partition.

Changing any part of a system catalog table is not permitted.

**Examples**

Add a column to a table:

```
ALTER TABLE distributors ADD COLUMN address varchar(30);
```

Rename an existing column:

```
ALTER TABLE distributors RENAME COLUMN address TO city;
```

Rename an existing table:

```
ALTER TABLE distributors RENAME TO suppliers;
```

Add a not-null constraint to a column:

```
ALTER TABLE distributors ALTER COLUMN street SET NOT NULL;
```

Add a check constraint to a table:

```
ALTER TABLE distributors ADD CONSTRAINT zipchk CHECK
  (char_length(zipcode) = 5);
```

Move a table to a different schema:

```
ALTER TABLE myschema.distributors SET SCHEMA yourschema;
```

Add a new partition to a partitioned table:

```
ALTER TABLE sales ADD PARTITION
  START (date '2017-02-01') INCLUSIVE
  END (date '2017-03-01') EXCLUSIVE;
```

Add a default partition to an existing partition design:

```
ALTER TABLE sales ADD DEFAULT PARTITION other;
```

Rename a partition:

```
ALTER TABLE sales RENAME PARTITION FOR ('2016-01-01') TO jan08;
```

Drop the first (oldest) partition in a range sequence:

```
ALTER TABLE sales DROP PARTITION FOR (RANK(1));
```

Exchange a table into your partition design:

```
ALTER TABLE sales EXCHANGE PARTITION FOR ('2016-01-01') WITH
  TABLE jan08;
```
Split the default partition (where the existing default partition’s name is other) to add a new monthly partition for January 2017:

```
ALTER TABLE sales SPLIT DEFAULT PARTITION
START ('2017-01-01') INCLUSIVE
END ('2017-02-01') EXCLUSIVE
INTO (PARTITION jan09, PARTITION other);
```

Split a monthly partition into two with the first partition containing dates January 1-15 and the second partition containing dates January 16-31:

```
ALTER TABLE sales SPLIT PARTITION FOR ('2016-01-01')
AT ('2016-01-16')
INTO (PARTITION jan081to15, PARTITION jan0816to31);
```

For a multi-level partitioned table that consists of three levels, year, quarter, and region, exchange a leaf partition region with the table region_new.

```
ALTER TABLE sales ALTER PARTITION year_1 ALTER PARTITION quarter_4 EXCHANGE
PARTITION region WITH TABLE region_new;
```

In the previous command, the two ALTER PARTITION clauses identify which region partition to exchange. Both clauses are required to identify the specific partition to exchange.

**Compatibility**

The **ADD**, **DROP**, and **SET DEFAULT** forms conform with the SQL standard. The other forms are Greenplum Database extensions of the SQL standard. Also, the ability to specify more than one manipulation in a single **ALTER TABLE** command is an extension.

**ALTER TABLE DROP COLUMN** can be used to drop the only column of a table, leaving a zero-column table. This is an extension of SQL, which disallows zero-column tables.

**See Also**

**CREATE TABLE**, **DROP TABLE**

**ALTER TABLESPACE**

Changes the definition of a tablespace.

**Synopsis**

```
ALTER TABLESPACE name RENAME TO newname

ALTER TABLESPACE name OWNER TO newowner
```

**Description**

**ALTER TABLESPACE** changes the definition of a tablespace.

You must own the tablespace to use **ALTER TABLESPACE**. To alter the owner, you must also be a direct or indirect member of the new owning role. (Note that superusers have these privileges automatically.)

**Parameters**

- **name**
  
The name of an existing tablespace.
The new name of the tablespace. The new name cannot begin with `pg_` or `gp_` (reserved for system tablespaces).

The new owner of the tablespace.

**Examples**

Rename tablespace `index_space` to `fast_raid`:

```
ALTER TABLESPACE index_space RENAME TO fast_raid;
```

Change the owner of tablespace `index_space`:

```
ALTER TABLESPACE index_space OWNER TO mary;
```

**Compatibility**

There is no `ALTER TABLESPACE` statement in the SQL standard.

**See Also**

`CREATE TABLESPACE`, `DROP TABLESPACE`

---

**ALTER TYPE**

Changes the definition of a data type.

**Synopsis**

```
ALTER TYPE name OWNER TO new_owner | SET SCHEMA new_schema
```

**Description**

`ALTER TYPE` changes the definition of an existing type. You can change the owner and the schema of a type.

You must own the type to use `ALTER TYPE`. To change the schema of a type, you must also have `CREATE` privilege on the new schema. To alter the owner, you must also be a direct or indirect member of the new owning role, and that role must have `CREATE` privilege on the type's schema. (These restrictions enforce that altering the owner does not do anything that could be done by dropping and recreating the type. However, a superuser can alter ownership of any type.)

**Parameters**

- `name`
  
  The name (optionally schema-qualified) of an existing type to alter.

- `new_owner`
  
  The user name of the new owner of the type.

- `new_schema`
  
  The new schema for the type.
Examples

To change the owner of the user-defined type email to joe:

```
ALTER TYPE email OWNER TO joe;
```

To change the schema of the user-defined type email to customers:

```
ALTER TYPE email SET SCHEMA customers;
```

Compatibility

There is no ALTER TYPE statement in the SQL standard.

See Also

CREATE TYPE, DROP TYPE

**ALTER USER**

Changes the definition of a database role (user).

Synopsis

```
ALTER USER name RENAME TO newname
ALTER USER name SET config_parameter {TO | =} {value | DEFAULT}
ALTER USER name RESET config_parameter
ALTER USER name RESOURCE QUEUE {queue_name | NONE}
ALTER USER name RESOURCE GROUP {group_name | NONE}
ALTER USER name [ [WITH] option [ ... ] ]
```

where option can be:

```
SUPERUSER | NOSUPERUSER
CREATEDB | NOCREATEDB
CREATEROLE | NOCREATEROLE
CREATEUSER | NOCREATEUSER
CREATEEXTABLE | NOCREATEEXTABLE
[ ( attribute='value'[, ...] ) ]
    where attributes and value are:
        type='readable'|'writable'
        protocol='gpfdist'|'http'
    INHERIT | NOINHERIT
    LOGIN | NOLOGIN
    CONNECTION LIMIT connlimit
    [ENCRYPTED | UNENCRYPTED] PASSWORD 'password'
    VALID UNTIL 'timestamp'
    [ DENY deny_point ]
    [ DENY BETWEEN deny_point AND deny_point]
    [ DROP DENY FOR deny_point ]
```

Description

ALTER USER is an alias for ALTER ROLE. See ALTER ROLE for more information.
Compatibility

The **ALTER USER** statement is a Greenplum Database extension. The SQL standard leaves the definition of users to the implementation.

See Also

**ALTER ROLE**

**ALTER VIEW**

Changes the definition of a view.

Synopsis

```
ALTER VIEW name RENAME TO newname
```

Description

**ALTER VIEW** changes the definition of a view. The only currently available functionality is to rename the view. To execute this command you must be the owner of the view.

Parameters

- **name**
  - The (optionally schema-qualified) name of an existing filespace.
- **newname**
  - The new name of the view.

Notes

Some variants of **ALTER TABLE** can be used with views as well; for example, to rename a view, it is also possible to use **ALTER TABLE RENAME**. To change the schema or owner of a view, you currently must use **ALTER TABLE**.

Examples

Rename the view *myview* to *newview*:

```
ALTER VIEW myview RENAME TO newview;
```

Change the owner of tablespace *myfs*:

```
ALTER FILESPACE myfs OWNER TO dba;
```

Compatibility

**ALTER VIEW** is a Greenplum Database extension of the SQL standard.

**CREATE VIEW**, **DROP VIEW** in the *Greenplum Database Utility Guide*

**ANALYZE**

Collects statistics about a database.
Synopsis

ANALYZE [VERBOSE] [table [ (column [, ...] ) ]]

ANALYZE [VERBOSE] {root_partition|leaf_partition} [ (column [, ...] )]

ANALYZE [VERBOSE] ROOTPARTITION {ALL | root_partition [ (column [, ...] )]}

Description

ANALYZE collects statistics about the contents of tables in the database, and stores the results in the system table `pg_statistic`. Subsequently, Greenplum Database uses these statistics to help determine the most efficient execution plans for queries. For information about the table statistics that are collected, see Notes.

With no parameter, `ANALYZE` collects statistics for every table in the current database. You can specify a table name to collect statistics for a single table. You can specify a set of column names, in which case the statistics only for those columns are collected.

`ANALYZE` does not collect statistics on external tables.

For partitioned tables, `ANALYZE` collects additional statistics, HyperLogLog (HLL) statistics, on the leaf child partitions. HLL statistics are used to derive number of distinct values (NDV) for queries against partitioned tables.

- When aggregating NDV estimates across multiple leaf child partitions, HLL statistics generate a more accurate NDV estimates than the standard table statistics.
- When updating HLL statistics, `ANALYZE` operations are required only on leaf child partitions that have changed. For example, `ANALYZE` is required if the leaf child partition data has changed, or if the leaf child partition has been exchanged with another table. For more information about updating partitioned table statistics, see Notes.

**Important:** If you intend to execute queries on partitioned tables with GPORCA enabled (the default), then you must collect statistics on the root partition of the partitioned table with the `ANALYZE` or `ANALYZE ROOTPARTITION` command. For information about collecting statistics on partitioned tables and when the `ROOTPARTITION` keyword is required, see Notes. For information about GPORCA, see Overview of GPORCA in the Greenplum Database Administrator Guide.

**Note:** You can also use the Greenplum Database utility `analyzedb` to update table statistics. The `analyzedb` utility can update statistics for multiple tables concurrently. The utility can also check table statistics and update statistics only if the statistics are not current or do not exist. For information about the utility, see the Greenplum Database Utility Guide.

Parameters

\{ root_partition | leaf_partition \} [ (column [, ...] ) ]

Collect statistics for partitioned tables including HLL statistics. HLL statistics are collected only on leaf child partitions.

`ANALYZE root_partition`, collects statistics on all leaf child partitions and the root partition.

`ANALYZE leaf_partition`, collects statistics on the leaf child partition.

By default, if you specify a leaf child partition, and all other leaf child partitions have statistics, `ANALYZE` updates the root partition statistics. If not all leaf child partitions have statistics, `ANALYZE` logs information about the leaf child partitions that do not have statistics. For information about when root partition statistics are collected, see Notes.

**ROOTPARTITION** [ALL]

Collect statistics only on the root partition of partitioned tables based on the data in the partitioned table. If possible, `ANALYZE` uses leaf child partition statistics to generate
root partition statistics. Otherwise, \texttt{ANALYZE} collects the statistics by sampling leaf child partition data. Statistics are not collected on the leaf child partitions, the data is only sampled. HLL statistics are not collected.

For information about when the \texttt{ROOTPARTITION} keyword is required, see Notes.

When you specify \texttt{ROOTPARTITION}, you must specify either \texttt{ALL} or the name of a partitioned table.

If you specify \texttt{ALL} with \texttt{ROOTPARTITION}, Greenplum Database collects statistics for the root partition of all partitioned tables in the database. If there are no partitioned tables in the database, a message stating that there are no partitioned tables is returned. For tables that are not partitioned tables, statistics are not collected.

If you specify a table name with \texttt{ROOTPARTITION} and the table is not a partitioned table, no statistics are collected for the table and a warning message is returned.

The \texttt{ROOTPARTITION} clause is not valid with \texttt{VACUUM ANALYZE}. The command \texttt{VACUUM ANALYZE ROOTPARTITION} returns an error.

The time to run \texttt{ANALYZE ROOTPARTITION} is similar to the time to analyze a non-partitioned table with the same data since \texttt{ANALYZE ROOTPARTITION} only samples the leaf child partition data.

For the partitioned table \texttt{sales_curr_yr}, this example command collects statistics only on the root partition of the partitioned table. \texttt{ANALYZE ROOTPARTITION sales_curr_yr;}

This example \texttt{ANALYZE} command collects statistics on the root partition of all the partitioned tables in the database.

\begin{verbatim}
ANALYZE ROOTPARTITION ALL;
\end{verbatim}

\textbf{VERBOSE}

Enables display of progress messages. Enables display of progress messages. When specified, \texttt{ANALYZE} emits this information

- The table that is being processed.
- The query that is executed to generate the sample table.
- The column for which statistics is being computed.
- The queries that are issued to collect the different statistics for a single column.
- The statistics that are collected.

\textbf{table}

The name (possibly schema-qualified) of a specific table to analyze. Defaults to all tables in the current database.

\textbf{column}

The name of a specific column to analyze. Defaults to all columns.

\textbf{Notes}

It is a good idea to run \texttt{ANALYZE} periodically, or just after making major changes in the contents of a table. Accurate statistics helps Greenplum Database choose the most appropriate query plan, and thereby improve the speed of query processing. A common strategy is to run \texttt{VACUUM} and \texttt{ANALYZE} once a day during a low-usage time of day. You can check for tables with missing statistics using the \texttt{gp_stats_missing} view, which is in the \texttt{gp_toolkit} schema:

\begin{verbatim}
SELECT * from gp_toolkit.gp_stats_missing;
\end{verbatim}

\texttt{ANALYZE} requires \texttt{SHARE UPDATE EXCLUSIVE} lock on the target table. This lock conflicts with these locks: \texttt{SHARE UPDATE EXCLUSIVE}, \texttt{SHARE}, \texttt{SHARE ROW EXCLUSIVE}, \texttt{EXCLUSIVE}, \texttt{ACCESS EXCLUSIVE}.
If you run `ANALYZE` on a table that does not contain data, statistics are not collected for the table. For example, if you perform a `TRUNCATE` operation on a table that has statistics, and then run `ANALYZE` on the table, the statistics do not change.

For a partitioned table, specifying which portion of the table to analyze, the root partition or subpartitions (leaf child partition tables) can be useful if the partitioned table has a large number of partitions that have been analyzed and only a few leaf child partitions have changed.

**Note:** When you create a partitioned table with the `CREATE TABLE` command, Greenplum Database creates the table that you specify (the root partition or parent table), and also creates a hierarchy of tables based on the partition hierarchy that you specified (the child tables).

- When you run `ANALYZE` on the root partitioned table, statistics are collected for all the leaf child partitions. Leaf child partitions are the lowest-level tables in the hierarchy of child tables created by Greenplum Database for use by the partitioned table.
- When you run `ANALYZE` on a leaf child partition, statistics are collected only for that leaf child partition and the root partition. If data in the leaf partition has changed (for example, you made significant updates to the leaf child partition data or you exchanged the leaf child partition), then you can run `ANALYZE` on the leaf child partition to collect table statistics. By default, if all other leaf child partitions have statistics, the command updates the root partition statistics.

For example, if you collected statistics on a partitioned table with a large number partitions and then updated data in only a few leaf child partitions, you can run `ANALYZE` only on those partitions to update statistics on the partitions and the statistics on the root partition.

- When you run `ANALYZE` on a child table that is not a leaf child partition, statistics are not collected.

For example, you can create a partitioned table with partitions for the years 2006 to 2016 and subpartitions for each month in each year. If you run `ANALYZE` on the root partition for the year 2013 no statistics are collected. If you run `ANALYZE` on the leaf child partition for March of 2013, statistics are collected only for that leaf child partition.

For a partitioned table that contains a leaf child partition that has been exchanged to use an external table, `ANALYZE` does not collect statistics for the external table partition:

- If `ANALYZE` is run on an external table partition, the partition is not analyzed.
- If `ANALYZE` or `ANALYZE ROOTPARTITION` is run on the root partition, external table partitions are not sampled and root table statistics do not include external table partition.
- If the `VERBOSE` clause is specified, an informational message is displayed: skipping external table.

The Greenplum Database server configuration parameter `optimizer_analyze_root_partition` affects when statistics are collected on the root partition of a partitioned table. If the parameter is `on` (the default), the `ROOTPARTITION` keyword is not required to collect statistics on the root partition when you run `ANALYZE`. Root partition statistics are collected when you run `ANALYZE` on the root partition, or when you run `ANALYZE` on a child leaf partition of the partitioned table and the other child leaf partitions have statistics. If the parameter is `off`, you must run `ANALYZE ROOTPARTITION` to collect root partition statistics.

The statistics collected by `ANALYZE` usually include a list of some of the most common values in each column and a histogram showing the approximate data distribution in each column. One or both of these may be omitted if `ANALYZE` deems them uninteresting (for example, in a unique-key column, there are no common values) or if the column data type does not support the appropriate operators.

For large tables, `ANALYZE` takes a random sample of the table contents, rather than examining every row. This allows even very large tables to be analyzed in a small amount of time. Note, however, that the statistics are only approximate, and will change slightly each time `ANALYZE` is run, even if the actual table contents did not change. This may result in small changes in the planner's estimated costs shown by `EXPLAIN`. In rare situations, this non-determinism will cause the query optimizer to choose a different query plan between runs of `ANALYZE`. To avoid this, raise the amount of statistics collected by `ANALYZE` by adjusting the `default_statistics_target` configuration parameter, or on a column-by-column basis by setting the per-column statistics target with `ALTER TABLE ... ALTER COLUMN ... SET`
STATISTICS (see ALTER TABLE). The target value sets the maximum number of entries in the most-common-value list and the maximum number of bins in the histogram. The default target value is 100, but this can be adjusted up or down to trade off accuracy of planner estimates against the time taken for ANALYZE and the amount of space occupied in pg_statistic. In particular, setting the statistics target to zero disables collection of statistics for that column. It may be useful to do that for columns that are never used as part of the WHERE, GROUP BY, or ORDER BY clauses of queries, since the planner will have no use for statistics on such columns.

The largest statistics target among the columns being analyzed determines the number of table rows sampled to prepare the statistics. Increasing the target causes a proportional increase in the time and space needed to do ANALYZE.

When Greenplum Database performs an ANALYZE operation to collect statistics for a table and detects that all the sampled table data pages are empty (do not contain valid data), Greenplum Database displays a message that a VACUUM FULL operation should be performed. If the sampled pages are empty, the table statistics will be inaccurate. Pages become empty after a large number of changes to the table, for example deleting a large number of rows. A VACUUM FULL operation removes the empty pages and allows an ANALYZE operation to collect accurate statistics.

If there are no statistics for the table, the server configuration parameter gp_enable_relsize_collection controls whether the legacy query optimizer uses a default statistics file or estimates the size of a table using the pg_relation_size function. By default, the legacy optimizer uses the default statistics file to estimate the number of rows if statistics are not available.

**Examples**

Collect statistics for the table mytable:

```
ANALYZE mytable;
```

**Compatibility**

There is no ANALYZE statement in the SQL standard.

**See Also**

ALTER TABLE, EXPLAIN, VACUUM, analyzedb utility in the Greenplum Database Utility Guide.

BEGIN

Starts a transaction block.

**Synopsis**

```
BEGIN [WORK | TRANSACTION] [transaction_mode]
[READ ONLY | READ WRITE]
```

where transaction_mode is one of:

```
ISOLATION LEVEL | {SERIALIZABLE | READ COMMITTED | READ UNCOMMITTED}
```

**Description**

BEGIN initiates a transaction block, that is, all statements after a BEGIN command will be executed in a single transaction until an explicit COMMIT or ROLLBACK is given. By default (without BEGIN), Greenplum Database executes transactions in autocommit mode, that is, each statement is executed in its own transaction and a commit is implicitly performed at the end of the statement (if execution was successful, otherwise a rollback is done).
Statements are executed more quickly in a transaction block, because transaction start/commit requires significant CPU and disk activity. Execution of multiple statements inside a transaction is also useful to ensure consistency when making several related changes: other sessions will be unable to see the intermediate states wherein not all the related updates have been done.

If the isolation level or read/write mode is specified, the new transaction has those characteristics, as if `SET TRANSACTION` was executed.

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>WORK</code></td>
<td>Optional key words. They have no effect.</td>
</tr>
<tr>
<td><code>TRANSACTION</code></td>
<td>Optional key words. They have no effect.</td>
</tr>
<tr>
<td><code>SERIALIZABLE</code></td>
<td>Optional key words. They have no effect.</td>
</tr>
<tr>
<td><code>READ COMMITTED</code></td>
<td>Optional key words. They have no effect.</td>
</tr>
<tr>
<td><code>READ UNCOMMITTED</code></td>
<td>Optional key words. They have no effect.</td>
</tr>
</tbody>
</table>

The SQL standard defines four transaction isolation levels: `READ COMMITTED`, `READ UNCOMMITTED`, and `SERIALIZABLE`, and `REPEATABLE READ`. The default behavior is that a statement can only see rows committed before it began (`READ COMMITTED`). In Greenplum Database `READ UNCOMMITTED` is treated the same as `READ COMMITTED`. `REPEATABLE READ` is not supported; use `SERIALIZABLE` if this behavior is required. `SERIALIZABLE` is the strictest transaction isolation. This level emulates serial transaction execution, as if transactions had been executed one after another, serially, rather than concurrently. Applications using this level must be prepared to retry transactions due to serialization failures.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>READ WRITE</code></td>
<td>Determines whether the transaction is read/write or read-only. Read/write is the default. When a transaction is read-only, the following SQL commands are disallowed: INSERT, UPDATE, DELETE, and COPY FROM if the table they would write to is not a temporary table; all CREATE, ALTER, and DROP commands; GRANT, REVOKE, TRUNCATE; and EXPLAIN ANALYZE and EXECUTE if the command they would execute is among those listed.</td>
</tr>
<tr>
<td><code>READ ONLY</code></td>
<td>Determines whether the transaction is read/write or read-only. Read/write is the default. When a transaction is read-only, the following SQL commands are disallowed: INSERT, UPDATE, DELETE, and COPY FROM if the table they would write to is not a temporary table; all CREATE, ALTER, and DROP commands; GRANT, REVOKE, TRUNCATE; and EXPLAIN ANALYZE and EXECUTE if the command they would execute is among those listed.</td>
</tr>
</tbody>
</table>

**Notes**

`START TRANSACTION` has the same functionality as `BEGIN`.

Use `COMMIT` or `ROLLBACK` to terminate a transaction block.

Issuing `BEGIN` when already inside a transaction block will provoke a warning message. The state of the transaction is not affected. To nest transactions within a transaction block, use savepoints (see `SAVEPOINT`).

**Examples**

To begin a transaction block:

```
BEGIN;
```

To begin a transaction block with the serializable isolation level:

```
BEGIN TRANSACTION ISOLATION LEVEL SERIALIZABLE;
```

**Compatibility**

`BEGIN` is a Greenplum Database language extension. It is equivalent to the SQL-standard command `START TRANSACTION`. 
Incidentally, the **BEGIN** key word is used for a different purpose in embedded SQL. You are advised to be careful about the transaction semantics when porting database applications.

**See Also**

`COMMIT`, `ROLLBACK`, `START TRANSACTION`, `SAVEPOINT`

### CHECKPOINT

Forces a transaction log checkpoint.

**Synopsis**

```
CHECKPOINT
```

**Description**

Write-Ahead Logging (WAL) puts a checkpoint in the transaction log every so often. The automatic checkpoint interval is set per Greenplum Database segment instance by the server configuration parameters `checkpoint_segments` and `checkpoint_timeout`. The `CHECKPOINT` command forces an immediate checkpoint when the command is issued, without waiting for a scheduled checkpoint.

A checkpoint is a point in the transaction log sequence at which all data files have been updated to reflect the information in the log. All data files will be flushed to disk.

Only superusers may call `CHECKPOINT`. The command is not intended for use during normal operation.

**Compatibility**

The `CHECKPOINT` command is a Greenplum Database language extension.

### CLOSE

Closes a cursor.

**Synopsis**

```
CLOSE cursor_name
```

**Description**

`CLOSE` frees the resources associated with an open cursor. After the cursor is closed, no subsequent operations are allowed on it. A cursor should be closed when it is no longer needed.

Every non-holdable open cursor is implicitly closed when a transaction is terminated by `COMMIT` or `ROLLBACK`. A holdable cursor is implicitly closed if the transaction that created it aborts via `ROLLBACK`. If the creating transaction successfully commits, the holdable cursor remains open until an explicit `CLOSE` is executed, or the client disconnects.

**Parameters**

`cursor_name`

The name of an open cursor to close.

**Notes**

Greenplum Database does not have an explicit `OPEN` cursor statement. A cursor is considered open when it is declared. Use the `DECLARE` statement to declare (and open) a cursor.
You can see all available cursors by querying the `pg Cursors` system view.

**Examples**

Close the cursor `portala`:

```sql
CLOSE portala;
```

**Compatibility**

`CLOSE` is fully conforming with the SQL standard.

**See Also**

`DECLARE, FETCH, MOVE`

---

**CLUSTER**

Physically reorders a heap storage table on disk according to an index. Not a recommended operation in Greenplum Database.

**Synopsis**

```
CLUSTER indexname ON tablename
CLUSTER tablename
CLUSTER
```

**Description**

`cluster` orders a heap storage table based on an index. `CLUSTER` is not supported on append-optimized storage tables. Clustering an index means that the records are physically ordered on disk according to the index information. If the records you need are distributed randomly on disk, then the database has to seek across the disk to get the records requested. If those records are stored more closely together, then the fetching from disk is more sequential. A good example for a clustered index is on a date column where the data is ordered sequentially by date. A query against a specific date range will result in an ordered fetch from the disk, which leverages faster sequential access.

Clustering is a one-time operation: when the table is subsequently updated, the changes are not clustered. That is, no attempt is made to store new or updated rows according to their index order. If one wishes, one can periodically recluster by issuing the command again.

When a table is being clustered using this command, Greenplum Database remembers on which index it was clustered. The form `CLUSTER tablename` reclusters the table on the same index that it was clustered before. `CLUSTER` without any parameter reclusters all previously clustered tables in the current database that the calling user owns, or all tables if called by a superuser. This form of `CLUSTER` cannot be executed inside a transaction block.

When a table is being clustered, an `ACCESS EXCLUSIVE` lock is acquired on it. This prevents any other database operations (both reads and writes) from operating on the table until the `CLUSTER` is finished.

**Parameters**

- `indexname`
  - The name of an index.
- `tablename`
  - The name (optionally schema-qualified) of a table.
Notes

In cases where you are accessing single rows randomly within a table, the actual order of the data in the table is unimportant. However, if you tend to access some data more than others, and there is an index that groups them together, you will benefit from using `CLUSTER`. If you are requesting a range of indexed values from a table, or a single indexed value that has multiple rows that match, `CLUSTER` will help because once the index identifies the table page for the first row that matches, all other rows that match are probably already on the same table page, and so you save disk accesses and speed up the query.

During the cluster operation, a temporary copy of the table is created that contains the table data in the index order. Temporary copies of each index on the table are created as well. Therefore, you need free space on disk at least equal to the sum of the table size and the index sizes.

Because the query optimizer records statistics about the ordering of tables, it is advisable to run `ANALYZE` on the newly clustered table. Otherwise, the planner may make poor choices of query plans.

There is another way to cluster data. The `CLUSTER` command reorders the original table by scanning it using the index you specify. This can be slow on large tables because the rows are fetched from the table in index order, and if the table is disordered, the entries are on random pages, so there is one disk page retrieved for every row moved. (Greenplum Database has a cache, but the majority of a big table will not fit in the cache.) The other way to cluster a table is to use a statement such as:

```
CREATE TABLE newtable AS SELECT * FROM table ORDER BY column;
```

This uses the Greenplum Database sorting code to produce the desired order, which is usually much faster than an index scan for disordered data. Then you drop the old table, use `ALTER TABLE ... RENAME` to rename `newtable` to the old name, and recreate the table's indexes. The big disadvantage of this approach is that it does not preserve OIDs, constraints, granted privileges, and other ancillary properties of the table — all such items must be manually recreated. Another disadvantage is that this way requires a sort temporary file about the same size as the table itself, so peak disk usage is about three times the table size instead of twice the table size.

**Note:** `CLUSTER` is not supported with append-optimized tables.

Examples

Cluster the table `employees` on the basis of its index `emp_ind`:

```
CLUSTER emp_ind ON emp;
```

Cluster a large table by recreating it and loading it in the correct index order:

```
CREATE TABLE newtable AS SELECT * FROM table ORDER BY column;
DROP table;
ALTER TABLE newtable RENAME TO table;
CREATE INDEX column_ix ON table (column);
VACUUM ANALYZE table;
```

Compatibility

There is no `CLUSTER` statement in the SQL standard.

See Also

`CREATE TABLE AS, CREATE INDEX`

**COMMENT**

Defines or change the comment of an object.
Synopsis

```
COMMENT ON
{ TABLE object_name |
  COLUMN table_name.column_name |
  AGGREGATE agg_name (agg_type [, ...]) |
  CAST (sourcetype AS targettype) |
  CONSTRAINT constraint_name ON table_name |
  CONVERSION object_name |
  DATABASE object_name |
  DOMAIN object_name |
  FILESPACE object_name |
  FUNCTION func_name ([[argmode] [argname] argtype [, ...]]) |
  INDEX object_name |
  LARGE OBJECT large_object_oid |
  OPERATOR op (leftoperand_type, rightoperand_type) |
  OPERATOR CLASS object_name USING index_method |
  [PROCEDURAL] LANGUAGE object_name |
  RESOURCE QUEUE object_name |
  ROLE object_name |
  RULE rule_name ON table_name |
  SCHEMA object_name |
  SEQUENCE object_name |
  TABLESPACE object_name |
  TRIGGER trigger_name ON table_name |
  TYPE object_name |
  VIEW object_name }
IS 'text'
```

Description

`COMMENT` stores a comment about a database object. To modify a comment, issue a new `COMMENT` command for the same object. Only one comment string is stored for each object. To remove a comment, write `NULL` in place of the text string. Comments are automatically dropped when the object is dropped.

Comments can be easily retrieved with the `psql` meta-commands `\dd`, `\d+`, and `\l+`. Other user interfaces to retrieve comments can be built atop the same built-in functions that `psql` uses, namely `obj_description`, `col_description`, and `shobj_description`.

Parameters

- `object_name`
- `table_name.column_name`
- `agg_name`
- `constraint_name`
- `func_name`
- `op`
- `rule_name`
- `trigger_name`

The name of the object to be commented. Names of tables, aggregates, domains, functions, indexes, operators, operator classes, sequences, types, and views may be schema-qualified.

**Note:** Greenplum Database does not support triggers.

- `agg_type`
  An input data type on which the aggregate function operates. To reference a zero-argument aggregate function, write `*` in place of the list of input data types.

- `sourcetype`
  The name of the source data type of the cast.
**targettype**

The name of the target data type of the cast.

**argmode**

The mode of a function argument: either IN, OUT, INOUT, or VARIADIC. If omitted, the default is IN. Note that COMMENT ON FUNCTION does not actually pay any attention to OUT arguments, since only the input arguments are needed to determine the function’s identity. So it is sufficient to list the IN, INOUT, and VARIADIC arguments.

**argname**

The name of a function argument. Note that COMMENT ON FUNCTION does not actually pay any attention to argument names, since only the argument data types are needed to determine the function’s identity.

**argtype**

The data type(s) of the function’s arguments (optionally schema-qualified), if any.

**large_object_oid**

The OID of the large object.

**PROCEDURAL**

This is a noise word.

**text**

The new comment, written as a string literal; or NULL to drop the comment.

### Notes

There is presently no security mechanism for comments: any user connected to a database can see all the comments for objects in that database (although only superusers can change comments for objects that they do not own). For shared objects such as databases, roles, and tablespaces comments are stored globally and any user connected to any database can see all the comments for shared objects. Therefore, do not put security-critical information in comments.

### Examples

Attach a comment to the table mytable:

```sql
COMMENT ON TABLE mytable IS 'This is my table.';
```

Remove it again:

```sql
COMMENT ON TABLE mytable IS NULL;
```

### Compatibility

There is no COMMENT statement in the SQL standard.

**COMMIT**

Commits the current transaction.

### Synopsis

```sql
COMMIT [WORK | TRANSACTION]
```
Description

`COMMIT` commits the current transaction. All changes made by the transaction become visible to others and are guaranteed to be durable if a crash occurs.

Parameters

```
WORK
TRANSACTION
```

Optional key words. They have no effect.

Notes

Use `ROLLBACK` to abort a transaction.

Issuing `COMMIT` when not inside a transaction does no harm, but it will provoke a warning message.

Examples

To commit the current transaction and make all changes permanent:

```
COMMIT;
```

Compatibility

The SQL standard only specifies the two forms `COMMIT` and `COMMIT WORK`. Otherwise, this command is fully conforming.

See Also

`BEGIN`, `END`, `START TRANSACTION`, `ROLLBACK`

COPY

Copies data between a file and a table.

Synopsis

```
COPY table [(column [, ...])] FROM ('file' | PROGRAM 'command' | STDIN)
[ [WITH]
  [ON SEGMENT]
  [BINARY]
  [OIDS]
  [HEADER]
  [DELIMITER [ AS ] 'delimiter']
  [NULL [ AS ] 'null string']
  [ESCAPE [ AS ] 'escape' | 'OFF']
  [NEWLINE [ AS ] 'LF' | 'CR' | 'CRLF']
  [CSV [QUOTE [ AS ] 'quote']
    [FORCE NOT NULL column [, ...]]
  ]
  [FILL MISSING FIELDS]
  [[LOG ERRORS]
   SEGMENT REJECT LIMIT count [ROWS | PERCENT] ]
]
COPY {table [(column [, ...])] | (query)} TO {'file' | PROGRAM 'command' | STDOUT}
[ [WITH]
  [ON SEGMENT]
  [BINARY]
  [OIDS]
  [HEADER]
```
Description

COPY moves data between Greenplum Database tables and standard file-system files. COPY TO copies the contents of a table to a file (or multiple files based on the segment ID if copying ON SEGMENT), while COPY FROM copies data from a file to a table (appending the data to whatever is in the table already). COPY TO can also copy the results of a SELECT query.

If a list of columns is specified, COPY will only copy the data in the specified columns to or from the file. If there are any columns in the table that are not in the column list, COPY FROM will insert the default values for those columns.

COPY with a file name instructs the Greenplum Database master host to directly read from or write to a file. The file must be accessible to the master host and the name must be specified from the viewpoint of the master host.

When COPY is used with the ON SEGMENT clause, the COPY TO causes segments to create individual segment-oriented files, which remain on the segment hosts. The file argument for ON SEGMENT takes the string literal <SEGID> (required) and uses either the absolute path or the <SEG_DATA_DIR> string literal. When the COPY operation is run, the segment IDs and the paths of the segment data directories are substituted for the string literal values.

The ON SEGMENT clause allows you to copy table data to files on segment hosts for use in operations such as migrating data between clusters or performing a backup. Segment data created by the ON SEGMENT clause can be restored by tools such as gpfdist, which is useful for high speed data loading.

Warning: Use of the ON SEGMENT clause is recommended for expert users only.

When STDIN or STDOUT is specified, data is transmitted via the connection between the client and the master. STDIN and STDOUT cannot be used with the ON SEGMENT clause.

If SEGMENT REJECT LIMIT is used, then a COPY FROM operation will operate in single row error isolation mode. In this release, single row error isolation mode only applies to rows in the input file with format errors — for example, extra or missing attributes, attributes of a wrong data type, or invalid client encoding sequences. Constraint errors such as violation of a NOT NULL, CHECK, or UNIQUE constraint will still be handled in 'all-or-nothing' input mode. The user can specify the number of error rows acceptable (on a per-segment basis), after which the entire COPY FROM operation will be aborted and no rows will be loaded. The count of error rows is per-segment, not per entire load operation. If the per-segment reject limit is not reached, then all rows not containing an error will be loaded and any error rows discarded. To keep error rows for further examination, specify the LOG ERRORS clause to capture error log information. The error information and the row is stored internally in Greenplum Database.

Outputs

On successful completion, a COPY command returns a command tag of the form, where count is the number of rows copied:

COPY count

If running a COPY FROM command in single row error isolation mode, the following notice message will be returned if any rows were not loaded due to format errors, where count is the number of rows rejected:

NOTICE: Rejected count badly formatted rows.
Parameters

table
The name (optionally schema-qualified) of an existing table.

column
An optional list of columns to be copied. If no column list is specified, all columns of the table will be copied.
When copying in text format, the default, a row of data in a column of type `bytea` can be up to 256MB.

query
A `SELECT` or `VALUES` command whose results are to be copied. Note that parentheses are required around the query.

file
The absolute path name of the input or output file.

PROGRAM 'command'
Specify a command to execute. The `command` must be specified from the viewpoint of the Greenplum Database master host system, and must be executable by the Greenplum Database administrator user (`gpadmin`). The `COPY FROM` command reads the input from the standard output of the command, and for the `COPY TO` command, the output is written to the standard input of the command.

The `command` is invoked by a shell. When passing arguments to the shell, strip or escape any special characters that have a special meaning for the shell. For security reasons, it is best to use a fixed command string, or at least avoid passing any user input in the string.
When `ON SEGMENT` is specified, the command must be executable on all Greenplum Database primary segment hosts by the Greenplum Database administrator user (`gpadmin`). The command is executed by each Greenplum segment instance. The `<SEGID>` is required in the `command`.

See the `ON SEGMENT` clause for information about command syntax requirements and the data that is copied when the clause is specified.

STDIN
Specifies that input comes from the client application. The `ON SEGMENT` clause is not supported with STDIN.

STDOUT
Specifies that output goes to the client application. The `ON SEGMENT` clause is not supported with STDOUT.

ON SEGMENT
Specify individual, segment data files on the segment hosts. Each file contains the table data that is managed by the primary segment instance. For example, when copying data to files from a table with a `COPY TO...ON SEGMENT` command, the command creates a file on the segment host for each segment instance on the host. Each file contains the table data that is managed by the segment instance.

The `COPY` command does not copy data from or to mirror segment instances and segment data files.

The keywords `STDIN` and `STDOUT` are not supported with `ON SEGMENT`.
The `<SEG_DATA_DIR>` and `<SEGID>` string literals are used to specify an absolute path and file name with the following syntax:

```
COPY table [TO|FROM] '<SEG_DATA_DIR>/gpdumpname<SEGID>_suffix' ON SEGMENT;
```
**<SEG_DATA_DIR>**

The string literal representing the absolute path of the segment instance data directory for `ON SEGMENT` copying. The angle brackets (< and >) are part of the string literal used to specify the path. `COPY` replaces the string literal with the segment path(s) when `COPY` is run. An absolute path can be used in place of the `<SEG_DATA_DIR>` string literal.

**<SEGID>**

The string literal representing the content ID number of the segment instance to be copied when copying `ON SEGMENT`. `<SEGID>` is a required part of the file name when `ON SEGMENT` is specified. The angle brackets are part of the string literal used to specify the file name.

With `COPY TO`, the string literal is replaced by the content ID of the segment instance when the `COPY` command is run.

With `COPY FROM`, specify the segment instance content ID in the name of the file and place that file on the segment instance host. There must be a file for each primary segment instance on each host. When the `COPY FROM` command is run, the data is copied from the file to the segment instance.

When the `PROGRAM` command clause is specified, the `<SEGID>` string literal is required in the `command`, the `<SEG_DATA_DIR>` string literal is optional. See Examples.

For a `COPY FROM...ON SEGMENT` command, the table distribution policy is checked when data is copied into the table. By default, an error is returned if a data row violates the table distribution policy. You can disable the distribution policy check with the server configuration parameter `gp_enable_segment_copy_checking`. See Notes.

**BINARY**

Causes all data to be stored or read in binary format rather than as text. You cannot specify the `DELIMITER`, `NULL`, or `CSV` options in binary mode. See Binary Format.

When copying in binary format, a row of data can be up to 1GB.

**OIDS**

Specifies copying the OID for each row. (An error is raised if OIDS is specified for a table that does not have OIDs, or in the case of copying a query.)

**delimiter**

The single ASCII character that separates columns within each row (line) of the file. The default is a tab character in text mode, a comma in CSV mode.

**null string**

The string that represents a null value. The default is `\N` (backslash-N) in text mode, and a empty value with no quotes in CSV mode. You might prefer an empty string even in text mode for cases where you don't want to distinguish nulls from empty strings. When using `COPY FROM`, any data item that matches this string will be stored as a null value, so you should make sure that you use the same string as you used with `COPY TO`.

**escape**

Specifies the single character that is used for C escape sequences (such as `\n`, `\t`, `\100`, and so on) and for quoting data characters that might otherwise be taken as row or column delimiters. Make sure to choose an escape character that is not used anywhere in your actual column data. The default escape character is `\` (backslash) for text files or `"` (double quote) for CSV files, however it is possible to specify any other character to represent an escape. It is also possible to disable escaping on text-formatted files by specifying the value `'OFF'` as the escape value. This is very useful for data such as web log data that has many embedded backslashes that are not intended to be escapes.

**NEWLINE**
Specifies the newline used in your data files — LF (Line feed, 0x0A), CR (Carriage return, 0x0D), or CRLF (Carriage return plus line feed, 0x0D 0x0A). If not specified, a Greenplum Database segment will detect the newline type by looking at the first row of data it receives and using the first newline type encountered.

**CSV**

Selects Comma Separated Value (CSV) mode. See CSV Format.

**HEADER**

Specifies that a file contains a header line with the names of each column in the file. On output, the first line contains the column names from the table, and on input, the first line is ignored.

**quote**

Specifies the quotation character in CSV mode. The default is double-quote.

**FORCE QUOTE**

In CSV COPY TO mode, forces quoting to be used for all non-NULL values in each specified column. NULL output is never quoted.

**FORCE NOT NULL**

In CSV COPY FROM mode, process each specified column as though it were quoted and hence not a NULL value. For the default null string in CSV mode (nothing between two delimiters), this causes missing values to be evaluated as zero-length strings.

**FILL MISSING FIELDS**

In COPY FROM more for both TEXT and CSV, specifying FILL MISSING FIELDS will set missing trailing field values to NULL (instead of reporting an error) when a row of data has missing data fields at the end of a line or row. Blank rows, fields with a NOT NULL constraint, and trailing delimiters on a line will still report an error.

**LOG ERRORS**

This is an optional clause that can precede a SEGMENT REJECT LIMIT clause to capture error log information about rows with formatting errors.

Error log information is stored internally and is accessed with the Greenplum Database built-in SQL function gp_read_error_log().

See Notes for information about the error log information and built-in functions for viewing and managing error log information.

**SEGMENT REJECT LIMIT count [ROWS | PERCENT]**

Runs a COPY FROM operation in single row error isolation mode. If the input rows have format errors they will be discarded provided that the reject limit count is not reached on any Greenplum Database segment instance during the load operation. The reject limit count can be specified as number of rows (the default) or percentage of total rows (1-100). If PERCENT is used, each segment starts calculating the bad row percentage only after the number of rows specified by the parameter gp_reject_percent_threshold has been processed. The default for gp_reject_percent_threshold is 300 rows. Constraint errors such as violation of a NOT NULL, CHECK, or UNIQUE constraint will still be handled in 'all-or-nothing' input mode. If the limit is not reached, all good rows will be loaded and any error rows discarded.

**Note:** Greenplum Database limits the initial number of rows that can contain formatting errors if the SEGMENT REJECT LIMIT is not triggered first or is not specified. If the first 1000 rows are rejected, the COPY operation is stopped and rolled back.

The limit for the number of initial rejected rows can be changed with the Greenplum Database server configuration parameter
gp_initial_bad_row_limit. See Server Configuration Parameters for information about the parameter.

**IGNORE EXTERNAL PARTITIONS**

When copying data from partitioned tables, data are not copied from leaf child partitions that are external tables. A message is added to the log file when data are not copied.

If this clause is not specified and Greenplum Database attempts to copy data from a leaf child partition that is an external table, an error is returned.

See the next section "Notes" for information about specifying an SQL query to copy data from leaf child partitions that are external tables.

**Notes**

COPY can only be used with tables, not with external tables or views. However, you can write COPY (SELECT * FROM viewname) TO ...

COPY only deals with the specific table named; it does not copy data to or from child tables. Thus for example COPY table TO shows the same data as SELECT * FROM ONLY table. But COPY (SELECT * FROM table) TO ... can be used to dump all of the data in an inheritance hierarchy.

Similarly, to copy data from a partitioned table with a leaf child partition that is an external table, use an SQL query to select the data to copy. For example, if the table my_sales contains a leaf child partition that is an external table, this command COPY my_sales TO stdout returns an error. This command sends the data to stdout:

```
COPY (SELECT * FROM my_sales ) TO stdout
```

The BINARY keyword causes all data to be stored/read as binary format rather than as text. It is somewhat faster than the normal text mode, but a binary-format file is less portable across machine architectures and Greenplum Database versions. Also, you cannot run COPY FROM in single row error isolation mode if the data is in binary format.

You must have SELECT privilege on the table whose values are read by COPY TO, and INSERT privilege on the table into which values are inserted by COPY FROM. It is sufficient to have column privileges on the columns listed in the command.

Files named in a COPY command are read or written directly by the database server, not by the client application. Therefore, they must reside on or be accessible to the Greenplum Database master host machine, not the client. They must be accessible to and readable or writable by the Greenplum Database system user (the user ID the server runs as), not the client. Only database superusers are permitted to name files with COPY, because this allows reading or writing any file that the server has privileges to access.

COPY FROM will invoke any triggers and check constraints on the destination table. However, it will not invoke rewrite rules. Note that in this release, violations of constraints are not evaluated for single row error isolation mode.

COPY input and output is affected by DateStyle. To ensure portability to other Greenplum Database installations that might use non-default DateStyle settings, DateStyle should be set to ISO before using COPY TO. It is also a good idea to avoid dumping data with IntervalStyle set to sql_standard, because negative interval values might be misinterpreted by a server that has a different setting for IntervalStyle.

Input data is interpreted according to ENCODING option or the current client encoding, and output data is encoded in ENCODING or the current client encoding, even if the data does not pass through the client but is read from or written to a file directly by the server.

When copying XML data from a file in text mode, the server configuration parameter xmloption affects the validation of the XML data that is copied. If the value is content (the default), XML data is validated
as an XML content fragment. If the parameter value is document, XML data is validated as an XML document. If the XML data is not valid, COPY returns an error.

By default, COPY stops operation at the first error. This should not lead to problems in the event of a COPY TO, but the target table will already have received earlier rows in a COPY FROM. These rows will not be visible or accessible, but they still occupy disk space. This may amount to a considerable amount of wasted disk space if the failure happened well into a large COPY FROM operation. You may wish to invoke VACUUM to recover the wasted space. Another option would be to use single row error isolation mode to filter out error rows while still loading good rows.

When a COPY FROM...ON SEGMENT command is run, the server configuration parameter gp_enable_segment_copy_checking controls whether the table distribution policy (from the table DISTRIBUTED clause) is checked when data is copied into the table. The default is to check the distribution policy. An error is returned if the row of data violates the distribution policy for the segment instance. For information about the parameter, see Server Configuration Parameters.

Data from a table that is generated by a COPY TO...ON SEGMENT command can be used to restore table data with COPY FROM...ON SEGMENT. However, data restored to the segments is distributed according to the table distribution policy at the time the files were generated with the COPY TO command. The COPY command might return table distribution policy errors, if you attempt to restore table data and the table distribution policy was changed after the COPY FROM...ON SEGMENT was run.

Note: If you run COPY FROM...ON SEGMENT and the server configuration parameter gp_enable_segment_copy_checking is false, manual redistribution of table data might be required. See the ALTER TABLE clause WITH REORGANIZE.

When you specify the LOG ERRORS clause, Greenplum Database captures errors that occur while reading the external table data. You can view and manage the captured error log data.

- Use the built-in SQL function gp_read_error_log('table_name'). It requires SELECT privilege on table_name. This example displays the error log information for data loaded into table ext_expenses with a COPY command:

```
SELECT * from gp_read_error_log('ext_expenses');
```

For information about the error log format, see Viewing Bad Rows in the Error Log in the Greenplum Database Administrator Guide.

The function returns FALSE if table_name does not exist.

- If error log data exists for the specified table, the new error log data is appended to existing error log data. The error log information is not replicated to mirror segments.

- Use the built-in SQL function gp_truncate_error_log('table_name') to delete the error log data for table_name. It requires the table owner privilege. This example deletes the error log information captured when moving data into the table ext_expenses:

```
SELECT gp_truncate_error_log('ext_expenses');
```

The function returns FALSE if table_name does not exist.

Specify the * wildcard character to delete error log information for existing tables in the current database. Specify the string *.* to delete all database error log information, including error log information that was not deleted due to previous database issues. If * is specified, database owner privilege is required. If *.* is specified, operating system super-user privilege is required.

When a Greenplum Database user who is not a superuser runs a COPY command, the command can be controlled by a resource queue. The resource queue must be configured with the ACTIVE_STATEMENTS parameter that specifies a maximum limit on the number of queries that can be executed by roles assigned to that queue. Greenplum Database does not apply a cost value or memory value to a COPY command, resource queues with only cost or memory limits do not affect the running of COPY commands.

A non-superuser can run only these types of COPY commands:
• COPY FROM command where the source is stdin
• COPY TO command where the destination is stdout

For information about resource queues, see "Resource Management with Resource Queues" in the Greenplum Database Administrator Guide.

File Formats

File formats supported by COPY.

Text Format

When COPY is used without the BINARY or CSV options, the data read or written is a text file with one line per table row. Columns in a row are separated by the delimiter character (tab by default). The column values themselves are strings generated by the output function, or acceptable to the input function, of each attribute's data type. The specified null string is used in place of columns that are null. COPY FROM will raise an error if any line of the input file contains more or fewer columns than are expected. If OIDS is specified, the OID is read or written as the first column, preceding the user data columns.

The data file has two reserved characters that have special meaning to COPY:

• The designated delimiter character (tab by default), which is used to separate fields in the data file.
• A UNIX-style line feed (\n or 0x0a), which is used to designate a new row in the data file. It is strongly recommended that applications generating COPY data convert data line feeds to UNIX-style line feeds rather than Microsoft Windows style carriage return line feeds (\r\n or 0x0a 0x0d).

If your data contains either of these characters, you must escape the character so COPY treats it as data and not as a field separator or new row.

By default, the escape character is a \ (backslash) for text-formatted files and a " (double quote) for csv-formatted files. If you want to use a different escape character, you can do so using the ESCAPE AS clause. Make sure to choose an escape character that is not used anywhere in your data file as an actual data value. You can also disable escaping in text-formatted files by using ESCAPE 'OFF'.

For example, suppose you have a table with three columns and you want to load the following three fields using COPY.

• percentage sign = %
• vertical bar = |
• backslash = \n
Your designated delimiter character is | (pipe character), and your designated escape character is * (asterisk). The formatted row in your data file would look like this:

percentage sign = % | vertical bar = *| | backslash = \n
Notice how the pipe character that is part of the data has been escaped using the asterisk character (*). Also notice that we do not need to escape the backslash since we are using an alternative escape character.

The following characters must be preceded by the escape character if they appear as part of a column value: the escape character itself, newline, carriage return, and the current delimiter character. You can specify a different escape character using the ESCAPE AS clause.

CSV Format

This format is used for importing and exporting the Comma Separated Value (CSV) file format used by many other programs, such as spreadsheets. Instead of the escaping used by Greenplum Database standard text mode, it produces and recognizes the common CSV escaping mechanism.

The values in each record are separated by the delimiter character. If the value contains the delimiter character, the quote character, the escape character (which is double quote by default), the null string, a carriage return, or line feed character, then the whole value is prefixed and suffixed by the quote
character. You can also use `FORCE QUOTE` to force quotes when outputting non-`NULL` values in specific columns.

The CSV format has no standard way to distinguish a `NULL` value from an empty string. Greenplum Database `COPY` handles this by quoting. A `NULL` is output as the `NULL` string and is not quoted, while a data value matching the `NULL` string is quoted. Therefore, using the default settings, a `NULL` is written as an unquoted empty string, while an empty string is written with double quotes (""). Reading values follows similar rules. You can use `FORCE NOT NULL` to prevent `NULL` input comparisons for specific columns.

Because backslash is not a special character in the CSV format, \\, the end-of-data marker, could also appear as a data value. To avoid any misinterpretation, a \\ data value appearing as a lone entry on a line is automatically quoted on output, and on input, if quoted, is not interpreted as the end-of-data marker. If you are loading a file created by another application that has a single unquoted column and might have a value of \\, you might need to quote that value in the input file.

**Note:** In CSV mode, all characters are significant. A quoted value surrounded by white space, or any characters other than `DELIMITER`, will include those characters. This can cause errors if you import data from a system that pads CSV lines with white space out to some fixed width. If such a situation arises you might need to preprocess the CSV file to remove the trailing white space, before importing the data into Greenplum Database.

CSV mode will both recognize and produce CSV files with quoted values containing embedded carriage returns and line feeds. Thus the files are not strictly one line per table row like text-mode files

**Note:** Many programs produce strange and occasionally perverse CSV files, so the file format is more a convention than a standard. Thus you might encounter some files that cannot be imported using this mechanism, and `COPY` might produce files that other programs cannot process.

**Binary Format**

The `BINARY` format consists of a file header, zero or more tuples containing the row data, and a file trailer. Headers and data are in network byte order.

- **File Header** — The file header consists of 15 bytes of fixed fields, followed by a variable-length header extension area. The fixed fields are:
  - **Signature** — 11-byte sequence `PGCOPY\n\0377\n\0` — note that the zero byte is a required part of the signature. (The signature is designed to allow easy identification of files that have been munged by a non-8-bit-clean transfer. This signature will be changed by end-of-line-translation filters, dropped zero bytes, dropped high bits, or parity changes.)
  - **Flags field** — 32-bit integer bit mask to denote important aspects of the file format. Bits are numbered from 0 (LSB) to 31 (MSB). Note that this field is stored in network byte order (most significant byte first), as are all the integer fields used in the file format. Bits 16-31 are reserved to denote critical file format issues; a reader should abort if it finds an unexpected bit set in this range. Bits 0-15 are reserved to signal backwards-compatible format issues; a reader should simply ignore any unexpected bits set in this range. Currently only one flag is defined, and the rest must be zero (Bit 16: 1 if data has OIDs, 0 if not).
  - **Header extension area length** — 32-bit integer, length in bytes of remainder of header, not including self. Currently, this is zero, and the first tuple follows immediately. Future changes to the format might allow additional data to be present in the header. A reader should silently skip over any header extension data it does not know what to do with. The header extension area is envisioned to contain a sequence of self-identifying chunks. The flags field is not intended to tell readers what is in the extension area. Specific design of header extension contents is left for a later release.
  - **Tuples** — Each tuple begins with a 16-bit integer count of the number of fields in the tuple. (Presently, all tuples in a table will have the same count, but that might not always be true.) Then, repeated for each field in the tuple, there is a 32-bit length word followed by that many bytes of field data. (The length word does not include itself, and can be zero.) As a special case, -1 indicates a NULL field value. No value bytes follow in the NULL case.

There is no alignment padding or any other extra data between fields.
Presently, all data values in a COPY BINARY file are assumed to be in binary format (format code one). It is anticipated that a future extension may add a header field that allows per-column format codes to be specified.

If OIDs are included in the file, the OID field immediately follows the field-count word. It is a normal field except that it is not included in the field-count. In particular it has a length word — this will allow handling of 4-byte vs. 8-byte OIDs without too much pain, and will allow OIDs to be shown as null if that ever proves desirable.

- **File Trailer** — The file trailer consists of a 16-bit integer word containing −1. This is easily distinguished from a tuple's field-count word. A reader should report an error if a field-count word is neither −1 nor the expected number of columns. This provides an extra check against somehow getting out of sync with the data.

### Examples

Copy a table to the client using the vertical bar (|) as the field delimiter:

```
COPY country TO STDOUT WITH DELIMITER '|';
```

Copy data from a file into the `country` table:

```
COPY country FROM '/home/usr1/sql/country_data';
```

Copy into a file just the countries whose names start with 'A':

```
COPY (SELECT * FROM country WHERE country_name LIKE 'A%') TO
'/home/usr1/sql/a_list_countries.copy';
```

Copy data from a file into the `sales` table using single row error isolation mode and log errors:

```
COPY sales FROM '/home/usr1/sql/sales_data' LOG ERRORS
SEGMENT REJECT LIMIT 10 ROWS;
```

To copy segment data for later use, use the `ON SEGMENT` clause. Use of the `COPY TO ON SEGMENT` command takes the form:

```
COPY table TO '<SEG_DATA_DIR>/gpdumpname<SEGID>_suffix' ON SEGMENT;
```

The `<SEGID>` is required. However, you can substitute an absolute path for the `<SEG_DATA_DIR>` string literal in the path.

When you pass in the string literal `<SEG_DATA_DIR>` and `<SEGID>` to COPY, COPY will fill in the appropriate values when the operation is run.

For example, if you have `mytable` with the segments and mirror segments like this:

<table>
<thead>
<tr>
<th>contentid</th>
<th>dbid</th>
<th>file segment location</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>1</td>
<td>/home/usr1/data1/gpsegdir0</td>
</tr>
<tr>
<td>0</td>
<td>3</td>
<td>/home/usr1/data_mirror1/gpsegdir0</td>
</tr>
<tr>
<td>1</td>
<td>4</td>
<td>/home/usr1/data2/gpsegdir1</td>
</tr>
<tr>
<td>1</td>
<td>2</td>
<td>/home/usr1/data_mirror2/gpsegdir1</td>
</tr>
</tbody>
</table>

running the command:

```
COPY mytable TO '<SEG_DATA_DIR>/gpbackup<SEGID>.txt' ON SEGMENT;
```

would result in the following files:

```
/home/usr1/data1/gpsegdir0/gpbackup0.txt
```
The content ID in the first column is the identifier inserted into the file path (for example, `gpsegdir0/gpbackup0.txt` above). Files are created on the segment hosts, rather than on the master, as they would be in a standard `COPY` operation. No data files are created for the mirror segments when using `ON SEGMENT` copying.

If an absolute path is specified, instead of `<SEG_DATA_DIR>`, such as in the statement

```sql
COPY mytable TO '/tmp/gpdir/gpbackup_<SEGID>.txt' ON SEGMENT;
```

files would be placed in `/tmp/gpdir` on every segment. The `gpfdist` tool can also be used to restore data files generated with `COPY TO` with the `ON SEGMENT` option if redistribution is necessary.

**Note:** Tools such as `gpfdist` can be used to restore data. The backup/restore tools will not work with files that were manually generated with `COPY TO ON SEGMENT`.

This example uses a `SELECT` statement to copy data to files on each segment:

```sql
COPY (SELECT * FROM testtbl) TO '/tmp/mytst<SEGID>' ON SEGMENT;
```

This example copies the data from the `lineitem` table and uses the `PROGRAM` clause to add the data to the `/tmp/lineitem_program.csv` file with `cat` utility. The file is placed on the Greenplum Database master.

```sql
COPY LINEITEM TO PROGRAM 'cat > /tmp/lineitem.csv' CSV;
```

This example uses the `PROGRAM` and `ON SEGMENT` clauses to copy data to files on the segment hosts. On the segment hosts, the `COPY` command replaces `<SEGID>` with the segment content ID to create a file for each segment instance on the segment host.

```sql
COPY LINEITEM TO PROGRAM 'cat > /tmp/lineitem_program<SEGID>.csv' ON SEGMENT CSV;
```

This example uses the `PROGRAM` and `ON SEGMENT` clauses to copy data from files on the segment hosts. The `COPY` command replaces `<SEGID>` with the segment content ID when copying data from the files. On the segment hosts, there must be a file for each segment instance where the file name contains the segment content ID on the segment host.

```sql
COPY LINEITEM_4 FROM PROGRAM 'cat /tmp/lineitem_program<SEGID>.csv' ON SEGMENT CSV;
```

**Compatibility**

There is no `COPY` statement in the SQL standard.

`CREATE EXTERNAL TABLE`

**CREATE AGGREGATE**

Defines a new aggregate function.

**Synopsis**

```sql
CREATE [ORDERED] AGGREGATE name (input_data_type [ , ... ]) ( SFUNC = sfunc,
```
### Description

**CREATE AGGREGATE** defines a new aggregate function. Some basic and commonly-used aggregate functions such as `count`, `min`, `max`, `sum`, `avg` and so on are already provided in Greenplum Database. If one defines new types or needs an aggregate function not already provided, then **CREATE AGGREGATE** can be used to provide the desired features.

An aggregate function is identified by its name and input data types. Two aggregate functions in the same schema can have the same name if they operate on different input types. The name and input data types of an aggregate function must also be distinct from the name and input data types of every ordinary function in the same schema.

An aggregate function is made from one, two or three ordinary functions (all of which must be **IMMUTABLE** functions):

- A state transition function `sfunc`
- An optional preliminary segment-level calculation function `prefunc`
- An optional final calculation function `ffunc`

These functions are used as follows:

```
sfunc( internal-state, next-data-values ) ---> next-internal-state
prefunc( internal-state, internal-state ) ---> next-internal-state
ffunc( internal-state ) ---> aggregate-value
```

You can specify `PREFUNC` as method for optimizing aggregate execution. By specifying `PREFUNC`, the aggregate can be executed in parallel on segments first and then on the master. When a two-level execution is performed, `SFUNC` is executed on the segments to generate partial aggregate results, and `PREFUNC` is executed on the master to aggregate the partial results from segments. If single-level aggregation is performed, all the rows are sent to the master and `SFUNC` is applied to the rows.

Single-level aggregation and two-level aggregation are equivalent execution strategies. Either type of aggregation can be implemented in a query plan. When you implement the functions `prefunc` and `sfunc`, you must ensure that the invocation of `sfunc` on the segment instances followed by `prefunc` on the master produce the same result as single-level aggregation that sends all the rows to the master and then applies only the `sfunc` to the rows.

Greenplum Database creates a temporary variable of data type `stype` to hold the current internal state of the aggregate function. At each input row, the aggregate argument values are calculated and the state transition function is invoked with the current state value and the new argument values to calculate a new internal state value. After all the rows have been processed, the final function is invoked once to calculate the aggregate return value. If there is no final function then the ending state value is returned as-is.

An aggregate function can provide an optional initial condition, an initial value for the internal state value. This is specified and stored in the database as a value of type text, but it must be a valid external representation of a constant of the state value data type. If it is not supplied then the state value starts out **NULL**.

If the state transition function is declared **STRICT**, then it cannot be called with **NULL** inputs. With such a transition function, aggregate execution behaves as follows. Rows with any null input values are ignored (the function is not called and the previous state value is retained). If the initial state value is **NULL**, then at the first row with all non-null input values, the first argument value replaces the state value, and the transition function is invoked at subsequent rows with all non-null input values. This is useful for implementing aggregates like `max`. Note that this behavior is only available when `state_data_type` is
the same as the first input_data_type. When these types are different, you must supply a non-null initial condition or use a nonstrict transition function.

If the state transition function is not declared STRICT, then it will be called unconditionally at each input row, and must deal with NULL inputs and NULL transition values for itself. This allows the aggregate author to have full control over the aggregate handling of NULL values.

If the final function is declared STRICT, then it will not be called when the ending state value is NULL; instead a NULL result will be returned automatically. (This is the normal behavior of STRICT functions.) In any case the final function has the option of returning a NULL value. For example, the final function for avg returns NULL when it sees there were zero input rows.

Single argument aggregate functions, such as min or max, can sometimes be optimized by looking into an index instead of scanning every input row. If this aggregate can be so optimized, indicate it by specifying a sort operator. The basic requirement is that the aggregate must yield the first element in the sort ordering induced by the operator; in other words:

```sql
SELECT agg(col) FROM tab;
```

must be equivalent to:

```sql
SELECT col FROM tab ORDER BY col USING sortop LIMIT 1;
```

Further assumptions are that the aggregate function ignores NULL inputs, and that it delivers a NULL result if and only if there were no non-null inputs. Ordinarily, a data type’s < operator is the proper sort operator for MIN, and > is the proper sort operator for MAX. Note that the optimization will never actually take effect unless the specified operator is the "less than" or "greater than" strategy member of a B-tree index operator class.

### Ordered Aggregates

If the optional qualification ORDERED appears, the created aggregate function is an ordered aggregate. In this case, the preliminary aggregation function, prefunc cannot be specified.

An ordered aggregate is called with the following syntax.

```
name ( arg [ , ... ] [ORDER BY sortspec [ , ...]])
```

If the optional ORDER BY is omitted, a system-defined ordering is used. The transition function sfunc of an ordered aggregate function is called on its input arguments in the specified order and on a single segment. There is a new column aggordered in the pg_aggregate table to indicate the aggregate function is defined as an ordered aggregate.

### Parameters

- **name**
  
  The name (optionally schema-qualified) of the aggregate function to create.

- **input_data_type**
  
  An input data type on which this aggregate function operates. To create a zero-argument aggregate function, write * in place of the list of input data types. An example of such an aggregate is count(*).

- **sfunc**
  
  The name of the state transition function to be called for each input row. For an N-argument aggregate function, the sfunc must take N+1 arguments, the first being of type state_data_type and the rest matching the declared input data types of the aggregate. The function must return a value of type state_data_type. This function takes the current state value and the current input data values, and returns the next state value.

- **state_data_type**
The data type for the aggregate state value.

prefunc

The name of a preliminary aggregation function. This is a function of two arguments, both of type state_data_type. It must return a value of state_data_type. A preliminary function takes two transition state values and returns a new transition state value representing the combined aggregation. In Greenplum Database, if the result of the aggregate function is computed in a segmented fashion, the preliminary aggregation function is invoked on the individual internal states in order to combine them into an ending internal state.

Note that this function is also called in hash aggregate mode within a segment. Therefore, if you call this aggregate function without a preliminary function, hash aggregate is never chosen. Since hash aggregate is efficient, consider defining preliminary function whenever possible.

ffunc

The name of the final function called to compute the aggregate result after all input rows have been traversed. The function must take a single argument of type state_data_type. The return data type of the aggregate is defined as the return type of this function. If ffunc is not specified, then the ending state value is used as the aggregate result, and the return type is state_data_type.

initial_condition

The initial setting for the state value. This must be a string constant in the form accepted for the data type state_data_type. If not specified, the state value starts out NULL.

sort_operator

The associated sort operator for a MIN- or MAX-like aggregate function. This is just an operator name (possibly schema-qualified). The operator is assumed to have the same input data types as the aggregate function (which must be a single-argument aggregate function).

Notes

The ordinary functions used to define a new aggregate function must be defined first. Note that in this release of Greenplum Database, it is required that the sfunc, ffunc, and prefunc functions used to create the aggregate are defined as IMMUTABLE.

If a user-defined aggregate is used in a window expression, a prefunc function must be defined for the aggregate.

If the value of the Greenplum Database server configuration parameter gp_enable_multiphase_agg is off, only single-level aggregation is performed.

Any compiled code (shared library files) for custom functions must be placed in the same location on every host in your Greenplum Database array (master and all segments). This location must also be in the LD_LIBRARY_PATH so that the server can locate the files.

Example

The following simple example creates an aggregate function that computes the sum of two columns.

Before creating the aggregate function, create two functions that are used as the SFUNC and PREFUNC functions of the aggregate function.

This function is specified as the SFUNC function in the aggregate function.

```sql
CREATE FUNCTION mysfunc_accum(numeric, numeric, numeric)
RETURNS numeric
AS 'select $1 + $2 + $3'
LANGUAGE SQL
IMMUTABLE
```
RETURNS NULL ON NULL INPUT;

This function is specified as the `PREFUNC` function in the aggregate function.

```sql
CREATE FUNCTION mypre_accum(numeric, numeric )
RETURNS numeric
AS 'select $1 + $2'
LANGUAGE SQL
IMMUTABLE
RETURNS NULL ON NULL INPUT;
```

This `CREATE AGGREGATE` command creates the aggregate function that adds two columns.

```sql
CREATE AGGREGATE agg_prefunc(numeric, numeric) (
    SFUNC = mysfunc_accum,
   STYPE = numeric,
    PREFUNC = mypre_accum,
    INITCOND = 0 );
```

The following commands create a table, adds some rows, and runs the aggregate function.

```sql
create table t1 (a int, b int) DISTRIBUTED BY (a);
insert into t1 values
    (10, 1),
    (20, 2),
    (30, 3);
select agg_prefunc(a, b) from t1;
```

This `EXPLAIN` command shows two phase aggregation.

```sql
explain select agg_prefunc(a, b) from t1;
```

**QUERY PLAN**

```
Aggregate (cost=1.10..1.11 rows=1 width=32) -> Gather Motion 2:1 (slice1; segments: 2) (cost=1.04..1.08 rows=1 width=32) -> Aggregate (cost=1.04..1.05 rows=1 width=32) -> Seq Scan on t1 (cost=0.00..1.03 rows=2 width=8) (4 rows)
```

**Compatibility**

`CREATE AGGREGATE` is a Greenplum Database language extension. The SQL standard does not provide for user-defined aggregate functions.

**See Also**

`ALTER AGGREGATE`, `DROP AGGREGATE`, `CREATE FUNCTION`

**CREATE CAST**

Defines a new cast.

**Synopsis**

```sql
CREATE CAST (sourcetype AS targettype)
WITH FUNCTION funcname (argtypes)
[AS ASSIGNMENT | AS IMPLICIT]
```
CREATE CAST (sourcetype AS targettype) WITHOUT FUNCTION
[AS ASSIGNMENT | AS IMPLICIT]

Description

CREATE CAST defines a new cast. A cast specifies how to perform a conversion between two data types. For example,

```sql
SELECT CAST(42 AS text);
```

converts the integer constant 42 to type text by invoking a previously specified function, in this case `text(int4)`. If no suitable cast has been defined, the conversion fails.

Two types may be binary compatible, which means that they can be converted into one another without invoking any function. This requires that corresponding values use the same internal representation. For instance, the types text and varchar are binary compatible.

By default, a cast can be invoked only by an explicit cast request, that is an explicit `CAST(x AS typename)` or `x::: typename` construct.

If the cast is marked AS ASSIGNMENT then it can be invoked implicitly when assigning a value to a column of the target data type. For example, supposing that foo.f1 is a column of type text, then:

```sql
INSERT INTO foo (f1) VALUES (42);
```

will be allowed if the cast from type integer to type text is marked AS ASSIGNMENT, otherwise not. The term assignment cast is typically used to describe this kind of cast.

If the cast is marked AS IMPLICIT then it can be invoked implicitly in any context, whether assignment or internally in an expression. The term implicit cast is typically used to describe this kind of cast. For example, since `||` takes text operands,

```sql
SELECT 'The time is ' || now();
```

will be allowed only if the cast from type timestamp to text is marked AS IMPLICIT. Otherwise, it will be necessary to write the cast explicitly, for example

```sql
SELECT 'The time is ' || CAST(now() AS text);
```

It is wise to be conservative about marking casts as implicit. An overabundance of implicit casting paths can cause Greenplum Database to choose surprising interpretations of commands, or to be unable to resolve commands at all because there are multiple possible interpretations. A good rule of thumb is to make a cast implicitly invokable only for information-preserving transformations between types in the same general type category. For example, the cast from int2 to int4 can reasonably be implicit, but the cast from float8 to int4 should probably be assignment-only. Cross-type-category casts, such as text to int4, are best made explicit-only.

To be able to create a cast, you must own the source or the target data type. To create a binary-compatible cast, you must be superuser.

Parameters

**sourcetype**

The name of the source data type of the cast.

**targettype**

The name of the target data type of the cast.

**funcname(argtypes)**
The function used to perform the cast. The function name may be schema-qualified. If it is not, the function will be looked up in the schema search path. The function's result data type must match the target type of the cast.

Cast implementation functions may have one to three arguments. The first argument type must be identical to the cast's source type. The second argument, if present, must be type int. It receives the type modifier associated with the destination type, or -1 if there is none. The third argument, if present, must be type boolean; it receives true if the cast is an explicit cast, false otherwise. The SQL specification demands different behaviors for explicit and implicit casts in some cases. This argument is supplied for functions that must implement such casts. It is not recommended that you design your own data types this way.

Ordinarily a cast must have different source and target data types. However, it is allowed to declare a cast with identical source and target types if it has a cast implementation function with more than one argument. This is used to represent type-specific length coercion functions in the system catalogs. The named function is used to coerce a value of the type to the type modifier value given by its second argument. (Since the grammar presently permits only certain built-in data types to have type modifiers, this feature is of no use for user-defined target types.)

When a cast has different source and target types and a function that takes more than one argument, it represents converting from one type to another and applying a length coercion in a single step. When no such entry is available, coercion to a type that uses a type modifier involves two steps, one to convert between data types and a second to apply the modifier.

**WITHOUT FUNCTION**
Indicates that the source type and the target type are binary compatible, so no function is required to perform the cast.

**AS ASSIGNMENT**
Indicates that the cast may be invoked implicitly in assignment contexts.

**AS IMPLICIT**
Indicates that the cast may be invoked implicitly in any context.

**Notes**
Note that in this release of Greenplum Database, user-defined functions used in a user-defined cast must be defined as IMMUTABLE. Any compiled code (shared library files) for custom functions must be placed in the same location on every host in your Greenplum Database array (master and all segments). This location must also be in the LD_LIBRARY_PATH so that the server can locate the files.

Remember that if you want to be able to convert types both ways you need to declare casts both ways explicitly.

It is recommended that you follow the convention of naming cast implementation functions after the target data type, as the built-in cast implementation functions are named. Many users are used to being able to cast data types using a function-style notation, that is `typename(x)`.

**Examples**
To create a cast from type text to type int4 using the function `int4(text)` (This cast is already predefined in the system.):

```sql
CREATE CAST (text AS int4) WITH FUNCTION int4(text);
```
Compatibility

The `CREATE CAST` command conforms to the SQL standard, except that SQL does not make provisions for binary-compatible types or extra arguments to implementation functions. `AS IMPLICIT` is a Greenplum Database extension, too.

See Also

`CREATE FUNCTION`, `CREATE TYPE`, `DROP CAST`

**CREATE CONVERSION**

Defines a new encoding conversion.

**Synopsis**

```
CREATE [DEFAULT] CONVERSION name FOR source_encoding TO dest_encoding FROM funcname
```

**Description**

`CREATE CONVERSION` defines a new conversion between character set encodings. Conversion names may be used in the `convert` function to specify a particular encoding conversion. Also, conversions that are marked `DEFAULT` can be used for automatic encoding conversion between client and server. For this purpose, two conversions, from encoding A to B and from encoding B to A, must be defined.

To create a conversion, you must have `EXECUTE` privilege on the function and `CREATE` privilege on the destination schema.

**Parameters**

- **DEFAULT**
  - Indicates that this conversion is the default for this particular source to destination encoding. There should be only one default encoding in a schema for the encoding pair.

- **name**
  - The name of the conversion. The conversion name may be schema-qualified. If it is not, the conversion is defined in the current schema. The conversion name must be unique within a schema.

- **source_encoding**
  - The source encoding name.

- **dest_encoding**
  - The destination encoding name.

- **funcname**
  - The function used to perform the conversion. The function name may be schema-qualified. If it is not, the function will be looked up in the path. The function must have the following signature:

    ```
    conv_proc(
        integer,  -- source encoding ID
        integer,  -- destination encoding ID
        cstring,  -- source string (null terminated C string)
        internal,  -- destination (fill with a null terminated C string)
        integer   -- source string length
    ) RETURNS void;
    ```
Notes
Note that in this release of Greenplum Database, user-defined functions used in a user-defined conversion must be defined as IMMUTABLE. Any compiled code (shared library files) for custom functions must be placed in the same location on every host in your Greenplum Database array (master and all segments). This location must also be in the LD_LIBRARY_PATH so that the server can locate the files.

Examples
To create a conversion from encoding UTF8 to LATIN1 using myfunc:

CREATE CONVERSION myconv FOR 'UTF8' TO 'LATIN1' FROM myfunc;

Compatibility
There is no CREATE CONVERSION statement in the SQL standard.

See Also
ALTER CONVERSION, CREATE FUNCTION, DROP CONVERSION

CREATE DATABASE
Creates a new database.

Synopsis

CREATE DATABASE name [ [WITH] [OWNER [=] dbowner] [TEMPLATE [=] template] [ENCODING [=] encoding] [TABLESPACE [=] tablespace] [CONNECTION LIMIT [=] conllimit ] ]

Description
CREATE DATABASE creates a new database. To create a database, you must be a superuser or have the special CREATEDB privilege.

The creator becomes the owner of the new database by default. Superusers can create databases owned by other users by using the OWNER clause. They can even create databases owned by users with no special privileges. Non-superusers with CREATEDB privilege can only create databases owned by themselves.

By default, the new database will be created by cloning the standard system database template1. A different template can be specified by writing TEMPLATE name. In particular, by writing TEMPLATE template0, you can create a clean database containing only the standard objects predefined by Greenplum Database. This is useful if you wish to avoid copying any installation-local objects that may have been added to template1.

Parameters

name
The name of a database to create.

dbowner
The name of the database user who will own the new database, or DEFAULT to use the default owner (the user executing the command).

template
The name of the template from which to create the new database, or DEFAULT to use the default template (template1).

**encoding**

Character set encoding to use in the new database. Specify a string constant (such as 'SQL_ASCII'), an integer encoding number, or DEFAULT to use the default encoding. For more information, see Character Set Support.

**tablespace**

The name of the tablespace that will be associated with the new database, or DEFAULT to use the template database's tablespace. This tablespace will be the default tablespace used for objects created in this database.

**connlimit**

The maximum number of concurrent connections possible. The default of -1 means there is no limitation.

**Notes**

CREATE DATABASE cannot be executed inside a transaction block.

When you copy a database by specifying its name as the template, no other sessions can be connected to the template database while it is being copied. New connections to the template database are locked out until CREATE DATABASE completes.

The CONNECTION LIMIT is not enforced against superusers.

**Examples**

To create a new database:

```sql
CREATE DATABASE gpdb;
```

To create a database sales owned by user salesapp with a default tablespace of salesspace:

```sql
CREATE DATABASE sales OWNER salesapp TABLESPACE salesspace;
```

To create a database music which supports the ISO-8859-1 character set:

```sql
CREATE DATABASE music ENCODING 'LATIN1';
```

**Compatibility**

There is no CREATE DATABASE statement in the SQL standard. Databases are equivalent to catalogs, whose creation is implementation-defined.

**See Also**

ALTER DATABASE, DROP DATABASE

**CREATE DOMAIN**

Defines a new domain.

**Synopsis**

```sql
CREATE DOMAIN name [AS] data_type [DEFAULT expression] 
[CONSTRAINT constraint_name] 
| NOT NULL | NULL
```
### Description

`CREATE DOMAIN` creates a new domain. A domain is essentially a data type with optional constraints (restrictions on the allowed set of values). The user who defines a domain becomes its owner. The domain name must be unique among the data types and domains existing in its schema.

Domains are useful for abstracting common constraints on fields into a single location for maintenance. For example, several tables might contain email address columns, all requiring the same `CHECK` constraint to verify the address syntax. It is easier to define a domain rather than setting up a column constraint for each table that has an email column.

### Parameters

- **name**
  
  The name (optionally schema-qualified) of a domain to be created.

- **data_type**
  
  The underlying data type of the domain. This may include array specifiers.

- **DEFAULT expression**
  
  Specifies a default value for columns of the domain data type. The value is any variable-free expression (but subqueries are not allowed). The data type of the default expression must match the data type of the domain. If no default value is specified, then the default value is the null value. The default expression will be used in any insert operation that does not specify a value for the column. If a default value is defined for a particular column, it overrides any default associated with the domain. In turn, the domain default overrides any default value associated with the underlying data type.

- **CONSTRAINT constraint_name**
  
  An optional name for a constraint. If not specified, the system generates a name.

- **NOT NULL**
  
  Values of this domain are not allowed to be null.

- **NULL**
  
  Values of this domain are allowed to be null. This is the default. This clause is only intended for compatibility with nonstandard SQL databases. Its use is discouraged in new applications.

- **CHECK (expression)**
  
  CHECK clauses specify integrity constraints or tests which values of the domain must satisfy. Each constraint must be an expression producing a Boolean result. It should use the key word `VALUE` to refer to the value being tested. Currently, `CHECK` expressions cannot contain subqueries nor refer to variables other than `VALUE`.

### Examples

Create the `us_zip_code` data type. A regular expression test is used to verify that the value looks like a valid US zip code.

```sql
CREATE DOMAIN us_zip_code AS TEXT CHECK
( VALUE ~ '^\d{5}$' OR VALUE ~ '^\d{5}-\d{4}$' );
```

### Compatibility

`CREATE DOMAIN` conforms to the SQL standard.
CREATE EXTENSION

Registers an extension in a Greenplum database.

Synopsis

```
CREATE EXTENSION [ IF NOT EXISTS ] extension_name
  [ WITH ] [ SCHEMA schema_name ]
  [ VERSION version ]
  [ FROM old_version ]
  [ CASCADE ]
```

Description

CREATE EXTENSION loads a new extension into the current database. There must not be an extension of the same name already loaded.

Loading an extension essentially amounts to running the extension script file. The script typically creates new SQL objects such as functions, data types, operators and index support methods. The CREATE EXTENSION command also records the identities of all the created objects, so that they can be dropped again if DROP EXTENSION is issued.

Loading an extension requires the same privileges that would be required to create the component extension objects. For most extensions this means superuser or database owner privileges are required. The user who runs CREATE EXTENSION becomes the owner of the extension for purposes of later privilege checks, as well as the owner of any objects created by the extension script.

Parameters

IF NOT EXISTS

Do not throw an error if an extension with the same name already exists. A notice is issued in this case. There is no guarantee that the existing extension is similar to the extension that would have been installed.

extension_name

The name of the extension to be installed. The name must be unique within the database. An extension is created from the details in the extension control file SHAREDIR/extension/extension_name.control.

SHAREDIR is the installation shared-data directory, for example /usr/local/greenplum-db/share/postgresql. The command pg_config --sharedir displays the directory.

SCHEMA schema_name

The name of the schema in which to install the extension objects. This assumes that the extension allows its contents to be relocated. The named schema must already exist. If not specified, and the extension control file does not specify a schema, the current default object creation schema is used.

If the extension specifies a schema parameter in its control file, then that schema cannot be overridden with a SCHEMA clause. Normally, an error is raised if a SCHEMA clause is given and it conflicts with the extension schema parameter. However, if the CASCADE clause is also given, then schema_name is ignored when it conflicts. The given schema_name is used for the installation of any needed extensions that do not a specify schema in their control files.

See Also

ALTER DOMAIN, DROP DOMAIN
The extension itself is not within any schema: extensions have unqualified names that must be unique within the database. But objects belonging to the extension can be within a schema.

**VERSION version**

The version of the extension to install. This can be written as either an identifier or a string literal. The default version is value that is specified in the extension control file.

**FROM old_version**

Specify FROM old_version only if you are attempting to install an extension that replaces an old-style module that is a collection of objects that is not packaged into an extension. If specified, CREATE EXTENSION runs an alternative installation script that absorbs the existing objects into the extension, instead of creating new objects. Ensure that SCHEMA clause specifies the schema containing these pre-existing objects.

The value to use for old_version is determined by the extension author, and might vary if there is more than one version of the old-style module that can be upgraded into an extension. For the standard additional modules supplied with pre-9.1 PostgreSQL, specify unpackaged for the old_version when updating a module to extension style.

**CASCADE**

Automatically install dependant extensions are not already installed. Dependant extensions are checked recursively and those dependencies are also installed automatically. If the SCHEMA clause is specified, the schema applies to the extension and all dependant extensions that are installed. Other options that are specified are not applied to the automatically-installed dependant extensions. In particular, default versions are always selected when installing dependant extensions.

**Notes**

The extensions currently available for loading can be identified from the pg_available_extensions or pg_available_extension_versions system views.

Before you use CREATE EXTENSION to load an extension into a database, the supporting extension files must be installed including an extension control file and at least one least one SQL script file. The support files must be installed in the same location on all Greenplum Database hosts. For information about creating new extensions, see PostgreSQL information about Packaging Related Objects into an Extension.

**Compatibility**

CREATE EXTENSION is a Greenplum Database extension.

**See Also**

ALTER EXTENSION, DROP EXTENSION

---

**CREATE EXTERNAL TABLE**

Defines a new external table.

**Synopsis**

```
CREATE [READABLE] EXTERNAL [TEMPORARY | TEMP] TABLE table_name
  ( column_name data_type [, ...] | LIKE other_table )
  LOCATION ('file://seghost[:port]/path/file' [, ...])
  | ('gpfdist://filehost[:port]/file_pattern[#transform=trans_name]' [, ...])

          [NULL [AS] 'null string']
          [ESCAPE [AS] 'escape' | 'OFF'] ))
   | 'CSV'
   ]

Description
CREATE EXTERNAL TABLE or CREATE EXTERNAL WEB TABLE creates a new readable external table
definition in Greenplum Database. Readable external tables are typically used for fast, parallel data
loading. Once an external table is defined, you can query its data directly (and in parallel) using SQL
commands. For example, you can select, join, or sort external table data. You can also create views for
external tables. DML operations (UPDATE, INSERT, DELETE, or TRUNCATE) are not allowed on readable
external tables, and you cannot create indexes on readable external tables.
**CREATE WRITABLE EXTERNAL TABLE** or **CREATE WRITABLE EXTERNAL WEB TABLE** creates a new writable external table definition in Greenplum Database. Writable external tables are typically used for unloading data from the database into a set of files or named pipes. Writable external web tables can also be used to output data to an executable program. Writable external tables can also be used as output targets for Greenplum parallel MapReduce calculations. Once a writable external table is defined, data can be selected from database tables and inserted into the writable external table. Writable external tables only allow **INSERT** operations – **SELECT**, **UPDATE**, **DELETE** or **TRUNCATE** are not allowed.

The main difference between regular external tables and external web tables is their data sources. Regular readable external tables access static flat files, whereas external web tables access dynamic data sources – either on a web server or by executing OS commands or scripts.

See [Working with External Data](#) for detailed information about working with external tables.

**Parameters**

**READABLE | WRITABLE**

Specifies the type of external table, readable being the default. Readable external tables are used for loading data into Greenplum Database. Writable external tables are used for unloading data.

**WEB**

Creates a readable or writable external web table definition in Greenplum Database. There are two forms of readable external web tables – those that access files via the **http://** protocol or those that access data by executing OS commands. Writable external web tables output data to an executable program that can accept an input stream of data. External web tables are not rescannable during query execution.

The **s3** protocol does not support external web tables. You can, however, create an external web table that executes a third-party tool to read data from or write data to S3 directly.

**TEMPORARY | TEMP**

If specified, creates a temporary readable or writable external table definition in Greenplum Database. Temporary external tables exist in a special schema; you cannot specify a schema name when you create the table. Temporary external tables are automatically dropped at the end of a session.

An existing permanent table with the same name is not visible to the current session while the temporary table exists, unless you reference the permanent table with its schema-qualified name.

**table_name**

The name of the new external table.

**column_name**

The name of a column to create in the external table definition. Unlike regular tables, external tables do not have column constraints or default values, so do not specify those.

**LIKE other_table**

The **LIKE** clause specifies a table from which the new external table automatically copies all column names, data types and Greenplum distribution policy. If the original table specifies any column constraints or default column values, those will not be copied over to the new external table definition.

**data_type**

The data type of the column.

**LOCATION**  

```
(protocol://host[:port]/path/file', [...])
```
If you use the `gphdfs` protocol (deprecated) to read or write a file to a Hadoop file system (HDFS), refer to *Specify gphdfs Protocol in an External Table Definition ( Deprecated)* for additional information about the `gphdfs` protocol LOCATION clause syntax.

If you use the `pxf` protocol to access an external data source, refer to the PXF Creating an External Table documentation for detailed information about the `pxf` protocol LOCATION clause syntax.

If you use the `s3` protocol to read or write to S3, refer to About the S3 Protocol URL for additional information about the `s3` protocol LOCATION clause syntax.

For readable external tables, specifies the URI of the external data source(s) to be used to populate the external table or web table. Regular readable external tables allow the `gpfdist` or `file` protocols. External web tables allow the http protocol. If port is omitted, port 8080 is assumed for `http` and `gpfdist` protocols, and port 9000 for the `gphdfs` protocol (deprecated). If using the `gpfdist` protocol, the path is relative to the directory from which `gpfdist` is serving files (the directory specified when you started the `gpfdist` program). Also, `gpfdist` can use wildcards or other C-style pattern matching (for example, a whitespace character is `[:space:]`) to denote multiple files in a directory. For example:

```
'gpfdist://filehost:8081/*'
'gpfdist://masterhost/my_load_file'
'file://seghost1/dbfast1/external/myfile.txt'
'http://intranet.example.com/finance/expenses.csv'
```

For writable external tables, specifies the URI location of the `gpfdist` process or S3 protocol that will collect data output from the Greenplum segments and write it to one or more named files. For `gpfdist` the path is relative to the directory from which `gpfdist` is serving files (the directory specified when you started the `gpfdist` program). If multiple `gpfdist` locations are listed, the segments sending data will be evenly divided across the available output locations. For example:

```
'gpfdist://outputhost:8081/data1.out,'
'gpfdist://outputhost:8081/data2.out'
```

With two `gpfdist` locations listed as in the above example, half of the segments would send their output data to the `data1.out` file and the other half to the `data2.out` file.

With the option `#transform=trans_name`, you can specify a transform to apply when loading or extracting data. The `trans_name` is the name of the transform in the YAML configuration file you specify with the you run the `gpfdist` utility. For information about specifying a transform, see `gpfdist` in the Greenplum Utility Guide.

**ON MASTER**

Restricts all table-related operations to the Greenplum master segment. Permitted only on readable and writable external tables created with the `s3` or custom protocols. The `gpfdist`, `gpfdists`, `gphdfs` (deprecated), `pxf`, and `file` protocols do not support `ON MASTER`.

**Note:** Be aware of potential resource impacts when reading from or writing to external tables you create with the `ON MASTER` clause. You may encounter performance issues when you restrict table operations solely to the Greenplum master segment.

**EXECUTE 'command' [ON ...]**

Allowed for readable external web tables or writable external tables only. For readable external web tables, specifies the OS command to be executed by the segment instances. The `command` can be a single OS command or a script. The `ON` clause is used to specify which segment instances will execute the given command.
ON ALL is the default. The command will be executed by every active (primary) segment instance on all segment hosts in the Greenplum Database system. If the command executes a script, that script must reside in the same location on all of the segment hosts and be executable by the Greenplum superuser (gpadmin).

ON MASTER runs the command on the master host only.

Note: Logging is not supported for external web tables when the ON MASTER clause is specified.

ON number means the command will be executed by the specified number of segments. The particular segments are chosen randomly at runtime by the Greenplum Database system. If the command executes a script, that script must reside in the same location on all of the segment hosts and be executable by the Greenplum superuser (gpadmin).

HOST means the command will be executed by one segment on each segment host (once per segment host), regardless of the number of active segment instances per host.

HOST segment_hostname means the command will be executed by all active (primary) segment instances on the specified segment host.

SEGMENT segment_id means the command will be executed only once by the specified segment. You can determine a segment instance's ID by looking at the content number in the system catalog table gp_segment_configuration. The content ID of the Greenplum Database master is always -1.

For writable external tables, the command specified in the EXECUTE clause must be prepared to have data piped into it. Since all segments that have data to send will write their output to the specified command or program, the only available option for the ON clause is ON ALL.

FORMAT 'TEXT | CSV | AVRO | PARQUET' (options)

When the FORMAT clause identifies delimited text (TEXT) or comma separated values (CSV) format, formatting options are similar to those available with the PostgreSQL COPY command. If the data in the file does not use the default column delimiter, escape character, null string and so on, you must specify the additional formatting options so that the data in the external file is read correctly by Greenplum Database. For information about using a custom format, see "Loading and Unloading Data" in the Greenplum Database Administrator Guide.

The AVRO and PARQUET formats are supported only when you specify the gphdfs protocol (deprecated). Refer to Accessing HDFS Data with gphdfs (Deprecated) for detailed information about the gphdfs protocol FORMAT clause syntax.

If you use the pxf protocol to access an external data source, refer to the PXF Creating an External Table documentation for detailed information about the pxf protocol FORMAT clause syntax.

FORMAT 'CUSTOM' (formatter=formatter_specification)

Specifies a custom data format. The formatter_specification specifies the function to use to format the data, followed by comma-separated parameters to the formatter function. The length of the formatter specification, the string including Formatter=, can be up to approximately 50K bytes.

If you use the pxf protocol to access an external data source, refer to the PXF Creating an External Table documentation for detailed information about the pxf protocol FORMAT clause syntax.

For general information about using a custom format, see "Loading and Unloading Data" in the Greenplum Database Administrator Guide.
Specifies a single ASCII character that separates columns within each row (line) of data. The default is a tab character in TEXT mode, a comma in CSV mode. In TEXT mode for readable external tables, the delimiter can be set to OFF for special use cases in which unstructured data is loaded into a single-column table.

For the s3 protocol, the delimiter cannot be a newline character (\n) or a carriage return character (\r).

NULL

Specifies the string that represents a NULL value. The default is \N (backslash-N) in TEXT mode, and an empty value with no quotations in CSV mode. You might prefer an empty string even in TEXT mode for cases where you do not want to distinguish NULL values from empty strings. When using external and web tables, any data item that matches this string will be considered a NULL value.

As an example for the text format, this FORMAT clause can be used to specify that the string of two single quotes (""') is a NULL value.

```
FORMAT 'text' (delimiter ',' null '""')
```

ESCAPE

Specifies the single character that is used for C escape sequences (such as \n, \t, \100, and so on) and for escaping data characters that might otherwise be taken as row or column delimiters. Make sure to choose an escape character that is not used anywhere in your actual column data. The default escape character is a \ (backslash) for text-formatted files and a " (double quote) for csv-formatted files, however it is possible to specify another character to represent an escape. It is also possible to disable escaping in text-formatted files by specifying the value 'OFF' as the escape value. This is very useful for data such as text-formatted web log data that has many embedded backslashes that are not intended to be escapes.

NEWLINE

Specifies the newline used in your data files – LF (Line feed, 0x0A), CR (Carriage return, 0x0D), or CRLF (Carriage return plus line feed, 0x0D 0x0A). If not specified, a Greenplum Database segment will detect the newline type by looking at the first row of data it receives and using the first newline type encountered.

HEADER

For readable external tables, specifies that the first line in the data file(s) is a header row (contains the names of the table columns) and should not be included as data for the table. If using multiple data source files, all files must have a header row.

For the s3 protocol, the column names in the header row cannot contain a newline character (\n) or a carriage return (\r).

The pxf protocol does not support the HEADER formatting option.

QUOTE

Specifies the quotation character for CSV mode. The default is double-quote (").

FORCE NOT NULL

In CSV mode, processes each specified column as though it were quoted and hence not a NULL value. For the default null string in CSV mode (nothing between two delimiters), this causes missing values to be evaluated as zero-length strings.

FORCE QUOTE

In CSV mode for writable external tables, forces quoting to be used for all non-NULL values in each specified column. If * is specified then non-NULL values will be quoted in all columns. NULL output is never quoted.

FILL MISSING FIELDS
In both TEXT and CSV mode for readable external tables, specifying \texttt{FILL MISSING FIELDS} will set missing trailing field values to NULL (instead of reporting an error) when a row of data has missing data fields at the end of a line or row. Blank rows, fields with a NOT NULL constraint, and trailing delimiters on a line will still report an error.

ENCODING \textquote{encoding}'

Character set encoding to use for the external table. Specify a string constant (such as \textquote{SQL_ASCII}), an integer encoding number, or \texttt{DEFAULT} to use the default client encoding. See \textit{Character Set Support}.

LOG ERRORS [PERSISTENTLY]

This is an optional clause that can precede a \texttt{SEGMENT REJECT LIMIT} clause to log information about rows with formatting errors. The error log data is stored internally. If error log data exists for a specified external table, new data is appended to existing error log data. The error log data is not replicated to mirror segments.

The data is deleted when the external table is dropped unless you specify the keyword \texttt{PERSISTENTLY}. If the keyword is specified, the log data persists after the external table is dropped.

The error log data is accessed with the Greenplum Database built-in SQL function \texttt{gp_read_error_log()}, or with the SQL function \texttt{gp_read_persistent_error_log()} if the PERSISTENTLY keyword is specified.

If you use the PERSISTENTLY keyword, you must install the functions that manage the persistent error log information.

See \textit{Notes} for information about the error log information and built-in functions for viewing and managing error log information.

SEGMENT REJECT LIMIT \texttt{count [ROWS | PERCENT]}

Runs a \texttt{COPY FROM} operation in single row error isolation mode. If the input rows have format errors they will be discarded provided that the reject limit count is not reached on any Greenplum segment instance during the load operation. The reject limit count can be specified as number of rows (the default) or percentage of total rows (1-100). If \texttt{PERCENT} is used, each segment starts calculating the bad row percentage only after the number of rows specified by the parameter \texttt{gp_reject_percent_threshold} has been processed.

The default for \texttt{gp_reject_percent_threshold} is 300 rows. Constraint errors such as violation of a NOT NULL, CHECK, or UNIQUE constraint will still be handled in “all-or-nothing” input mode. If the limit is not reached, all good rows will be loaded and any error rows discarded.

Note: When reading an external table, Greenplum Database limits the initial number of rows that can contain formatting errors if the SEGMENT REJECT LIMIT is not triggered first or is not specified. If the first 1000 rows are rejected, the \texttt{COPY} operation is stopped and rolled back.

The limit for the number of initial rejected rows can be changed with the Greenplum Database server configuration parameter \texttt{gp_initial_bad_row_limit}. See \textit{Server Configuration Parameters} for information about the parameter.

DISTRIBUTED BY \texttt{(column, [ ... ])}

\texttt{DISTRIBUTED RANDOMLY}

Used to declare the Greenplum Database distribution policy for a writable external table. By default, writable external tables are distributed randomly. If the source table you are exporting data from has a hash distribution policy, defining the same distribution key column(s) for the writable external table will improve unload performance by eliminating the need to move rows over the interconnect. When you issue an unload command such as \texttt{INSERT INTO wex_table SELECT * FROM source_table}, the rows that are
unloaded can be sent directly from the segments to the output location if the two tables have the same hash distribution policy.

**Examples**

Start the `gpfdist` file server program in the background on port 8081 serving files from directory `/var/data/staging`:

```
$ gpfdist -p 8081 -d /var/data/staging -l /home/gpadmin/log &
```

Create a readable external table named `ext_customer` using the `gpfdist` protocol and any text formatted files (*.*txt) found in the `gpfdist` directory. The files are formatted with a pipe (|) as the column delimiter and an empty space as NULL. Also access the external table in single row error isolation mode:

```sql
CREATE EXTERNAL TABLE ext_customer
    (id int, name text, sponsor text)
    LOCATION ( 'gpfdist://filehost:8081/*.txt' )
    FORMAT 'TEXT' ( DELIMITER '|' NULL ' ')
    LOG ERRORS SEGMENT REJECT LIMIT 5;
```

Create the same readable external table definition as above, but with CSV formatted files:

```sql
CREATE EXTERNAL TABLE ext_customer
    (id int, name text, sponsor text)
    LOCATION ( 'gpfdist://filehost:8081/*.csv' )
    FORMAT 'CSV' ( DELIMITER ',' );
```

Create a readable external table named `ext_expenses` using the file protocol and several CSV formatted files that have a header row:

```sql
CREATE EXTERNAL TABLE ext_expenses (name text, date date, amount float4, category text, description text)
    FORMAT 'CSV' ( HEADER );
```

Create a readable external web table that executes a script once per segment host:

```sql
CREATE EXTERNAL WEB TABLE log_output (linenum int, message text) EXECUTE '/var/load_scripts/get_log_data.sh' ON HOST
    FORMAT 'TEXT' (DELIMITER '|');
```

Create a writable external table named `sales_out` that uses `gpfdist` to write output data to a file named `sales.out`. The files are formatted with a pipe (|) as the column delimiter and an empty space as NULL.

```sql
CREATE WRITABLE EXTERNAL TABLE sales_out (LIKE sales)
    LOCATION ('gpfdist://etl1:8081/sales.out')
    FORMAT 'TEXT' ( DELIMITER '|' NULL ' ')
    DISTRIBUTED BY (txn_id);
```
Create a writable external web table that pipes output data received by the segments to an executable script named `to_adreport_etl.sh`:

```
CREATE WRITABLE EXTERNAL WEB TABLE campaign_out
LIKE campaign
EXECUTE '/var/unload_scripts/to_adreport_etl.sh'
FORMAT 'TEXT' (DELIMITER '|');
```

Use the writable external table defined above to unload selected data:

```
INSERT INTO campaign_out SELECT * FROM campaign WHERE customer_id=123;
```

**Notes**

When you specify the `LOG ERRORS` clause, Greenplum Database captures errors that occur while reading the external table data. For information about the error log format, see [Viewing Bad Rows in the Error Log](#).

You can view and manage the captured error log data. The functions to manage log data depend on whether the data is persistent (the `PERSISTENTLY` keyword is used with the `LOG ERRORS` clause).

- Functions that manage non-persistent error log data from external tables that were defined without the `PERSISTENTLY` keyword.
  - The built-in SQL function `gp_read_error_log('table_name')` displays error log information for an external table. This example displays the error log data from the external table `ext_expenses`.
    ```
    SELECT * from gp_read_error_log('ext_expenses');
    ```

  The function returns no data if you created the external table with the `LOG ERRORS` statement or if the external table does not exist.

- The built-in SQL function `gp_truncate_error_log('table_name')` deletes the error log data for `table_name`. This example deletes the error log data captured from the external table `ext_expenses`:
  ```
  SELECT gp_truncate_error_log('ext_expenses');
  ```

  Dropping the table also deletes the table's log data. The function does not truncate log data if the external table is defined with the `LOG ERRORS PERSISTENTLY` clause.

  The function returns `FALSE` if the table does not exist.

- Functions that manage persistent error log data from external tables that were defined with the `PERSISTENTLY` keyword.
  - Note: The functions that manage persistent error log data from external tables are defined in the file `$GPHOME/share/postgresql/contrib/gpexterrorhandle.sql`. The functions must be installed in the databases that use persistent error log data from an external table. This `psql` command installs the functions into the database `testdb`.
    ```
    psql -d test -U gpadmin -f $GPHOME/share/postgresql/contrib/gpexterrorhandle.sql
    ```

  - The SQL function `gp_read_persistent_error_log('table_name')` displays persistent log data for an external table.
    The function returns no data if you created the external table without the `PERSISTENTLY` keyword. The function returns persistent log data for an external table even after the table has been dropped.

  - The SQL function `gp_truncate_persistent_error_log('table_name')` truncates persistent log data for a table.
For persistent log data, you must manually delete the data. Dropping the external table does not delete persistent log data.

- These items apply to both non-persistent and persistent error log data and the related functions.
  - The `gp_read_*` functions require `SELECT` privilege on the table.
  - The `gp_truncate_*` functions require owner privilege on the table.
  - You can use the `*` wildcard character to delete error log information for existing tables in the current database. Specify the string `*.*` to delete all database error log information, including error log information that was not deleted due to previous database issues. If `*` is specified, database owner privilege is required. If `*.` is specified, operating system super-user privilege is required. Non-persistent and persistent error log data must be deleted with their respective `gp_truncate_*` functions.

When multiple Greenplum Database external tables are defined with the `gpfdist`, `gpfdsists`, or `file` protocol and access the same named pipe a Linux system, Greenplum Database restricts access to the named pipe to a single reader. An error is returned if a second reader attempts to access the named pipe.

### Compatibility

`CREATE EXTERNAL TABLE` is a Greenplum Database extension. The SQL standard makes no provisions for external tables.

### See Also

`CREATE TABLE AS`, `CREATE TABLE`, `COPY`, `SELECT INTO`, `INSERT`
function). Also, CREATE OR REPLACE FUNCTION will not let you change the return type of an existing function. To do that, you must drop and recreate the function. If you drop and then recreate a function, you will have to drop existing objects (rules, views, triggers, and so on) that refer to the old function. Use CREATE OR REPLACE FUNCTION to change a function definition without breaking objects that refer to the function.

For more information about creating functions, see the User Defined Functions section of the PostgreSQL documentation.

Limited Use of VOLATILE and STABLE Functions

To prevent data from becoming out-of-sync across the segments in Greenplum Database, any function classified as STABLE or VOLATILE cannot be executed at the segment level if it contains SQL or modifies the database in any way. For example, functions such as random() or timeofday() are not allowed to execute on distributed data in Greenplum Database because they could potentially cause inconsistent data between the segment instances.

To ensure data consistency, VOLATILE and STABLE functions can safely be used in statements that are evaluated on and execute from the master. For example, the following statements are always executed on the master (statements without a FROM clause):

```sql
SELECT setval('myseq', 201);
SELECT foo();
```

In cases where a statement has a FROM clause containing a distributed table and the function used in the FROM clause simply returns a set of rows, execution may be allowed on the segments:

```sql
SELECT * FROM foo();
```

One exception to this rule are functions that return a table reference (rangeFuncs) or functions that use the refCursor data type. Note that you cannot return a refcursor from any kind of function in Greenplum Database.

Parameters

**name**

The name (optionally schema-qualified) of the function to create.

**argmode**

The mode of an argument: either IN, OUT, INOUT, or VARIADIC. Only OUT arguments can follow an argument declared as VARIADIC. If omitted, the default is IN.

**argname**

The name of an argument. Some languages (currently only PL/pgSQL) let you use the name in the function body. For other languages the name of an input argument is just extra documentation. But the name of an output argument is significant, since it defines the column name in the result row type. (If you omit the name for an output argument, the system will choose a default column name.)

**argtype**

The data type(s) of the function's arguments (optionally schema-qualified), if any. The argument types may be base, composite, or domain types, or may reference the type of a table column.

Depending on the implementation language it may also be allowed to specify pseudotypes such as cstring. Pseudotypes indicate that the actual argument type is either incompletely specified, or outside the set of ordinary SQL data types.

The type of a column is referenced by writing `tablename.columnname%TYPE`. Using this feature can sometimes help make a function independent of changes to the definition of a table.
**defexpr**

An expression to be used as the default value if the parameter is not specified. The expression must be coercible to the argument type of the parameter. Only IN and INOUT parameters can have a default value. Each input parameter in the argument list that follows a parameter with a default value must have a default value as well.

**rettype**

The return data type (optionally schema-qualified). The return type can be a base, composite, or domain type, or may reference the type of a table column. Depending on the implementation language it may also be allowed to specify pseudotypes such as cstring. If the function is not supposed to return a value, specify void as the return type.

When there are OUT or INOUT parameters, the RETURNS clause may be omitted. If present, it must agree with the result type implied by the output parameters: RECORD if there are multiple output parameters, or the same type as the single output parameter.

The SETOF modifier indicates that the function will return a set of items, rather than a single item.

The type of a column is referenced by writing `tablename.columnname%TYPE`.

**langname**

The name of the language that the function is implemented in. May be SQL, C, internal, or the name of a user-defined procedural language. See `CREATE LANGUAGE` for the procedural languages supported in Greenplum Database. For backward compatibility, the name may be enclosed by single quotes.

**IMMUTABLE**
**STABLE**
**VOLATILE**

These attributes inform the query optimizer about the behavior of the function. At most one choice may be specified. If none of these appear, VOLATILE is the default assumption. Since Greenplum Database currently has limited use of VOLATILE functions, if a function is truly IMMUTABLE, you must declare it as so to be able to use it without restrictions.

IMMUTABLE indicates that the function cannot modify the database and always returns the same result when given the same argument values. It does not do database lookups or otherwise use information not directly present in its argument list. If this option is given, any call of the function with all-constant arguments can be immediately replaced with the function value.

STABLE indicates that the function cannot modify the database, and that within a single table scan it will consistently return the same result for the same argument values, but that its result could change across SQL statements. This is the appropriate selection for functions whose results depend on database lookups, parameter values (such as the current time zone), and so on. Also note that the `current_timestamp` family of functions qualify as stable, since their values do not change within a transaction.

VOLATILE indicates that the function value can change even within a single table scan, so no optimizations can be made. Relatively few database functions are volatile in this sense; some examples are `random()`, `timeofday()`. But note that any function that has side-effects must be classified volatile, even if its result is quite predictable, to prevent calls from being optimized away; an example is `setval()`.

**CALLED ON NULL INPUT**
**RETURNS NULL ON NULL INPUT**
**STRICT**

CALLED ON NULL INPUT (the default) indicates that the function will be called normally when some of its arguments are null. It is then the function author's responsibility to check for null values if necessary and respond appropriately. RETURNS NULL ON NULL INPUT or STRICT indicates that the function always returns null whenever any of its arguments
are null. If this parameter is specified, the function is not executed when there are null arguments; instead a null result is assumed automatically.

**[EXTERNAL] SECURITY INVOKER**

**[EXTERNAL] SECURITY DEFINER**

SECURITY INVOKER (the default) indicates that the function is to be executed with the privileges of the user that calls it. SECURITY DEFINER specifies that the function is to be executed with the privileges of the user that created it. The key word EXTERNAL is allowed for SQL conformance, but it is optional since, unlike in SQL, this feature applies to all functions not just external ones.

**COST execution_cost**

A positive number identifying the estimated execution cost for the function, in cpu_operator_cost units. If the function returns a set, execution_cost identifies the cost per returned row. If the cost is not specified, C-language and internal functions default to 1 unit, while functions in other languages default to 100 units. The planner tries to evaluate the function less often when you specify larger execution_cost values.

**configuration_parameter value**

The SET clause applies a value to a session configuration parameter when the function is entered. The configuration parameter is restored to its prior value when the function exits. SET FROM CURRENT applies the session’s current value of the parameter when the function is entered.

**definition**

A string constant defining the function; the meaning depends on the language. It may be an internal function name, the path to an object file, an SQL command, or text in a procedural language.

**obj_file, link_symbol**

This form of the AS clause is used for dynamically loadable C language functions when the function name in the C language source code is not the same as the name of the SQL function. The string obj_file is the name of the file containing the dynamically loadable object, and link_symbol is the name of the function in the C language source code. If the link symbol is omitted, it is assumed to be the same as the name of the SQL function being defined. It is recommended to locate shared libraries either relative to $libdir (which is located at $GPHOME/lib) or through the dynamic library path (set by the dynamic_library_path server configuration parameter). This simplifies version upgrades if the new installation is at a different location.

**describe_function**

The name of a callback function to execute when a query that calls this function is parsed. The callback function returns a tuple descriptor that indicates the result type.

**Notes**

Any compiled code (shared library files) for custom functions must be placed in the same location on every host in your Greenplum Database array (master and all segments). This location must also be in the LD_LIBRARY_PATH so that the server can locate the files. It is recommended to locate shared libraries either relative to $libdir (which is located at $GPHOME/lib) or through the dynamic library path (set by the dynamic_library_path server configuration parameter) on all master segment instances in the Greenplum array.

The full SQL type syntax is allowed for input arguments and return value. However, some details of the type specification (such as the precision field for type numeric) are the responsibility of the underlying function implementation and are not recognized or enforced by the CREATE FUNCTION command.
Greenplum Database allows function overloading. The same name can be used for several different functions so long as they have distinct argument types. However, the C names of all functions must be different, so you must give overloaded C functions different C names (for example, use the argument types as part of the C names).

Two functions are considered the same if they have the same names and input argument types, ignoring any `OUT` parameters. Thus for example these declarations conflict:

```sql
CREATE FUNCTION foo(int) ...  
CREATE FUNCTION foo(int, out text) ...
```

Functions that have different argument type lists are not considered to conflict at creation time, but if argument defaults are provided, they might conflict in use. For example, consider:

```sql
CREATE FUNCTION foo(int) ...  
CREATE FUNCTION foo(int, int default 42) ...
```

The call `foo(10)`, will fail due to the ambiguity about which function should be called.

When repeated `CREATE FUNCTION` calls refer to the same object file, the file is only loaded once. To unload and reload the file, use the `LOAD` command.

You must have the `USAGE` privilege on a language to be able to define a function using that language.

It is often helpful to use dollar quoting to write the function definition string, rather than the normal single quote syntax. Without dollar quoting, any single quotes or backslashes in the function definition must be escaped by doubling them. A dollar-quoted string constant consists of a dollar sign (`$`), an optional tag of zero or more characters, another dollar sign, an arbitrary sequence of characters that makes up the string content, a dollar sign, the same tag that began this dollar quote, and a dollar sign. Inside the dollar-quoted string, single quotes, backslashes, or any character can be used without escaping. The string content is always written literally. For example, here are two different ways to specify the string "Dianne's horse" using dollar quoting:

```
$$Dianne's horse$$
$SomeTag$Dianne's horse$SomeTag$
```

If a `SET` clause is attached to a function, the effects of a `SET LOCAL` command executed inside the function for the same variable are restricted to the function; the configuration parameter's prior value is still restored when the function exits. However, an ordinary `SET` command (without `LOCAL`) overrides the `CREATE FUNCTION SET` clause, much as it would for a previous `SET LOCAL` command. The effects of such a command will persist after the function exits, unless the current transaction is rolled back.

If a function with a `VARIADIC` argument is declared as `STRICT`, the strictness check tests that the variadic array as a whole is non-null. PL/pgSQL will still call the function if the array has null elements.

### Using Functions With Queries on Distributed Data

In some cases, Greenplum Database does not support using functions in a query where the data in a table specified in the `FROM` clause is distributed over Greenplum Database segments. As an example, this SQL query contains the function `func()`:

```sql
SELECT func(a) FROM table1;
```

The function is not supported for use in the query if all of the following conditions are met:

- The data of table `table1` is distributed over Greenplum Database segments.
- The function `func()` reads or modifies data from distributed tables.
- The function `func()` returns more than one row or takes an argument (`a`) that comes from `table1`.

If any of the conditions are not met, the function is supported. Specifically, the function is supported if any of the following conditions apply:
- The function `func()` does not access data from distributed tables, or accesses data that is only on the Greenplum Database master.
- The table `table1` is a master only table.
- The function `func()` returns only one row and only takes input arguments that are constant values. The function is supported if it can be changed to require no input arguments.

**Examples**

A very simple addition function:

```sql
CREATE FUNCTION add(integer, integer) RETURNS integer
    AS 'select $1 + $2;'
    LANGUAGE SQL
    IMMUTABLE
    RETURNS NULL ON NULL INPUT;
```

Increment an integer, making use of an argument name, in PL/pgSQL:

```sql
CREATE OR REPLACE FUNCTION increment(i integer) RETURNS integer
    AS $$
    BEGIN
        RETURN i + 1;
    END;
    $$ LANGUAGE plpgsql;
```

Increase the default segment host memory per query for a PL/pgSQL function:

```sql
CREATE OR REPLACE FUNCTION function_with_query() RETURNS SETOF text
    AS $$
    BEGIN
        RETURN QUERY
        EXPLAIN ANALYZE SELECT * FROM large_table;
    END;
    $$ LANGUAGE plpgsql
    SET statement_mem='256MB';
```

Use polymorphic types to return an `ENUM` array:

```sql
CREATE TYPE rainbow AS ENUM('red','orange','yellow','green','blue','indigo','violet');
CREATE FUNCTION return_enum_as_array(anyenum, anyelement, anyelement)
    RETURNS TABLE (ae anyenum, aa anyarray)
    AS $$
    SELECT $1, array[$2, $3]
    $$ LANGUAGE SQL STABLE;
SELECT * FROM return_enum_as_array('red'::rainbow, 'green'::rainbow, 'blue'::rainbow);
```

Return a record containing multiple output parameters:

```sql
CREATE FUNCTION dup(in int, out f1 int, out f2 text)
    AS $$ SELECT $1, CAST($1 AS text) || ' is text' $$
    LANGUAGE SQL;
SELECT * FROM dup(42);
```

You can do the same thing more verbosely with an explicitly named composite type:

```sql
CREATE TYPE dup_result AS (f1 int, f2 text);
CREATE FUNCTION dup(int) RETURNS dup_result
    AS $$ SELECT $1, CAST($1 AS text) || ' is text' $$
    LANGUAGE SQL;
```
SELECT * FROM dup(42);

Compatibility

CREATE FUNCTION is defined in SQL:1999 and later. The Greenplum Database version is similar but not fully compatible. The attributes are not portable, neither are the different available languages.

For compatibility with some other database systems, argmode can be written either before or after argname. But only the first way is standard-compliant.

The SQL standard does not specify parameter defaults.

ALTER FUNCTION, DROP FUNCTION, LOAD

CREATE GROUP

Defines a new database role.

Synopsis

CREATE GROUP name [[WITH] option [ ... ]]

where option can be:

- SUPERUSER | NOSUPERUSER
- CREATEDB | NOCREATEDB
- CREATEROLE | NOCREATEROLE
- CREATEUSER | NOCREATEUSER
- CREATEEXTTABLE | NOCREATEEXTTABLE
- [ ( attribute='value'[, ...] ) ]
- INHERIT | NOINHERIT
- LOGIN | NOLOGIN
- CONNECTION LIMIT connlimit
- [ ENCRYPTED | UNENCRYPTED ] PASSWORD 'password'
- VALID UNTIL 'timestamp'
- IN ROLE rolename [, ...]
- ROLE rolename [, ...]
- ADMIN rolename [, ...]
- RESOURCE QUEUE queue_name
- RESOURCE GROUP group_name
- [ DENY deny_point ]
- [ DENY BETWEEN deny_point AND deny_point]

Description

CREATE GROUP is an alias for CREATE ROLE.

Compatibility

There is no CREATE GROUP statement in the SQL standard.

See Also

CREATE ROLE
**CREATE INDEX**

Defines a new index.

**Synopsis**

```
CREATE [UNIQUE] INDEX name ON table
    [USING btree|bitmap|gist]
    ( {column | (expression)} [opclass] [, ...] )
    [ WITH ( FILLFACTOR = value ) ]
    [TABLESPACE tablespace]
    [WHERE predicate]
```

**Description**

CREATE INDEX constructs an index on the specified table. Indexes are primarily used to enhance database performance (though inappropriate use can result in slower performance).

The key field(s) for the index are specified as column names, or alternatively as expressions written in parentheses. Multiple fields can be specified if the index method supports multicolumn indexes.

An index field can be an expression computed from the values of one or more columns of the table row. This feature can be used to obtain fast access to data based on some transformation of the basic data. For example, an index computed on `upper(col)` would allow the clause `WHERE upper(col) = 'JIM'` to use an index.

Greenplum Database provides the index methods B-tree, bitmap, and GiST. Users can also define their own index methods, but that is fairly complicated.

When the `WHERE` clause is present, a partial index is created. A partial index is an index that contains entries for only a portion of a table, usually a portion that is more useful for indexing than the rest of the table. For example, if you have a table that contains both billed and unbilled orders where the unbilled orders take up a small fraction of the total table and yet is most often selected, you can improve performance by creating an index on just that portion.

The expression used in the `WHERE` clause may refer only to columns of the underlying table, but it can use all columns, not just the ones being indexed. Subqueries and aggregate expressions are also forbidden in `WHERE`. The same restrictions apply to index fields that are expressions.

All functions and operators used in an index definition must be immutable. Their results must depend only on their arguments and never on any outside influence (such as the contents of another table or a parameter value). This restriction ensures that the behavior of the index is well-defined. To use a user-defined function in an index expression or `WHERE` clause, remember to mark the function `IMMUTABLE` when you create it.

**Parameters**

**UNIQUE**

Checks for duplicate values in the table when the index is created and each time data is added. Duplicate entries will generate an error. Unique indexes only apply to B-tree indexes. In Greenplum Database, unique indexes are allowed only if the columns of the index key are the same as (or a superset of) the Greenplum distribution key. On partitioned tables, a unique index is only supported within an individual partition - not across all partitions.

**name**

The name of the index to be created. The index is always created in the same schema as its parent table.

**table**
The name (optionally schema-qualified) of the table to be indexed.

**btree | bitmap | gist**

The name of the index method to be used. Choices are `btree`, `bitmap`, and `gist`. The default method is `btree`.

Currently, only the B-tree and GiST index methods support multicolumn indexes. Up to 32 fields can be specified by default. Only B-tree currently supports unique indexes.

GPORCA supports only B-tree, bitmap, and GiST indexes. GPORCA ignores indexes created with unsupported indexing methods.

**column**

The name of a column of the table on which to create the index. Only the B-tree, bitmap, and GiST index methods support multicolumn indexes.

**expression**

An expression based on one or more columns of the table. The expression usually must be written with surrounding parentheses, as shown in the syntax. However, the parentheses may be omitted if the expression has the form of a function call.

**opclass**

The name of an operator class. The operator class identifies the operators to be used by the index for that column. For example, a B-tree index on four-byte integers would use the `int4_ops` class (this operator class includes comparison functions for four-byte integers).

In practice the default operator class for the column's data type is usually sufficient. The main point of having operator classes is that for some data types, there could be more than one meaningful ordering. For example, a complex-number data type could be sorted by either absolute value or by real part. We could do this by defining two operator classes for the data type and then selecting the proper class when making an index.

**FILLFACTOR**

The fillfactor for an index is a percentage that determines how full the index method will try to pack index pages. For B-trees, leaf pages are filled to this percentage during initial index build, and also when extending the index at the right (largest key values). If pages subsequently become completely full, they will be split, leading to gradual degradation in the index’s efficiency.

B-trees use a default fillfactor of 90, but any value from 10 to 100 can be selected. If the table is static then fillfactor 100 is best to minimize the index’s physical size, but for heavily updated tables a smaller fillfactor is better to minimize the need for page splits. The other index methods use fillfactor in different but roughly analogous ways; the default fillfactor varies between methods.

**tablespace**

The tablespace in which to create the index. If not specified, the default tablespace is used.

**predicate**

The constraint expression for a partial index.

**Notes**

When an index is created on a partitioned table, the index is propagated to all the child tables created by Greenplum Database. Creating an index on a table that is created by Greenplum Database for use by a partitioned table is not supported.

**UNIQUE** indexes are allowed only if the index columns are the same as (or a superset of) the Greenplum distribution key columns.

**UNIQUE** indexes are not allowed on append-optimized tables.
A **UNIQUE** index can be created on a partitioned table. However, uniqueness is enforced only within a partition; uniqueness is not enforced between partitions. For example, for a partitioned table with partitions that are based on year and a subpartitions that are based on quarter, uniqueness is enforced only on each individual quarter partition. Uniqueness is not enforced between quarter partitions.

Indexes are not used for **IS NULL** clauses by default. The best way to use indexes in such cases is to create a partial index using an **IS NULL** predicate.

**bitmap** indexes perform best for columns that have between 100 and 100,000 distinct values. For a column with more than 100,000 distinct values, the performance and space efficiency of a bitmap index decline. The size of a bitmap index is proportional to the number of rows in the table times the number of distinct values in the indexed column.

Columns with fewer than 100 distinct values usually do not benefit much from any type of index. For example, a gender column with only two distinct values for male and female would not be a good candidate for an index.

Prior releases of Greenplum Database also had an R-tree index method. This method has been removed because it had no significant advantages over the GiST method. If **USING rtree** is specified, **CREATE INDEX** will interpret it as **USING gist**.

For more information on the GiST index type, refer to the *PostgreSQL documentation*.

The use of hash and GIN indexes has been disabled in Greenplum Database.

**Examples**

To create a B-tree index on the column **title** in the table **films**:

```sql
CREATE UNIQUE INDEX title_idx ON films (title);
```

To create a bitmap index on the column **gender** in the table **employee**:

```sql
CREATE INDEX gender_bmp_idx ON employee USING bitmap (gender);
```

To create an index on the expression **lower(title)**, allowing efficient case-insensitive searches:

```sql
CREATE INDEX lower_title_idx ON films ((lower(title)));
```

To create an index with non-default fill factor:

```sql
CREATE UNIQUE INDEX title_idx ON films (title) WITH (fillfactor = 70);
```

To create an index on the column **code** in the table **films** and have the index reside in the tablespace **indexspace**:

```sql
CREATE INDEX code_idx ON films(code) TABLESPACE indexspace;
```

**Compatibility**

**CREATE INDEX** is a Greenplum Database language extension. There are no provisions for indexes in the SQL standard.

Greenplum Database does not support the concurrent creation of indexes (**CONCURRENTLY** keyword not supported).

**See Also**

*ALTER INDEX*, *DROP INDEX*, *CREATE TABLE*, *CREATE OPERATOR CLASS*
CREATE LANGUAGE
Defines a new procedural language.

Synopsis

CREATE [PROCEDURAL] LANGUAGE name

CREATE [TRUSTED] [PROCEDURAL] LANGUAGE name
   HANDLER call_handler [ INLINE inline_handler ]
   [VALIDATOR valfunction]

Description

CREATE LANGUAGE registers a new procedural language with a Greenplum database. Subsequently, functions and trigger procedures can be defined in this new language.

**Note:** Most procedural languages for Greenplum Database have been made into "extensions," and should therefore be installed with CREATE EXTENSION, not CREATE LANGUAGE. Using CREATE LANGUAGE directly should be restricted to extension installation scripts. If you have a "bare" language in your database, perhaps as a result of an upgrade, you can convert it to an extension using CREATE EXTENSION langname FROM unpackaged.

Superusers can register a new language with a Greenplum database. A database owner can also register within that database any language listed in the pg_pltemplate catalog in which the tmpldbacreate field is true. The default configuration allows only trusted languages to be registered by database owners. The creator of a language becomes its owner and can later drop it, rename it, or assign ownership to a new user.

CREATE LANGUAGE effectively associates the language name with a call handler that is responsible for executing functions written in that language. For a function written in a procedural language (a language other than C or SQL), the database server has no built-in knowledge about how to interpret the function's source code. The task is passed to a special handler that knows the details of the language. The handler could either do all the work of parsing, syntax analysis, execution, and so on or it could serve as a bridge between Greenplum Database and an existing implementation of a programming language. The handler itself is a C language function compiled into a shared object and loaded on demand, just like any other C function. Therese procedural language packages are included in the standard Greenplum Database distribution: PL/pgSQL, PL/Perl, and PL/Python. Language handlers have also been added for PL/Java and PL/R, but those languages are not pre-installed with Greenplum Database. See the topic on Procedural Languages in the PostgreSQL documentation for more information on developing functions using these procedural languages.

The PL/Perl, PL/Java, and PL/R libraries require the correct versions of Perl, Java, and R to be installed, respectively.

On RHEL and SUSE platforms, download the appropriate extensions from Pivotal Network, then install the extensions using the Greenplum Package Manager (gppkg) utility to ensure that all dependencies are installed as well as the extensions. See the Greenplum Database Utility Guide for details about gppkg.

There are two forms of the CREATE LANGUAGE command. In the first form, the user specifies the name of the desired language and the Greenplum Database server uses the pg_pltemplate system catalog to determine the correct parameters. In the second form, the user specifies the language parameters as well as the language name. You can use the second form to create a language that is not defined in pg_pltemplate.

When the server finds an entry in the pg_pltemplate catalog for the given language name, it will use the catalog data even if the command includes language parameters. This behavior simplifies loading of old dump files, which are likely to contain out-of-date information about language support functions.
Parameters

**TRUSTED**

Ignored if the server has an entry for the specified language name in `pg_pltemplate`. Specifies that the call handler for the language is safe and does not offer an unprivileged user any functionality to bypass access restrictions. If this key word is omitted when registering the language, only users with the superuser privilege can use this language to create new functions.

**PROCEDURAL**

This is a noise word.

**name**

The name of the new procedural language. The name must be unique among the languages in the database. Built-in support is included for `plpgsql`, `plperl`, and `plpythonu`. The languages `plpgsql` (PL/pgSQL) and `plpythonu` (PL/Python) are installed by default in Greenplum Database.

**HANDLER**

`call_handler`

Ignored if the server has an entry for the specified language name in `pg_pltemplate`. The name of a previously registered function that will be called to execute the procedural language functions. The call handler for a procedural language must be written in a compiled language such as C with version 1 call convention and registered with Greenplum Database as a function taking no arguments and returning the `language_handler` type, a placeholder type that is simply used to identify the function as a call handler.

**INLINE**

`inline_handler`

The name of a previously registered function that is called to execute an anonymous code block in this language that is created with the `DO` command. If an `inline_handler` function is not specified, the language does not support anonymous code blocks. The handler function must take one argument of type `internal`, which is the `DO` command internal representation. The function typically return `void`. The return value of the handler is ignored.

**VALIDATOR**

`valfunction`

Ignored if the server has an entry for the specified language name in `pg_pltemplate`. The name of a previously registered function that will be called to execute the procedural language functions. The call handler for a procedural language must be written in a compiled language such as C with version 1 call convention and registered with Greenplum Database as a function taking no arguments and returning the `language_handler` type, a placeholder type that is simply used to identify the function as a call handler.

Notes

The PL/pgSQL language is already registered in all databases by default. The PL/Python language extension is installed but not registered.

The system catalog `pg_language` records information about the currently installed languages.

To create functions in a procedural language, a user must have the `USAGE` privilege for the language. By default, `USAGE` is granted to `PUBLIC` (everyone) for trusted languages. This may be revoked if desired.

Procedural languages are local to individual databases. You create and drop languages for individual databases.

The call handler function and the validator function (if any) must already exist if the server does not have an entry for the language in `pg_pltemplate`. But when there is an entry, the functions need not already exist; they will be automatically defined if not present in the database.
Any shared library that implements a language must be located in the same `LD_LIBRARY_PATH` location on all segment hosts in your Greenplum Database array.

### Examples

The preferred way of creating any of the standard procedural languages is to use `CREATE EXTENSION` instead of `CREATE LANGUAGE`. For example:

```
CREATE EXTENSION plperl;
```

For a language not known in the `pg_pltemplate` catalog:

```
CREATE FUNCTION plsample_call_handler() RETURNS language_handler
  AS '$libdir/plsample'
  LANGUAGE C;
CREATE LANGUAGE plsample
  HANDLER plsample_call_handler;
```

### Compatibility

`CREATE LANGUAGE` is a Greenplum Database extension.

**See Also**

`ALTER LANGUAGE`, `CREATE EXTENSION`, `CREATE FUNCTION`, `DROP EXTENSION`, `DROP LANGUAGE`, `GRANT DO`  

---

**CREATE OPERATOR**

Defines a new operator.

### Synopsis

```
CREATE OPERATOR name (  
  PROCEDURE = funcname  
  [, LEFTARG = lefttype] [, RIGHTARG = righttype]  
  [, COMMUTATOR = com_op] [, NEGATOR = neg_op]  
  [, RESTRICT = res_proc] [, JOIN = join_proc]  
  [, HASHES] [, MERGES] )
```

### Description

`CREATE OPERATOR` defines a new operator. The user who defines an operator becomes its owner.

The operator name is a sequence of up to `NAMEDATALEN`-1 (63 by default) characters from the following list: `+ - * / < > = ~ ! @ # % ^ & | ` ?

There are a few restrictions on your choice of name:

- `--` and `/` cannot appear anywhere in an operator name, since they will be taken as the start of a comment.
- A multicharacter operator name cannot end in `+` or `−`, unless the name also contains at least one of these characters: `~ ! @ # % ^ & | ` ?

For example, `@-` is an allowed operator name, but `*−` is not. This restriction allows Greenplum Database to parse SQL-compliant commands without requiring spaces between tokens.

The operator `!=` is mapped to `<>` on input, so these two names are always equivalent.
At least one of \texttt{LEFTARG} and \texttt{RIGHTARG} must be defined. For binary operators, both must be defined. For right unary operators, only \texttt{LEFTARG} should be defined, while for left unary operators only \texttt{RIGHTARG} should be defined.

The \texttt{funcname} procedure must have been previously defined using \texttt{CREATE FUNCTION}, must be \texttt{IMMUTABLE}, and must be defined to accept the correct number of arguments (either one or two) of the indicated types.

The other clauses specify optional operator optimization clauses. These clauses should be provided whenever appropriate to speed up queries that use the operator. But if you provide them, you must be sure that they are correct. Incorrect use of an optimization clause can result in server process crashes, subtly wrong output, or other unexpected results. You can always leave out an optimization clause if you are not sure about it.

**Parameters**

\begin{itemize}
  \item \texttt{name} \\
      The (optionally schema-qualified) name of the operator to be defined. Two operators in the same schema can have the same name if they operate on different data types.
  \item \texttt{funcname} \\
      The function used to implement this operator (must be an \texttt{IMMUTABLE} function).
  \item \texttt{lefttype} \\
      The data type of the operator's left operand, if any. This option would be omitted for a left-unary operator.
  \item \texttt{righttype} \\
      The data type of the operator's right operand, if any. This option would be omitted for a right-unary operator.
  \item \texttt{com_op} \\
      The optional \texttt{COMMUTATOR} clause names an operator that is the commutator of the operator being defined. We say that operator A is the commutator of operator B if \((x \ A \ y) = (y \ B \ x)\) for all possible input values \(x, y\). Notice that B is also the commutator of A. For example, operators \(<\) and \(\geq\) for a particular data type are usually each others commutators, and operator \(+\) is usually commutative with itself. But operator \(-\) is usually not commutative with anything. The left operand type of a commutable operator is the same as the right operand type of its commutator, and vice versa. So the name of the commutator operator is all that needs to be provided in the \texttt{COMMUTATOR} clause.
  \item \texttt{neg_op} \\
      The optional \texttt{NEGATOR} clause names an operator that is the negator of the operator being defined. We say that operator A is the negator of operator B if both return Boolean results and \((x \ A \ y) = \text{NOT} (x \ B \ y)\) for all possible inputs \(x, y\). Notice that B is also the negator of A. For example, \(<\) and \(\geq\) are a negator pair for most data types. An operator's negator must have the same left and/or right operand types as the operator to be defined, so only the operator name need be given in the \texttt{NEGATOR} clause.
  \item \texttt{res_proc} \\
      The optional \texttt{RESTRICT} names a restriction selectivity estimation function for the operator. Note that this is a function name, not an operator name. \texttt{RESTRICT} clauses only make sense for binary operators that return \texttt{boolean}. The idea behind a restriction selectivity estimator is to guess what fraction of the rows in a table will satisfy a \texttt{WHERE}-clause condition of the form:

      \begin{verbatim}
      \text{column \ OP \ constant}
      \end{verbatim}

      for the current operator and a particular constant value. This assists the optimizer by giving it some idea of how many rows will be eliminated by \texttt{WHERE} clauses that have this form.
\end{itemize}
You can usually just use one of the following system standard estimator functions for many of your own operators:

- eqsel for =
- neqsel for <>
- scalarltsel for < or <=
- scalargtsel for > or >=

**join_proc**

The optional JOIN clause names a join selectivity estimation function for the operator. Note that this is a function name, not an operator name. JOIN clauses only make sense for binary operators that return boolean. The idea behind a join selectivity estimator is to guess what fraction of the rows in a pair of tables will satisfy a WHERE-clause condition of the form

```
table1.column1 OP table2.column2
```

for the current operator. This helps the optimizer by letting it figure out which of several possible join sequences is likely to take the least work.

You can usually just use one of the following system standard join selectivity estimator functions for many of your own operators:

- eqjoinsel for =
- neqjoinsel for <>
- scalarltjoinsel for < or <=
- scalargtjoinsel for > or >=
- areajoinsel for 2D area-based comparisons
- positionjoinsel for 2D position-based comparisons
- contjoinsel for 2D containment-based comparisons

**HASHES**

The optional HASHES clause tells the system that it is permissible to use the hash join method for a join based on this operator. HASHES only makes sense for a binary operator that returns boolean. The hash join operator can only return true for pairs of left and right values that hash to the same hash code. If two values are put in different hash buckets, the join will never compare them, implicitly assuming that the result of the join operator must be false. Because of this, it never makes sense to specify HASHES for operators that do not represent equality.

In most cases, it is only practical to support hashing for operators that take the same data type on both sides. However, you can design compatible hash functions for two or more data types, which are functions that will generate the same hash codes for "equal" values, even if the values are differently represented.

To be marked HASHES, the join operator must appear in a hash index operator class. Attempts to use the operator in hash joins will fail at run time if no such operator class exists. The system needs the operator class to find the data-type-specific hash function for the operator's input data type. You must also supply a suitable hash function before you can create the operator class. Exercise care when preparing a hash function, as there are machine-dependent ways in which it could fail to function correctly. For example, on machines that meet the IEEE floating-point standard, negative zero and positive zero are different values (different bit patterns) but are defined to compare as equal. If a float value could contain a negative zero, define it to generate the same hash value as positive zero.
A hash-joinable operator must have a commutator (itself, if the two operand data types are the same, or a related equality operator if they are different) that appears in the same operator family. Otherwise, planner errors can occur when the operator is used. For better optimization, a hash operator family that supports multiple data types should provide equality operators for every combination of the data types.

**Note:** The function underlying a hash-joinable operator must be marked immutable or stable; an operator marked as volatile will not be used. If a hash-joinable operator has an underlying function that is marked strict, the function must also be complete, returning true or false, and not null, for any two non-null inputs.

**MERGES**

The **MERGES** clause, if present, tells the system that it is permissible to use the merge-join method for a join based on this operator. **MERGES** only makes sense for a binary operator that returns boolean, and in practice the operator must represent equality for some data type or pair of data types.

Merge join is based on the idea of sorting the left- and right-hand tables into order and then scanning them in parallel. This means both data types must be capable of being fully ordered, and the join operator must be one that can only succeed for pairs of values that fall at equivalent places in the sort order. In practice, this means that the join operator must behave like an equality operator. However, you can merge-join two distinct data types so long as they are logically compatible. For example, the `smallint-versus-integer` equality operator is merge-joinable. Only sorting operators that bring both data types into a logically compatible sequence are needed.

To be marked **MERGES**, the join operator must appear as an equality member of a btree index operator family. This is not enforced when you create the operator, because the referencing operator family does not exist until later. However, the operator will not actually be used for merge joins unless a matching operator family can be found. The **MERGE** flag thus acts as a suggestion to the planner to look for a matching operator family.

A merge-joinable operator must have a commutator that appears in the same operator family. This would be itself, if the two operand data types are the same, or a related equality operator if the data types are different. Without an appropriate commutator, planner errors can occur when the operator is used. Also, although not strictly required, a btree operator family that supports multiple data types should be able to provide equality operators for every combination of the data types; this allows better optimization.

**Note:** SORT1, SORT2, LTCMP, and GTCMP were formerly used to specify the names of sort operators associated with a merge-joinable operator. Information about associated operators is now found by looking at B-tree operator families; specifying any of these operators will be ignored, except that it will implicitly set MERGES to true.

**Notes**

Any functions used to implement the operator must be defined as **IMMUTABLE**.

**Examples**

Here is an example of creating an operator for adding two complex numbers, assuming we have already created the definition of type `complex`. First define the function that does the work, then define the operator:

```sql
CREATE FUNCTION complex_add(complex, complex)
RETURNS complex
AS 'filename', 'complex_add'
LANGUAGE C IMMUTABLE STRICT;
```
CREATE OPERATOR + (  
  leftarg = complex,  
  rightarg = complex,  
  procedure = complex_add,  
  commutator = +  
);

To use this operator in a query:

```
SELECT (a + b) AS c FROM test_complex;
```

**Compatibility**

CREATE OPERATOR is a Greenplum Database language extension. The SQL standard does not provide for user-defined operators.

**See Also**

CREATE FUNCTION, CREATE TYPE, ALTER OPERATOR, DROP OPERATOR

---

**CREATE OPERATOR CLASS**

Defines a new operator class.

**Synopsis**

```
CREATE OPERATOR CLASS name [DEFAULT] FOR TYPE data_type  
  USING index_method AS  
  {  
    OPERATOR strategy_number op_name [(op_type, op_type)] [RECHECK]  
    | FUNCTION support_number funcname (argument_type [, ...] )  
    | STORAGE storage_type  
  } [, ... ]
```

**Description**

CREATE OPERATOR CLASS creates a new operator class. An operator class defines how a particular data type can be used with an index. The operator class specifies that certain operators will fill particular roles or strategies for this data type and this index method. The operator class also specifies the support procedures to be used by the index method when the operator class is selected for an index column. All the operators and functions used by an operator class must be defined before the operator class is created. Any functions used to implement the operator class must be defined as IMMUTABLE.

CREATE OPERATOR CLASS does not presently check whether the operator class definition includes all the operators and functions required by the index method, nor whether the operators and functions form a self-consistent set. It is the user's responsibility to define a valid operator class.

You must be a superuser to create an operator class.

**Parameters**

- **name**
  The (optionally schema-qualified) name of the operator class to be defined. Two operator classes in the same schema can have the same name only if they are for different index methods.

- **DEFAULT**
  Makes the operator class the default operator class for its data type. At most one operator class can be the default for a specific data type and index method.
**data_type**

The column data type that this operator class is for.

**index_method**

The name of the index method this operator class is for. Choices are `btree`, `bitmap`, and `gist`.

**strategy_number**

The operators associated with an operator class are identified by `strategy numbers`, which serve to identify the semantics of each operator within the context of its operator class. For example, B-trees impose a strict ordering on keys, lesser to greater, and so operators like `less than` and `greater than or equal` to are interesting with respect to a B-tree. These strategies can be thought of as generalized operators. Each operator class specifies which actual operator corresponds to each strategy for a particular data type and interpretation of the index semantics. The corresponding strategy numbers for each index method are as follows:

**Table 101: B-tree and Bitmap Strategies**

<table>
<thead>
<tr>
<th>Operation</th>
<th>Strategy Number</th>
</tr>
</thead>
<tbody>
<tr>
<td>less than</td>
<td>1</td>
</tr>
<tr>
<td>less than or equal</td>
<td>2</td>
</tr>
<tr>
<td>equal</td>
<td>3</td>
</tr>
<tr>
<td>greater than or equal</td>
<td>4</td>
</tr>
<tr>
<td>greater than</td>
<td>5</td>
</tr>
</tbody>
</table>

**Table 102: GiST Two-Dimensional Strategies (R-Tree)**

<table>
<thead>
<tr>
<th>Operation</th>
<th>Strategy Number</th>
</tr>
</thead>
<tbody>
<tr>
<td>strictly left of</td>
<td>1</td>
</tr>
<tr>
<td>does not extend to right of</td>
<td>2</td>
</tr>
<tr>
<td>overlaps</td>
<td>3</td>
</tr>
<tr>
<td>does not extend to left of</td>
<td>4</td>
</tr>
<tr>
<td>strictly right of</td>
<td>5</td>
</tr>
<tr>
<td>same</td>
<td>6</td>
</tr>
<tr>
<td>contains</td>
<td>7</td>
</tr>
<tr>
<td>contained by</td>
<td>8</td>
</tr>
<tr>
<td>does not extend above</td>
<td>9</td>
</tr>
<tr>
<td>strictly below</td>
<td>10</td>
</tr>
<tr>
<td>strictly above</td>
<td>11</td>
</tr>
<tr>
<td>does not extend below</td>
<td>12</td>
</tr>
</tbody>
</table>

**operator_name**

The name (optionally schema-qualified) of an operator associated with the operator class.

**op_type**
The operand data type(s) of an operator, or NONE to signify a left-unary or right-unary operator. The operand data types may be omitted in the normal case where they are the same as the operator class data type.

RECHECK

If present, the index is "lossy" for this operator, and so the rows retrieved using the index must be rechecked to verify that they actually satisfy the qualification clause involving this operator.

**support_number**

Index methods require additional support routines in order to work. These operations are administrative routines used internally by the index methods. As with strategies, the operator class identifies which specific functions should play each of these roles for a given data type and semantic interpretation. The index method defines the set of functions it needs, and the operator class identifies the correct functions to use by assigning them to the **support function numbers** as follows:

**Table 103: B-tree and Bitmap Support Functions**

<table>
<thead>
<tr>
<th>Function</th>
<th>Support Number</th>
</tr>
</thead>
<tbody>
<tr>
<td>Compare two keys and return an integer less than zero, zero, or greater than zero, indicating whether the first key is less than, equal to, or greater than the second.</td>
<td>1</td>
</tr>
</tbody>
</table>

**Table 104: GiST Support Functions**

<table>
<thead>
<tr>
<th>Function</th>
<th>Support Number</th>
</tr>
</thead>
<tbody>
<tr>
<td>consistent - determine whether key satisfies the query qualifier.</td>
<td>1</td>
</tr>
<tr>
<td>union - compute union of a set of keys.</td>
<td>2</td>
</tr>
<tr>
<td>compress - compute a compressed representation of a key or value to be indexed.</td>
<td>3</td>
</tr>
<tr>
<td>decompress - compute a decompressed representation of a compressed key.</td>
<td>4</td>
</tr>
<tr>
<td>penalty - compute penalty for inserting new key into subtree with given subtree's key.</td>
<td>5</td>
</tr>
<tr>
<td>picksplit - determine which entries of a page are to be moved to the new page and compute the union keys for resulting pages.</td>
<td>6</td>
</tr>
<tr>
<td>equal - compare two keys and return true if they are equal.</td>
<td>7</td>
</tr>
</tbody>
</table>

**funcname**

The name (optionally schema-qualified) of a function that is an index method support procedure for the operator class.

**argument_types**

The parameter data type(s) of the function.

**storage_type**
The data type actually stored in the index. Normally this is the same as the column data type, but the GiST index method allows it to be different. The `STORAGE` clause must be omitted unless the index method allows a different type to be used.

**Notes**

Because the index machinery does not check access permissions on functions before using them, including a function or operator in an operator class is the same as granting public execute permission on it. This is usually not an issue for the sorts of functions that are useful in an operator class.

The operators should not be defined by SQL functions. A SQL function is likely to be inlined into the calling query, which will prevent the optimizer from recognizing that the query matches an index.

Any functions used to implement the operator class must be defined as `IMMUTABLE`.

**Examples**

The following example command defines a GiST index operator class for the data type `int4` (array of `int4`):

```
CREATE OPERATOR CLASS gist__int_ops
DEFAULT FOR TYPE _int4 USING gist AS
  OPERATOR 3 &&,
  OPERATOR 6 = RECHECK,
  OPERATOR 7 @>,
  OPERATOR 8 <@,
  OPERATOR 20 @@ (_int4, query_int),
  FUNCTION 1 g_int_consistent (internal, _int4, int4),
  FUNCTION 2 g_int_union (bytea, internal),
  FUNCTION 3 g_int_compress (internal),
  FUNCTION 4 g_int_decompress (internal),
  FUNCTION 5 g_int_penalty (internal, internal, internal),
  FUNCTION 6 g_int_picksplit (internal, internal),
  FUNCTION 7 g_int_same (_int4, _int4, internal);
```

**Compatibility**

`CREATE OPERATOR CLASS` is a Greenplum Database extension. There is no `CREATE OPERATOR CLASS` statement in the SQL standard.

**See Also**

`ALTER OPERATOR CLASS, DROP OPERATOR CLASS, CREATE FUNCTION`

**CREATE OPERATOR FAMILY**

Defines a new operator family.

**Synopsis**

```
CREATE OPERATOR FAMILY name USING index_method
```

**Description**

`CREATE OPERATOR FAMILY` creates a new operator family. An operator family defines a collection of related operator classes, and perhaps some additional operators and support functions that are compatible with these operator classes but not essential for the functioning of any individual index. (Operators and functions that are essential to indexes should be grouped within the relevant operator class, rather than being "loose" in the operator family. Typically, single-data-type operators are bound to operator classes,
while cross-data-type operators can be loose in an operator family containing operator classes for both
data types.)

The new operator family is initially empty. It should be populated by issuing subsequent CREATE
OPERATOR CLASS commands to add contained operator classes, and optionally ALTER OPERATOR
FAMILY commands to add "loose" operators and their corresponding support functions.

If a schema name is given then the operator family is created in the specified schema. Otherwise it is
created in the current schema. Two operator families in the same schema can have the same name only if
they are for different index methods.

The user who defines an operator family becomes its owner. Presently, the creating user must be a
superuser. (This restriction is made because an erroneous operator family definition could confuse or even
-crash the server.)

**Parameters**

*name*

The (optionally schema-qualified) name of the operator family to be defined. The name can
be schema-qualified.

*index_method*

The name of the index method this operator family is for.

**Compatibility**

CREATE OPERATOR FAMILY is a Greenplum Database extension. There is no CREATE OPERATOR
FAMILY statement in the SQL standard.

**See Also**

ALTER OPERATOR FAMILY, DROP OPERATOR FAMILY, CREATE FUNCTION, ALTER OPERATOR
CLASS, CREATE OPERATOR CLASS, DROP OPERATOR CLASS

---

### CREATE PROTOCOL

Registers a custom data access protocol that can be specified when defining a Greenplum Database
external table.

**Synopsis**

```sql
CREATE [TRUSTED] PROTOCOL name ( [readfunc='read_call_handler'] [, writefunc='write_call_handler'] [, validatorfunc='validate_handler'] )
```

**Description**

CREATE PROTOCOL associates a data access protocol name with call handlers that are responsible for
reading from and writing data to an external data source.

The CREATE PROTOCOL command must specify either a read call handler or a write call handler. The call
handlers specified in the CREATE PROTOCOL command must be defined in the database.

The protocol name can be specified in a CREATE EXTERNAL TABLE command.

For information about creating and enabling a custom data access protocol, see "Example Custom Data

**Parameters**

TRUSTED
If not specified, only superusers and the protocol owner can create external tables using the protocol. If specified, superusers and the protocol owner can \texttt{GRANT} permissions on the protocol to other database roles.

\textbf{name}

The name of the data access protocol. The protocol name is case sensitive. The name must be unique among the protocols in the database.

\textbf{readfunc= 'read\_call\_handler'}

The name of a previously registered function that Greenplum Database calls to read data from an external data source. The command must specify either a read call handler or a write call handler.

\textbf{writefunc= 'write\_call\_handler'}

The name of a previously registered function that Greenplum Database calls to write data to an external data source. The command must specify either a read call handler or a write call handler.

\textbf{validatorfunc='validate\_handler'}

An optional validator function that validates the URL specified in the \texttt{CREATE EXTERNAL TABLE} command.

\textbf{Notes}

Greenplum Database handles external tables of type \texttt{file}, \texttt{gpfdist}, and \texttt{gpfdists} internally. The custom protocol \texttt{gphdfs} (deprecated) is registered in Greenplum Database by default. See \texttt{Configuring and Using S3 External Tables} for information about enabling the \texttt{s3} protocol. See the \texttt{Greenplum Platform Extension Framework (PXF)} documentation for information about configuring the PXF extension and using the \texttt{pxf} protocol.

Any shared library that implements a data access protocol must be located in the same location on all Greenplum Database segment hosts. For example, the shared library can be in a location specified by the operating system environment variable \texttt{LD\_LIBRARY\_PATH} on all hosts. You can also specify the location when you define the handler function. For example, when you define the \texttt{s3} protocol in the \texttt{CREATE PROTOCOL} command, you specify \texttt{$libdir/gps3ext.so} as the location of the shared object, where \texttt{$libdir} is located at \texttt{$GPHOME/lib}.

\textbf{Compatibility}

\texttt{CREATE PROTOCOL} is a Greenplum Database extension.

\textbf{See Also}

\texttt{ALTER PROTOCOL, CREATE EXTERNAL TABLE, DROP PROTOCOL, GRANT}

\textbf{CREATE RESOURCE GROUP}

Defines a new resource group.

\textbf{Synopsis}

\texttt{CREATE RESOURCE GROUP name WITH (group\_attribute=value [, ... ])}

where \texttt{group\_attribute} is:

- \texttt{CPU\_RATE\_LIMIT=integer} \texttt{| CPUSET=tuple}
- \texttt{MEMORY\_LIMIT=integer}
- \texttt{[ CONCURRENCY=integer ]}
- \texttt{[ MEMORY\_SHARED\_QUOTA=integer ]}
Description

Creates a new resource group for Greenplum Database resource management. You can create resource groups to manage resources for roles or to manage the resources of a Greenplum Database external component such as PL/Container.

A resource group that you create to manage a user role identifies concurrent transaction, memory, and CPU limits for the role when resource groups are enabled. You may assign such resource groups to one or more roles.

A resource group that you create to manage the resources of a Greenplum Database external component such as PL/Container identifies the memory and CPU limits for the component when resource groups are enabled. These resource groups use cgroups for both CPU and memory management. Assignment of resource groups to external components is component-specific. For example, you assign a PL/Container resource group when you configure a PL/Container runtime. You cannot assign a resource group that you create for external components to a role, nor can you assign a resource group that you create for roles to an external component.

You must have SUPERUSER privileges to create a resource group. The maximum number of resource groups allowed in your Greenplum Database cluster is 100.

Greenplum Database pre-defines two default resource groups: admin_group and default_group. These group names, as well as the group name none, are reserved.

To set appropriate limits for resource groups, the Greenplum Database administrator must be familiar with the queries typically executed on the system, as well as the users/roles executing those queries and the external components they may be using, such as PL/Containers.

After creating a resource group for a role, assign the group to one or more roles using the ALTER ROLE or CREATE ROLE commands.

After you create a resource group to manage the CPU and memory resources of an external component, configure the external component to use the resource group. For example, configure the PL/Container runtime resource_group_id.

Parameters

name

The name of the resource group.

CONCURRENY integer

The maximum number of concurrent transactions, including active and idle transactions, that are permitted for this resource group. The CONCURRENY value must be an integer in the range [0 .. max_connections]. The default CONCURRENY value for resource groups defined for roles is 20.

You must set CONCURRENY to zero (0) for resource groups that you create for external components.

Note: You cannot set the CONCURRENY value for the admin_group to zero (0).

CPU_RATE_LIMIT integer

Required. You must specify only one of CPU_RATE_LIMIT or CPUSET when you create a resource group.

CPU_RATE_LIMIT is the percentage of CPU resources to allocate to this resource group. The minimum CPU percentage you can specify for a resource group is 1. The maximum is...
100. The sum of the CPU_RATE_LIMIT values specified for all resource groups defined in the Greenplum Database cluster must be less than or equal to 100.

CPUSET identifies the CPU cores to reserve for this resource group. The CPU cores that you specify in tuple must be available in the system and cannot overlap with any CPU cores that you specify for other resource groups.

tuple is a comma-separated list of single core numbers or core number intervals. You must enclose tuple in single quotes, for example, ‘1,3-4’.

**Note:** You can configure CPUSET for a resource group only after you have enabled resource group-based resource management for your Greenplum Database cluster.

**MEMORY_LIMIT integer**

Required. The total percentage of Greenplum Database memory resources to reserve for this resource group. The minimum memory percentage you can specify for a resource group is 0. The maximum is 100.

When you specify a MEMORY_LIMIT of 0, Greenplum Database reserves no memory for the resource group, but uses global shared memory to fulfill all memory requests in the group. If MEMORY_LIMIT is 0, MEMORY_SPILL_RATIO must also be 0.

The sum of the MEMORY_LIMIT values specified for all resource groups defined in the Greenplum Database cluster must be less than or equal to 100.

**MEMORY_SHARED QUOTA integer**

The quota of shared memory in the resource group. Resource groups with a MEMORY_SHARED QUOTA threshold set aside a percentage of memory allotted to the resource group to share across transactions. This shared memory is allocated on a first-come, first-served basis as available. A transaction may use none, some, or all of this memory. The minimum memory shared quota percentage you can specify for a resource group is 0. The maximum is 100. The default MEMORY_SHARED QUOTA value is 20.

**MEMORY_SPILL_RATIO integer**

The memory usage threshold for memory-intensive operators in a transaction. When this threshold is reached, a transaction spills to disk. You can specify an integer percentage value from 0 to 100 inclusive. The default MEMORY_SPILL_RATIO value is 20. When MEMORY_SPILL_RATIO is 0, Greenplum Database uses the statement_mem server configuration parameter value to control initial query operator memory.

**MEMORY_AUDITOR {vmtracker | cgroup}**

The memory auditor for the resource group. Greenplum Database employs virtual memory tracking for role resources and cgroup memory tracking for resources used by external components. The default MEMORY_AUDITOR is vmtracker. When you create a resource group with vmtracker memory auditing, Greenplum Database tracks that resource group's memory internally.

When you create a resource group specifying the cgroup MEMORY_AUDITOR, Greenplum Database defers the accounting of memory used by that resource group to cgroups. CONCURRENCY must be zero (0) for a resource group that you create for external components such as PL/Container. You cannot assign a resource group that you create for external components to a Greenplum Database role.

**Notes**

You cannot submit a CREATE RESOURCE GROUP command in an explicit transaction or sub-transaction.
Use the `gp_toolkit.gp_resgroup_config` system view to display the limit settings of all resource groups:

```
SELECT * FROM gp_toolkit.gp_resgroup_config;
```

**Examples**

Create a resource group with CPU and memory limit percentages of 35:

```
CREATE RESOURCE GROUP rgroup1 WITH (CPU_RATE_LIMIT=35, MEMORY_LIMIT=35);
```

Create a resource group with a concurrent transaction limit of 20, a memory limit of 15, and a CPU limit of 25:

```
CREATE RESOURCE GROUP rgroup2 WITH (CONCURRENCY=20, MEMORY_LIMIT=15, CPU_RATE_LIMIT=25);
```

Create a resource group to manage PL/Container resources specifying a memory limit of 10, and a CPU limit of 10:

```
CREATE RESOURCE GROUP plc_run1 WITH (MEMORY_LIMIT=10, CPU_RATE_LIMIT=10, CONCURRENCY=0, MEMORY_AUDITOR=cgroup);
```

Create a resource group with a memory limit percentage of 11 to which you assign CPU cores 1 to 3:

```
CREATE RESOURCE GROUP rgroup3 WITH (CPUSET='1-3', MEMORY_LIMIT=11);
```

**Compatibility**

`CREATE RESOURCE GROUP` is a Greenplum Database extension. There is no provision for resource groups or resource management in the SQL standard.

**See Also**

`ALTER ROLE, CREATE ROLE, ALTER RESOURCE GROUP, DROP RESOURCE GROUP`

---

**CREATE RESOURCE QUEUE**

Defines a new resource queue.

**Synopsis**

```
CREATE RESOURCE QUEUE name WITH (queue_attribute=value [, ... ])
```

where `queue_attribute` is:

```
ACTIVE_STATEMENTS=integer
 | MAX_COST=float [ COST_OVERCOMMIT={TRUE|FALSE} ]
 | MIN_COST=float
 | PRIORITY={MIN|LOW|MEDIUM|HIGH|MAX}
 | MEMORY_LIMIT='memory_units'

MAX_COST=float [ COST_OVERCOMMIT={TRUE|FALSE} ]
 | ACTIVE_STATEMENTS=integer
 | MIN_COST=float
 | PRIORITY={MIN|LOW|MEDIUM|HIGH|MAX}
 | MEMORY_LIMIT='memory_units'
```
Description

Creates a new resource queue for Greenplum Database resource management. A resource queue must have either an `ACTIVE_STATEMENTS` or a `MAX_COST` value (or it can have both). Only a superuser can create a resource queue.

Resource queues with an `ACTIVE_STATEMENTS` threshold set a maximum limit on the number of queries that can be executed by roles assigned to that queue. It controls the number of active queries that are allowed to run at the same time. The value for `ACTIVE_STATEMENTS` should be an integer greater than 0.

Resource queues with a `MAX_COST` threshold set a maximum limit on the total cost of queries that can be executed by roles assigned to that queue. Cost is measured in the estimated total cost for the query as determined by the Greenplum Database query planner (as shown in the `EXPLAIN` output for a query). Therefore, an administrator must be familiar with the queries typically executed on the system in order to set an appropriate cost threshold for a queue. Cost is measured in units of disk page fetches; 1.0 equals one sequential disk page read. The value for `MAX_COST` is specified as a floating point number (for example 100.0) or can also be specified as an exponent (for example 1e+2). If a resource queue is limited based on a cost threshold, then the administrator can allow `COST_OVERCOMMIT=TRUE` (the default). This means that a query that exceeds the allowed cost threshold will be allowed to run but only when the system is idle. If `COST_OVERCOMMIT=FALSE` is specified, queries that exceed the cost limit will always be rejected and never allowed to run. Specifying a value for `MIN_COST` allows the administrator to define a cost for small queries that will be exempt from resource queueing.

**Note:** GPORCA and the legacy Greenplum Database query optimizer utilize different query costing models and may compute different costs for the same query. The Greenplum Database resource queue resource management scheme neither differentiates nor aligns costs between GPORCA and the legacy optimizer; it uses the literal cost value returned from the optimizer to throttle queries.

When resource queue-based resource management is active, use the `MEMORY_LIMIT` and `ACTIVE_STATEMENTS` limits for resource queues rather than configuring cost-based limits. Even when using GPORCA, Greenplum Database may fall back to using the legacy query optimizer for certain queries, so using cost-based limits can lead to unexpected results.

If a value is not defined for `ACTIVE_STATEMENTS` or `MAX_COST`, it is set to -1 by default (meaning no limit). After defining a resource queue, you must assign roles to the queue using the `ALTER ROLE` or `CREATE ROLE` command.

You can optionally assign a `PRIORITY` to a resource queue to control the relative share of available CPU resources used by queries associated with the queue in relation to other resource queues. If a value is not defined for `PRIORITY`, queries associated with the queue have a default priority of MEDIUM.

Resource queues with an optional `MEMORY_LIMIT` threshold set a maximum limit on the amount of memory that all queries submitted through a resource queue can consume on a segment host. This determines the total amount of memory that all worker processes of a query can consume on a segment host during query execution. Greenplum recommends that `MEMORY_LIMIT` be used in conjunction with `ACTIVE_STATEMENTS` rather than with `MAX_COST`. The default amount of memory allotted per query on statement-based queues is: `MEMORY_LIMIT / ACTIVE_STATEMENTS`. The default amount of memory allotted per query on cost-based queues is: `MEMORY_LIMIT * (query_cost / MAX_COST)`.

The default memory allotment can be overridden on a per-query basis using the `statement_mem` server configuration parameter, provided that `MEMORY_LIMIT` or `max_statement_mem` is not exceeded. For example, to allocate more memory to a particular query:

```sql
=> SET statement_mem='2GB';
=> SELECT * FROM my_big_table WHERE column='value' ORDER BY id;
=> RESET statement_mem;
```

The `MEMORY_LIMIT` value for all of your resource queues should not exceed the amount of physical memory of a segment host. If workloads are staggered over multiple queues, memory allocations can be oversubscribed. However, queries can be cancelled during execution if the segment host memory limit specified in `gp_vmem_protect_limit` is exceeded.
For information about `statement_mem`, `max_statement`, and `gp_vmem_protect_limit`, see Server Configuration Parameters.

### Parameters

**name**

The name of the resource queue.

**ACTIVE_STATEMENTS integer**

Resource queues with an `ACTIVE_STATEMENTS` threshold limit the number of queries that can be executed by roles assigned to that queue. It controls the number of active queries that are allowed to run at the same time. The value for `ACTIVE_STATEMENTS` should be an integer greater than 0.

**MEMORY_LIMIT 'memory_units'**

Sets the total memory quota for all statements submitted from users in this resource queue. Memory units can be specified in kB, MB or GB. The minimum memory quota for a resource queue is 10MB. There is no maximum, however the upper boundary at query execution time is limited by the physical memory of a segment host. The default is no limit (-1).

**MAX_COST float**

Resource queues with a `MAX_COST` threshold set a maximum limit on the total cost of queries that can be executed by roles assigned to that queue. Cost is measured in the estimated total cost for the query as determined by the Greenplum Database query optimizer (as shown in the `EXPLAIN` output for a query). Therefore, an administrator must be familiar with the queries typically executed on the system in order to set an appropriate cost threshold for a queue. Cost is measured in units of disk page fetches; 1.0 equals one sequential disk page read. The value for `MAX_COST` is specified as a floating point number (for example 100.0) or can also be specified as an exponent (for example 1e+2).

**COST_OVERCOMMIT boolean**

If a resource queue is limited based on `MAX_COST`, then the administrator can allow `COST_OVERCOMMIT` (the default). This means that a query that exceeds the allowed cost threshold will be allowed to run but only when the system is idle. If `COST_OVERCOMMIT=FALSE` is specified, queries that exceed the cost limit will always be rejected and never allowed to run.

**MIN_COST float**

The minimum query cost limit of what is considered a small query. Queries with a cost under this limit will not be queued and run immediately. Cost is measured in the estimated total cost for the query as determined by the Greenplum Database query planner (as shown in the `EXPLAIN` output for a query). Therefore, an administrator must be familiar with the queries typically executed on the system in order to set an appropriate cost for what is considered a small query. Cost is measured in units of disk page fetches; 1.0 equals one sequential disk page read. The value for `MIN_COST` is specified as a floating point number (for example 100.0) or can also be specified as an exponent (for example 1e+2).

**PRIORITY={MIN|LOW|MEDIUM|HIGH|MAX}**

Sets the priority of queries associated with a resource queue. Queries or statements in queues with higher priority levels will receive a larger share of available CPU resources in case of contention. Queries in low-priority queues may be delayed while higher priority queries are executed. If no priority is specified, queries associated with the queue have a priority of `MEDIUM`. 
Notes
Use the `gp_toolkit.gp_resqueue_status` system view to see the limit settings and current status of a resource queue:

```
SELECT * from gp_toolkit.gp_resqueue_status WHERE rsqname='queue_name';
```

There is also another system view named `pg_stat_resqueues` which shows statistical metrics for a resource queue over time. To use this view, however, you must enable the `stats_queue_level` server configuration parameter. See "Managing Workload and Resources" in the Greenplum Database Administrator Guide for more information about using resource queues.

`CREATE RESOURCE QUEUE` cannot be run within a transaction.

Also, an SQL statement that is run during the execution of an `EXPLAIN ANALYZE` command is excluded from resource queues.

Examples
Create a resource queue with an active query limit of 20:

```
CREATE RESOURCE QUEUE myqueue WITH (ACTIVE_STATEMENTS=20);
```

Create a resource queue with an active query limit of 20 and a total memory limit of 2000MB (each query will be allocated 100MB of segment host memory at execution time):

```
CREATE RESOURCE QUEUE myqueue WITH (ACTIVE_STATEMENTS=20,
MEMORY_LIMIT='2000MB');
```

Create a resource queue with a query cost limit of 3000.0:

```
CREATE RESOURCE QUEUE myqueue WITH (MAX_COST=3000.0);
```

Create a resource queue with a query cost limit of $3^{10}$ (or 30000000000.0) and do not allow overcommit. Allow small queries with a cost under 500 to run immediately:

```
CREATE RESOURCE QUEUE myqueue WITH (MAX_COST=3e+10,
COST_OVERCOMMIT=FALSE, MIN_COST=500.0);
```

Create a resource queue with both an active query limit and a query cost limit:

```
CREATE RESOURCE QUEUE myqueue WITH (ACTIVE_STATEMENTS=30,
MAX_COST=5000.00);
```

Create a resource queue with an active query limit of 5 and a maximum priority setting:

```
CREATE RESOURCE QUEUE myqueue WITH (ACTIVE_STATEMENTS=5,
PRIORITY=MAX);
```

Compatibility
`CREATE RESOURCE QUEUE` is a Greenplum Database extension. There is no provision for resource queues or resource management in the SQL standard.

See Also
`ALTER ROLE`, `CREATE ROLE`, `ALTER RESOURCE QUEUE`, `DROP RESOURCE QUEUE`
**CREATE ROLE**

Defines a new database role (user or group).

**Synopsis**

```sql
CREATE ROLE name [[WITH] option [ ... ]]
```

where `option` can be:

- `SUPERUSER | NOSUPERUSER`
- `CREATEDB | NOCREATEDB`
- `CREATEROLE | NOCREATEROLE`
- `CREATEUSER | NOCREATEUSER`
- `CREATEEXTABLE | NOCREATEEXTABLE`
- `INHERIT | NOINHERIT`
- `LOGIN | NOLOGIN`
- `CONNECTION LIMIT conlimit`
- `[ ENCRYPTED | UNENCRYPTED ] PASSWORD 'password'
- `VALID UNTIL 'timestamp'
- `IN ROLE rolename [, ...]
- `ROLE rolename [, ...]
- `ADMIN rolename [, ...]
- `RESOURCE QUEUE queue_name`
- `RESOURCE GROUP group_name`
- `[ DENY deny_point ]`
- `[ DENY BETWEEN deny_point AND deny_point]`

**Description**

`CREATE ROLE` adds a new role to a Greenplum Database system. A role is an entity that can own database objects and have database privileges. A role can be considered a user, a group, or both depending on how it is used. You must have `CREATEROLE` privilege or be a database superuser to use this command.

Note that roles are defined at the system-level and are valid for all databases in your Greenplum Database system.

**Parameters**

- `name`
  - The name of the new role.

  `SUPERUSER | NOSUPERUSER`

  If `SUPERUSER` is specified, the role being defined will be a superuser, who can override all access restrictions within the database. Superuser status is dangerous and should be used only when really needed. You must yourself be a superuser to create a new superuser. `NOSUPERUSER` is the default.

  `CREATEDB | NOCREATEDB`

  If `CREATEDB` is specified, the role being defined will be allowed to create new databases. `NOCREATEDB` (the default) will deny a role the ability to create databases.
CREATEROLE
NOCREATEROLE

If CREATEROLE is specified, the role being defined will be allowed to create new roles, alter other roles, and drop other roles. NOCREATEROLE (the default) will deny a role the ability to create roles or modify roles other than their own.

CREATEUSER
NOCREATEUSER

These clauses are obsolete, but still accepted, spellings of SUPERUSER and NOSUPERUSER. Note that they are not equivalent to the CREATEROLE and NOCREATEROLE clauses.

CREATEEXTTABLE
NOCREATEEXTTABLE

If CREATEEXTTABLE is specified, the role being defined is allowed to create external tables. The default type is readable and the default protocol is gpfdist, if not specified. Valid types are gpfdist, gpfdists, http, and https. NOCREATEEXTTABLE (the default type) denies the role the ability to create external tables. Note that external tables that use the file or execute protocols can only be created by superusers.

Use the GRANT...ON PROTOCOL command to allow users to create and use external tables with a custom protocol type, including the gphdfs (deprecated), s3, and pxf protocols included with Greenplum Database.

INHERIT
NOINHERIT

If specified, INHERIT (the default) allows the role to use whatever database privileges have been granted to all roles it is directly or indirectly a member of. With NOINHERIT, membership in another role only grants the ability to SET ROLE to that other role.

LOGIN
NOLOGIN

If specified, LOGIN allows a role to log in to a database. A role having the LOGIN attribute can be thought of as a user. Roles with NOLOGIN (the default) are useful for managing database privileges, and can be thought of as groups.

CONNECTION LIMIT connlimit

The number maximum of concurrent connections this role can make. The default of -1 means there is no limitation.

PASSWORD password

Sets the user password for roles with the LOGIN attribute. If you do not plan to use password authentication you can omit this option. If no password is specified, the password will be set to null and password authentication will always fail for that user. A null password can optionally be written explicitly as PASSWORD NULL.

ENCRYPTED
UNENCRYPTED

These key words control whether the password is stored encrypted in the system catalogs. (If neither is specified, the default behavior is determined by the configuration parameter password_encryption.) If the presented password string is already in MD5-encrypted format, then it is stored encrypted as-is, regardless of whether ENCRYPTED or UNENCRYPTED is specified (since the system cannot decrypt the specified encrypted password string). This allows reloading of encrypted passwords during dump/restore.

Note that older clients may lack support for the MD5 authentication mechanism that is needed to work with passwords that are stored encrypted.

VALID UNTIL 'timestamp'
The VALID UNTIL clause sets a date and time after which the role's password is no longer valid. If this clause is omitted the password will never expire.

**IN ROLE rolename**

Adds the new role as a member of the named roles. Note that there is no option to add the new role as an administrator; use a separate GRANT command to do that.

**ROLE rolename**

Adds the named roles as members of this role, making this new role a group.

**ADMIN rolename**

The ADMIN clause is like ROLE, but the named roles are added to the new role WITH ADMIN OPTION, giving them the right to grant membership in this role to others.

**RESOURCE GROUP group_name**

The name of the resource group to assign to the the new role. The role will be subject to the concurrent transaction, memory, and CPU limits configured for the resource group. You can assign a single resource group to one or more roles.

If you do not specify a resource group for a new role, the role is automatically assigned the default resource group for the role's capability, admin_group for SUPERUSER roles, default_group for non-admin roles.

You can assign the admin_group resource group to any role having the SUPERUSER attribute.

You can assign the default_group resource group to any role.

You cannot assign a resource group that you create for an external component to a role.

**RESOURCE QUEUE queue_name**

The name of the resource queue to which the new user-level role is to be assigned. Only roles with LOGIN privilege can be assigned to a resource queue. The special keyword NONE means that the role is assigned to the default resource queue. A role can only belong to one resource queue.

Roles with the SUPERUSER attribute are exempt from resource queue limits. For a superuser role, queries always run immediately regardless of limits imposed by an assigned resource queue.

**DENY deny_point**

**DENY BETWEEN deny_point AND deny_point**

The DENY and DENY BETWEEN keywords set time-based constraints that are enforced at login. DENY sets a day or a day and time to deny access. DENY BETWEEN sets an interval during which access is denied. Both use the parameter deny_point that has the following format:

```plaintext
DAY day [ TIME 'time' ]
```

The two parts of the deny_point parameter use the following formats:

For day:

```plaintext
{ 'Sunday' | 'Monday' | 'Tuesday' | 'Wednesday' | 'Thursday' | 'Friday' | 'Saturday' | 0-6 }
```

For time:

```plaintext
{ 00-23 : 00-59 | 01-12 : 00-59 { AM | PM } }
```
The `DENY BETWEEN` clause uses two `deny_point` parameters:

```
DENY BETWEEN deny_point AND deny_point
```

For more information and examples about time-based constraints, see "Managing Roles and Privileges" in the Greenplum Database Administrator Guide.

**Notes**

The preferred way to add and remove role members (manage groups) is to use `GRANT` and `REVOKE`.

The `VALID UNTIL` clause defines an expiration time for a password only, not for the role. The expiration time is not enforced when logging in using a non-password-based authentication method.

The `INHERIT` attribute governs inheritance of grantable privileges (access privileges for database objects and role memberships). It does not apply to the special role attributes set by `CREATE ROLE` and `ALTER ROLE`. For example, being a member of a role with `CREATEDB` privilege does not immediately grant the ability to create databases, even if `INHERIT` is set. These privileges/attributes are never inherited: `SUPERUSER`, `CREATEDB`, `CREATEROLE`, `CREATEEXTTABLE`, `LOGIN`, `RESOURCE GROUP`, and `RESOURCE QUEUE`. The attributes must be set on each user-level role.

The `INHERIT` attribute is the default for reasons of backwards compatibility. In prior releases of Greenplum Database, users always had access to all privileges of groups they were members of. However, `NOINHERIT` provides a closer match to the semantics specified in the SQL standard.

Be careful with the `CREATEROLE` privilege. There is no concept of inheritance for the privileges of a `CREATEROLE`-role. That means that even if a role does not have a certain privilege but is allowed to create other roles, it can easily create another role with different privileges than its own (except for creating roles with superuser privileges). For example, if a role has the `CREATEROLE` privilege but not the `CREATEDB` privilege, it can create a new role with the `CREATEDB` privilege. Therefore, regard roles that have the `CREATEROLE` privilege as almost-superuser-roles.

The `CONNECTION LIMIT` option is never enforced for superusers.

Caution must be exercised when specifying an unencrypted password with this command. The password will be transmitted to the server in clear-text, and it might also be logged in the client's command history or the server log. The client program `createuser`, however, transmits the password encrypted. Also, `psql` contains a command `\password` that can be used to safely change the password later.

**Examples**

Create a role that can log in, but don’t give it a password:

```
CREATE ROLE jonathan LOGIN;
```

Create a role that belongs to a resource queue:

```
CREATE ROLE jonathan LOGIN RESOURCE QUEUE poweruser;
```

Create a role with a password that is valid until the end of 2016 (CREATE USER is the same as CREATE ROLE except that it implies LOGIN):

```
CREATE USER joelle WITH PASSWORD 'jw8s0F4' VALID UNTIL '2017-01-01';
```

Create a role that can create databases and manage other roles:

```
CREATE ROLE admin WITH CREATEDB CREATEROLE;
```
Create a role that does not allow login access on Sundays:

```sql
CREATE ROLE user3 DENY DAY 'Sunday';
```

Create a role that can create readable and writable external tables of type 'gpfdist':

```sql
CREATE ROLE jan WITH CREATEEXTTABLE(type='readable', protocol='gpfdist')
  CREATEEXTTABLE(type='writable', protocol='gpfdist');
```

Create a role, assigning a resource group:

```sql
CREATE ROLE bill RESOURCE GROUP rg_light;
```

**Compatibility**

The SQL standard defines the concepts of users and roles, but it regards them as distinct concepts and leaves all commands defining users to be specified by the database implementation. In Greenplum Database users and roles are unified into a single type of object. Roles therefore have many more optional attributes than they do in the standard.

`CREATE ROLE` is in the SQL standard, but the standard only requires the syntax:

```sql
CREATE ROLE name [WITH ADMIN rolename]
```

Allowing multiple initial administrators, and all the other options of `CREATE ROLE`, are Greenplum Database extensions.

The behavior specified by the SQL standard is most closely approximated by giving users the `NOINHERIT` attribute, while roles are given the `INHERIT` attribute.

**See Also**

`SET ROLE`, `ALTER ROLE`, `DROP ROLE`, `GRANT`, `REVOKE`, `CREATE RESOURCE QUEUE CREATE RESOURCE` GROUP

**CREATE RULE**

Defines a new rewrite rule.

**Synopsis**

```sql
CREATE [OR REPLACE] RULE name AS ON event
to table [WHERE condition]
do [ALSO | INSTEAD] { NOTHING | command | (command; command ... ) }
```

**Description**

`CREATE RULE` defines a new rule applying to a specified table or view. `CREATE OR REPLACE RULE` will either create a new rule, or replace an existing rule of the same name for the same table.

The Greenplum Database rule system allows one to define an alternate action to be performed on insertions, updates, or deletions in database tables. A rule causes additional or alternate commands to be executed when a given command on a given table is executed. Rules can be used on views as well. It is important to realize that a rule is really a command transformation mechanism, or command macro. The transformation happens before the execution of the commands starts. It does not operate independently for each physical row as does a trigger.
ON SELECT rules must be unconditional INSTEAD rules and must have actions that consist of a single SELECT command. Thus, an ON SELECT rule effectively turns the table into a view, whose visible contents are the rows returned by the rule's SELECT command rather than whatever had been stored in the table (if anything). It is considered better style to write a CREATE VIEW command than to create a real table and define an ON SELECT rule for it.

You can create the illusion of an updatable view by defining ON INSERT, ON UPDATE, and ON DELETE rules to replace update actions on the view with appropriate updates on other tables.

There is a catch if you try to use conditional rules for view updates: there must be an unconditional INSTEAD rule for each action you wish to allow on the view. If the rule is conditional, or is not INSTEAD, then the system will still reject attempts to perform the update action, because it thinks it might end up trying to perform the action on the dummy table of the view in some cases. If you want to handle all the useful cases in conditional rules, add an unconditional DO INSTEAD NOTHING rule to ensure that the system understands it will never be called on to update the dummy table. Then make the conditional rules non-INSTEAD; in the cases where they are applied, they add to the default INSTEAD NOTHING action. (This method does not currently work to support RETURNING queries, however.)

**Parameters**

**name**

The name of a rule to create. This must be distinct from the name of any other rule for the same table. Multiple rules on the same table and same event type are applied in alphabetical name order.

**event**

The event is one of SELECT, INSERT, UPDATE, or DELETE.

**table**

The name (optionally schema-qualified) of the table or view the rule applies to.

**condition**

Any SQL conditional expression (returning boolean). The condition expression may not refer to any tables except NEW and OLD, and may not contain aggregate functions. NEW and OLD refer to values in the referenced table. NEW is valid in ON INSERT and ON UPDATE rules to refer to the new row being inserted or updated. OLD is valid in ON UPDATE and ON DELETE rules to refer to the existing row being updated or deleted.

**INSTEAD**

INSTEAD indicates that the commands should be executed instead of the original command.

**ALSO**

ALSO indicates that the commands should be executed in addition to the original command. If neither ALSO nor INSTEAD is specified, ALSO is the default.

**command**

The command or commands that make up the rule action. Valid commands are SELECT, INSERT, UPDATE, or DELETE. The special table names NEW and OLD may be used to refer to values in the referenced table. NEW is valid in ON INSERT and ON UPDATE rules to refer to the new row being inserted or updated. OLD is valid in ON UPDATE and ON DELETE rules to refer to the existing row being updated or deleted.

**Notes**

You must be the owner of a table to create or change rules for it.

It is very important to take care to avoid circular rules. Recursive rules are not validated at rule create time, but will report an error at execution time.
Examples
Create a rule that inserts rows into the child table b2001 when a user tries to insert into the partitioned parent table rank:

```
CREATE RULE b2001 AS ON INSERT TO rank WHERE gender='M' and year='2001' DO INSTEAD INSERT INTO b2001 VALUES (NEW.id, NEW.rank, NEW.year, NEW.gender, NEW.count);
```

Compatibility
CREATE RULE is a Greenplum Database language extension, as is the entire query rewrite system.

See Also
DROP RULE, CREATE TABLE, CREATE VIEW

CREATE SCHEMA
Defines a new schema.

Synopsis
```
CREATE SCHEMA schema_name [AUTHORIZATION username]
  [schema_element [ ... ]]
```
```
CREATE SCHEMA AUTHORIZATION rolename [schema_element [ ... ]]
```

Description
CREATE SCHEMA enters a new schema into the current database. The schema name must be distinct from the name of any existing schema in the current database.

A schema is essentially a namespace: it contains named objects (tables, data types, functions, and operators) whose names may duplicate those of other objects existing in other schemas. Named objects are accessed either by qualifying their names with the schema name as a prefix, or by setting a search path that includes the desired schema(s). A CREATE command specifying an unqualified object name creates the object in the current schema (the one at the front of the search path, which can be determined with the function current_schema).

Optionally, CREATE SCHEMA can include subcommands to create objects within the new schema. The subcommands are treated essentially the same as separate commands issued after creating the schema, except that if the AUTHORIZATION clause is used, all the created objects will be owned by that role.

Parameters
```
schema_name
```
The name of a schema to be created. If this is omitted, the user name is used as the schema name. The name cannot begin with pg_, as such names are reserved for system catalog schemas.

```
rolename
```
The name of the role who will own the schema. If omitted, defaults to the role executing the command. Only superusers may create schemas owned by roles other than themselves.

```
schema_element
```
An SQL statement defining an object to be created within the schema. Currently, only CREATE TABLE, CREATE VIEW, CREATE INDEX, CREATE SEQUENCE, CREATE
TRIGGER and GRANT are accepted as clauses within CREATE SCHEMA. Other kinds of objects may be created in separate commands after the schema is created.

Note: Greenplum Database does not support triggers.

Notes
To create a schema, the invoking user must have the CREATE privilege for the current database or be a superuser.

Examples
Create a schema:

```
CREATE SCHEMA myschema;
```

Create a schema for role joe (the schema will also be named joe):

```
CREATE SCHEMA AUTHORIZATION joe;
```

Compatibility
The SQL standard allows a DEFAULT CHARACTER SET clause in CREATE SCHEMA, as well as more subcommand types than are presently accepted by Greenplum Database.

The SQL standard specifies that the subcommands in CREATE SCHEMA may appear in any order. The present Greenplum Database implementation does not handle all cases of forward references in subcommands; it may sometimes be necessary to reorder the subcommands in order to avoid forward references.

According to the SQL standard, the owner of a schema always owns all objects within it. Greenplum Database allows schemas to contain objects owned by users other than the schema owner. This can happen only if the schema owner grants the CREATE privilege on the schema to someone else.

See Also
ALTER SCHEMA, DROP SCHEMA

CREATE SEQUENCE
Defines a new sequence generator.

Synopsis

```
CREATE [TEMPORARY | TEMP] SEQUENCE name
[INCREMENT [BY] value]
[MINVALUE minvalue | NO MINVALUE]
[MAXVALUE maxvalue | NO MAXVALUE]
[START [ WITH ] start]
[CACHE cache]
[[NO] CYCLE]
[OWNED BY { table.column | NONE }]
```

Description
CREATE SEQUENCE creates a new sequence number generator. This involves creating and initializing a new special single-row table. The generator will be owned by the user issuing the command.
If a schema name is given, then the sequence is created in the specified schema. Otherwise it is created in
the current schema. Temporary sequences exist in a special schema, so a schema name may not be given
when creating a temporary sequence. The sequence name must be distinct from the name of any other
sequence, table, index, or view in the same schema.

After a sequence is created, you use the `nextval()` function to operate on the sequence. For example, to
insert a row into a table that gets the next value of a sequence:

```sql
INSERT INTO distributors VALUES (nextval('myserial'), 'acme');
```

You can also use the function `setval()` to operate on a sequence, but only for queries that do not
operate on distributed data. For example, the following query is allowed because it resets the sequence
counter value for the sequence generator process on the master:

```sql
SELECT setval('myserial', 201);
```

But the following query will be rejected in Greenplum Database because it operates on distributed data:

```sql
INSERT INTO product VALUES (setval('myserial', 201), 'gizmo');
```

In a regular (non-distributed) database, functions that operate on the sequence go to the local sequence
table to get values as they are needed. In Greenplum Database, however, keep in mind that each
segment is its own distinct database process. Therefore the segments need a single point of truth to go
for sequence values so that all segments get incremented correctly and the sequence moves forward in
the right order. A sequence server process runs on the master and is the point-of-truth for a sequence in a
Greenplum distributed database. Segments get sequence values at runtime from the master.

Because of this distributed sequence design, there are some limitations on the functions that operate on a
sequence in Greenplum Database:

- `lastval()` and `currval()` functions are not supported.
- `setval()` can only be used to set the value of the sequence generator on the master, it cannot be
  used in subqueries to update records on distributed table data.
- `nextval()` sometimes grabs a block of values from the master for a segment to use, depending on
  the query. So values may sometimes be skipped in the sequence if all of the block turns out not to be
  needed at the segment level. Note that a regular PostgreSQL database does this too, so this is not
  something unique to Greenplum Database.

Although you cannot update a sequence directly, you can use a query like:

```sql
SELECT * FROM sequence_name;
```

to examine the parameters and current state of a sequence. In particular, the `last_value` field of the
sequence shows the last value allocated by any session.

**Parameters**

<table>
<thead>
<tr>
<th>TEMPORARY</th>
<th>TEMP</th>
</tr>
</thead>
</table>
| If specified, the sequence object is created only for this session, and is automatically
  dropped on session exit. Existing permanent sequences with the same name are not
  visible (in this session) while the temporary sequence exists, unless they are referenced
  with schema-qualified names.

- **name**
  The name (optionally schema-qualified) of the sequence to be created.

- **increment**
Specifies which value is added to the current sequence value to create a new value. A positive value will make an ascending sequence, a negative one a descending sequence. The default value is 1.

```
minvalue
```

**NO MINVALUE**

Determines the minimum value a sequence can generate. If this clause is not supplied or **NO MINVALUE** is specified, then defaults will be used. The defaults are 1 and -263-1 for ascending and descending sequences, respectively.

```
maxvalue
```

**NO MAXVALUE**

Determines the maximum value for the sequence. If this clause is not supplied or **NO MAXVALUE** is specified, then default values will be used. The defaults are 263-1 and -1 for ascending and descending sequences, respectively.

```
start
```

Allows the sequence to begin anywhere. The default starting value is **minvalue** for ascending sequences and **maxvalue** for descending ones.

```
cache
```

Specifies how many sequence numbers are to be preallocated and stored in memory for faster access. The minimum (and default) value is 1 (no cache).

```
CYCLE
```

**NO CYCLE**

Allows the sequence to wrap around when the **maxvalue** (for ascending) or **minvalue** (for descending) has been reached. If the limit is reached, the next number generated will be the **minvalue** (for ascending) or **maxvalue** (for descending). If **NO CYCLE** is specified, any calls to **nextval()** after the sequence has reached its maximum value will return an error. If not specified, **NO CYCLE** is the default.

```
OWNED BY table.column
```

**OWNED BY NONE**

Causes the sequence to be associated with a specific table column, such that if that column (or its whole table) is dropped, the sequence will be automatically dropped as well. The specified table must have the same owner and be in the same schema as the sequence. **OWNED BY NONE**, the default, specifies that there is no such association.

**Notes**

Sequences are based on bigint arithmetic, so the range cannot exceed the range of an eight-byte integer (-223372036854775808 to 223372036854775807).

Although multiple sessions are guaranteed to allocate distinct sequence values, the values may be generated out of sequence when all the sessions are considered. For example, session A might reserve values 1..10 and return **nextval=1**, then session B might reserve values 11..20 and return **nextval=11** before session A has generated **nextval=2**. Thus, you should only assume that the **nextval()** values are all distinct, not that they are generated purely sequentially. Also, **last_value** will reflect the latest value reserved by any session, whether or not it has yet been returned by **nextval()**.

**Examples**

Create a sequence named **myseq**:

```
CREATE SEQUENCE myseq START 101;
```
Insert a row into a table that gets the next value of the sequence named \textit{idseq}:

```
INSERT INTO distributors VALUES (nextval('idseq'), 'acme');
```

Reset the sequence counter value on the master:

```
SELECT setval('myseq', 201);
```

Illegal use of \texttt{setval()} in Greenplum Database (setting sequence values on distributed data):

```
INSERT INTO product VALUES (setval('myseq', 201), 'gizmo');
```

**Compatibility**

\texttt{CREATE SEQUENCE} conforms to the SQL standard, with the following exceptions:

- The \texttt{AS data\_type} expression specified in the SQL standard is not supported.
- Obtaining the next value is done using the \texttt{nextval()} function instead of the \texttt{NEXT VALUE FOR} expression specified in the SQL standard.
- The \texttt{OWNED BY} clause is a Greenplum Database extension.

**See Also**

\texttt{ALTER SEQUENCE, DROP SEQUENCE}

**\texttt{CREATE TABLE}**

Defines a new table.

\textbf{Note:} Referential integrity syntax (foreign key constraints) is accepted but not enforced.

**Description**

`CREATE TABLE` creates an initially empty table in the current database. The user who issues the command owns the table.

If you specify a schema name, Greenplum creates the table in the specified schema. Otherwise Greenplum creates the table in the current schema. Temporary tables exist in a special schema, so you cannot specify a schema name when creating a temporary table. Table names must be distinct from the name of any other table, external table, sequence, index, or view in the same schema.

The optional constraint clauses specify conditions that new or updated rows must satisfy for an insert or update operation to succeed. A constraint is an SQL object that helps define the set of valid values in the table in various ways. Constraints apply to tables, not to partitions. You cannot add a constraint to a partition or subpartition.

Referential integrity constraints (foreign keys) are accepted but not enforced. The information is kept in the system catalogs but is otherwise ignored.

There are two ways to define constraints: table constraints and column constraints. A column constraint is defined as part of a column definition. A table constraint definition is not tied to a particular column, and it can encompass more than one column. Every column constraint can also be written as a table constraint; a column constraint is only a notational convenience for use when the constraint only affects one column.

When creating a table, there is an additional clause to declare the Greenplum Database distribution policy. If a `DISTRIBUTED BY` or `DISTRIBUTED RANDOMLY` clause is not supplied, then Greenplum assigns a hash distribution policy to the table using either the `PRIMARY KEY` (if the table has one) or the first column of the table as the distribution key. Columns of geometric or user-defined data types are not eligible as Greenplum distribution key columns. If a table does not have a column of an eligible data type, the rows are distributed based on a round-robin or random distribution. To ensure an even distribution of data in your Greenplum Database system, you want to choose a distribution key that is unique for each record, or if that is not possible, then choose `DISTRIBUTED RANDOMLY`.

The `PARTITION BY` clause allows you to divide the table into multiple sub-tables (or parts) that, taken together, make up the parent table and share its schema. Though the sub-tables exist as independent tables, the Greenplum Database restricts their use in important ways. Internally, partitioning is implemented as a special form of inheritance. Each child table partition is created with a distinct `CHECK` constraint which limits the data the table can contain, based on some defining criteria. The `CHECK` constraints are also used by the query optimizer to determine which table partitions to scan in order to satisfy a given query predicate. These partition constraints are managed automatically by the Greenplum Database.

**Parameters**

**GLOBAL | LOCAL**

These keywords are present for SQL standard compatibility, but have no effect in Greenplum Database.

**TEMPORARY | TEMP**

If specified, the table is created as a temporary table. Temporary tables are automatically dropped at the end of a session, or optionally at the end of the current transaction (see `ON COMMIT`). Existing permanent tables with the same name are not visible to the current session while the temporary table exists, unless they are referenced with schema-qualified names. Any indexes created on a temporary table are automatically temporary as well.

`table_name`

The name (optionally schema-qualified) of the table to be created.

`column_name`

The name of a column to be created in the new table.

`data_type`
The data type of the column. This may include array specifiers.

For table columns that contain textual data, specify the data type `VARCHAR` or `TEXT`. Specifying the data type `CHAR` is not recommended. In Greenplum Database, the data types `VARCHAR` or `TEXT` handles padding added to the data (space characters added after the last non-space character) as significant characters, the data type `CHAR` does not. See Notes.

**DEFAULT** `default_expr`

The `DEFAULT` clause assigns a default data value for the column whose column definition it appears within. The value is any variable-free expression (subqueries and cross-references to other columns in the current table are not allowed). The data type of the default expression must match the data type of the column. The default expression will be used in any insert operation that does not specify a value for the column. If there is no default for a column, then the default is null.

**ENCODING** ( `storage_directive [, ...]` )

For a column, the optional `ENCODING` clause specifies the type of compression and block size for the column data. See `storage_options` for `COMPRESSIONTYPE`, `COMPRESSLEVEL`, and `BLOCKSIZE` values.

The clause is valid only for append-optimized, column-oriented tables.

Column compression settings are inherited from the table level to the partition level to the subpartition level. The lowest-level settings have priority.

**INHERITS**

The optional `INHERITS` clause specifies a list of tables from which the new table automatically inherits all columns. Use of `INHERITS` creates a persistent relationship between the new child table and its parent table(s). Schema modifications to the parent(s) normally propagate to children as well, and by default the data of the child table is included in scans of the parent(s).

In Greenplum Database, the `INHERITS` clause is not used when creating partitioned tables. Although the concept of inheritance is used in partition hierarchies, the inheritance structure of a partitioned table is created using the `PARTITION BY` clause.

If the same column name exists in more than one parent table, an error is reported unless the data types of the columns match in each of the parent tables. If there is no conflict, then the duplicate columns are merged to form a single column in the new table. If the column name list of the new table contains a column name that is also inherited, the data type must likewise match the inherited column(s), and the column definitions are merged into one. However, inherited and new column declarations of the same name need not specify identical constraints: all constraints provided from any declaration are merged together and all are applied to the new table. If the new table explicitly specifies a default value for the column, this default overrides any defaults from inherited declarations of the column. Otherwise, any parents that specify default values for the column must all specify the same default, or an error will be reported.

**LIKE other_table [ {INCLUDING | EXCLUDING} {DEFAULTS | CONSTRAINTS} ]**

The `LIKE` clause specifies a table from which the new table automatically copies all column names, data types, not-null constraints, and distribution policy. Storage properties like append-optimized or partition structure are not copied. Unlike `INHERITS`, the new table and original table are completely decoupled after creation is complete.

Default expressions for the copied column definitions will only be copied if `INCLUDING DEFAULTS` is specified. The default behavior is to exclude default expressions, resulting in the copied columns in the new table having null defaults.

Not-null constraints are always copied to the new table. `CHECK` constraints will only be copied if `INCLUDING CONSTRAINTS` is specified; other types of constraints will never be
copied. Also, no distinction is made between column constraints and table constraints — when constraints are requested, all check constraints are copied.

Note also that unlike INHERITS, copied columns and constraints are not merged with similarly named columns and constraints. If the same name is specified explicitly or in another LIKE clause an error is signalled.

**CONSTRANT constraint_name**

An optional name for a column or table constraint. If the constraint is violated, the constraint name is present in error messages, so constraint names like *column must be positive* can be used to communicate helpful constraint information to client applications. (Double-quotes are needed to specify constraint names that contain spaces.) If a constraint name is not specified, the system generates a name.

*Note:* The specified *constraint_name* is used for the constraint, but a system-generated unique name is used for the index name. In some prior releases, the provided name was used for both the constraint name and the index name.

**NULL | NOT NULL**

Specifies if the column is or is not allowed to contain null values. NULL is the default.

**UNIQUE ( column constraint )**

**UNIQUE ( column_name [, . . . ] ) ( table constraint )**

The **UNIQUE** constraint specifies that a group of one or more columns of a table may contain only unique values. The behavior of the unique table constraint is the same as that for column constraints, with the additional capability to span multiple columns. For the purpose of a unique constraint, null values are not considered equal. The column(s) that are unique must contain all the columns of the Greenplum distribution key. In addition, the <key> must contain all the columns in the partition key if the table is partitioned. Note that a <key> constraint in a partitioned table is not the same as a simple UNIQUE INDEX.

For information about unique constraint management and limitations, see *Notes*.

**PRIMARY KEY ( column constraint )**

**PRIMARY KEY ( column_name [, . . . ] ) ( table constraint )**

The primary key constraint specifies that a column or columns of a table may contain only unique (non-duplicate), non-null values. Technically, **PRIMARY KEY** is merely a combination of **UNIQUE** and **NOT NULL**, but identifying a set of columns as primary key also provides metadata about the design of the schema, as a primary key implies that other tables may rely on this set of columns as a unique identifier for rows. For a table to have a primary key, it must be hash distributed (not randomly distributed), and the primary key The column(s) that are unique must contain all the columns of the Greenplum distribution key. In addition, the <key> must contain all the columns in the partition key if the table is partitioned. Note that a <key> constraint in a partitioned table is not the same as a simple UNIQUE INDEX.

For information about primary key management and limitations, see *Notes*.

**CHECK ( expression )**

The **CHECK** clause specifies an expression producing a Boolean result which new or updated rows must satisfy for an insert or update operation to succeed. Expressions evaluating to **TRUE** or **UNKNOWN** succeed. Should any row of an insert or update operation produce a **FALSE** result an error exception is raised and the insert or update does not alter the database. A check constraint specified as a column constraint should reference that column's value only, while an expression appearing in a table constraint may reference multiple columns. **CHECK** expressions cannot contain subqueries nor refer to variables other than columns of the current row.

**REFERENCES table_name [ ( column_name [, . . . ] ) ]**
The `REFERENCES` and `FOREIGN KEY` clauses specify referential integrity constraints (foreign key constraints). Greenplum accepts referential integrity constraints as specified in PostgreSQL syntax but does not enforce them. See the PostgreSQL documentation for information about referential integrity constraints.

```sql
FOREIGN KEY (column_name [, ...] )
REFERENCES table_name [ (column_name [, ...] )
[ key_match_type ] [ key_action ] [ key_checking_mode ]
```

The `REFERENCES` and `FOREIGN KEY` clauses specify referential integrity constraints (foreign key constraints). Greenplum accepts referential integrity constraints as specified in PostgreSQL syntax but does not enforce them. See the PostgreSQL documentation for information about referential integrity constraints.

```sql
WITH ( storage_option=value )
```

The `WITH` clause can be used to set storage options for the table or its indexes. Note that you can also set storage parameters on a particular partition or subpartition by declaring the `WITH` clause in the partition specification. The lowest-level settings have priority.

The following storage options are available:

- **APPENDONLY** — Set to `TRUE` to create the table as an append-optimized table. If `FALSE` or not declared, the table will be created as a regular heap-storage table.
- **BLOCKSIZE** — Set to the size, in bytes for each block in a table. The `BLOCKSIZE` must be between 8192 and 2097152 bytes, and be a multiple of 8192. The default is 32768.
- **ORIENTATION** — Set to `column` for column-oriented storage, or `row` (the default) for row-oriented storage. This option is only valid if `APPENDONLY=TRUE`. Heap-storage tables can only be row-oriented.
- **CHECKSUM** — This option is valid only for append-optimized tables (`APPENDONLY=TRUE`). The value `TRUE` is the default and enables CRC checksum validation for append-optimized tables. The checksum is calculated during block creation and is stored on disk. Checksum validation is performed during block reads. If the checksum calculated during the read does not match the stored checksum, the transaction is aborted. If you set the value to `FALSE` to disable checksum validation, checking the table data for on-disk corruption will not be performed.
- **COMPRESSSTYPE** — Set to `ZLIB` (the default), `RLE-TYPE`, or `QUICKLZ`¹ to specify the type of compression used. The value `NONE` disables compression. QuickLZ uses less CPU power and compresses data faster at a lower compression ratio than zlib. Conversely, zlib provides more compact compression ratios at lower speeds. This option is only valid if `APPENDONLY=TRUE`.

Note: ¹QuickLZ compression is available only in the commercial release of Pivotal Greenplum Database.

The value `RLE-TYPE` is supported only if `ORIENTATION=column` is specified, Greenplum Database uses the run-length encoding (RLE) compression algorithm. RLE compresses data better than the zlib or QuickLZ compression algorithm when the same data value occurs in many consecutive rows.

For columns of type `BIGINT`, `INTEGER`, `DATE`, `TIME`, or `TIMESTAMP`, delta compression is also applied if the `COMPRESSIONTYPE` option is set to `RLE-TYPE` compression. The delta compression algorithm is based on the delta between column values in consecutive rows and is designed to improve compression when data is loaded in sorted order or the compression is applied to column data that is in sorted order.

For information about using table compression, see "Choosing the Table Storage Model" in the Greenplum Database Administrator Guide.

- **COMPRESSLEVEL** — For zlib compression of append-optimized tables, set to an integer value between 1 (fastest compression) to 9 (highest compression ratio). QuickLZ
The Greenplum Database allows compression of data to save storage space. The compression level can only be set to 1. If not declared, the default is 1. For RLE_TYPE, the compression level can be set an integer value between 1 (fastest compression) to 4 (highest compression ratio).

This option is valid only if APPENDONLY=True.

**FILLFACTOR** — See CREATE INDEX for more information about this index storage parameter.

**OIDS** — Set to OIDS=False (the default) so that rows do not have object identifiers assigned to them. Greenplum strongly recommends that you do not enable OIDS when creating a table. On large tables, such as those in a typical Greenplum Database system, using OIDs for table rows can cause wrap-around of the 32-bit OID counter. Once the counter wraps around, OIDs can no longer be assumed to be unique, which not only makes them useless to user applications, but can also cause problems in the Greenplum Database system catalog tables. In addition, excluding OIDs from a table reduces the space required to store the table on disk by 4 bytes per row, slightly improving performance. OIDs are not allowed on partitioned tables or append-optimized column-oriented tables.

**ON COMMIT**

The behavior of temporary tables at the end of a transaction block can be controlled using ON COMMIT. The three options are:

- **PRESERVE ROWS** - No special action is taken at the ends of transactions for temporary tables. This is the default behavior.
- **DELETE ROWS** - All rows in the temporary table will be deleted at the end of each transaction block. Essentially, an automatic TRUNCATE is done at each commit.
- **DROP** - The temporary table will be dropped at the end of the current transaction block.

**TABLESPACE** `tablespace`

The name of the tablespace in which the new table is to be created. If not specified, the database’s default tablespace is used.

**USING INDEX TABLESPACE** `tablespace`

This clause allows selection of the tablespace in which the index associated with a UNIQUE or PRIMARY KEY constraint will be created. If not specified, the database’s default tablespace is used.

**DISTRIBUTED BY (column, [ ... ] )**

**DISTRIBUTED RANDOMLY**

Used to declare the Greenplum Database distribution policy for the table. DISTRIBUTED BY uses hash distribution with one or more columns declared as the distribution key. For the most even data distribution, the distribution key should be the primary key of the table or a unique column (or set of columns). If that is not possible, then you may choose DISTRIBUTED RANDOMLY, which will send the data round-robin to the segment instances.

The Greenplum Database server configuration parameter `gp_create_table_random_default_distribution` controls the default table distribution policy if the DISTRIBUTED BY clause is not specified when you create a table. Greenplum Database follows these rules to create a table if a distribution policy is not specified.

If the value of the parameter is off (the default), Greenplum Database chooses the table distribution key based on the command. If the LIKE or INHERITS clause is specified in table creation command, the created table uses the same distribution key as the source or parent table.

If the value of the parameter is set to on, Greenplum Database follows these rules:
If PRIMARY KEY or UNIQUE columns are not specified, the distribution of the table is random (DISTRIBUTED RANDOMLY). Table distribution is random even if the table creation command contains the LIKE or INHERITS clause.

If PRIMARY KEY or UNIQUE columns are specified, a DISTRIBUTED BY clause must also be specified. If a DISTRIBUTED BY clause is not specified as part of the table creation command, the command fails.

For information about the parameter, see "Server Configuration Parameters."

**PARTITION BY**

Declares one or more columns by which to partition the table.

When creating a partitioned table, Greenplum Database creates the root partitioned table (the root partition) with the specified table name. Greenplum Database also creates a hierarchy of tables, child tables, that are the subpartitions based on the partitioning options that you specify. The Greenplum Database `pg_partition` system views contain information about the subpartition tables.

For each partition level (each hierarchy level of tables), a partitioned table can have a maximum of 32,767 partitions.

**Note:** Greenplum Database stores partitioned table data in the leaf child tables, the lowest-level tables in the hierarchy of child tables for use by the partitioned table.

**partition_type**

Declares partition type: LIST (list of values) or RANGE (a numeric or date range).

**partition_specification**

Declares the individual partitions to create. Each partition can be defined individually or, for range partitions, you can use the EVERY clause (with a START and optional END clause) to define an increment pattern to use to create the individual partitions.

**DEFAULT PARTITION name** — Declares a default partition. When data does not match to an existing partition, it is inserted into the default partition. Partition designs that do not have a default partition will reject incoming rows that do not match to an existing partition.

**PARTITION name** — Declares a name to use for the partition. Partitions are created using the following naming convention: `parentname_level#_prt_givenname`.

**VALUES** — For list partitions, defines the value(s) that the partition will contain.

**START** — For range partitions, defines the starting range value for the partition. By default, start values are INCLUSIVE. For example, if you declared a start date of '2016-01-01', then the partition would contain all dates greater than or equal to '2016-01-01'. Typically the data type of the START expression is the same type as the partition key column. If that is not the case, then you must explicitly cast to the intended data type.

**END** — For range partitions, defines the ending range value for the partition. By default, end values are EXCLUSIVE. For example, if you declared an end date of '2016-02-01', then the partition would contain all dates less than but not equal to '2016-02-01'. Typically the data type of the END expression is the same type as the partition key column. If that is not the case, then you must explicitly cast to the intended data type.

**EVERY** — For range partitions, defines how to increment the values from START to END to create individual partitions. Typically the data type of the EVERY expression is the same type as the partition key column. If that is not the case, then you must explicitly cast to the intended data type.

**WITH** — Sets the table storage options for a partition. For example, you may want older partitions to be append-optimized tables and newer partitions to be regular heap tables.

**TABLESPACE** — The name of the tablespace in which the partition is to be created.
**SUBPARTITION BY**
Declares one or more columns by which to subpartition the first-level partitions of the table. The format of the subpartition specification is similar to that of a partition specification described above.

**SUBPARTITION TEMPLATE**
Instead of declaring each subpartition definition individually for each partition, you can optionally declare a subpartition template to be used to create the subpartitions (lower level child tables). This subpartition specification would then apply to all parent partitions.

**Notes**
- In Greenplum Database (a Postgres-based system) the data types VARCHAR or TEXT handles padding added to the textual data (space characters added after the last non-space character) as significant characters, the data type CHAR does not.

  In Greenplum Database, values of type CHAR($n$) are padded with trailing spaces to the specified width $n$. The values are stored and displayed with the spaces. However, the padding spaces are treated as semantically insignificant. When the values are distributed, the trailing spaces are disregarded. The trailing spaces are also treated as semantically insignificant when comparing two values of data type CHAR, and the trailing spaces are removed when converting a character value to one of the other string types.

- Using OIDs in new applications is not recommended: where possible, using a SERIAL or other sequence generator as the table’s primary key is preferred. However, if your application does make use of OIDs to identify specific rows of a table, it is recommended to create a unique constraint on the OID column of that table, to ensure that OIDs in the table will indeed uniquely identify rows even after counter wrap-around. Avoid assuming that OIDs are unique across tables; if you need a database-wide unique identifier, use the combination of table OID and row OID for the purpose.

- Greenplum Database has some special conditions for primary key and unique constraints with regards to columns that are the distribution key in a Greenplum table. For a unique constraint to be enforced in Greenplum Database, the table must be hash-distributed (not DISTRIBUTED RANDOMLY), and the constraint columns must be the same as (or a superset of) the table’s distribution key columns. Also, the distribution key must be a left-subset of the constraint columns with the columns in the correct order. For example, if the primary key is (a,b,c), the distribution key can be only one of the following: (a), (a,b), or (a,b,c).

  A primary key constraint is simply a combination of a unique constraint and a not-null constraint.

  Greenplum Database automatically creates a UNIQUE index for each UNIQUE or PRIMARY KEY constraint to enforce uniqueness. Thus, it is not necessary to create an index explicitly for primary key columns. UNIQUE and PRIMARY KEY constraints are not allowed on append-optimized tables because the UNIQUE indexes that are created by the constraints are not allowed on append-optimized tables.

- Foreign key constraints are not supported in Greenplum Database.

  For inherited tables, unique constraints, primary key constraints, indexes and table privileges are not inherited in the current implementation.

- For append-optimized tables, UPDATE and DELETE are not allowed in a serializable transaction and will cause the transaction to abort. CLUSTER, DECLARE...FOR UPDATE, and triggers are not supported with append-optimized tables.

- To insert data into a partitioned table, you specify the root partitioned table, the table created with the CREATE TABLE command. You also can specify a leaf child table of the partitioned table in an INSERT command. An error is returned if the data is not valid for the specified leaf child table. Specifying a child table that is not a leaf child table in the INSERT command is not supported. Execution of other DML commands such as UPDATE and DELETE on any child table of a partitioned table is not supported. These commands must be executed on the root partitioned table, the table created with the CREATE TABLE command.
• The default values for these table storage options can be specified with the server configuration parameter \texttt{gp_default_storage_option}.

• \texttt{APPENDONLY}
• \texttt{BLOCKSIZE}
• \texttt{CHECKSUM}
• \texttt{COMPRESSTYPE}
• \texttt{COMPRESSLEVEL}
• \texttt{ORIENTATION}

The defaults can be set for the system, a database, or a user. For information about setting storage options, see the server configuration parameter \texttt{gp_default_storage_options}.

**Important:** The current Greenplum Database legacy optimizer allows list partitions with multi-column (composite) partition keys. GPORCA does not support composite keys, so using composite partition keys is not recommended.

**Examples**

Create a table named \textit{rank} in the schema named \textit{baby} and distribute the data using the columns \textit{rank}, \textit{gender}, and \textit{year}:

```sql
CREATE TABLE baby.rank (id int, rank int, year smallint, gender char(1), count int ) DISTRIBUTED BY (rank, gender, year);
```

Create table \textit{films} and table \textit{distributors} (the primary key will be used as the Greenplum distribution key by default):

```sql
CREATE TABLE films (code char(5) CONSTRAINT firstkey PRIMARY KEY, title varchar(40) NOT NULL, did integer NOT NULL, date_prod date, kind varchar(10), len interval hour to minute);
CREATE TABLE distributors (did integer PRIMARY KEY DEFAULT nextval('serial'), name varchar(40) NOT NULL CHECK (name <> ''),
);
```

Create a gzip-compressed, append-optimized table:

```sql
CREATE TABLE sales (txn_id int, qty int, date date) WITH (appendonly=true, compresslevel=5) DISTRIBUTED BY (txn_id);
```

Create a three level partitioned table using subpartition templates and default partitions at each level:

```sql
CREATE TABLE sales (id int, year int, month int, day int, region text) DISTRIBUTED BY (id) PARTITION BY RANGE (year)
    SUBPARTITION BY RANGE (month)
    SUBPARTITION TEMPLATE (START (1) END (13) EVERY (1), DEFAULT SUBPARTITION other_months )
```
SUBPARTITION BY LIST (region)
SUBPARTITION TEMPLATE (
  SUBPARTITION usa VALUES ('usa'),
  SUBPARTITION europe VALUES ('europe'),
  SUBPARTITION asia VALUES ('asia'),
  DEFAULT SUBPARTITION other_regions)

( START (2008) END (2016) EVERY (1),
  DEFAULT PARTITION outlying_years);

Compatibility

CREATE TABLE command conforms to the SQL standard, with the following exceptions:

- **Temporary Tables** — In the SQL standard, temporary tables are defined just once and automatically exist (starting with empty contents) in every session that needs them. Greenplum Database instead requires each session to issue its own CREATE TEMPORARY TABLE command for each temporary table to be used. This allows different sessions to use the same temporary table name for different purposes, whereas the standard's approach constrains all instances of a given temporary table name to have the same table structure.

  The standard's distinction between global and local temporary tables is not in Greenplum Database. Greenplum Database will accept the GLOBAL and LOCAL keywords in a temporary table declaration, but they have no effect.

  If the ON COMMIT clause is omitted, the SQL standard specifies that the default behavior as ON COMMIT DELETE ROWS. However, the default behavior in Greenplum Database is ON COMMIT PRESERVE ROWS. The ON COMMIT DROP option does not exist in the SQL standard.

- **Column Check Constraints** — The SQL standard says that CHECK column constraints may only refer to the column they apply to; only CHECK table constraints may refer to multiple columns. Greenplum Database does not enforce this restriction; it treats column and table check constraints alike.

- **NULL Constraint** — The NULL constraint is a Greenplum Database extension to the SQL standard that is included for compatibility with some other database systems (and for symmetry with the NOT NULL constraint). Since it is the default for any column, its presence is not required.

- **Inheritance** — Multiple inheritance via the INHERITS clause is a Greenplum Database language extension. SQL:1999 and later define single inheritance using a different syntax and different semantics. SQL:1999-style inheritance is not yet supported by Greenplum Database.

- **Partitioning** — Table partitioning via the PARTITION BY clause is a Greenplum Database language extension.

- **Zero-column tables** — Greenplum Database allows a table of no columns to be created (for example, CREATE TABLE foo();). This is an extension from the SQL standard, which does not allow zero-column tables. Zero-column tables are not in themselves very useful, but disallowing them creates odd special cases for ALTER TABLE DROP COLUMN, so Greenplum decided to ignore this spec restriction.

- **WITH clause** — The WITH clause is a Greenplum Database extension; neither storage parameters nor OIDs are in the standard.

- **Tablespaces** — The Greenplum Database concept of tablespaces is not part of the SQL standard. The clauses TABLESPACE and USING INDEX TABLESPACE are extensions.

- **Data Distribution** — The Greenplum Database concept of a parallel or distributed database is not part of the SQL standard. The DISTRIBUTED clauses are extensions.

ALTER TABLE, DROP TABLE, CREATE EXTERNAL TABLE, CREATE TABLE AS

CREATE TABLE AS

Defines a new table from the results of a query.
Synopsis

CREATE [ [GLOBAL | LOCAL] {TEMPORARY | TEMP} ] TABLE table_name
  [ (column_name [, ...] ) ]
  [ WITH ( storage_parameter=value [, ... ] ) ]
  [ON COMMIT {PRESERVE ROWS | DELETE ROWS | DROP}]
  [TABLESPACE tablespace]
AS query
  [DISTRIBUTED BY (column, [ ... ] ) | DISTRIBUTED RANDOMLY]

where storage_parameter is:

APPENDONLY={TRUE|FALSE}
BLOCKSIZE={8192-2097152}
ORIENTATION={COLUMN|ROW}
COMPRESSTYPE={ZLIB|QUICKLZ}
COMPRESSLEVEL={1-9 | 1}
FILLFACTOR={10-100}
OIDS={TRUE|FALSE}

Description

CREATE TABLE AS creates a table and fills it with data computed by a SELECT command. The table columns have the names and data types associated with the output columns of the SELECT, however you can override the column names by giving an explicit list of new column names.

CREATE TABLE AS creates a new table and evaluates the query just once to fill the new table initially. The new table will not track subsequent changes to the source tables of the query.

Parameters

GLOBAL | LOCAL
These keywords are present for SQL standard compatibility, but have no effect in Greenplum Database.

TEMPORARY | TEMP
If specified, the new table is created as a temporary table. Temporary tables are automatically dropped at the end of a session, or optionally at the end of the current transaction (see ON COMMIT). Existing permanent tables with the same name are not visible to the current session while the temporary table exists, unless they are referenced with schema-qualified names. Any indexes created on a temporary table are automatically temporary as well.

table_name
The name (optionally schema-qualified) of the new table to be created.

column_name
The name of a column in the new table. If column names are not provided, they are taken from the output column names of the query. If the table is created from an EXECUTE command, a column name list cannot be specified.

WITH ( storage_parameter=value )
The WITH clause can be used to set storage options for the table or its indexes. Note that you can also set different storage parameters on a particular partition or subpartition by declaring the WITH clause in the partition specification. The following storage options are available:

APPENDONLY — Set to TRUE to create the table as an append-optimized table. If FALSE or not declared, the table will be created as a regular heap-storage table.
**BLOCKSIZE** — Set to the size, in bytes for each block in a table. The **BLOCKSIZE** must be between 8192 and 2097152 bytes, and be a multiple of 8192. The default is 32768.

**ORIENTATION** — Set to **column** for column-oriented storage, or **row** (the default) for row-oriented storage. This option is only valid if **APPENDONLY=TRUE**. Heap-storage tables can only be row-oriented.

**COMPRESSTYPE** — Set to **ZLIB** (the default) or **QUICKLZ**¹ to specify the type of compression used. QuickLZ uses less CPU power and compresses data faster at a lower compression ratio than zlib. Conversely, zlib provides more compact compression ratios at lower speeds. This option is only valid if **APPENDONLY=TRUE**.

**Note:** ¹QuickLZ compression is available only in the commercial release of Pivotal Greenplum Database.

**COMPRESSLEVEL** — For zlib compression of append-optimized tables, set to a value between 1 (fastest compression) to 9 (highest compression ratio). QuickLZ compression level can only be set to 1. If not declared, the default is 1. This option is only valid if **APPENDONLY=TRUE**.

**FILLFACTOR** — See **CREATE INDEX** for more information about this index storage parameter.

**OIDS** — Set to **OIDS=FALSE** (the default) so that rows do not have object identifiers assigned to them. Greenplum strongly recommends that you do not enable OIDS when creating a table. On large tables, such as those in a typical Greenplum Database system, using OIDs for table rows can cause wrap-around of the 32-bit OID counter. Once the counter wraps around, OIDs can no longer be assumed to be unique, which not only makes them useless to user applications, but can also cause problems in the Greenplum Database system catalog tables. In addition, excluding OIDs from a table reduces the space required to store the table on disk by 4 bytes per row, slightly improving performance. OIDS are not allowed on column-oriented tables.

**ON COMMIT**

The behavior of temporary tables at the end of a transaction block can be controlled using **ON COMMIT**. The three options are:

**PRESERVE ROWS** — No special action is taken at the ends of transactions for temporary tables. This is the default behavior.

**DELETE ROWS** — All rows in the temporary table will be deleted at the end of each transaction block. Essentially, an automatic **TRUNCATE** is done at each commit.

**DROP** — The temporary table will be dropped at the end of the current transaction block.

**TABLESPACE** **tablespace**

The tablespace is the name of the tablespace in which the new table is to be created. If not specified, the database's default tablespace is used.

**AS** **query**

A **SELECT** or **VALUES** command, or an **EXECUTE** command that runs a prepared **SELECT** or **VALUES** query.

**DISTRIBUTED BY** (**column**, [ ... ])

**DISTRIBUTED RANDOMLY**

Used to declare the Greenplum Database distribution policy for the table. **DISTRIBUTED** by uses hash distribution with one or more columns declared as the distribution key. For the most even data distribution, the distribution key should be the primary key of the table or a unique column (or set of columns). If that is not possible, then you may choose **DISTRIBUTED RANDOMLY**, which will send the data round-robin to the segment instances.

The Greenplum Database server configuration parameter **gp_create_table_random_default_distribution** controls the default table
distribution policy if the DISTRIBUTED BY clause is not specified when you create a table. Greenplum Database follows these rules to create a table if a distribution policy is not specified.

- If the legacy query optimizer creates the table, and the value of the parameter is off, the table distribution policy is determined based on the command.
- If the legacy query optimizer creates the table, and the value of the parameter is on, the table distribution policy is random.
- If GPORCA creates the table, the table distribution policy is random. The parameter value has no affect.

For information about the parameter, see "Server Configuration Parameters." For information about the legacy query optimizer and GPORCA, see "Querying Data" in the Greenplum Database Administrator Guide.

Notes

This command is functionally similar to SELECT INTO, but it is preferred since it is less likely to be confused with other uses of the SELECT INTO syntax. Furthermore, CREATE TABLE AS offers a superset of the functionality offered by SELECT INTO.

CREATE TABLE AS can be used for fast data loading from external table data sources. See CREATE EXTERNAL TABLE.

Examples

Create a new table films_recent consisting of only recent entries from the table films:

```
CREATE TABLE films_recent AS SELECT * FROM films WHERE date_prod >= '2007-01-01';
```

Create a new temporary table films_recent, consisting of only recent entries from the table films, using a prepared statement. The new table has OIDs and will be dropped at commit:

```
PREPARE recentfilms(date) AS SELECT * FROM films WHERE date_prod > $1;
CREATE TEMP TABLE films_recent WITH (OIDS) ON COMMIT DROP AS EXECUTE recentfilms('2007-01-01');
```

Compatibility

CREATE TABLE AS conforms to the SQL standard, with the following exceptions:

- The standard requires parentheses around the subquery clause; in Greenplum Database, these parentheses are optional.
- The standard defines a WITH [NO] DATA clause; this is not currently implemented by Greenplum Database. The behavior provided by Greenplum Database is equivalent to the standard's WITH DATA case. WITH NO DATA can be simulated by appending LIMIT 0 to the query.
- Greenplum Database handles temporary tables differently from the standard; see CREATE TABLE for details.
- The WITH clause is a Greenplum Database extension; neither storage parameters nor OIDs are in the standard.
- The Greenplum Database concept of tablespaces is not part of the standard. The TABLESPACE clause is an extension.

CREATE EXTERNAL TABLE, CREATE EXTERNAL TABLE, EXECUTE, SELECT, SELECT INTO, VALUES
**CREATE TABLESPACE**

Defines a new tablespace.

**Synopsis**

```
CREATE TABLESPACE tablespace_name [OWNER username]
    FILESPACE filespace_name
```

**Description**

`CREATE TABLESPACE` registers a new tablespace for your Greenplum Database system. The tablespace name must be distinct from the name of any existing tablespace in the system.

A tablespace allows superusers to define an alternative location on the file system where the data files containing database objects (such as tables and indexes) may reside.

A user with appropriate privileges can pass a tablespace name to `CREATE DATABASE`, `CREATE TABLE`, or `CREATE INDEX` to have the data files for these objects stored within the specified tablespace.

In Greenplum Database, there must be a file system location defined for the master, each primary segment, and each mirror segment in order for the tablespace to have a location to store its objects across an entire Greenplum system. This collection of file system locations is defined in a filespace object. A filespace must be defined before you can create a tablespace. See `gpfilespace` in the *Greenplum Database Utility Guide* for more information.

**Parameters**

- `tablespacename`
  
  The name of a tablespace to be created. The name cannot begin with `pg_` or `gp_`, as such names are reserved for system tablespaces.

- `OWNER username`
  
  The name of the user who will own the tablespace. If omitted, defaults to the user executing the command. Only superusers may create tablespaces, but they can assign ownership of tablespaces to non-superusers.

- `FILESPACE`
  
  The name of a Greenplum Database filespace that was defined using the `gpfilespace` management utility.

**Notes**

You must first create a filespace to be used by the tablespace. See `gpfilespace` in the *Greenplum Database Utility Guide* for more information.

Tablespaces are only supported on systems that support symbolic links.

`CREATE TABLESPACE` cannot be executed inside a transaction block.

**Examples**

Create a new tablespace by specifying the corresponding filespace to use:

```
CREATE TABLESPACE mytblspace FILESPACE myfilespace;
```

**Compatibility**

`CREATE TABLESPACE` is a Greenplum Database extension.
CREATE TYPE

Defines a new data type.

Synopsis

CREATE TYPE name AS ( attribute_name data_type [, ... ] )

CREATE TYPE name AS ENUM ( 'label' [, ... ] )

CREATE TYPE name ( 
 INPUT = input_function,
 OUTPUT = output_function
 [, RECEIVE = receive_function ]
 [, SEND = send_function ]
 [, TYPMOD_IN = type_modifier_input_function ]
 [, TYPMOD_OUT = type_modifier_output_function ]
 [, INTERNALLENGTH = { internallength | VARIABLE } ]
 [, PASSEDBYVALUE ]
 [, ALIGNMENT = alignment ]
 [, STORAGE = storage ]
 [, DEFAULT = default ]
 [, ELEMENT = element ]
 [, DELIMITER = delimiter ] )

CREATE TYPE name

Description

CREATE TYPE registers a new data type for use in the current database. The user who defines a type becomes its owner.

If a schema name is given then the type is created in the specified schema. Otherwise it is created in the current schema. The type name must be distinct from the name of any existing type or domain in the same schema. The type name must also be distinct from the name of any existing table in the same schema.

Composite Types

The first form of CREATE TYPE creates a composite type. The composite type is specified by a list of attribute names and data types. This is essentially the same as the row type of a table, but using CREATE TYPE avoids the need to create an actual table when all that is wanted is to define a type. A stand-alone composite type is useful as the argument or return type of a function.

Enumerated Types

The second form of CREATE TYPE creates an enumerated (ENUM) type, as described in Enumerated Types in the PostgreSQL documentation. Enum types take a list of one or more quoted labels, each of which must be less than NAMEDATALEN bytes long (64 in a standard build).

Base Types

The third form of CREATE TYPE creates a new base type (scalar type). The parameters may appear in any order, not only that shown in the syntax, and most are optional. You must register two or more functions (using CREATE FUNCTION) before defining the type. The support functions input_function and output_function are required, while the functions receive_function, send_function, type_modifier_input_function, type_modifier_output_function, and analyze_function are optional. Generally
these functions have to be coded in C or another low-level language. In Greenplum Database, any function used to implement a data type must be defined as IMMUTABLE.

The input_function converts the type's external textual representation to the internal representation used by the operators and functions defined for the type. output_function performs the reverse transformation. The input function may be declared as taking one argument of type cstring, or as taking three arguments of types cstring, oid, integer. The first argument is the input text as a C string, the second argument is the type's own OID (except for array types, which instead receive their element type's OID), and the third is the typmod of the destination column, if known (~1 will be passed if not). The input function must return a value of the data type itself. Usually, an input function should be declared STRICT; if it is not, it will be called with a NULL first parameter when reading a NULL input value. The function must still return NULL in this case, unless it raises an error. (This case is mainly meant to support domain input functions, which may need to reject NULL inputs.) The output function must be declared as taking one argument of the new data type. The output function must return type cstring. Output functions are not invoked for NULL values.

The optional receive_function converts the type’s external binary representation to the internal representation. If this function is not supplied, the type cannot participate in binary input. The binary representation should be chosen to be cheap to convert to internal form, while being reasonably portable. (For example, the standard integer data types use network byte order as the external binary representation, while the internal representation is in the machine's native byte order.) The receive function should perform adequate checking to ensure that the value is valid. The receive function may be declared as taking one argument of type internal, or as taking three arguments of types internal, oid, integer. The first argument is a pointer to a StringInfo buffer holding the received byte string; the optional arguments are the same as for the text input function. The receive function must return a value of the data type itself. Usually, a receive function should be declared STRICT; if it is not, it will be called with a NULL first parameter when reading a NULL input value. The function must still return NULL in this case, unless it raises an error. (This case is mainly meant to support domain receive functions, which may need to reject NULL inputs.) Similarly, the optional send_function converts from the internal representation to the external binary representation. If this function is not supplied, the type cannot participate in binary output. The send function must be declared as taking one argument of the new data type. The send function must return type bytea. Send functions are not invoked for NULL values.

The optional type_modifier_input_function and type_modifier_output_function are required if the type supports modifiers. Modifiers are optional constraints attached to a type declaration, such as char(5) or numeric(30,2). While Greenplum Database allows user-defined types to take one or more simple constants or identifiers as modifiers, this information must fit into a single non-negative integer value for storage in the system catalogs. Greenplum Database passes the declared modifier(s) to the type_modifier_input_function in the form of a cstring array. The modifier input function must check the values for validity, throwing an error if they are incorrect. If the values are correct, the modifier input function returns a single non-negative integer value that Greenplum Database stores as the column typmod. Type modifiers are rejected if the type was not defined with a type_modifier_input_function. The type_modifier_output_function converts the internal integer typmod value back to the correct form for user display. The modifier output function must return a cstring value that is the exact string to append to the type name. For example, numeric's function might return (30,2). The type_modifier_output_function is optional. When not specified, the default display format is the stored typmod integer value enclosed in parentheses.

You should at this point be wondering how the input and output functions can be declared to have results or arguments of the new type, when they have to be created before the new type can be created. The answer is that the type should first be defined as a shell type, which is a placeholder type that has no properties except a name and an owner. This is done by issuing the command CREATE TYPE name, with no additional parameters. Then the I/O functions can be defined referencing the shell type. Finally, CREATE TYPE with a full definition replaces the shell entry with a complete, valid type definition, after which the new type can be used normally.

While the details of the new type's internal representation are only known to the I/O functions and other functions you create to work with the type, there are several properties of the internal representation that must be declared to Greenplum Database. Foremost of these is internal_length. Base data types
can be fixed-length, in which case `internallength` is a positive integer, or variable length, indicated by setting `internallength` to `VARIABLE`. (Internally, this is represented by setting `typlen` to `−1`.) The internal representation of all variable-length types must start with a 4-byte integer giving the total length of this value of the type.

The optional flag `PASSEDBYVALUE` indicates that values of this data type are passed by value, rather than by reference. You may not pass by value types whose internal representation is larger than the size of the `Datum` type (4 bytes on most machines, 8 bytes on a few).

The `alignment` parameter specifies the storage alignment required for the data type. The allowed values equate to alignment on 1, 2, 4, or 8 byte boundaries. Note that variable-length types must have an alignment of at least 4, since they necessarily contain an `int4` as their first component.

The `storage` parameter allows selection of storage strategies for variable-length data types. (Only `plain` is allowed for fixed-length types.) `plain` specifies that data of the type will always be stored in-line and not compressed. `extended` specifies that the system will first try to compress a long data value, and will move the value out of the main table row if it's still too long. `external` allows the value to be moved out of the main table, but the system will not try to compress it. `main` allows compression, but discourages moving the value out of the main table. (Data items with this storage strategy may still be moved out of the main table if there is no other way to make a row fit, but they will be kept in the main table preferentially over `extended` and `external` items.)

A default value may be specified, in case a user wants columns of the data type to default to something other than the null value. Specify the default with the `DEFAULT` key word. (Such a default may be overridden by an explicit `DEFAULT` clause attached to a particular column.)

To indicate that a type is an array, specify the type of the array elements using the `ELEMENT` key word. For example, to define an array of 4-byte integers (int4), specify `ELEMENT = int4`. More details about array types appear below.

To indicate the delimiter to be used between values in the external representation of arrays of this type, `delimiter` can be set to a specific character. The default delimiter is the comma (,). Note that the delimiter is associated with the array element type, not the array type itself.

**Array Types**

Whenever a user-defined base data type is created, Greenplum Database automatically creates an associated array type, whose name consists of the base type's name prepended with an underscore. The parser understands this naming convention, and translates requests for columns of type `foo[]` into requests for type `_foo`. The implicitly-created array type is variable length and uses the built-in input and output functions `array_in` and `array_out`.

You might reasonably ask why there is an `ELEMENT` option, if the system makes the correct array type automatically. The only case where it's useful to use `ELEMENT` is when you are making a fixed-length type that happens to be internally an array of a number of identical things, and you want to allow these things to be accessed directly by subscripting, in addition to whatever operations you plan to provide for the type as a whole. For example, type `name` allows its constituent `char` elements to be accessed this way. A 2-D point type could allow its two component numbers to be accessed like `point[0]` and `point[1]`. Note that this facility only works for fixed-length types whose internal form is exactly a sequence of identical fixed-length fields. A subscriptable variable-length type must have the generalized internal representation used by `array_in` and `array_out`. For historical reasons, subscripting of fixed-length array types starts from zero, rather than from one as for variable-length arrays.

**Parameters**

`name`

The name (optionally schema-qualified) of a type to be created.

`attribute_name`

The name of an attribute (column) for the composite type.

`data_type`
The name of an existing data type to become a column of the composite type.

**label**

A string literal representing the textual label associated with one value of an enum type.

**input_function**

The name of a function that converts data from the type's external textual form to its internal form.

**output_function**

The name of a function that converts data from the type's internal form to its external textual form.

**receive_function**

The name of a function that converts data from the type's external binary form to its internal form.

**send_function**

The name of a function that converts data from the type's internal form to its external binary form.

**type_modifier_input_function**

The name of a function that converts an array of modifier(s) for the type to internal form.

**type_modifier_output_function**

The name of a function that converts the internal form of the type's modifier(s) to external textual form.

**internallength**

A numeric constant that specifies the length in bytes of the new type's internal representation. The default assumption is that it is variable-length.

**alignment**

The storage alignment requirement of the data type. Must be one of `char`, `int2`, `int4`, or `double`. The default is `int4`.

**storage**

The storage strategy for the data type. Must be one of `plain`, `external`, `extended`, or `main`. The default is `plain`.

**default**

The default value for the data type. If this is omitted, the default is null.

**element**

The type being created is an array; this specifies the type of the array elements.

**delimiter**

The delimiter character to be used between values in arrays made of this type.

**Notes**

User-defined type names cannot begin with the underscore character `_` and can only be 62 characters long (or in general `NAMEDATALEN - 2`, rather than the `NAMEDATALEN - 1` characters allowed for other names). Type names beginning with underscore are reserved for internally-created array type names.

Because there are no restrictions on use of a data type once it's been created, creating a base type is tantamount to granting public execute permission on the functions mentioned in the type definition. (The creator of the type is therefore required to own these functions.) This is usually not an issue for the sorts of functions that are useful in a type definition. But you might want to think twice before designing a type in a way that would require 'secret' information to be used while converting it to or from external form.
Before Greenplum Database version 2.4, the syntax `CREATE TYPE name` did not exist. The way to create a new base type was to create its input function first. In this approach, Greenplum Database will first see the name of the new data type as the return type of the input function. The shell type is implicitly created in this situation, and then it can be referenced in the definitions of the remaining I/O functions. This approach still works, but is deprecated and may be disallowed in some future release. Also, to avoid accidentally cluttering the catalogs with shell types as a result of simple typos in function definitions, a shell type will only be made this way when the input function is written in C.

**Examples**

This example creates a composite type and uses it in a function definition:

```sql
CREATE TYPE compfoo AS (f1 int, f2 text);
CREATE FUNCTION getfoo() RETURNS SETOF compfoo AS $$
  SELECT fooid, fooname FROM foo
$$ LANGUAGE SQL;
```

This example creates the enumerated type `mood` and uses it in a table definition.

```sql
CREATE TYPE mood AS ENUM ('sad', 'ok', 'happy');
CREATE TABLE person (
  name text,
  current_mood mood
);
INSERT INTO person VALUES ('Moe', 'happy');
SELECT * FROM person WHERE current_mood = 'happy';
```

```
<table>
<thead>
<tr>
<th>name</th>
<th>current_mood</th>
</tr>
</thead>
<tbody>
<tr>
<td>Moe</td>
<td>happy</td>
</tr>
</tbody>
</table>
```

(1 row)

This example creates the base data type `box` and then uses the type in a table definition:

```sql
CREATE TYPE box;
CREATE FUNCTION my_box_in_function(cstring) RETURNS box AS ...
;
CREATE FUNCTION my_box_out_function(box) RETURNS cstring AS ...
;
CREATE TYPE box (
  INTERNALLENGTH = 16,
  INPUT = my_box_in_function,
  OUTPUT = my_box_out_function
);
CREATE TABLE myboxes (
  id integer,
  description box
);
```

If the internal structure of `box` were an array of four `float4` elements, we might instead use:

```sql
CREATE TYPE box (INTERNALLENGTH = 16,
  INPUT = my_box_in_function,
  OUTPUT = my_box_out_function,
  ELEMENT = float4
);
which would allow a box value’s component numbers to be accessed by subscripting. Otherwise the type behaves the same as before.

This example creates a large object type and uses it in a table definition:

```sql
CREATE TYPE bigobj (
    INPUT = lo_filein, OUTPUT = lo_fileout,
    INTERNALLENGTH = VARIABLE
);
CREATE TABLE big_objs (
    id integer,
    obj bigobj
);
```

Compatibility

This `CREATE TYPE` command is a Greenplum Database extension. There is a `CREATE TYPE` statement in the SQL standard that is rather different in detail.

See Also

`CREATE FUNCTION`, `ALTER TYPE`, `DROP TYPE`, `CREATE DOMAIN`

**CREATE USER**

Defines a new database role with the `LOGIN` privilege by default.

Synopsis

```sql
CREATE USER name [[WITH] option [ ... ]]]
```

where `option` can be:

- `SUPERUSER` | `NOSUPERUSER`
- `CREATEDB` | `NOCREATEDB`
- `CREATEROLE` | `NOCREATEROLE`
- `CREATEUSER` | `NOCREATEUSER`
- `CREATEEXTTABLE` | `NOCREATEEXTTABLE`
- `INHERIT` | `NOINHERIT`
- `LOGIN` | `NOLOGIN`
- `CONNECTION LIMIT connlimit`
- `[ ENCRYPTED | UNENCRYPTED ] PASSWORD 'password'`
- `VALID UNTIL 'timestamp'`
- `IN ROLE rolename [, ...]`
- `ROLE rolename [, ...]`
- `ADMIN rolename [, ...]`
- `RESOURCE QUEUE queue_name`
- `RESOURCE GROUP group_name`
- `[ DENY deny_point ]`
- `[ DENY BETWEEN deny_point AND deny_point]`
Description

CREATE USER is an alias for CREATE ROLE.

The only difference between CREATE ROLE and CREATE USER is that LOGIN is assumed by default with CREATE USER, whereas NOLOGIN is assumed by default with CREATE ROLE.

Compatibility

There is no CREATE USER statement in the SQL standard.

See Also

CREATE ROLE

CREATE VIEW

Defines a new view.

Synopsis

```
CREATE [OR REPLACE] [TEMP | TEMPORARY] VIEW name
  [ ( column_name [, ...] ) ]
AS query
```

Description

CREATE VIEW defines a view of a query. The view is not physically materialized. Instead, the query is run every time the view is referenced in a query.

CREATE OR REPLACE VIEW is similar, but if a view of the same name already exists, it is replaced. You can only replace a view with a new query that generates the identical set of columns (same column names and data types).

If a schema name is given then the view is created in the specified schema. Otherwise it is created in the current schema. Temporary views exist in a special schema, so a schema name may not be given when creating a temporary view. The name of the view must be distinct from the name of any other view, table, sequence, or index in the same schema.

Parameters

TEMPORARY | TEMP

If specified, the view is created as a temporary view. Temporary views are automatically dropped at the end of the current session. Existing permanent relations with the same name are not visible to the current session while the temporary view exists, unless they are referenced with schema-qualified names. If any of the tables referenced by the view are temporary, the view is created as a temporary view (whether TEMPORARY is specified or not).

name

The name (optionally schema-qualified) of a view to be created.

column_name

An optional list of names to be used for columns of the view. If not given, the column names are deduced from the query.

query

A SELECT or VALUES command which will provide the columns and rows of the view.
Notes
Views in Greenplum Database are read only. The system will not allow an insert, update, or delete on a view. You can get the effect of an updatable view by creating rewrite rules on the view into appropriate actions on other tables. For more information see CREATE RULE.

Be careful that the names and data types of the view's columns will be assigned the way you want. For example:

```
CREATE VIEW vista AS SELECT 'Hello World';
```

is bad form in two ways: the column name defaults to `?column?`, and the column data type defaults to `unknown`. If you want a string literal in a view's result, use something like:

```
CREATE VIEW vista AS SELECT text 'Hello World' AS hello;
```

Access to tables referenced in the view is determined by permissions of the view owner not the current user (even if the current user is a superuser). This can be confusing in the case of superusers, since superusers typically have access to all objects. In the case of a view, even superusers must be explicitly granted access to tables referenced in the view if they are not the owner of the view.

However, functions called in the view are treated the same as if they had been called directly from the query using the view. Therefore the user of a view must have permissions to call any functions used by the view.

If you create a view with an `ORDER BY` clause, the `ORDER BY` clause is ignored when you do a `SELECT` from the view.

Examples
Create a view consisting of all comedy films:

```
CREATE VIEW comedies AS SELECT * FROM films WHERE kind = 'comedy';
```

Create a view that gets the top ten ranked baby names:

```
CREATE VIEW topten AS SELECT name, rank, gender, year FROM names, rank WHERE rank < '11' AND names.id=rank.id;
```

Compatibility
The SQL standard specifies some additional capabilities for the `CREATE VIEW` statement that are not in Greenplum Database. The optional clauses for the full SQL command in the standard are:

- **CHECK OPTION** — This option has to do with updatable views. All `INSERT` and `UPDATE` commands on the view will be checked to ensure data satisfy the view-defining condition (that is, the new data would be visible through the view). If they do not, the update will be rejected.
- **LOCAL** — Check for integrity on this view.
- **CASCADED** — Check for integrity on this view and on any dependent view. **CASCADED** is assumed if neither **CASCADED** nor **LOCAL** is specified.

`CREATE OR REPLACE VIEW` is a Greenplum Database language extension. So is the concept of a temporary view.

See Also
`SELECT, DROP VIEW`
**DEALLOCATE**

Deallocates a prepared statement.

**Synopsis**

```
DEALLOCATE [PREPARE] name
```

**Description**

DEALLOCATE is used to deallocate a previously prepared SQL statement. If you do not explicitly deallocate a prepared statement, it is deallocated when the session ends.

For more information on prepared statements, see `PREPARE`.

**Parameters**

- **PREPARE**
  - Optional key word which is ignored.
- **name**
  - The name of the prepared statement to deallocate.

**Examples**

Deallocated the previously prepared statement named `insert_names`:

```
DEALLOCATE insert_names;
```

**Compatibility**

The SQL standard includes a DEALLOCATE statement, but it is only for use in embedded SQL.

**See Also**

`EXECUTE`, `PREPARE`

---

**DECLARE**

Defines a cursor.

**Synopsis**

```
DECLARE name [BINARY] [INSENSITIVE] [NO SCROLL] CURSOR
[(WITH | WITHOUT) HOLD]
FOR query [FOR READ ONLY]
```

**Description**

DECLARE allows a user to create cursors, which can be used to retrieve a small number of rows at a time out of a larger query. Cursors can return data either in text or in binary format using `FETCH`.

Normal cursors return data in text format, the same as a `SELECT` would produce. Since data is stored natively in binary format, the system must do a conversion to produce the text format. Once the information comes back in text form, the client application may need to convert it to a binary format to manipulate it. In addition, data in the text format is often larger in size than in the binary format. Binary cursors return the
data in a binary representation that may be more easily manipulated. Nevertheless, if you intend to display
the data as text anyway, retrieving it in text form will save you some effort on the client side.

As an example, if a query returns a value of one from an integer column, you would get a string of 1
with a default cursor whereas with a binary cursor you would get a 4-byte field containing the internal
representation of the value (in big-endian byte order).

Binary cursors should be used carefully. Many applications, including psql, are not prepared to handle
binary cursors and expect data to come back in the text format.

Note:
When the client application uses the 'extended query' protocol to issue a \texttt{FETCH} command, the
Bind protocol message specifies whether data is to be retrieved in text or binary format. This choice
overrides the way that the cursor is defined. The concept of a binary cursor as such is thus obsolete
when using extended query protocol — any cursor can be treated as either text or binary.

A cursor can be specified in the \texttt{WHERE CURRENT OF} clause of the \texttt{UPDATE} or \texttt{DELETE} statement to
update or delete table data. The \texttt{UPDATE} or \texttt{DELETE} statement can only be executed on the server, for
example in an interactive psql session or a script. Language extensions such as PL/pgSQL do not have
support for updatable cursors.

\textbf{Parameters}

\textit{name}

The name of the cursor to be created.

\textbf{BINARY}

Causes the cursor to return data in binary rather than in text format.

\textbf{INSENSITIVE}

Indicates that data retrieved from the cursor should be unaffected by updates to the tables
underlying the cursor while the cursor exists. In Greenplum Database, all cursors are
insensitive. This key word currently has no effect and is present for compatibility with the
SQL standard.

\textbf{NO SCROLL}

A cursor cannot be used to retrieve rows in a nonsequential fashion. This is the default
behavior in Greenplum Database, since scrollable cursors (\texttt{SCROLL}) are not supported.

\textbf{WITH HOLD}

\textbf{WITHOUT HOLD}

\texttt{WITH HOLD} specifies that the cursor may continue to be used after the transaction that
created it successfully commits. \texttt{WITHOUT HOLD} specifies that the cursor cannot be used
outside of the transaction that created it. \texttt{WITHOUT HOLD} is the default.

\texttt{WITH HOLD} cannot be specified when the \textit{query} includes a \texttt{FOR UPDATE} or \texttt{FOR
SHARE} clause.

\textit{query}

A \texttt{SELECT} or \texttt{VALUES} command which will provide the rows to be returned by the cursor.

If the cursor is used in the \texttt{WHERE CURRENT OF} clause of the \texttt{UPDATE} or \texttt{DELETE}
command, the \texttt{SELECT} command must satisfy the following conditions:

- Cannot reference a view or external table.
- References only one table.

The table must be updatable. For example, the following are not updatable: table
functions, set-returning functions, append-only tables, columnar tables.

- Cannot contain any of the following:
  - A grouping clause
• A set operation such as UNION ALL or UNION DISTINCT
• A sorting clause
• A windowing clause
• A join or a self-join

Specifying the FOR UPDATE clause in the SELECT command prevents other sessions from changing the rows between the time they are fetched and the time they are updated. Without the FOR UPDATE clause, a subsequent use of the UPDATE or DELETE command with the WHERE CURRENT OF clause has no effect if the row was changed since the cursor was created.

**Note:** Specifying the FOR UPDATE clause in the SELECT command locks the entire table, not just the selected rows.

**FOR READ ONLY**

FOR READ ONLY indicates that the cursor is used in a read-only mode.

**Notes**

Unless WITH HOLD is specified, the cursor created by this command can only be used within the current transaction. Thus, DECLARE without WITH HOLD is useless outside a transaction block: the cursor would survive only to the completion of the statement. Therefore Greenplum Database reports an error if this command is used outside a transaction block. Use BEGIN, COMMIT and ROLLBACK to define a transaction block.

If WITH HOLD is specified and the transaction that created the cursor successfully commits, the cursor can continue to be accessed by subsequent transactions in the same session. (But if the creating transaction is aborted, the cursor is removed.) A cursor created with WITH HOLD is closed when an explicit CLOSE command is issued on it, or the session ends. In the current implementation, the rows represented by a held cursor are copied into a temporary file or memory area so that they remain available for subsequent transactions.

If you create a cursor with the DECLARE command in a transaction, you cannot use the SET command in the transaction until you close the cursor with the CLOSE command.

Scrollable cursors are not currently supported in Greenplum Database. You can only use FETCH to move the cursor position forward, not backwards.

DECLARE FOR UPDATE is not supported with append-optimized tables.

You can see all available cursors by querying the pg_cursors system view.

**Examples**

Declare a cursor:

```
DECLARE mycursor CURSOR FOR SELECT * FROM mytable;
```

**Compatibility**

SQL standard allows cursors only in embedded SQL and in modules. Greenplum Database permits cursors to be used interactively.

Greenplum Database does not implement an OPEN statement for cursors. A cursor is considered to be open when it is declared.

The SQL standard allows cursors to move both forward and backward. All Greenplum Database cursors are forward moving only (not scrollable).

Binary cursors are a Greenplum Database extension.
See Also
CLOSE, DELETE, FETCH, MOVE, SELECT, UPDATE

DELETE

Deletes rows from a table.

Synopsis

DELETE FROM [ONLY] table [[AS] alias]
[USING usinglist]
[WHERE condition | WHERE CURRENT OF cursor_name ]

Description

DELETE deletes rows that satisfy the WHERE clause from the specified table. If the WHERE clause is absent, the effect is to delete all rows in the table. The result is a valid, but empty table.

By default, DELETE will delete rows in the specified table and all its child tables. If you wish to delete only from the specified table mentioned, you must use the ONLY clause.

There are two ways to delete rows in a table using information contained in other tables in the database: using sub-selects, or specifying additional tables in the USING clause. Which technique is more appropriate depends on the specific circumstances.

If the WHERE CURRENT OF clause is specified, the row that is deleted is the one most recently fetched from the specified cursor.

You must have the DELETE privilege on the table to delete from it.

Outputs

On successful completion, a DELETE command returns a command tag of the form

DELETE count

The count is the number of rows deleted. If count is 0, no rows matched the condition (this is not considered an error).

Parameters

ONLY

If specified, delete rows from the named table only. When not specified, any tables inheriting from the named table are also processed.

table

The name (optionally schema-qualified) of an existing table.

alias

A substitute name for the target table. When an alias is provided, it completely hides the actual name of the table. For example, given DELETE FROM foo AS f, the remainder of the DELETE statement must refer to this table as f not foo.

usinglist

A list of table expressions, allowing columns from other tables to appear in the WHERE condition. This is similar to the list of tables that can be specified in the FROM Clause of a SELECT statement; for example, an alias for the table name can be specified. Do not repeat the target table in the usinglist, unless you wish to set up a self-join.

condition
An expression returning a value of type boolean, which determines the rows that are to be deleted.

cursor_name
The name of the cursor to use in a WHERE CURRENT OF condition. The row to be deleted is the one most recently fetched from this cursor. The cursor must be a simple (non-join, non-aggregate) query on the DELETE target table.

WHERE CURRENT OF cannot be specified together with a Boolean condition.

The DELETE...WHERE CURRENT OF cursor statement can only be executed on the server, for example in an interactive psql session or a script. Language extensions such as PL/pgSQL do not have support for updatable cursors.

See DECLARE for more information about creating cursors.

Notes
Greenplum Database lets you reference columns of other tables in the WHERE condition by specifying the other tables in the USING clause. For example, to the name Hannah from the rank table, one might do:

```
DELETE FROM rank USING names WHERE names.id = rank.id AND name = 'Hannah';
```

What is essentially happening here is a join between rank and names, with all successfully joined rows being marked for deletion. This syntax is not standard. However, this join style is usually easier to write and faster to execute than a more standard sub-select style, such as:

```
DELETE FROM rank WHERE id IN (SELECT id FROM names WHERE name = 'Hannah');
```

When using DELETE to remove all the rows of a table (for example: DELETE * FROM table;), Greenplum Database adds an implicit TRUNCATE command (when user permissions allow). The added TRUNCATE command frees the disk space occupied by the deleted rows without requiring a VACUUM of the table. This improves scan performance of subsequent queries, and benefits ELT workloads that frequently insert and delete from temporary tables.

Execution of UPDATE and DELETE commands directly on a specific partition (child table) of a partitioned table is not supported. Instead, these commands must be executed on the root partitioned table, the table created with the CREATE TABLE command.

For a partitioned table, all the child tables are locked during the DELETE operation.

Examples
Delete all films but musicals:

```
DELETE FROM films WHERE kind <> 'Musical';
```

Clear the table films:

```
DELETE FROM films;
```

Delete using a join:

```
DELETE FROM rank USING names WHERE names.id = rank.id AND name = 'Hannah';
```
Compatibility

This command conforms to the SQL standard, except that the USING clause is a Greenplum Database extension.

See Also

DECLARE, TRUNCATE

**DISCARD**

Discards the session state.

**Synopsis**

```
DISCARD { ALL | PLANS | TEMPORARY | TEMP }
```

**Description**

**DISCARD** releases internal resources associated with a database session. This command is useful for partially or fully resetting the session's state. There are several subcommands to release different types of resources. **DISCARD ALL** is not supported by Greenplum Database.

**Parameters**

**PLANS**

Releases all cached query plans, forcing re-planning to occur the next time the associated prepared statement is used.

**SEQUENCES**

Discards all cached sequence-related state, including any preallocated sequence values that have not yet been returned by `nextval()`. (See **CREATE SEQUENCE** for a description of preallocated sequence values.)

**TEMPORARY/TEMP**

Drops all temporary tables created in the current session.

**ALL**

Releases all temporary resources associated with the current session and resets the session to its initial state.

**Note:** Greenplum Database does not support **DISCARD ALL** and returns a notice message if you attempt to run the command.

As an alternative, you can run the following commands to release temporary session resources:

```
SET SESSION AUTHORIZATION DEFAULT;
RESET ALL;
DEALLOCATE ALL;
CLOSE ALL;
SELECT pg_advisory_unlock_all();
DISCARD PLANS;
DISCARD SEQUENCES;
DISCARD TEMP;
```

**Compatibility**

**DISCARD** is a Greenplum Database extension.
DO

Executes an anonymous code block as a transient anonymous function.

Synopsis

```
DO [ LANGUAGE lang_name ] code
```

Description

DO executes an anonymous code block, or in other words a transient anonymous function in a procedural language.

The code block is treated as though it were the body of a function with no parameters, returning void. It is parsed and executed a single time.

The optional LANGUAGE clause can appear either before or after the code block.

Anonymous blocks are procedural language structures that provide the capability to create and execute procedural code on the fly without persistently storing the code as database objects in the system catalogs. The concept of anonymous blocks is similar to UNIX shell scripts, which enable several manually entered commands to be grouped and executed as one step. As the name implies, anonymous blocks do not have a name, and for this reason they cannot be referenced from other objects. Although built dynamically, anonymous blocks can be easily stored as scripts in the operating system files for repetitive execution.

Anonymous blocks are standard procedural language blocks. They carry the syntax and obey the rules that apply to the procedural language, including declaration and scope of variables, execution, exception handling, and language usage.

The compilation and execution of anonymous blocks are combined in one step, while a user-defined function needs to be re-defined before use each time its definition changes.

Parameters

- **code**: The procedural language code to be executed. This must be specified as a string literal, just as with the CREATE FUNCTION command. Use of a dollar-quoted literal is recommended. Optional keywords have no effect. These procedural languages are supported: PL/pgSQL (plpgsql), PL/Python (plpythonu), and PL/Perl (plperl and plperlu).

- **lang_name**: The name of the procedural language that the code is written in. The default is plpgsql. The language must be installed on the Greenplum Database system and registered in the database.

Notes

The PL/pgSQL language is installed on the Greenplum Database system and is registered in a user created database. The PL/Python language is installed by default, but not registered. Other languages are not installed or registered. The system catalog pg_language contains information about the registered languages in a database.

The user must have USAGE privilege for the procedural language, or must be a superuser if the language is untrusted. This is the same privilege requirement as for creating a function in the language.
Examples
This PL/pgSQL example grants all privileges on all views in schema public to role webuser:

```
DO $$
DECLARE r record;
BEGIN
  FOR r IN SELECT table_schema, table_name FROM information_schema.tables
    WHERE table_type = 'VIEW' AND table_schema = 'public'
  LOOP
    EXECUTE 'GRANT ALL ON ' || quote_ident(r.table_schema) || '.' ||
      quote_ident(r.table_name) || ' TO webuser';
  END LOOP;
END$$;
```

This PL/pgSQL example determines if a Greenplum Database user is a superuser. In the example, the anonymous block retrieves the input value from a temporary table.

```
CREATE TEMP TABLE list AS VALUES ('gpadmin') DISTRIBUTED RANDOMLY;

DO $$
DECLARE
  name TEXT := 'gpadmin' ;
  superuser TEXT := '' ;
  t1_row   pg_authid%ROWTYPE;
BEGIN
  SELECT * INTO t1_row FROM pg_authid, list
    WHERE pg_authid.rolname = name ;
  IF t1_row.rolsuper = 'f' THEN
    superuser := 'not ' ;
  END IF ;
  RAISE NOTICE 'user % is %a superuser', t1_row.rolname, superuser ;
END $$ LANGUAGE plpgsql ;
```

Note: The example PL/pgSQL uses SELECT with the INTO clause. It is different from the SQL command SELECT INTO.

Compatibility
There is no do statement in the SQL standard.

See Also
CREATE LANGUAGE Greenplum PL/pgSQL Procedural Language

DROP AGGREGATE
Removes an aggregate function.

Synopsis

```
DROP AGGREGATE [IF EXISTS] name ( type [, ...] ) [CASCADE | RESTRICT]
```

Description
DROP AGGREGATE will delete an existing aggregate function. To execute this command the current user must be the owner of the aggregate function.

Parameters
IF EXISTS
Do not throw an error if the aggregate does not exist. A notice is issued in this case.

**name**

The name (optionally schema-qualified) of an existing aggregate function.

**type**

An input data type on which the aggregate function operates. To reference a zero-argument aggregate function, write * in place of the list of input data types.

**CASCADE**

Automatically drop objects that depend on the aggregate function.

**RESTRICT**

Refuse to drop the aggregate function if any objects depend on it. This is the default.

### Examples

To remove the aggregate function `myavg` for type `integer`:

```sql
DROP AGGREGATE myavg(integer);
```

### Compatibility

There is no `DROP AGGREGATE` statement in the SQL standard.

### See Also

`ALTER AGGREGATE`,  
`CREATE AGGREGATE`

---

**DROP CAST**

Removes a cast.

### Synopsis

```sql
DROP CAST [IF EXISTS] (sourcetype AS targettype) [CASCADE | RESTRICT]
```

### Description

`DROP CAST` will delete a previously defined cast. To be able to drop a cast, you must own the source or the target data type. These are the same privileges that are required to create a cast.

### Parameters

**IF EXISTS**

Do not throw an error if the cast does not exist. A notice is issued in this case.

**sourcetype**

The name of the source data type of the cast.

**targettype**

The name of the target data type of the cast.

**CASCADE**

**RESTRICT**

These keywords have no effect since there are no dependencies on casts.
Examples
To drop the cast from type text to type int:

```
DROP CAST (text AS int);
```

Compatibility
There DROP CAST command conforms to the SQL standard.

See Also
CREATE CAST

**DROP CONVERSION**

Removes a conversion.

**Synopsis**

```
DROP CONVERSION [IF EXISTS] name [CASCADE | RESTRICT]
```

**Description**

DROP CONVERSION removes a previously defined conversion. To be able to drop a conversion, you must own the conversion.

**Parameters**

**IF EXISTS**

Do not throw an error if the conversion does not exist. A notice is issued in this case.

**name**

The name of the conversion. The conversion name may be schema-qualified.

**CASCADE**

**RESTRICT**

These keywords have no effect since there are no dependencies on conversions.

**Examples**

Drop the conversion named myname:

```
DROP CONVERSION myname;
```

Compatibility
There is no DROP CONVERSION statement in the SQL standard.

**See Also**

ALTER CONVERSION, CREATE CONVERSION

**DROP DATABASE**

Removes a database.
Synopsis

DROP DATABASE [IF EXISTS] name

Description

DROP DATABASE drops a database. It removes the catalog entries for the database and deletes the directory containing the data. It can only be executed by the database owner. Also, it cannot be executed while you or anyone else are connected to the target database. (Connect to postgres or any other database to issue this command.)

Warning: DROP DATABASE cannot be undone. Use it with care!

Parameters

IF EXISTS
Do not throw an error if the database does not exist. A notice is issued in this case.

name
The name of the database to remove.

Notes

DROP DATABASE cannot be executed inside a transaction block.
This command cannot be executed while connected to the target database. Thus, it might be more convenient to use the program dropdb instead, which is a wrapper around this command.

Examples

Drop the database named testdb:

DROP DATABASE testdb;

Compatibility

There is no DROP DATABASE statement in the SQL standard.

See Also

ALTER DATABASE, CREATE DATABASE

DROP DOMAIN

Removes a domain.

Synopsis

DROP DOMAIN [IF EXISTS] name [, ...] [CASCADE | RESTRICT]

Description

DROP DOMAIN removes a previously defined domain. You must be the owner of a domain to drop it.

Parameters

IF EXISTS
Do not throw an error if the domain does not exist. A notice is issued in this case.
name

The name (optionally schema-qualified) of an existing domain.

CASCADE

Automatically drop objects that depend on the domain (such as table columns).

RESTRICT

Refuse to drop the domain if any objects depend on it. This is the default.

Examples

Drop the domain named zipcode:

```sql
DROP DOMAIN zipcode;
```

Compatibility

This command conforms to the SQL standard, except for the `IF EXISTS` option, which is a Greenplum Database extension.

See Also

`ALTER DOMAIN`, `CREATE DOMAIN`

---

**DROP EXTENSION**

Removes an extension from a Greenplum database.

**Synopsis**

```sql
DROP EXTENSION [ IF EXISTS ] name [, ...] [ CASCADE | RESTRICT ]
```

**Description**

`DROP EXTENSION` removes extensions from the database. Dropping an extension causes its component objects to be dropped as well.

**Note:** The required supporting extension files what were installed to create the extension are not deleted. The files must be manually removed from the Greenplum Database hosts.

You must own the extension to use `DROP EXTENSION`.

This command fails if any of the extension objects are in use in the database. For example, if a table is defined with columns of the extension type. Add the `CASCADE` option to forcibly remove those dependent objects.

**Important:** Before issuing a `DROP EXTENSION` with the `CASCADE` keyword, you should be aware of all object that depend on the extension to avoid unintended consequences.

**Parameters**

**IF EXISTS**

Do not throw an error if the extension does not exist. A notice is issued.

**name**

The name of an installed extension.

**CASCADE**
Automatically drop objects that depend on the extension, and in turn all objects that depend on those objects. See the PostgreSQL information about *Dependency Tracking*.

**RESTRICT**

Refuse to drop an extension if any objects depend on it, other than the extension member objects. This is the default.

**Compatibility**

DROP EXTENSION is a Greenplum Database extension.

**See Also**

CREATE EXTENSION, ALTER EXTENSION

---

**DROP EXTERNAL TABLE**

Removes an external table definition.

**Synopsis**

```
DROP EXTERNAL [WEB] TABLE [IF EXISTS] name [CASCADE | RESTRICT]
```

**Description**

DROP EXTERNAL TABLE drops an existing external table definition from the database system. The external data sources or files are not deleted. To execute this command you must be the owner of the external table.

**Parameters**

**WEB**

Optional keyword for dropping external web tables.

**IF EXISTS**

Do not throw an error if the external table does not exist. A notice is issued in this case.

**name**

The name (optionally schema-qualified) of an existing external table.

**CASCADE**

Automatically drop objects that depend on the external table (such as views).

**RESTRICT**

Refuse to drop the external table if any objects depend on it. This is the default.

**Examples**

Remove the external table named *staging* if it exists:

```
DROP EXTERNAL TABLE IF EXISTS staging;
```

**Compatibility**

There is no DROP EXTERNAL TABLE statement in the SQL standard.
See Also

CREATE EXTERNAL TABLE

**DROP FILESPACE**

Removes a filespace.

**Synopsis**

```
DROP FILESPACE [IF EXISTS] filespacename
```

**Description**

DROP FILESPACE removes a filespace definition and its system-generated data directories from the system.

A filespace can only be dropped by its owner or a superuser. The filespace must be empty of all tablespace objects before it can be dropped. It is possible that tablespaces in other databases may still be using a filespace even if no tablespaces in the current database are using the filespace.

**Parameters**

- **IF EXISTS**
  - Do not throw an error if the filespace does not exist. A notice is issued in this case.
- **filespacename**
  - The name of the filespace to remove.

**Examples**

Remove the tablespace `myfs`:

```
DROP FILESPACE myfs;
```

**Compatibility**

There is no DROP FILESPACE statement in the SQL standard or in PostgreSQL.

**See Also**

ALTER FILESPACE, DROP TABLESPACE, gpfilespace in the Greenplum Database Utility Guide

**DROP FUNCTION**

Removes a function.

**Synopsis**

```
DROP FUNCTION [IF EXISTS] name ( [ [argmode] [argname] argtype [, ...] ] ) [CASCADE | RESTRICT]
```

**Description**

DROP FUNCTION removes the definition of an existing function. To execute this command the user must be the owner of the function. The argument types to the function must be specified, since several different functions may exist with the same name and different argument lists.
Parameters

**IF EXISTS**
Do not throw an error if the function does not exist. A notice is issued in this case.

**name**
The name (optionally schema-qualified) of an existing function.

**argmode**
The mode of an argument: either IN, OUT, INOUT, or VARIADIC. If omitted, the default is IN. Note that DROP FUNCTION does not actually pay any attention to OUT arguments, since only the input arguments are needed to determine the function's identity. So it is sufficient to list the IN, INOUT, and VARIADIC arguments.

**argname**
The name of an argument. Note that DROP FUNCTION does not actually pay any attention to argument names, since only the argument data types are needed to determine the function's identity.

**argtype**
The data type(s) of the function's arguments (optionally schema-qualified), if any.

**CASCADE**
Automatically drop objects that depend on the function such as operators.

**RESTRICT**
Refuse to drop the function if any objects depend on it. This is the default.

Examples

Drop the square root function:

```
DROP FUNCTION sqrt(integer);
```

Compatibility

A DROP FUNCTION statement is defined in the SQL standard, but it is not compatible with this command.

See Also

CREATE FUNCTION, ALTER FUNCTION

**DROP GROUP**

Removes a database role.

Synopsis

```
DROP GROUP [IF EXISTS] name [, ...]
```

Description

DROP GROUP is an alias for DROP ROLE. See DROP ROLE for more information.

Compatibility

There is no DROP GROUP statement in the SQL standard.
See Also
DROP ROLE

**DROP INDEX**

Removes an index.

**Synopsis**

```
DROP INDEX [IF EXISTS] name [, ...] [CASCADE | RESTRICT]
```

**Description**

DROP INDEX drops an existing index from the database system. To execute this command you must be the owner of the index.

**Parameters**

- **IF EXISTS**
  Do not throw an error if the index does not exist. A notice is issued in this case.

- **name**
  The name (optionally schema-qualified) of an existing index.

- **CASCADE**
  Automatically drop objects that depend on the index.

- **RESTRICT**
  Refuse to drop the index if any objects depend on it. This is the default.

**Examples**

Remove the index *title_idx*:

```
DROP INDEX title_idx;
```

**Compatibility**

DROP INDEX is a Greenplum Database language extension. There are no provisions for indexes in the SQL standard.

See Also

ALTER INDEX, CREATE INDEX, REINDEX

**DROP LANGUAGE**

Removes a procedural language.

**Synopsis**

```
DROP [PROCEDURAL] LANGUAGE [IF EXISTS] name [CASCADE | RESTRICT]
```
**Description**

`DROP LANGUAGE` will remove the definition of the previously registered procedural language. You must be a superuser or owner of the language to drop a language.

**Parameters**

- **PROCEDURAL**
  
  Optional keyword - has no effect.

- **IF EXISTS**
  
  Do not throw an error if the language does not exist. A notice is issued in this case.

- **name**
  
  The name of an existing procedural language. For backward compatibility, the name may be enclosed by single quotes.

- **CASCADE**
  
  Automatically drop objects that depend on the language (such as functions written in that language).

- **RESTRICT**
  
  Refuse to drop the language if any objects depend on it. This is the default.

**Examples**

Remove the procedural language `plsample`:

```sql
DROP LANGUAGE plsample;
```

**Compatibility**

There is no `DROP LANGUAGE` statement in the SQL standard.

**See Also**

- `ALTER LANGUAGE`
- `CREATE LANGUAGE`

---

**DROP OPERATOR**

Removes an operator.

**Synopsis**

```sql
DROP OPERATOR [IF EXISTS] name ( {lefttype | NONE} ,
    {righttype | NONE} ) [CASCADE | RESTRICT]
```

**Description**

`DROP OPERATOR` drops an existing operator from the database system. To execute this command you must be the owner of the operator.

**Parameters**

- **IF EXISTS**
  
  Do not throw an error if the operator does not exist. A notice is issued in this case.

- **name**
  
  The name (optionally schema-qualified) of an existing operator.
lefttype
The data type of the operator's left operand; write NONE if the operator has no left operand.

righttype
The data type of the operator's right operand; write NONE if the operator has no right operand.

CASCADE
Automatically drop objects that depend on the operator.

RESTRICT
Refuse to drop the operator if any objects depend on it. This is the default.

Examples
Remove the power operator a^b for type integer:

```
DROP OPERATOR ^ (integer, integer);
```

Remove the left unary bitwise complement operator ~b for type bit:

```
DROP OPERATOR ~ (none, bit);
```

Remove the right unary factorial operator x! for type bigint:

```
DROP OPERATOR ! (bigint, none);
```

Compatibility
There is no DROP OPERATOR statement in the SQL standard.

See Also
ALTER OPERATOR, CREATE OPERATOR

DROP OPERATOR CLASS
Removes an operator class.

Synopsis

```
DROP OPERATOR CLASS [IF EXISTS] name USING index_method [CASCADE | RESTRICT]
```

Description

DROP OPERATOR CLASS drops an existing operator class. To execute this command you must be the owner of the operator class.

Parameters

**IF EXISTS**
Do not throw an error if the operator class does not exist. A notice is issued in this case.

**name**
The name (optionally schema-qualified) of an existing operator class.

**index_method**
The name of the index access method the operator class is for.
CASCADE
Automatically drop objects that depend on the operator class.

RESTRICT
Refuse to drop the operator class if any objects depend on it. This is the default.

Examples
Remove the B-tree operator class widget_ops:

```
DROP OPERATOR CLASS widget_ops USING btree;
```

This command will not succeed if there are any existing indexes that use the operator class. Add CASCADE to drop such indexes along with the operator class.

Compatibility
There is no DROP OPERATOR CLASS statement in the SQL standard.

See Also
ALTER OPERATOR CLASS, CREATE OPERATOR CLASS

**DROP OPERATOR FAMILY**

Removes an operator family.

**Synopsis**

```
DROP OPERATOR FAMILY [IF EXISTS] name USING index_method [CASCADE | RESTRICT]
```

**Description**

DROP OPERATOR FAMILY drops an existing operator family. To execute this command you must be the owner of the operator family.

DROP OPERATOR FAMILY includes dropping any operator classes contained in the family, but it does not drop any of the operators or functions referenced by the family. If there are any indexes depending on operator classes within the family, you will need to specify CASCADE for the drop to complete.

**Parameters**

IF EXISTS
Do not throw an error if the operator family does not exist. A notice is issued in this case.

name
The name (optionally schema-qualified) of an existing operator family.

index_method
The name of the index access method the operator family is for.

CASCADE
Automatically drop objects that depend on the operator family.

RESTRICT
Refuse to drop the operator family if any objects depend on it. This is the default.
Examples
Remove the B-tree operator family float_ops:

```
DROP OPERATOR FAMILY float_ops USING btree;
```

This command will not succeed if there are any existing indexes that use the operator family. Add CASCADE to drop such indexes along with the operator family.

Compatibility
There is no DROP OPERATOR FAMILY statement in the SQL standard.

See Also
ALTER OPERATOR FAMILY, CREATE OPERATOR FAMILY, ALTER OPERATOR CLASS, CREATE OPERATOR CLASS, DROP OPERATOR CLASS

DROP OWNED
Removes database objects owned by a database role.

Synopsis

```
DROP OWNED BY name [, ...] [CASCADE | RESTRICT]
```

Description
DROP OWNED drops all the objects in the current database that are owned by one of the specified roles. Any privileges granted to the given roles on objects in the current database will also be revoked.

Parameters

- **name**
  The name of a role whose objects will be dropped, and whose privileges will be revoked.

- **CASCADE**
  Automatically drop objects that depend on the affected objects.

- **RESTRICT**
  Refuse to drop the objects owned by a role if any other database objects depend on one of the affected objects. This is the default.

Notes
DROP OWNED is often used to prepare for the removal of one or more roles. Because DROP OWNED only affects the objects in the current database, it is usually necessary to execute this command in each database that contains objects owned by a role that is to be removed.

Using the CASCADE option may make the command recurse to objects owned by other users.

The REASSIGN OWNED command is an alternative that reassigns the ownership of all the database objects owned by one or more roles.

Examples
Remove any database objects owned by the role named sally:

```
DROP OWNED BY sally;
```
Compatibility
The `DROP OWNED` statement is a Greenplum Database extension.

See Also
`REASSIGN OWNED, DROP ROLE`

**DROP PROTOCOL**
Removes a external table data access protocol from a database.

**Synopsis**
```
DROP PROTOCOL [IF EXISTS] name
```

**Description**
`DROP PROTOCOL` removes the specified protocol from a database. A protocol name can be specified in the `CREATE EXTERNAL TABLE` command to read data from or write data to an external data source.

**Warning:** If you drop a data access prococol, external tables that have been defined with the protocol will no longer be able to access the external data source.

**Parameters**
- **IF EXISTS**
  Do not throw an error if the protocol does not exist. A notice is issued in this case.
- **name**
  The name of an existing data access protocol.

**Notes**
If you drop a data access protocol, the call handlers that defined in the database that are associated with the protocol are not dropped. You must drop the functions manually.

Shared libraries that were used by the protocol should also be removed from the Greenplum Database hosts.

**Compatibility**
`DROP PROTOCOL` is a Greenplum Database extension.

**See Also**
`CREATE EXTERNAL TABLE, CREATE PROTOCOL`

**DROP RESOURCE GROUP**
Removes a resource group.

**Synopsis**
```
DROP RESOURCE GROUP group_name
```
Description

This command removes a resource group from Greenplum Database. Only a superuser can drop a resource group. When you drop a resource group, the memory and CPU resources reserved by the group are returned to Greenplum Database.

To drop a role resource group, the group cannot be assigned to any roles, nor can it have any statements pending or running in the group. If you drop a resource group that you created for an external component, the behavior is determined by the external component. For example, dropping a resource group that you assigned to a PL/Container runtime kills running containers in the group.

You cannot drop the pre-defined `admin_group` and `default_group` resource groups.

Parameters

`group_name`

The name of the resource group to remove.

Notes

You cannot submit a `DROP RESOURCE GROUP` command in an explicit transaction or sub-transaction.

Use `ALTER ROLE` to remove a resource group assigned to a specific user/role.

Perform the following query to view all of the currently active queries for all resource groups:

```sql
SELECT usename, current_query, waiting, procpid, rsgid, rsgname, rsgqueueduration
FROM pg_stat_activity;
```

To view the resource group assignments, perform the following query on the `pg_roles` and `pg_resgroup` system catalog tables:

```sql
SELECT rolname, rsgname
FROM pg_roles, pg_resgroup
WHERE pg_roles.rolresgroup=pg_resgroup.oid;
```

Examples

Remove the resource group assigned to a role. This operation then assigns the default resource group `default_group` to the role:

```sql
ALTER ROLE bob RESOURCE GROUP NONE;
```

Remove the resource group named `adhoc`:

```sql
DROP RESOURCE GROUP adhoc;
```

Compatibility

The `DROP RESOURCE GROUP` statement is a Greenplum Database extension.

See Also

`ALTER RESOURCE GROUP`, `CREATE RESOURCE GROUP`, `ALTER ROLE`

**DROP RESOURCE QUEUE**

Removes a resource queue.
Synopsis

DROP RESOURCE QUEUE queue_name

Description
This command removes a resource queue from Greenplum Database. To drop a resource queue, the queue cannot have any roles assigned to it, nor can it have any statements waiting in the queue. Only a superuser can drop a resource queue.

Parameters
queue_name

The name of a resource queue to remove.

Notes
Use ALTER ROLE to remove a user from a resource queue.

To see all the currently active queries for all resource queues, perform the following query of the pg_locks table joined with the pg_roles and pg_resqueue tables:

```
SELECT rolname, rsqname, locktype, objid, pid, mode, granted FROM pg_roles, pg_resqueue, pg_locks WHERE pg_roles.rolresqueue=pg_locks.objid AND pg_locks.objid=pg_resqueue.oid;
```

To see the roles assigned to a resource queue, perform the following query of the pg_roles and pg_resqueue system catalog tables:

```
SELECT rolname, rsqname FROM pg_roles, pg_resqueue WHERE pg_roles.rolresqueue=pg_resqueue.oid;
```

Examples
Remove a role from a resource queue (and move the role to the default resource queue, pg_default):

```
ALTER ROLE bob RESOURCE QUEUE NONE;
```

Remove the resource queue named adhoc:

```
DROP RESOURCE QUEUE adhoc;
```

Compatibility
The DROP RESOURCE QUEUE statement is a Greenplum Database extension.

See Also
ALTER RESOURCE QUEUE, CREATE RESOURCE QUEUE, ALTER ROLE

DROP ROLE

Removes a database role.
Synopsis

```
DROP ROLE [IF EXISTS] name [, ...]
```

Description

`DROP ROLE` removes the specified role(s). To drop a superuser role, you must be a superuser yourself. To drop non-superuser roles, you must have `CREATEROLE` privilege.

A role cannot be removed if it is still referenced in any database; an error will be raised if so. Before dropping the role, you must drop all the objects it owns (or reassign their ownership) and revoke any privileges the role has been granted. The `REASSIGN OWNED` and `DROP OWNED` commands can be useful for this purpose.

However, it is not necessary to remove role memberships involving the role; `DROP ROLE` automatically revokes any memberships of the target role in other roles, and of other roles in the target role. The other roles are not dropped nor otherwise affected.

Parameters

- **IF EXISTS**
  - Do not throw an error if the role does not exist. A notice is issued in this case.
- **name**
  - The name of the role to remove.

Examples

Remove the roles named `sally` and `bob`:

```
DROP ROLE sally, bob;
```

Compatibility

The SQL standard defines `DROP ROLE`, but it allows only one role to be dropped at a time, and it specifies different privilege requirements than Greenplum Database uses.

See Also

`REASSIGN OWNED`, `DROP OWNED`, `CREATE ROLE`, `ALTER ROLE`, `SET ROLE`

**DROP RULE**

Removes a rewrite rule.

Synopsis

```
DROP RULE [IF EXISTS] name ON relation [CASCADE | RESTRICT]
```

Description

`DROP RULE` drops a rewrite rule from a table or view.

Parameters

- **IF EXISTS**
  - Do not throw an error if the rule does not exist. A notice is issued in this case.
- **name**
The name of the rule to remove.

relation

The name (optionally schema-qualified) of the table or view that the rule applies to.

CASCADE

Automatically drop objects that depend on the rule.

RESTRICT

Refuse to drop the rule if any objects depend on it. This is the default.

Examples

Remove the rewrite rule sales_2006 on the table sales:

DROP RULE sales_2006 ON sales;

Compatibility

There is no DROP RULE statement in the SQL standard.

See Also

CREATE RULE

DROP SCHEMA

Removes a schema.

Synopsis

DROP SCHEMA [IF EXISTS] name [, ...] [CASCADE | RESTRICT]

Description

DROP SCHEMA removes schemas from the database. A schema can only be dropped by its owner or a superuser. Note that the owner can drop the schema (and thereby all contained objects) even if he does not own some of the objects within the schema.

Parameters

IF EXISTS

Do not throw an error if the schema does not exist. A notice is issued in this case.

name

The name of the schema to remove.

CASCADE

Automatically drops any objects contained in the schema (tables, functions, etc.).

RESTRICT

Refuse to drop the schema if it contains any objects. This is the default.

Examples

Remove the schema mystuff from the database, along with everything it contains:

DROP SCHEMA mystuff CASCADE;
**Compatibility**

DROP SCHEMA is fully conforming with the SQL standard, except that the standard only allows one schema to be dropped per command. Also, the **IF EXISTS** option is a Greenplum Database extension.

**See Also**

CREATE SCHEMA, ALTER SCHEMA

## DROP SEQUENCE

Removes a sequence.

### Synopsis

```
DROP SEQUENCE [IF EXISTS] name [, ...] [CASCADE | RESTRICT]
```

### Description

DROP SEQUENCE removes a sequence generator table. You must own the sequence to drop it (or be a superuser).

### Parameters

**IF EXISTS**

Do not throw an error if the sequence does not exist. A notice is issued in this case.

**name**

The name (optionally schema-qualified) of the sequence to remove.

**CASCADE**

Automatically drop objects that depend on the sequence.

**RESTRICT**

Refuse to drop the sequence if any objects depend on it. This is the default.

### Examples

Remove the sequence `myserial`:

```
DROP SEQUENCE myserial;
```

### Compatibility

DROP SEQUENCE is fully conforming with the SQL standard, except that the standard only allows one sequence to be dropped per command. Also, the **IF EXISTS** option is a Greenplum Database extension.

**See Also**

ALTER SEQUENCE, CREATE SEQUENCE

## DROP TABLE

Removes a table.
Synopsis

```
DROP TABLE [IF EXISTS] name [, ...] [CASCADE | RESTRICT]
```

Description

DROP TABLE removes tables from the database. Only its owner may drop a table. To empty a table of rows without removing the table definition, use DELETE or TRUNCATE.

DROP TABLE always removes any indexes, rules, triggers, and constraints that exist for the target table. However, to drop a table that is referenced by a view, CASCADE must be specified. CASCADE will remove a dependent view entirely.

Parameters

**IF EXISTS**

Do not throw an error if the table does not exist. A notice is issued in this case.

**name**

The name (optionally schema-qualified) of the table to remove.

**CASCADE**

Automatically drop objects that depend on the table (such as views).

**RESTRICT**

Refuse to drop the table if any objects depend on it. This is the default.

Examples

Remove the table mytable:

```
DROP TABLE mytable;
```

Compatibility

DROP TABLE is fully conforming with the SQL standard, except that the standard only allows one table to be dropped per command. Also, the IF EXISTS option is a Greenplum Database extension.

See Also

CREATE TABLE, ALTER TABLE, TRUNCATE

**DROP TABLESPACE**

Removes a tablespace.

Synopsis

```
DROP TABLESPACE [IF EXISTS] tablespacename
```

Description

DROP TABLESPACE removes a tablespace from the system.

A tablespace can only be dropped by its owner or a superuser. The tablespace must be empty of all database objects before it can be dropped. It is possible that objects in other databases may still reside in the tablespace even if no objects in the current database are using the tablespace.
**Parameters**

*IF EXISTS*

Do not throw an error if the tablespace does not exist. A notice is issued in this case.

*tablespacename*

The name of the tablespace to remove.

**Examples**

Remove the tablespace `mystuff`:

```
DROP TABLESPACE mystuff;
```

**Compatibility**

`DROP TABLESPACE` is a Greenplum Database extension.

**See Also**

`CREATE TABLESPACE, ALTER TABLESPACE`

---

**DROP TYPE**

Removes a data type.

**Synopsis**

```
DROP TYPE [IF EXISTS] name [, ...] [CASCADE | RESTRICT]
```

**Description**

`DROP TYPE` will remove a user-defined data type. Only the owner of a type can remove it.

**Parameters**

*IF EXISTS*

Do not throw an error if the type does not exist. A notice is issued in this case.

*name*

The name (optionally schema-qualified) of the data type to remove.

*CASCADE*

Automatically drop objects that depend on the type (such as table columns, functions, operators).

*RESTRICT*

Refuse to drop the type if any objects depend on it. This is the default.

**Examples**

Remove the data type `box`:

```
DROP TYPE box;
```
Compatibility

This command is similar to the corresponding command in the SQL standard, apart from the `IF EXISTS` option, which is a Greenplum Database extension. But note that the `CREATE TYPE` command and the data type extension mechanisms in Greenplum Database differ from the SQL standard.

See Also

`ALTER TYPE, CREATE TYPE`

**DROP USER**

Removes a database role.

Synopsis

```
DROP USER [IF EXISTS] name [, ...]
```

Description

`DROP USER` is an alias for `DROP ROLE`. See `DROP ROLE` for more information.

Compatibility

There is no `DROP USER` statement in the SQL standard. The SQL standard leaves the definition of users to the implementation.

See Also

`DROP ROLE`

**DROP VIEW**

Removes a view.

Synopsis

```
DROP VIEW [IF EXISTS] name [, ...] [CASCADE | RESTRICT]
```

Description

`DROP VIEW` will remove an existing view. Only the owner of a view can remove it.

Parameters

- **IF EXISTS**
  
  Do not throw an error if the view does not exist. A notice is issued in this case.

- **name**
  
  The name (optionally schema-qualified) of the view to remove.

- **CASCADE**
  
  Automatically drop objects that depend on the view (such as other views).

- **RESTRICT**
  
  Refuse to drop the view if any objects depend on it. This is the default.
Examples
Remove the view topten;

DROP VIEW topten;

Compatibility
DROP VIEW is fully conforming with the SQL standard, except that the standard only allows one view to be dropped per command. Also, the IF EXISTS option is a Greenplum Database extension.

See Also
CREATE VIEW

END
Commits the current transaction.

Synopsis
END [WORK | TRANSACTION]

Description
END commits the current transaction. All changes made by the transaction become visible to others and are guaranteed to be durable if a crash occurs. This command is a Greenplum Database extension that is equivalent to COMMIT.

Parameters
WORK
TRANSACTION
Optional keywords. They have no effect.

Examples
Commit the current transaction:

END;

Compatibility
END is a Greenplum Database extension that provides functionality equivalent to COMMIT, which is specified in the SQL standard.

See Also
BEGIN, ROLLBACK, COMMIT

EXECUTE
Executes a prepared SQL statement.
Synopsis

EXECUTE name [ (parameter [, ...] ) ]

Description

EXECUTE is used to execute a previously prepared statement. Since prepared statements only exist for the duration of a session, the prepared statement must have been created by a PREPARE statement executed earlier in the current session.

If the PREPARE statement that created the statement specified some parameters, a compatible set of parameters must be passed to the EXECUTE statement, or else an error is raised. Note that (unlike functions) prepared statements are not overloaded based on the type or number of their parameters; the name of a prepared statement must be unique within a database session.

For more information on the creation and usage of prepared statements, see PREPARE.

Parameters

name

The name of the prepared statement to execute.

parameter

The actual value of a parameter to the prepared statement. This must be an expression yielding a value that is compatible with the data type of this parameter, as was determined when the prepared statement was created.

Examples

Create a prepared statement for an INSERT statement, and then execute it:

```
PREPARE fooplan (int, text, bool, numeric) AS INSERT INTO foo VALUES($1, $2, $3, $4);
EXECUTE fooplan(1, 'Hunter Valley', 't', 200.00);
```

Compatibility

The SQL standard includes an EXECUTE statement, but it is only for use in embedded SQL. This version of the EXECUTE statement also uses a somewhat different syntax.

See Also

DEALLOCATE, PREPARE

EXPLAIN

Show the query plan of a statement.

Synopsis

EXPLAIN [ANALYZE] [VERBOSE] statement

Description

EXPLAIN displays the query plan that the Greenplum planner generates for the supplied statement. Query plans are a tree plan of nodes. Each node in the plan represents a single operation, such as table scan, join, aggregation or a sort.
Plans should be read from the bottom up as each node feeds rows into the node directly above it. The bottom nodes of a plan are usually table scan operations (sequential, index or bitmap index scans). If the query requires joins, aggregations, or sorts (or other operations on the raw rows) then there will be additional nodes above the scan nodes to perform these operations. The topmost plan nodes are usually the Greenplum Database motion nodes (redistribute, explicit redistribute, broadcast, or gather motions). These are the operations responsible for moving rows between the segment instances during query processing.

The output of `EXPLAIN` has one line for each node in the plan tree, showing the basic node type plus the following cost estimates that the planner made for the execution of that plan node:

- **cost** — measured in units of disk page fetches; that is, 1.0 equals one sequential disk page read. The first estimate is the start-up cost (cost of getting to the first row) and the second is the total cost (cost of getting all rows). Note that the total cost assumes that all rows will be retrieved, which may not always be the case (if using `LIMIT` for example).
- **rows** — the total number of rows output by this plan node. This is usually less than the actual number of rows processed or scanned by the plan node, reflecting the estimated selectivity of any `WHERE` clause conditions. Ideally the top-level nodes estimate will approximate the number of rows actually returned, updated, or deleted by the query.
- **width** — total bytes of all the rows output by this plan node.

It is important to note that the cost of an upper-level node includes the cost of all its child nodes. The topmost node of the plan has the estimated total execution cost for the plan. This is this number that the planner seeks to minimize. It is also important to realize that the cost only reflects things that the query optimizer cares about. In particular, the cost does not consider the time spent transmitting result rows to the client.

`EXPLAIN ANALYZE` causes the statement to be actually executed, not only planned. The `EXPLAIN ANALYZE` plan shows the actual results along with the planner's estimates. This is useful for seeing whether the planner's estimates are close to reality. In addition to the information shown in the `EXPLAIN` plan, `EXPLAIN ANALYZE` will show the following additional information:

- The total elapsed time (in milliseconds) that it took to run the query.
- The number of workers (segments) involved in a plan node operation. Only segments that return rows are counted.
- The maximum number of rows returned by the segment that produced the most rows for an operation. If multiple segments produce an equal number of rows, the one with the longest time to end is the one chosen.
- The segment id number of the segment that produced the most rows for an operation.
- For relevant operations, the `work_mem` used by the operation. If `work_mem` was not sufficient to perform the operation in memory, the plan will show how much data was spilled to disk and how many passes over the data were required for the lowest performing segment. For example:

```
Work_mem used: 64K bytes avg, 64K bytes max (seg0).
Work_mem wanted: 90K bytes avg, 90K bytes max (seg0) to abate workfile I/O affecting 2 workers.
[seg0] pass 0: 488 groups made from 488 rows; 263 rows written to workfile
[seg0] pass 1: 263 groups made from 263 rows
```

- The time (in milliseconds) it took to retrieve the first row from the segment that produced the most rows, and the total time taken to retrieve all rows from that segment. The `<time> to first row` may be omitted if it is the same as the `<time> to end`.

**Important:** Keep in mind that the statement is actually executed when `EXPLAIN ANALYZE` is used. Although `EXPLAIN ANALYZE` will discard any output that a `SELECT` would return, other side
effects of the statement will happen as usual. If you wish to use `EXPLAIN ANALYZE` on a DML statement without letting the command affect your data, use this approach:

```sql
BEGIN;
EXPLAIN ANALYZE ...
ROLLBACK;
```

**Parameters**

- **name**
  The name of the prepared statement to execute.

- **parameter**
  The actual value of a parameter to the prepared statement. This must be an expression yielding a value that is compatible with the data type of this parameter, as was determined when the prepared statement was created.

**Notes**

In order to allow the query optimizer to make reasonably informed decisions when optimizing queries, the `ANALYZE` statement should be run to record statistics about the distribution of data within the table. If you have not done this (or if the statistical distribution of the data in the table has changed significantly since the last time `ANALYZE` was run), the estimated costs are unlikely to conform to the real properties of the query, and consequently an inferior query plan may be chosen.

An SQL statement that is run during the execution of an `EXPLAIN ANALYZE` command is excluded from Greenplum Database resource queues.

For more information about query profiling, see "Query Profiling" in the Greenplum Database Administrator Guide. For more information about resource queues, see "Resource Management with Resource Queues" in the Greenplum Database Administrator Guide.

**Examples**

To illustrate how to read an `EXPLAIN` query plan, consider the following example for a very simple query:

```sql
EXPLAIN SELECT * FROM names WHERE name = 'Joelle';
```

<table>
<thead>
<tr>
<th>QUERY PLAN</th>
</tr>
</thead>
<tbody>
<tr>
<td>Gather Motion 2:1 (slice1) (cost=0.00..20.88 rows=1 width=13)</td>
</tr>
<tr>
<td>-&gt; Seq Scan on 'names' (cost=0.00..20.88 rows=1 width=13)</td>
</tr>
<tr>
<td>Filter: name::text ~~ 'Joelle':::text</td>
</tr>
</tbody>
</table>

If we read the plan from the bottom up, the query optimizer starts by doing a sequential scan of the `names` table. Notice that the `WHERE` clause is being applied as a `filter` condition. This means that the scan operation checks the condition for each row it scans, and outputs only the ones that pass the condition.

The results of the scan operation are passed up to a `gather motion` operation. In Greenplum Database, a gather motion is when segments send rows up to the master. In this case we have 2 segment instances sending to 1 master instance (2:1). This operation is working on `slice1` of the parallel query execution plan. In Greenplum Database a query plan is divided into `slices` so that portions of the query plan can be worked on in parallel by the segments.

The estimated startup cost for this plan is 00.00 (no cost) and a total cost of 20.88 disk page fetches. The planner is estimating that this query will return one row.

**Compatibility**

There is no `EXPLAIN` statement defined in the SQL standard.
**See Also**

ANALYZE

**FETCH**

Retrieves rows from a query using a cursor.

**Synopsis**

```
FETCH [ forward_direction { FROM | IN } ] cursorname
```

where `forward_direction` can be empty or one of:

- NEXT
- FIRST
- LAST
- ABSOLUTE `count`
- RELATIVE `count`
- `count`
- ALL
- FORWARD
- FORWARD `count`
- FORWARD ALL

**Description**

`FETCH` retrieves rows using a previously-created cursor.

A cursor has an associated position, which is used by `FETCH`. The cursor position can be before the first row of the query result, on any particular row of the result, or after the last row of the result. When created, a cursor is positioned before the first row. After fetching some rows, the cursor is positioned on the row most recently retrieved. If `FETCH` runs off the end of the available rows then the cursor is left positioned after the last row. `FETCH` ALL will always leave the cursor positioned after the last row.

The forms NEXT, FIRST, LAST, ABSOLUTE, RELATIVE fetch a single row after moving the cursor appropriately. If there is no such row, an empty result is returned, and the cursor is left positioned before the first row or after the last row as appropriate.

The forms using FORWARD retrieve the indicated number of rows moving in the forward direction, leaving the cursor positioned on the last-returned row (or after all rows, if the count exceeds the number of rows available). Note that it is not possible to move a cursor position backwards in Greenplum Database, since scrollable cursors are not supported. You can only move a cursor forward in position using `FETCH`.

RELATIVE 0 and FORWARD 0 request fetching the current row without moving the cursor, that is, re-fetching the most recently fetched row. This will succeed unless the cursor is positioned before the first row or after the last row, in which case no row is returned.

**Outputs**

On successful completion, a `FETCH` command returns a command tag of the form

```
FETCH count
```

The count is the number of rows fetched (possibly zero). Note that in `psql`, the command tag will not actually be displayed, since `psql` displays the fetched rows instead.

**Parameters**

`forward_direction`
Defines the fetch direction and number of rows to fetch. Only forward fetches are allowed in Greenplum Database. It can be one of the following:

**NEXT**

Fetch the next row. This is the default if direction is omitted.

**FIRST**

Fetch the first row of the query (same as **ABSOLUTE 1**). Only allowed if it is the first **FETCH** operation using this cursor.

**LAST**

Fetch the last row of the query (same as **ABSOLUTE -1**).

**ABSOLUTE count**

Fetch the specified row of the query. Position after last row if count is out of range. Only allowed if the row specified by **count** moves the cursor position forward.

**RELATIVE count**

Fetch the specified row of the query **count** rows ahead of the current cursor position. **RELATIVE 0** re-fetches the current row, if any. Only allowed if **count** moves the cursor position forward.

**count**

Fetch the next **count** number of rows (same as **FORWARD count**).

**ALL**

Fetch all remaining rows (same as **FORWARD ALL**).

**FORWARD**

Fetch the next row (same as **NEXT**).

**FORWARD count**

Fetch the next **count** number of rows. **FORWARD 0** re-fetches the current row.

**FORWARD ALL**

Fetch all remaining rows.

**cursorname**

The name of an open cursor.

**Notes**

Greenplum Database does not support scrollable cursors, so you can only use ** FETCH** to move the cursor position forward.

**ABSOLUTE** fetches are not any faster than navigating to the desired row with a relative move: the underlying implementation must traverse all the intermediate rows anyway.

**DECLARE** is used to define a cursor. Use **MOVE** to change cursor position without retrieving data.

**Examples**

-- Start the transaction:

```
BEGIN;
```

-- Set up a cursor:

```
DECLARE mycursor CURSOR FOR SELECT * FROM films;
```
-- Fetch the first 5 rows in the cursor mycursor:

<table>
<thead>
<tr>
<th>code</th>
<th>title</th>
<th>did</th>
<th>date_prod</th>
<th>kind</th>
<th>len</th>
</tr>
</thead>
<tbody>
<tr>
<td>BL101</td>
<td>The Third Man</td>
<td>101</td>
<td>1949-12-23</td>
<td>Drama</td>
<td>01:44</td>
</tr>
<tr>
<td>BL102</td>
<td>The African Queen</td>
<td>101</td>
<td>1951-08-11</td>
<td>Romantic</td>
<td>01:43</td>
</tr>
<tr>
<td>JL201</td>
<td>Une Femme est une Femme</td>
<td>102</td>
<td>1961-03-12</td>
<td>Romantic</td>
<td>01:25</td>
</tr>
<tr>
<td>P_301</td>
<td>Vertigo</td>
<td>103</td>
<td>1958-11-14</td>
<td>Action</td>
<td>02:08</td>
</tr>
<tr>
<td>P_302</td>
<td>Becket</td>
<td>103</td>
<td>1964-02-03</td>
<td>Drama</td>
<td>02:28</td>
</tr>
</tbody>
</table>

-- Close the cursor and end the transaction:

CLOSE mycursor;
COMMIT;

Change the kind column of the table films in the row at the c_films cursor's current position:

UPDATE films SET kind = 'Dramatic' WHERE CURRENT OF c_films;

Compatibility

SQL standard allows cursors only in embedded SQL and in modules. Greenplum Database permits cursors to be used interactively.

The variant of FETCH described here returns the data as if it were a SELECT result rather than placing it in host variables. Other than this point, FETCH is fully upward-compatible with the SQL standard.

The FETCH forms involving FORWARD, as well as the forms FETCH count and FETCHALL, in which FORWARD is implicit, are Greenplum Database extensions. BACKWARD is not supported.

The SQL standard allows only FROM preceding the cursor name; the option to use IN is an extension.

GRANT { SELECT | INSERT | ALL [ PRIVILEGES ] } 
ON PROTOCOL protocolname 
TO username

Description

The GRANT command has two basic variants: one that grants privileges on a database object (table, view, foreign table, sequence, database, foreign-data wrapper, foreign server, function, procedural language, schema, or tablespace), and one that grants membership in a role.

GRANT on Database Objects

This variant of the GRANT command gives specific privileges on a database object to one or more roles. These privileges are added to those already granted, if any.

The key word PUBLIC indicates that the privileges are to be granted to all roles, including those that may be created later. PUBLIC may be thought of as an implicitly defined group-level role that always includes all roles. Any particular role will have the sum of privileges granted directly to it, privileges granted to any role it is presently a member of, and privileges granted to PUBLIC.

If WITH GRANT OPTION is specified, the recipient of the privilege may in turn grant it to others. Without a grant option, the recipient cannot do that. Grant options cannot be granted to PUBLIC.

There is no need to grant privileges to the owner of an object (usually the role that created it), as the owner has all privileges by default. The right to drop an object, or to alter its definition in any way is not described by a grantable privilege; it is inherent in the owner, and cannot be granted or revoked. The owner implicitly has all grant options for the object, too.

Depending on the type of object, the initial default privileges may include granting some privileges to PUBLIC. The default is no public access for tables, schemas, and tablespaces; CONNECT privilege and TEMP table creation privilege for databases; EXECUTE privilege for functions; and USAGE privilege for languages. The object owner may of course revoke these privileges.

GRANT on Roles

This variant of the GRANT command grants membership in a role to one or more other roles. Membership in a role is significant because it conveys the privileges granted to a role to each of its members.
If `WITH ADMIN OPTION` is specified, the member may in turn grant membership in the role to others, and revoke membership in the role as well. Database superusers can grant or revoke membership in any role to anyone. Roles having `CREATEROLE` privilege can grant or revoke membership in any role that is not a superuser.

Unlike the case with privileges, membership in a role cannot be granted to `PUBLIC`.

**GRANT on Protocols**

After creating a custom protocol, specify `CREATE TRUSTED PROTOCOL` to be able to allow any user besides the owner to access it. If the protocol is not trusted, you cannot give any other user permission to use it to read or write data. After a `TRUSTED` protocol is created, you can specify which other users can access it with the `GRANT` command.

- To allow a user to create a readable external table with a trusted protocol
  ```sql
  GRANT SELECT ON PROTOCOL protocolname TO username
  ```
- To allow a user to create a writable external table with a trusted protocol
  ```sql
  GRANT INSERT ON PROTOCOL protocolname TO username
  ```
- To allow a user to create both readable and writable external tables with a trusted protocol
  ```sql
  GRANT ALL ON PROTOCOL protocolname TO username
  ```

You can also use this command to grant users permissions to create and use `hdfs`, `s3`, and `pxf` external tables. However, external tables of type `http`, `https`, `gpfdist`, and `gpfdists`, are implemented internally in Greenplum Database instead of as custom protocols. For these types, use the `CREATE ROLE` or `ALTER ROLE` command to set the `CREATEEXTTABLE` or `NOCREATEEXTTABLE` attribute for each user. See `CREATE ROLE` for syntax and examples.

**Parameters**

**SELECT**

- Allows `SELECT` from any column of the specified table, view, or sequence. Also allows the use of `COPY TO`.

**INSERT**

- Allows `INSERT` of a new row into the specified table. Also allows `COPY FROM`.

**UPDATE**

- Allows `UPDATE` of any column of the specified table. `SELECT ... FOR UPDATE` and `SELECT ... FOR SHARE` also require this privilege (as well as the `SELECT` privilege). For sequences, this privilege allows the use of the `nextval()` and `setval()` functions.

**DELETE**

- Allows `DELETE` of a row from the specified table.

**REFERENCES**

This keyword is accepted, although foreign key constraints are currently not supported in Greenplum Database. To create a foreign key constraint, it is necessary to have this privilege on both the referencing and referenced tables.

**TRIGGER**

- Allows the creation of a trigger on the specified table.

  **Note:** Greenplum Database does not support triggers.

**TRUNCATE**

- Allows `TRUNCATE` of all rows from the specified table.
CREATE

For databases, allows new schemas to be created within the database.
For schemas, allows new objects to be created within the schema. To rename an existing object, you must own the object and have this privilege for the containing schema.
For tablespaces, allows tables and indexes to be created within the tablespace, and allows databases to be created that have the tablespace as their default tablespace. (Note that revoking this privilege will not alter the placement of existing objects.)

CONNECT

Allows the user to connect to the specified database. This privilege is checked at connection startup (in addition to checking any restrictions imposed by pg_hba.conf).

TEMPORARY TEMP

Allows temporary tables to be created while using the database.

EXECUTE

Allows the use of the specified function and the use of any operators that are implemented on top of the function. This is the only type of privilege that is applicable to functions. (This syntax works for aggregate functions, as well.)

USAGE

For procedural languages, allows the use of the specified language for the creation of functions in that language. This is the only type of privilege that is applicable to procedural languages.
For schemas, allows access to objects contained in the specified schema (assuming that the objects' own privilege requirements are also met). Essentially this allows the grantee to look up objects within the schema.
For sequences, this privilege allows the use of the nextval() function.
For foreign-data wrappers, this privilege enables the grantee to create new servers using that foreign-data wrapper.
For servers, this privilege enables the grantee to create, alter, and drop their own user's user mappings associated with that server. Also, it enables the grantee to query the options of the server and associated user mappings.

ALL PRIVILEGES

Grant all of the available privileges at once. The PRIVILEGES key word is optional in Greenplum Database, though it is required by strict SQL.

PUBLIC

A special group-level role that denotes that the privileges are to be granted to all roles, including those that may be created later.

WITH GRANT OPTION

The recipient of the privilege may in turn grant it to others.

WITH ADMIN OPTION

The member of a role may in turn grant membership in the role to others.

Notes

Database superusers can access all objects regardless of object privilege settings. One exception to this rule is view objects. Access to tables referenced in the view is determined by permissions of the view owner not the current user (even if the current user is a superuser).

If a superuser chooses to issue a GRANT or REVOKE command, the command is performed as though it were issued by the owner of the affected object. In particular, privileges granted via such a command will
appear to have been granted by the object owner. For role membership, the membership appears to have been granted by the containing role itself.

**GRANT** and **REVOKE** can also be done by a role that is not the owner of the affected object, but is a member of the role that owns the object, or is a member of a role that holds privileges **WITH GRANT OPTION** on the object. In this case the privileges will be recorded as having been granted by the role that actually owns the object or holds the privileges **WITH GRANT OPTION**.

Granting permission on a table does not automatically extend permissions to any sequences used by the table, including sequences tied to SERIAL columns. Permissions on a sequence must be set separately.

Greenplum Database does not support granting or revoking privileges for individual columns of a table. One possible workaround is to create a view having just the desired columns and then grant privileges to that view.

The **GRANT** command cannot be used to set privileges for the protocols **file**, **gpfdist**, or **gpfdists**. These protocols are implemented internally in Greenplum Database. Instead, use the **CREATE ROLE** or **ALTER ROLE** command to set the **CREATEEXTTABLE** attribute for the role.

Use psql's \z meta-command to obtain information about existing privileges for an object.

### Examples

Grant insert privilege to all roles on table `mytable`:

```sql
GRANT INSERT ON mytable TO PUBLIC;
```

Grant all available privileges to role `sally` on the view `topten`. Note that while the above will indeed grant all privileges if executed by a superuser or the owner of `topten`, when executed by someone else it will only grant those permissions for which the granting role has grant options.

```sql
GRANT ALL PRIVILEGES ON topten TO sally;
```

Grant membership in role `admins` to user `joe`:

```sql
GRANT admins TO joe;
```

### Compatibility

The **PRIVILEGES** key word in is required in the SQL standard, but optional in Greenplum Database. The SQL standard does not support setting the privileges on more than one object per command.

Greenplum Database allows an object owner to revoke his own ordinary privileges: for example, a table owner can make the table read-only to himself by revoking his own **INSERT**, **UPDATE**, **DELETE**, and **TRUNCATE** privileges. This is not possible according to the SQL standard. Greenplum Database treats the owner's privileges as having been granted by the owner to himself; therefore he can revoke them too. In the SQL standard, the owner's privileges are granted by an assumed **system** entity.

The SQL standard allows setting privileges for individual columns within a table.

The SQL standard provides for a **USAGE** privilege on other kinds of objects: character sets, collations, translations, domains.

Privileges on databases, tablespaces, schemas, and languages are Greenplum Database extensions.

### See Also

**REVOKE**, **CREATE ROLE**, **ALTER ROLE**
**INSERT**

Inserts new rows into a table.

**Synopsis**

```sql
INSERT INTO table [( column [, ...] )]
   {DEFAULT VALUES | VALUES ( {expression | DEFAULT} [, ...] )
   [, ...] | query}
```

**Description**

*INSERT* inserts new rows into a table. One can insert one or more rows specified by value expressions, or zero or more rows resulting from a query.

The target column names may be listed in any order. If no list of column names is given at all, the default is the columns of the table in their declared order. The values supplied by the *VALUES* clause or query are associated with the explicit or implicit column list left-to-right.

Each column not present in the explicit or implicit column list will be filled with a default value, either its declared default value or null if there is no default.

If the expression for any column is not of the correct data type, automatic type conversion will be attempted.

You must have *INSERT* privilege on a table in order to insert into it.

**Outputs**

On successful completion, an *INSERT* command returns a command tag of the form:

```
INSERT oid count
```

The *count* is the number of rows inserted. If count is exactly one, and the target table has OIDs, then *oid* is the OID assigned to the inserted row. Otherwise *oid* is zero.

**Parameters**

*table*

The name (optionally schema-qualified) of an existing table.

*column*

The name of a column in table. The column name can be qualified with a subfield name or array subscript, if needed. (Inserting into only some fields of a composite column leaves the other fields null.)

*DEFAULT VALUES*

All columns will be filled with their default values.

*expression*

An expression or value to assign to the corresponding column.

*DEFAULT*

The corresponding column will be filled with its default value.

*query*

A query (*SELECT* statement) that supplies the rows to be inserted. Refer to the *SELECT* statement for a description of the syntax.
Notes
To insert data into a partitioned table, you specify the root partitioned table, the table created with the
CREATE TABLE command. You also can specify a leaf child table of the partitioned table in an INSERT
command. An error is returned if the data is not valid for the specified leaf child table. Specifying a child
table that is not a leaf child table in the INSERT command is not supported. Execution of other DML
commands such as UPDATE and DELETE on any child table of a partitioned table is not supported. These
commands must be executed on the root partitioned table, the table created with the CREATE TABLE
command.

For a partitioned table, all the child tables are locked during the INSERT operation.

For append-optimized tables, Greenplum Database supports a maximum of 127 concurrent INSERT
transactions into a single append-optimized table.

For writable S3 external tables, the INSERT operation uploads to one or more files in the configured S3
bucket, as described in s3:// Protocol. Pressing Ctrl-c cancels the INSERT and stops uploading to S3.

Examples
Insert a single row into table films:

```
INSERT INTO films VALUES ('UA502', 'Bananas', 105, '1971-07-13', 'Comedy', '82 minutes');
```

In this example, the length column is omitted and therefore it will have the default value:

```
INSERT INTO films (code, title, did, date_prod, kind) VALUES ('T_601', 'Yojimbo', 106, '1961-06-16', 'Drama');
```

This example uses the DEFAULT clause for the date_prod column rather than specifying a value:

```
INSERT INTO films VALUES ('UA502', 'Bananas', 105, DEFAULT, 'Comedy', '82 minutes');
```

To insert a row consisting entirely of default values:

```
INSERT INTO films DEFAULT VALUES;
```

To insert multiple rows using the multirow VALUES syntax:

```
INSERT INTO films (code, title, did, date_prod, kind) VALUES
('B6717', 'Tampopo', 110, '1985-02-10', 'Comedy'),
('HG120', 'The Dinner Game', 140, DEFAULT, 'Comedy');
```

This example inserts some rows into table films from a table tmp_films with the same column layout as
films:

```
INSERT INTO films SELECT * FROM tmp_films WHERE date_prod < '2004-05-07';
```

Compatibility

INSERT conforms to the SQL standard. The case in which a column name list is omitted, but not all the
columns are filled from the VALUES clause or query, is disallowed by the standard.

Possible limitations of the query clause are documented under SELECT.
LOAD

Loads or reloads a shared library file.

Synopsis

LOAD 'filename'

Description

This command loads a shared library file into the Greenplum Database server address space. If the file had been loaded previously, it is first unloaded. This command is primarily useful to unload and reload a shared library file that has been changed since the server first loaded it. To make use of the shared library, function(s) in it need to be declared using the CREATE FUNCTION command.

The file name is specified in the same way as for shared library names in CREATE FUNCTION; in particular, one may rely on a search path and automatic addition of the system's standard shared library file name extension.

Note that in Greenplum Database the shared library file (.so file) must reside in the same path location on every host in the Greenplum Database array (masters, segments, and mirrors).

Only database superusers can load shared library files.

Parameters

filename

The path and file name of a shared library file. This file must exist in the same location on all hosts in your Greenplum Database array.

Examples

Load a shared library file:

```
LOAD '/usr/local/greenplum-db/lib/myfuncs.so';
```

Compatibility

LOAD is a Greenplum Database extension.

See Also

CREATE FUNCTION

LOCK

Locks a table.

Synopsis

LOCK [TABLE] name [, ...] [IN lockmode MODE] [NOWAIT]
where `lockmode` is one of:

```
ACCESS SHARE | ROW SHARE | ROW EXCLUSIVE | SHARE UPDATE EXCLUSIVE
| SHARE | SHARE ROW EXCLUSIVE | EXCLUSIVE | ACCESS EXCLUSIVE
```

**Description**

`LOCK TABLE` obtains a table-level lock, waiting if necessary for any conflicting locks to be released. If `NOWAIT` is specified, `LOCK TABLE` does not wait to acquire the desired lock: if it cannot be acquired immediately, the command is aborted and an error is emitted. Once obtained, the lock is held for the remainder of the current transaction. There is no `UNLOCK TABLE` command; locks are always released at transaction end.

When acquiring locks automatically for commands that reference tables, Greenplum Database always uses the least restrictive lock mode possible. `LOCK TABLE` provides for cases when you might need more restrictive locking. For example, suppose an application runs a transaction at the `Read Committed` isolation level and needs to ensure that data in a table remains stable for the duration of the transaction. To achieve this you could obtain `SHARE` lock mode over the table before querying. This will prevent concurrent data changes and ensure subsequent reads of the table see a stable view of committed data, because `SHARE` lock mode conflicts with the `ROW EXCLUSIVE` lock acquired by writers, and your `LOCK TABLE name` statement will wait until any concurrent holders of `ROW EXCLUSIVE` mode locks commit or roll back. Thus, once you obtain the lock, there are no uncommitted writes outstanding; furthermore none can begin until you release the lock.

To achieve a similar effect when running a transaction at the `Serializable` isolation level, you have to execute the `LOCK TABLE` statement before executing any `SELECT` or data modification statement. A serializable transaction’s view of data will be frozen when its first `SELECT` or data modification statement begins. A `LOCK TABLE` later in the transaction will still prevent concurrent writes — but it won’t ensure that what the transaction reads corresponds to the latest committed values.

If a transaction of this sort is going to change the data in the table, then it should use `SHARE ROW EXCLUSIVE` lock mode instead of `SHARE` mode. This ensures that only one transaction of this type runs at a time. Without this, a deadlock is possible: two transactions might both acquire `SHARE` mode, and then be unable to also acquire `ROW EXCLUSIVE` mode to actually perform their updates. Note that a transaction’s own locks never conflict, so a transaction can acquire `ROW EXCLUSIVE` mode when it holds `SHARE` mode — but not if anyone else holds `SHARE` mode. To avoid deadlocks, make sure all transactions acquire locks on the same objects in the same order, and if multiple lock modes are involved for a single object, then transactions should always acquire the most restrictive mode first.

**Parameters**

`name`

The name (optionally schema-qualified) of an existing table to lock.

If multiple tables are given, tables are locked one-by-one in the order specified in the `LOCK TABLE` command.

`lockmode`

The lock mode specifies which locks this lock conflicts with. If no lock mode is specified, then `ACCESS EXCLUSIVE`, the most restrictive mode, is used. Lock modes are as follows:

- **ACCESS SHARE** — Conflicts with the `ACCESS EXCLUSIVE` lock mode only. The `SELECT` command acquires a lock of this mode on referenced tables. In general, any query that only reads a table and does not modify it will acquire this lock mode.
- **ROW SHARE** — Conflicts with the `EXCLUSIVE` and `ACCESS EXCLUSIVE` lock modes. The `SELECT FOR SHARE` command automatically acquires a lock of this mode on the target table(s) (in addition to `ACCESS SHARE` locks on any other tables that are referenced but not selected `FOR SHARE`).
- **ROW EXCLUSIVE** — Conflicts with the **SHARE**, **SHARE ROW EXCLUSIVE**, **EXCLUSIVE**, and **ACCESS EXCLUSIVE** lock modes. The commands **INSERT** and **COPY** automatically acquire this lock mode on the target table (in addition to **ACCESS SHARE** locks on any other referenced tables).

- **SHARE UPDATE EXCLUSIVE** — Conflicts with the **SHARE UPDATE EXCLUSIVE**, **SHARE**, **SHARE ROW EXCLUSIVE**, **EXCLUSIVE**, and **ACCESS EXCLUSIVE** lock modes. This mode protects a table against concurrent schema changes and **VACUUM** runs. Acquired by **VACUUM** (without **FULL**) on heap tables and **ANALYZE**.

- **SHARE** — Conflicts with the **ROW EXCLUSIVE**, **SHARE UPDATE EXCLUSIVE**, **SHARE ROW EXCLUSIVE**, **EXCLUSIVE**, and **ACCESS EXCLUSIVE** lock modes. This mode protects a table against concurrent data changes. Acquired automatically by **CREATE INDEX**.

- **SHARE ROW EXCLUSIVE** — Conflicts with the **ROW EXCLUSIVE**, **SHARE UPDATE EXCLUSIVE**, **SHARE ROW EXCLUSIVE**, **EXCLUSIVE**, and **ACCESS EXCLUSIVE** lock modes. This lock mode is not automatically acquired by any **Greenplum Database** command.

- **EXCLUSIVE** — Conflicts with locks of all modes (**ACCESS SHARE**, **ROW SHARE**, **ROW EXCLUSIVE**, **SHARE UPDATE EXCLUSIVE**, **SHARE**, **SHARE ROW EXCLUSIVE**, **EXCLUSIVE**, and **ACCESS EXCLUSIVE**). This mode allows only concurrent **ACCESS SHARE** locks, i.e., only reads from the table can proceed in parallel with a transaction holding this lock mode. This lock mode is automatically acquired for **UPDATE**, **SELECT FOR UPDATE**, and **DELETE** in **Greenplum Database** (which is more restrictive locking than in regular **PostgreSQL**).

- **ACCESS EXCLUSIVE** — Conflicts with locks of all modes (**ACCESS SHARE**, **ROW SHARE**, **ROW EXCLUSIVE**, **SHARE UPDATE EXCLUSIVE**, **SHARE**, **SHARE ROW EXCLUSIVE**, **EXCLUSIVE**, and **ACCESS EXCLUSIVE**). This mode guarantees that the holder is the only transaction accessing the table in any way. Acquired automatically by the **ALTER TABLE**, **DROP TABLE**, **TRUNCATE**, **REINDEX**, **CLUSTER**, and **VACUUM FULL** commands. This is the default lock mode for **LOCK TABLE** statements that do not specify a mode explicitly. This lock is also briefly acquired by **VACUUM** (without **FULL**) on append-optimized tables during processing.

**NOWAIT**

Specifies that **LOCK TABLE** should not wait for any conflicting locks to be released: if the specified lock(s) cannot be acquired immediately without waiting, the transaction is aborted.

**Notes**

**LOCK TABLE** ... **IN ACCESS SHARE Mode** requires **SELECT** privileges on the target table. All other forms of **LOCK** require **UPDATE** and/or **DELETE** privileges.

**LOCK TABLE** is useful only inside a transaction block (**BEGIN/COMMIT** pair), since the lock is dropped as soon as the transaction ends. A **LOCK TABLE** command appearing outside any transaction block forms a self-contained transaction, so the lock will be dropped as soon as it is obtained.

**LOCK TABLE** only deals with table-level locks, and so the mode names involving **ROW** are all misnomers. These mode names should generally be read as indicating the intention of the user to acquire row-level locks within the locked table. Also, **ROW EXCLUSIVE** mode is a sharable table lock. Keep in mind that all the lock modes have identical semantics so far as **LOCK TABLE** is concerned, differing only in the rules about which modes conflict with which. For information on how to acquire an actual row-level lock, see the **FOR UPDATE/FOR SHARE** clause in the **SELECT** reference documentation.
Examples

Obtain a SHARE lock on the films table when going to perform inserts into the films_user_comments table:

```sql
BEGIN WORK;
LOCK TABLE films IN SHARE MODE;
SELECT id FROM films
    WHERE name = 'Star Wars: Episode I - The Phantom Menace';
-- Do ROLLBACK if record was not returned
INSERT INTO films_user_comments VALUES
    (_id_, 'GREAT! I was waiting for it for so long!');
COMMIT WORK;
```

Take a SHARE ROW EXCLUSIVE lock on a table when performing a delete operation:

```sql
BEGIN WORK;
LOCK TABLE films IN SHARE ROW EXCLUSIVE MODE;
DELETE FROM films_user_comments WHERE id IN
    (SELECT id FROM films WHERE rating < 5);
DELETE FROM films WHERE rating < 5;
COMMIT WORK;
```

Compatibility

There is no `LOCK TABLE` in the SQL standard, which instead uses `SET TRANSACTION` to specify concurrency levels on transactions. Greenplum Database supports that too.

Except for `ACCESS SHARE`, `ACCESS EXCLUSIVE`, and `SHARE UPDATE EXCLUSIVE` lock modes, the Greenplum Database lock modes and the `LOCK TABLE` syntax are compatible with those present in Oracle.

See Also

`BEGIN`, `SET TRANSACTION`, `SELECT`

**MOVE**

Positions a cursor.

Synopsis

```
MOVE [ forward_direction {FROM | IN} ] cursorname
```

where `forward_direction` can be empty or one of:

- NEXT
- FIRST
- LAST
- ABSOLUTE `count`
- RELATIVE `count`
- `count`
- ALL
- FORWARD
- FORWARD `count`
- FORWARD ALL
**Description**

MOVE repositions a cursor without retrieving any data. MOVE works exactly like the FETCH command, except it only positions the cursor and does not return rows.

Note that it is not possible to move a cursor position backwards in Greenplum Database, since scrollable cursors are not supported. You can only move a cursor forward in position using MOVE.

**Outputs**

On successful completion, a MOVE command returns a command tag of the form

```
MOVE count
```

The count is the number of rows that a FETCH command with the same parameters would have returned (possibly zero).

**Parameters**

- `forward_direction`
  See FETCH for more information.

- `cursorname`
  The name of an open cursor.

**Examples**

```
-- Start the transaction:
BEGIN;

-- Set up a cursor:
DECLARE mycursor CURSOR FOR SELECT * FROM films;

-- Move forward 5 rows in the cursor mycursor:
MOVE FORWARD 5 IN mycursor;
MOVE 5

--Fetch the next row after that (row 6):
FETCH 1 FROM mycursor;

| code  | title  | did | date_prod  |  kind | len |
|-------+--------+-----+------------+--------+-----|
| P_303 | 48 Hrs | 103 | 1982-10-22 | Action | 01:37 |
(1 row)

-- Close the cursor and end the transaction:
CLOSE mycursor;
COMMIT;
```

**Compatibility**

There is no MOVE statement in the SQL standard.

**See Also**

`DECLARE, FETCH, CLOSE`
**PREPARE**

Prepare a statement for execution.

**Synopsis**

```
PREPARE name [ (datatype [, ...] ) ] AS statement
```

**Description**

**PREPARE** creates a prepared statement, possibly with unbound parameters. A prepared statement is a server-side object that can be used to optimize performance. A prepared statement may be subsequently executed with a binding for its parameters. Greenplum Database may choose to replan the query for different executions of the same prepared statement.

Prepared statements can take parameters: values that are substituted into the statement when it is executed. When creating the prepared statement, refer to parameters by position, using $1, $2, etc. A corresponding list of parameter data types can optionally be specified. When a parameter's data type is not specified or is declared as unknown, the type is inferred from the context in which the parameter is used (if possible). When executing the statement, specify the actual values for these parameters in the **EXECUTE** statement.

Prepared statements only last for the duration of the current database session. When the session ends, the prepared statement is forgotten, so it must be recreated before being used again. This also means that a single prepared statement cannot be used by multiple simultaneous database clients; however, each client can create their own prepared statement to use. The prepared statement can be manually cleaned up using the **DEALLOCATE** command.

Prepared statements have the largest performance advantage when a single session is being used to execute a large number of similar statements. The performance difference will be particularly significant if the statements are complex to plan or rewrite, for example, if the query involves a join of many tables or requires the application of several rules. If the statement is relatively simple to plan and rewrite but relatively expensive to execute, the performance advantage of prepared statements will be less noticeable.

**Parameters**

- **name**
  An arbitrary name given to this particular prepared statement. It must be unique within a single session and is subsequently used to execute or deallocate a previously prepared statement.

- **datatype**
  The data type of a parameter to the prepared statement. If the data type of a particular parameter is unspecified or is specified as unknown, it will be inferred from the context in which the parameter is used. To refer to the parameters in the prepared statement itself, use $1, $2, etc.

- **statement**
  Any **SELECT**, **INSERT**, **UPDATE**, **DELETE**, or **VALUES** statement.

**Notes**

In some situations, the query plan produced for a prepared statement will be inferior to the query plan that would have been chosen if the statement had been submitted and executed normally. This is because when the statement is planned and the planner attempts to determine the optimal query plan, the actual values of any parameters specified in the statement are unavailable. Greenplum Database collects statistics on the distribution of data in the table, and can use constant values in a statement to make
guesses about the likely result of executing the statement. Since this data is unavailable when planning
prepared statements with parameters, the chosen plan may be suboptimal. To examine the query plan
Greenplum Database has chosen for a prepared statement, use EXPLAIN.

For more information on query planning and the statistics collected by Greenplum Database for that
purpose, see the ANALYZE documentation.

You can see all available prepared statements of a session by querying the `pg_prepared_statements`
system view.

**Examples**

Create a prepared statement for an INSERT statement, and then execute it:

```sql
PREPARE fooplan (int, text, bool, numeric) AS INSERT INTO foo VALUES($1, $2, $3, $4);
EXECUTE fooplan(1, 'Hunter Valley', 't', 200.00);
```

Create a prepared statement for a SELECT statement, and then execute it. Note that the data type of the
second parameter is not specified, so it is inferred from the context in which `$2` is used:

```sql
PREPARE usrrptplan (int) AS SELECT * FROM users u, logs l
WHERE u.usrid=$1 AND u.usrid=l.usrid AND l.date = $2;
EXECUTE usrrptplan(1, current_date);
```

**Compatibility**

The SQL standard includes a PREPARE statement, but it is only for use in embedded SQL. This version of
the PREPARE statement also uses a somewhat different syntax.

**See Also**

EXECUTE, DEALLOCATE

**REASSIGN OWNED**

Changes the ownership of database objects owned by a database role.

**Synopsis**

```
REASSIGN OWNED BY old_role [, ...] TO new_role
```  

**Description**

REASSIGN OWNED reassigns all the objects in the current database that are owned by `old_role` to
`new_role`. Note that it does not change the ownership of the database itself.

**Parameters**

- **old_role**
  
  The name of a role. The ownership of all the objects in the current database owned by this
  role will be reassigned to `new_role`.

- **new_role**
  
  The name of the role that will be made the new owner of the affected objects.
Notes
REASSIGN OWNED is often used to prepare for the removal of one or more roles. Because REASSIGN OWNED only affects the objects in the current database, it is usually necessary to execute this command in each database that contains objects owned by a role that is to be removed.

The DROP OWNED command is an alternative that drops all the database objects owned by one or more roles.

The REASSIGN OWNED command does not affect the privileges granted to the old roles in objects that are not owned by them. Use DROP OWNED to revoke those privileges.

Examples
Reassign any database objects owned by the role named sally and bob to admin;

REASSIGN OWNED BY sally, bob TO admin;

Compatibility
The REASSIGN OWNED statement is a Greenplum Database extension.

See Also
DROP OWNED, DROP ROLE

REINDEX
Rebuilds indexes.

Synopsis
REINDEX {INDEX | TABLE | DATABASE | SYSTEM} name

Description
REINDEX rebuilds an index using the data stored in the index's table, replacing the old copy of the index.

There are several scenarios in which to use REINDEX:

- An index has become bloated, that is, it contains many empty or nearly-empty pages. This can occur with B-tree indexes in Greenplum Database under certain uncommon access patterns. REINDEX provides a way to reduce the space consumption of the index by writing a new version of the index without the dead pages.

- You have altered the FILLFACTOR storage parameter for an index, and wish to ensure that the change has taken full effect.

Parameters
INDEX
Recreate the specified index.

TABLE
Recreate all indexes of the specified table. If the table has a secondary TOAST table, that is reindexed as well.

DATABASE
Recreate all indexes within the current database. Indexes on shared system catalogs are skipped. This form of REINDEX cannot be executed inside a transaction block.

SYSTEM
Recreate all indexes on system catalogs within the current database. Indexes on user tables are not processed. Also, indexes on shared (global) system catalogs are skipped. This form of `REINDEX` cannot be executed inside a transaction block.

**name**

The name of the specific index, table, or database to be reindexed. Index and table names may be schema-qualified. Presently, `REINDEX DATABASE` and `REINDEX SYSTEM` can only reindex the current database, so their parameter must match the current database's name.

**Notes**

`REINDEX` is similar to a drop and recreate of the index in that the index contents are rebuilt from scratch. However, the locking considerations are rather different. `REINDEX` locks out writes but not reads of the index's parent table. It also takes an exclusive lock on the specific index being processed, which will block reads that attempt to use that index. In contrast, `DROP INDEX` momentarily takes exclusive lock on the parent table, blocking both writes and reads. The subsequent `CREATE INDEX` locks out writes but not reads; since the index is not there, no read will attempt to use it, meaning that there will be no blocking but reads may be forced into expensive sequential scans.

Reindexing a single index or table requires being the owner of that index or table. Reindexing a database requires being the owner of the database (note that the owner can therefore rebuild indexes of tables owned by other users). Of course, superusers can always reindex anything.

`REINDEX` does not update the `reltuples` and `relpages` statistics for the index. To update those statistics, run `ANALYZE` on the table after reindexing.

If you suspect that shared global system catalog indexes are corrupted, they can only be reindexed in Greenplum utility mode. The typical symptom of a corrupt shared index is "index is not a btree" errors, or else the server crashes immediately at startup due to reliance on the corrupted indexes. Contact Greenplum Customer Support for assistance in this situation.

**Examples**

Rebuild a single index:

```
REINDEX INDEX my_index;
```

Rebuild all the indexes on the table `my_table`:

```
REINDEX TABLE my_table;
```

**Compatibility**

There is no `REINDEX` command in the SQL standard.

**See Also**

`CREATE INDEX`, `DROP INDEX`, `VACUUM`

**RELEASE SAVEPOINT**

Destroys a previously defined savepoint.

**Synopsis**

```
RELEASE [SAVEPOINT] savepoint_name
```
Description

RELEASE SAVEPOINT destroys a savepoint previously defined in the current transaction.

Destroying a savepoint makes it unavailable as a rollback point, but it has no other user visible behavior. It does not undo the effects of commands executed after the savepoint was established. (To do that, see ROLLBACK TO SAVEPOINT.) Destroying a savepoint when it is no longer needed may allow the system to reclaim some resources earlier than transaction end.

RELEASE SAVEPOINT also destroys all savepoints that were established after the named savepoint was established.

Parameters

savepoint_name

The name of the savepoint to destroy.

Examples

To establish and later destroy a savepoint:

```sql
BEGIN;
  INSERT INTO table1 VALUES (3);
  SAVEPOINT my_savepoint;
  INSERT INTO table1 VALUES (4);
  RELEASE SAVEPOINT my_savepoint;
COMMIT;
```

The above transaction will insert both 3 and 4.

Compatibility

This command conforms to the SQL standard. The standard specifies that the key word SAVEPOINT is mandatory, but Greenplum Database allows it to be omitted.

See Also

BEGIN, SAVEPOINT, ROLLBACK TO SAVEPOINT, COMMIT

RESET

Restores the value of a system configuration parameter to the default value.

Synopsis

```sql
RESET configuration_parameter
RESET ALL
```

Description

RESET restores system configuration parameters to their default values. RESET is an alternative spelling for SET configuration_parameter TO DEFAULT.

The default value is defined as the value that the parameter would have had, had no SET ever been issued for it in the current session. The actual source of this value might be a compiled-in default, the master postgresql.conf configuration file, command-line options, or per-database or per-user default settings.

See Server Configuration Parameters for more information.
Parameters

configuration_parameter

The name of a system configuration parameter. See Server Configuration Parameters for details.

ALL

Resets all settable configuration parameters to their default values.

Examples

Set the statement_mem configuration parameter to its default value:

```
RESET statement_mem;
```

Compatibility

RESET is a Greenplum Database extension.

See Also

SET

REVOKE

Removes access privileges.

Synopsis

```
REVOKE [GRANT OPTION FOR] ( [SELECT | INSERT | UPDATE | DELETE |
    REFERENCES | TRIGGER | TRUNCATE ] [, ...] | ALL [PRIVILEGES] )
ON [TABLE] tablename [, ...]
FROM { rolename | PUBLIC } [, ...]
[CASCADE | RESTRICT]

REVOKE [GRANT OPTION FOR] ( {USAGE | SELECT | UPDATE} [, ...]
    | ALL [PRIVILEGES] )
ON SEQUENCE sequencename [, ...]
FROM { rolename | PUBLIC } [, ...]
[CASCADE | RESTRICT]

REVOKE [GRANT OPTION FOR] ( {CREATE | CONNECT |
    TEMPORARY | TEMP} [, ...] | ALL [PRIVILEGES] )
ON DATABASE dbname [, ...]
FROM { rolename | PUBLIC } [, ...]
[CASCADE | RESTRICT]

REVOKE [GRANT OPTION FOR] (EXECUTE | ALL [PRIVILEGES])
ON FUNCTION funcname ( [[argmode] [argname] argtype
    [, ...]] ) [, ...]
FROM { rolename | PUBLIC } [, ...]
[CASCADE | RESTRICT]

REVOKE [GRANT OPTION FOR] (USAGE | ALL [PRIVILEGES])
ON LANGUAGE langname [, ...]
FROM { rolename | PUBLIC } [, ...]
[CASCADE | RESTRICT]

REVOKE [GRANT OPTION FOR] (CREATE | USAGE) [, ...]
    | ALL [PRIVILEGES] )
ON SCHEMA schemaname [, ...]
```
### Description

The `REVOKE` command revokes previously granted privileges from one or more roles. The key word **PUBLIC** refers to the implicitly defined group of all roles.

See the description of the `GRANT` command for the meaning of the privilege types.

Note that any particular role will have the sum of privileges granted directly to it, privileges granted to any role it is presently a member of, and privileges granted to **PUBLIC**. Thus, for example, revoking `SELECT` privilege from **PUBLIC** does not necessarily mean that all roles have lost `SELECT` privilege on the object: those who have it granted directly or via another role will still have it. Similarly, revoking `SELECT` from a user might not prevent that user from using `SELECT` if **PUBLIC** or another membership role still has `SELECT` rights.

If `GRANT OPTION FOR` is specified, only the grant option for the privilege is revoked, not the privilege itself. Otherwise, both the privilege and the grant option are revoked.

If a role holds a privilege with grant option and has granted it to other roles then the privileges held by those other roles are called dependent privileges. If the privilege or the grant option held by the first role is being revoked and dependent privileges exist, those dependent privileges are also revoked if `CASCADE` is specified, else the revoke action will fail. This recursive revocation only affects privileges that were granted through a chain of roles that is traceable to the role that is the subject of this `REVOKE` command. Thus, the affected roles may effectively keep the privilege if it was also granted through other roles.

When revoking membership in a role, `GRANT OPTION` is instead called `ADMIN OPTION`, but the behavior is similar.

### Parameters

See `GRANT`.

### Examples

Revoke insert privilege for the public on table `films`:

```sql
REVOKE INSERT ON films FROM PUBLIC;
```

Revoke all privileges from role `sally` on view `topten`. Note that this actually means revoke all privileges that the current role granted (if not a superuser).

```sql
REVOKE ALL PRIVILEGES ON topten FROM sally;
```

Revoke membership in role `admins` from user `joe`:

```sql
REVOKE admins FROM joe;
```
Compatibility
The compatibility notes of the `GRANT` command also apply to `REVOKE`.

Either `RESTRICT` or `CASCADE` is required according to the standard, but Greenplum Database assumes `RESTRICT` by default.

See Also
`GRANT`

**ROLLBACK**
Aborts the current transaction.

**Synopsis**
```
ROLLBACK [WORK | TRANSACTION]
```

**Description**
`ROLLBACK` rolls back the current transaction and causes all the updates made by the transaction to be discarded.

**Parameters**
- `WORK`
- `TRANSACTION`
  Optional key words. They have no effect.

**Notes**
Use `COMMIT` to successfully end the current transaction.
Issuing `ROLLBACK` when not inside a transaction does no harm, but it will provoke a warning message.

**Examples**
To discard all changes made in the current transaction:
```
ROLLBACK;
```

**Compatibility**
The SQL standard only specifies the two forms `ROLLBACK` and `ROLLBACK WORK`. Otherwise, this command is fully conforming.

See Also
`BEGIN`, `COMMIT`, `SAVEPOINT`, `ROLLBACK TO SAVEPOINT`

**ROLLBACK TO SAVEPOINT**
Rolls back the current transaction to a savepoint.

**Synopsis**
```
ROLLBACK [WORK | TRANSACTION] TO [SAVEPOINT] savepoint_name
```
Description
This command will roll back all commands that were executed after the savepoint was established. The
savepoint remains valid and can be rolled back to again later, if needed.

ROLLBACK TO SAVEPOINT implicitly destroys all savepoints that were established after the named
savepoint.

Parameters
WORK
TRANSACTION
Optional key words. They have no effect.

savepoint_name
The name of a savepoint to roll back to.

Notes
Use RELEASE SAVEPOINT to destroy a savepoint without discarding the effects of commands executed
after it was established.

Specifying a savepoint name that has not been established is an error.

Cursors have somewhat non-transactional behavior with respect to savepoints. Any cursor that is opened
inside a savepoint will be closed when the savepoint is rolled back. If a previously opened cursor is
affected by a FETCH command inside a savepoint that is later rolled back, the cursor position remains at
the position that FETCH left it pointing to (that is, FETCH is not rolled back). Closing a cursor is not undone
by rolling back, either. A cursor whose execution causes a transaction to abort is put in a can't-execute
state, so while the transaction can be restored using ROLLBACK TO SAVEPOINT, the cursor can no longer
be used.

Examples
To undo the effects of the commands executed after my_savepoint was established:

ROLLBACK TO SAVEPOINT my_savepoint;

Cursor positions are not affected by a savepoint rollback:

BEGIN;
DECLARE foo CURSOR FOR SELECT 1 UNION SELECT 2;
SAVEPOINT foo;
FETCH 1 FROM foo;
column
--------
1
ROLLBACK TO SAVEPOINT foo;
FETCH 1 FROM foo;
column
--------
2
COMMIT;

Compatibility
The SQL standard specifies that the key word SAVEPOINT is mandatory, but Greenplum Database (and
Oracle) allow it to be omitted. SQL allows only WORK, not TRANSACTION, as a noise word after ROLLBACK.
Also, SQL has an optional clause AND [NO] CHAIN which is not currently supported by Greenplum
Database. Otherwise, this command conforms to the SQL standard.
**SAVEPOINT**

Defines a new savepoint within the current transaction.

**Synopsis**

```
SAVEPOINT savepoint_name
```

**Description**

`SAVEPOINT` establishes a new savepoint within the current transaction.

A savepoint is a special mark inside a transaction that allows all commands that are executed after it was established to be rolled back, restoring the transaction state to what it was at the time of the savepoint.

**Parameters**

*savepoint_name*

The name of the new savepoint.

**Notes**

Use `ROLLBACK TO SAVEPOINT` to rollback to a savepoint. Use `RELEASE SAVEPOINT` to destroy a savepoint, keeping the effects of commands executed after it was established.

Savepoints can only be established when inside a transaction block. There can be multiple savepoints defined within a transaction.

**Examples**

To establish a savepoint and later undo the effects of all commands executed after it was established:

```
BEGIN;
  INSERT INTO table1 VALUES (1);
  SAVEPOINT my_savepoint;
  INSERT INTO table1 VALUES (2);
  ROLLBACK TO SAVEPOINT my_savepoint;
  INSERT INTO table1 VALUES (3);
COMMIT;
```

The above transaction will insert the values 1 and 3, but not 2.

To establish and later destroy a savepoint:

```
BEGIN;
  INSERT INTO table1 VALUES (3);
  SAVEPOINT my_savepoint;
  INSERT INTO table1 VALUES (4);
  RELEASE SAVEPOINT my_savepoint;
COMMIT;
```

The above transaction will insert both 3 and 4.
Compatibility

SQL requires a savepoint to be destroyed automatically when another savepoint with the same name is established. In Greenplum Database, the old savepoint is kept, though only the more recent one will be used when rolling back or releasing. (Releasing the newer savepoint will cause the older one to again become accessible to `ROLLBACK TO SAVEPOINT` and `RELEASE SAVEPOINT`.) Otherwise, `SAVEPOINT` is fully SQL conforming.

See Also

`BEGIN`, `COMMIT`, `ROLLBACK`, `RELEASE SAVEPOINT`, `ROLLBACK TO SAVEPOINT`

**SELECT**

Retrieves rows from a table or view.

**Synopsis**

```
[ WITH [ RECURSIVE] with_query [ , ... ] ]
SELECT [ ALL | DISTINCT [ON ( expression [ , ... ] ) ] ]
   * | expression [[AS] output_name] [ , ... ]
   [FROM from_item [ , ... ]]
   [WHERE condition]
   [GROUP BY grouping_element [ , ... ]]
   [HAVING condition [ , ... ]]
   [WINDOW window_name AS ( window_specification )]
   [{UNION | INTERSECT | EXCEPT} [ALL] select ]
   [ , ... ]
   [LIMIT { count | ALL }]
   [OFFSET start]
   [FOR { UPDATE | SHARE} [ OF table_name [ , ... ] ] [ NOWAIT ] [ ... ] ]
```

where `with_query`: is:

```
with_query_name [ ( column_name [ , ... ] ) ] AS ( select )
```

where `grouping_element` can be one of:

```
() | expression
ROLLUP ( expression [ , ... ] )
CUBE ( expression [ , ... ] )
GROUPING SETS ( { grouping_element [ , ... ] } )
```

where `window_specification` can be:

```
[ window_name ]
[ PARTITION BY expression [ , ... ] ]
[ ORDER BY expression [ ASC | DESC | USING operator ] [ NULLS { FIRST | LAST } ]
   [ , ... ]
   [{ RANGE | ROWS }
      { UNBOUNDED PRECEDING
         expression PRECEDING
         CURRENT ROW
         BETWEEN window_frame_bound AND window_frame_bound }]
```

where `window_frame_bound` can be one of:

```
UNBOUNDED PRECEDING
expression PRECEDING
CURRENT ROW
```
where `from_item` can be one of:

```

[ONLY] table_name [[AS] alias [{ column_alias [, ...] }]]
(select) [AS] alias [{ column_alias [, ...] }]
with_query_name [ [AS] alias [{ column_alias [, ...] }]]
function_name ( [argument [, ...]] ) [AS] alias
    [{ column_alias [, ...] ]
    [ column_definition [, ...] ]
function_name ( [argument [, ...]] ) AS
    ( column_definition [, ...] )

from_item [NATURAL] join_type from_item
    [ON join_condition | USING ( join_column [, ...] )]
```

**Note:** The RECURSIVE keyword is a Beta feature.

**Description**

`SELECT` retrieves rows from zero or more tables. The general processing of `SELECT` is as follows:

1. All queries in the `WITH` clause are computed. These effectively serve as temporary tables that can be referenced in the `FROM` list.
2. All elements in the `FROM` list are computed. (Each element in the `FROM` list is a real or virtual table.) If more than one element is specified in the `FROM` list, they are cross-joined together.
3. If the `WHERE` clause is specified, all rows that do not satisfy the condition are eliminated from the output.
4. If the `GROUP BY` clause is specified, the output is divided into groups of rows that match on one or more of the defined grouping elements. If the `HAVING` clause is present, it eliminates groups that do not satisfy the given condition.
5. If a window expression is specified (and optional `WINDOW` clause), the output is organized according to the positional (row) or value-based (range) window frame.
6. `DISTINCT` eliminates duplicate rows from the result. `DISTINCT ON` eliminates rows that match on all the specified expressions. `ALL` (the default) will return all candidate rows, including duplicates.
7. The actual output rows are computed using the `SELECT` output expressions for each selected row.
8. Using the operators `UNION`, `INTERSECT`, and `EXCEPT`, the output of more than one `SELECT` statement can be combined to form a single result set. The `UNION` operator returns all rows that are in one or both of the result sets. The `INTERSECT` operator returns all rows that are strictly in both result sets. The `EXCEPT` operator returns the rows that are in the first result set but not in the second. In all three cases, duplicate rows are eliminated unless `ALL` is specified.
9. If the `ORDER BY` clause is specified, the returned rows are sorted in the specified order. If `ORDER BY` is not given, the rows are returned in whatever order the system finds fastest to produce.
10. If the `LIMIT` or `OFFSET` clause is specified, the `SELECT` statement only returns a subset of the result rows.
11. If `FOR UPDATE` or `FOR SHARE` is specified, the `SELECT` statement locks the entire table against concurrent updates.

You must have `SELECT` privilege on a table to read its values. The use of `FOR UPDATE` or `FOR SHARE` requires `UPDATE` privilege as well.

**Parameters**

**The WITH Clause**

The optional `WITH` clause allows you to specify one or more subqueries that can be referenced by name in the primary query. The subqueries effectively act as temporary tables or views for the duration of the primary query. Each subquery can be a `SELECT`, or `VALUES` command.
A *with_query_name* without schema qualification must be specified for each query in the *WITH* clause. Optionally, a list of column names can be specified; if the list of column names is omitted, the names are inferred from the subquery. The primary query and the *WITH* queries are all (notionally) executed at the same time.

The *RECURSIVE* keyword can be enabled by setting the server configuration parameter `gp_recursive_cte_prototype` to *true*. For information about the parameter, see *Server Configuration Parameters*.

**Note:** The *RECURSIVE* keyword is a Beta feature.

If *RECURSIVE* is specified, it allows a subquery to reference itself by name. Such a subquery, the *select* portion of the *with_query*, must have the form

```sql
non_recursive_term UNION [ALL] recursive_term
```

The recursive self-reference must appear on the right-hand side of the *UNION* [ALL]. Only one recursive self-reference is permitted per query.

If the *RECURSIVE* keyword is specified, the *WITH* queries need not be ordered: a query can reference another query that is later in the list. However, circular references, or mutual recursion, are not supported.

Without the *RECURSIVE* keyword, *WITH* queries can only reference sibling *WITH* queries that are earlier in the *WITH* list.

**WITH RECURSIVE** limitations. These items are not supported,

- A recursive *WITH* clause that contains the following in the *recursive_term*.
  - Subqueries with a self-reference
  - *DISTINCT* clause
  - *GROUP BY* clause
  - A window function
- A recursive *WITH* clause where the *with_query_name* is a part of a set operation.

An example the set operation limitation. This query returns an error because the set operation *UNION* contains a reference to the table *foo*.

```sql
WITH RECURSIVE foo(i) AS (
    SELECT 1
    UNION ALL
    SELECT i+1 FROM (SELECT * FROM foo UNION SELECT 0) bar
)
SELECT * FROM foo LIMIT 5;
```

This recursive CTE is allowed because the set operation *UNION* does not have a reference to the CTE *foo*.

```sql
WITH RECURSIVE foo(i) AS (
    SELECT 1
    UNION ALL
    SELECT i+1 FROM (SELECT * FROM bar UNION SELECT 0) bar, foo
    WHERE foo.i = bar.a
)
SELECT * FROM foo LIMIT 5;
```

See *WITH Queries (Common Table Expressions)* in the *Greenplum Database Administrator Guide* for additional information.

**The SELECT List**
The `SELECT` list (between the key words `SELECT` and `FROM`) specifies expressions that form the output rows of the `SELECT` statement. The expressions can (and usually do) refer to columns computed in the `FROM` clause.

Using the clause `[AS] output_name`, another name can be specified for an output column. This name is primarily used to label the column for display. It can also be used to refer to the column's value in `ORDER BY` and `GROUP BY` clauses, but not in the `WHERE` or `HAVING` clauses; there you must write out the expression instead. The `AS` keyword is optional in most cases (such as when declaring an alias for column names, constants, function calls, and simple unary operator expressions). In cases where the declared alias is a reserved SQL keyword, the `output_name` must be enclosed in double quotes to avoid ambiguity.

An expression in the `SELECT` list can be a constant value, a column reference, an operator invocation, a function call, an aggregate expression, a window expression, a scalar subquery, and so on. A number of constructs can be classified as an expression but do not follow any general syntax rules. These generally have the semantics of a function or operator. For information about SQL value expressions and function calls, see "Querying Data" in the Greenplum Database Administrator Guide.

Instead of an expression, `*` can be written in the output list as a shorthand for all the columns of the selected rows. Also, you can write `table_name.*` as a shorthand for the columns coming from just that table.

The FROM Clause

The `FROM` clause specifies one or more source tables for the `SELECT`. If multiple sources are specified, the result is the Cartesian product (cross join) of all the sources. But usually qualification conditions are added to restrict the returned rows to a small subset of the Cartesian product. The `FROM` clause can contain the following elements:

`table_name`

The name (optionally schema-qualified) of an existing table or view. If `ONLY` is specified, only that table is scanned. If `ONLY` is not specified, the table and all its descendant tables (if any) are scanned.

`alias`

A substitute name for the `FROM` item containing the alias. An alias is used for brevity or to eliminate ambiguity for self-joins (where the same table is scanned multiple times). When an alias is provided, it completely hides the actual name of the table or function; for example given `FROM foo AS f`, the remainder of the `SELECT` must refer to this `FROM` item as `f` not `foo`. If an alias is written, a column alias list can also be written to provide substitute names for one or more columns of the table.

`select`

A sub-`SELECT` can appear in the `FROM` clause. This acts as though its output were created as a temporary table for the duration of this single `SELECT` command. Note that the sub-`SELECT` must be surrounded by parentheses, and an alias must be provided for it. A `VALUES` command can also be used here. See "Non-standard Clauses" in the Compatibility section for limitations of using correlated sub-selects in Greenplum Database.

`with_query_name`

A `with_query` is referenced in the `FROM` clause by specifying its `with_query_name`, just as though the name were a table name. The `with_query_name` cannot contain a schema qualifier. An alias can be provided in the same way as for a table.

The `with_query` hides a table of the same name for the purposes of the primary query. If necessary, you can refer to a table of the same name by qualifying the table name with the schema.

`function_name`

Function calls can appear in the `FROM` clause. (This is especially useful for functions that return result sets, but any function can be used.) This acts as though its output were
created as a temporary table for the duration of this single SELECT command. An alias may also be used. If an alias is written, a column alias list can also be written to provide substitute names for one or more attributes of the function's composite return type. If the function has been defined as returning the record data type, then an alias or the key word AS must be present, followed by a column definition list in the form (column_name data_type [, ... ]). The column definition list must match the actual number and types of columns returned by the function.

**join_type**

One of:

- [INNER] JOIN
- LEFT [OUTER] JOIN
- RIGHT [OUTER] JOIN
- FULL [OUTER] JOIN
- CROSS JOIN

For the INNER and OUTER join types, a join condition must be specified, namely exactly one of NATURAL, ON join_condition, or USING (join_column [, ...]). See below for the meaning. For CROSS JOIN, none of these clauses may appear.

A JOIN clause combines two FROM items. Use parentheses if necessary to determine the order of nesting. In the absence of parentheses, JOINs nest left-to-right. In any case JOIN binds more tightly than the commas separating FROM items.

CROSS JOIN and INNER JOIN produce a simple Cartesian product, the same result as you get from listing the two items at the top level of FROM, but restricted by the join condition (if any). CROSS JOIN is equivalent to INNER JOIN ON(TRUE), that is, no rows are removed by qualification. These join types are just a notational convenience, since they do nothing you could not do with plain FROM and WHERE.

LEFT OUTER JOIN returns all rows in the qualified Cartesian product (i.e., all combined rows that pass its join condition), plus one copy of each row in the left-hand table for which there was no right-hand row that passed the join condition. This left-hand row is extended to the full width of the joined table by inserting null values for the right-hand columns. Note that only the JOIN clause's own condition is considered while deciding which rows have matches. Outer conditions are applied afterwards.

Conversely, RIGHT OUTER JOIN returns all the joined rows, plus one row for each unmatched right-hand row (extended with nulls on the left). This is just a notational convenience, since you could convert it to a LEFT OUTER JOIN by switching the left and right inputs.

FULL OUTER JOIN returns all the joined rows, plus one row for each unmatched left-hand row (extended with nulls on the right), plus one row for each unmatched right-hand row (extended with nulls on the left).

**ON join_condition**

join_condition is an expression resulting in a value of type boolean (similar to a WHERE clause) that specifies which rows in a join are considered to match.

**USING (join_column [, ...])**

A clause of the form USING (a, b, ...) is shorthand for ON left_table.a = right_table.a AND left_table.b = right_table.b ... . Also, USING implies that only one of each pair of equivalent columns will be included in the join output, not both.

**NATURAL**

NATURAL is shorthand for a USING list that mentions all columns in the two tables that have the same names.
The WHERE Clause

The optional WHERE clause has the general form:

```
WHERE condition
```

where condition is any expression that evaluates to a result of type boolean. Any row that does not satisfy this condition will be eliminated from the output. A row satisfies the condition if it returns true when the actual row values are substituted for any variable references.

The GROUP BY Clause

The optional GROUP BY clause has the general form:

```
GROUP BY grouping_element [, ...]
```

where grouping_element can be one of:

- ()
- expression
- ROLLUP (expression [, ...])
- CUBE (expression [, ...])
- GROUPING SETS ((grouping_element [, ...]))

GROUP BY will condense into a single row all selected rows that share the same values for the grouped expressions. expression can be an input column name, or the name or ordinal number of an output column (SELECT list item), or an arbitrary expression formed from input-column values. In case of ambiguity, a GROUP BY name will be interpreted as an input-column name rather than an output column name.

Aggregate functions, if any are used, are computed across all rows making up each group, producing a separate value for each group (whereas without GROUP BY, an aggregate produces a single value computed across all the selected rows). When GROUP BY is present, it is not valid for the SELECT list expressions to refer to ungrouped columns except within aggregate functions, since there would be more than one possible value to return for an ungrouped column.

Greenplum Database has the following additional OLAP grouping extensions (often referred to as supergroups):

ROLLUP

A ROLLUP grouping is an extension to the GROUP BY clause that creates aggregate subtotals that roll up from the most detailed level to a grand total, following a list of grouping columns (or expressions). ROLLUP takes an ordered list of grouping columns, calculates the standard aggregate values specified in the GROUP BY clause, then creates progressively higher-level subtotals, moving from right to left through the list. Finally, it creates a grand total. A ROLLUP grouping can be thought of as a series of grouping sets. For example:

```
GROUP BY ROLLUP (a, b, c)
```

is equivalent to:

```
GROUP BY GROUPING SETS( (a, b, c), (a, b), (a), () )
```

Notice that the $n$ elements of a ROLLUP translate to $n+1$ grouping sets. Also, the order in which the grouping expressions are specified is significant in a ROLLUP.

CUBE

A CUBE grouping is an extension to the GROUP BY clause that creates subtotals for all of the possible combinations of the given list of grouping columns (or expressions). In terms
of multidimensional analysis, CUBE generates all the subtotals that could be calculated for a data cube with the specified dimensions. For example:

```
GROUP BY CUBE (a,b,c)
```

is equivalent to:

```
GROUP BY GROUPING SETS( (a,b,c), (a,b), (a,c), (b,c), (a),
(b), (c), () )
```

Notice that $n$ elements of a CUBE translate to $2^n$ grouping sets. Consider using CUBE in any situation requiring cross-tabular reports. CUBE is typically most suitable in queries that use columns from multiple dimensions rather than columns representing different levels of a single dimension. For instance, a commonly requested cross-tabulation might need subtotals for all the combinations of month, state, and product.

**GROUPING SETS**

You can selectively specify the set of groups that you want to create using a GROUPING SETS expression within a GROUP BY clause. This allows precise specification across multiple dimensions without computing a whole ROLLUP or CUBE. For example:

```
GROUP BY GROUPING SETS( (a,c), (a,b) )
```

If using the grouping extension clauses ROLLUP, CUBE, or GROUPING SETS, two challenges arise. First, how do you determine which result rows are subtotals, and then the exact level of aggregation for a given subtotal. Or, how do you differentiate between result rows that contain both stored NULL values and "NULL" values created by the ROLLUP or CUBE. Secondly, when duplicate grouping sets are specified in the GROUP BY clause, how do you determine which result rows are duplicates? There are two additional grouping functions you can use in the SELECT list to help with this:

- **grouping(column [, ...])** — The grouping function can be applied to one or more grouping attributes to distinguish super-aggregated rows from regular grouped rows. This can be helpful in distinguishing a "NULL" representing the set of all values in a super-aggregated row from a NULL value in a regular row. Each argument in this function produces a bit — either 1 or 0, where 1 means the result row is super-aggregated, and 0 means the result row is from a regular grouping. The grouping function returns an integer by treating these bits as a binary number and then converting it to a base-10 integer.

- **group_id()** — For grouping extension queries that contain duplicate grouping sets, the group_id function is used to identify duplicate rows in the output. All unique grouping set output rows will have a group_id value of 0. For each duplicate grouping set detected, the group_id function assigns a group_id number greater than 0. All output rows in a particular duplicate grouping set are identified by the same group_id number.

**The WINDOW Clause**

The WINDOW clause is used to define a window that can be used in the OVER() expression of a window function such as rank or avg. For example:

```
SELECT vendor, rank() OVER (mywindow) FROM sale
GROUP BY vendor
WINDOW mywindow AS (ORDER BY sum(prc*qty));
```

A WINDOW clause has this general form:

```
WINDOW window_name AS (window_specification)
```
where `window_specification` can be:

```
[window_name]
[PARTITION BY expression [, ...]]
[ORDER BY expression [ASC | DESC | USING operator] [NULLS {FIRST | LAST}] [, ...]]
{[ROWS | RANGE]
  ( UNBOUNDED PRECEDING
  expression PRECEDING
  CURRENT ROW
  BETWEEN window_frame_bound AND window_frame_bound )}
```

- `window_name`  
  Gives a name to the window specification.

**PARTITION BY**

The `PARTITION BY` clause organizes the result set into logical groups based on the unique values of the specified expression. When used with window functions, the functions are applied to each partition independently. For example, if you follow `PARTITION BY` with a column name, the result set is partitioned by the distinct values of that column. If omitted, the entire result set is considered one partition.

**ORDER BY**

The `ORDER BY` clause defines how to sort the rows in each partition of the result set. If omitted, rows are returned in whatever order is most efficient and may vary. **Note:** Columns of data types that lack a coherent ordering, such as `time`, are not good candidates for use in the `ORDER BY` clause of a window specification. Time, with or without time zone, lacks a coherent ordering because addition and subtraction do not have the expected effects. For example, the following is not generally true: `x::time < x::time + '2 hour'::interval`

**ROWS | RANGE**

Use either a `ROWS` or `RANGE` clause to express the bounds of the window. The window bound can be one, many, or all rows of a partition. You can express the bound of the window either in terms of a range of data values offset from the value in the current row (`RANGE`), or in terms of the number of rows offset from the current row (`ROWS`). When using the `RANGE` clause, you must also use an `ORDER BY` clause. This is because the calculation performed to produce the window requires that the values be sorted. Additionally, the `ORDER BY` clause cannot contain more than one expression, and the expression must result in either a date or a numeric value. When using the `ROWS` or `RANGE` clauses, if you specify only a starting row, the current row is used as the last row in the window.

- **PRECEDING** — The `PRECEDING` clause defines the first row of the window using the current row as a reference point. The starting row is expressed in terms of the number of rows preceding the current row. For example, in the case of `ROWS` framing, `5 PRECEDING` sets the window to start with the fifth row preceding the current row. In the case of `RANGE` framing, it sets the window to start with the first row whose ordering column value precedes that of the current row by 5 in the given order. If the specified order is ascending by date, this will be the first row within 5 days before the current row. `UNBOUNDED PRECEDING` sets the first row in the window to be the first row in the partition.

- **BETWEEN** — The `BETWEEN` clause defines the first and last row of the window, using the current row as a reference point. First and last rows are expressed in terms of the number of rows preceding and following the current row, respectively. For example,
BETWEEN 3 PRECEDING AND 5 FOLLOWING sets the window to start with the third row preceding the current row, and end with the fifth row following the current row. Use BETWEEN UNBOUNDED PRECEDING AND UNBOUNDED FOLLOWING to set the first and last rows in the window to be the first and last row in the partition, respectively. This is equivalent to the default behavior if no ROW or RANGE clause is specified.

FOLLOWING — The FOLLOWING clause defines the last row of the window using the current row as a reference point. The last row is expressed in terms of the number of rows following the current row. For example, in the case of ROWS framing, 5 FOLLOWING sets the window to end with the fifth row following the current row. In the case of RANGE framing, it sets the window to end with the last row whose ordering column value follows that of the current row by 5 in the given order. If the specified order is ascending by date, this will be the last row within 5 days after the current row. Use UNBOUNDED FOLLOWING to set the last row in the window to be the last row in the partition.

If you do not specify a ROW or a RANGE clause, the window bound starts with the first row in the partition (UNBOUNDED PRECEDING) and ends with the current row (CURRENT ROW) if ORDER BY is used. If an ORDER BY is not specified, the window starts with the first row in the partition (UNBOUNDED PRECEDING) and ends with last row in the partition (UNBOUNDED FOLLOWING).

The HAVING Clause

The optional HAVING clause has the general form:

```
HAVING condition
```

where `condition` is the same as specified for the WHERE clause. HAVING eliminates group rows that do not satisfy the condition. HAVING is different from WHERE: WHERE filters individual rows before the application of GROUP BY, while HAVING filters group rows created by GROUP BY. Each column referenced in `condition` must unambiguously reference a grouping column, unless the reference appears within an aggregate function.

The presence of HAVING turns a query into a grouped query even if there is no GROUP BY clause. This is the same as what happens when the query contains aggregate functions but no GROUP BY clause. All the selected rows are considered to form a single group, and the SELECT list and HAVING clause can only reference table columns from within aggregate functions. Such a query will emit a single row if the HAVING condition is true, zero rows if it is not true.

The UNION Clause

The UNION clause has this general form:

```
select_statement UNION [ALL] select_statement
```

where `select_statement` is any SELECT statement without an ORDER BY, LIMIT, FOR UPDATE, or FOR SHARE clause. (ORDER BY and LIMIT can be attached to a subquery expression if it is enclosed in parentheses. Without parentheses, these clauses will be taken to apply to the result of the UNION, not to its right-hand input expression.)

The UNION operator computes the set union of the rows returned by the involved SELECT statements. A row is in the set union of two result sets if it appears in at least one of the result sets. The two SELECT statements that represent the direct operands of the UNION must produce the same number of columns, and corresponding columns must be of compatible data types.

The result of UNION does not contain any duplicate rows unless the ALL option is specified. ALL prevents elimination of duplicates. (Therefore, UNION ALL is usually significantly quicker than UNION; use ALL when you can.)

Multiple UNION operators in the same SELECT statement are evaluated left to right, unless otherwise indicated by parentheses.
Currently, **FOR UPDATE** and **FOR SHARE** may not be specified either for a **UNION** result or for any input of a **UNION**.

The **INTERSECT** Clause

The **INTERSECT** clause has this general form:

```
select_statement INTERSECT [ALL] select_statement
```

where `select_statement` is any SELECT statement without an **ORDER BY**, **LIMIT**, **FOR UPDATE**, or **FOR SHARE** clause.

The **INTERSECT** operator computes the set intersection of the rows returned by the involved SELECT statements. A row is in the intersection of two result sets if it appears in both result sets.

The result of **INTERSECT** does not contain any duplicate rows unless the **ALL** option is specified. With **ALL**, a row that has \( m \) duplicates in the left table and \( n \) duplicates in the right table will appear \( \min(m, n) \) times in the result set.

Multiple **INTERSECT** operators in the same SELECT statement are evaluated left to right, unless parentheses dictate otherwise. **INTERSECT** binds more tightly than **UNION**. That is, a **UNION** \( B \) **INTERSECT** \( C \) will be read as a **UNION** \( B \) **INTERSECT** \( C \).

Currently, **FOR UPDATE** and **FOR SHARE** may not be specified either for an **INTERSECT** result or for any input of an **INTERSECT**.

The **EXCEPT** Clause

The **EXCEPT** clause has this general form:

```
select_statement EXCEPT [ALL] select_statement
```

where `select_statement` is any SELECT statement without an **ORDER BY**, **LIMIT**, **FOR UPDATE**, or **FOR SHARE** clause.

The **EXCEPT** operator computes the set of rows that are in the result of the left SELECT statement but not in the result of the right one.

The result of **EXCEPT** does not contain any duplicate rows unless the **ALL** option is specified. With **ALL**, a row that has \( m \) duplicates in the left table and \( n \) duplicates in the right table will appear \( \max(m-n,0) \) times in the result set.

Multiple **EXCEPT** operators in the same SELECT statement are evaluated left to right, unless parentheses dictate otherwise. **EXCEPT** binds at the same level as **UNION**.

Currently, **FOR UPDATE** and **FOR SHARE** may not be specified either for an **EXCEPT** result or for any input of an **EXCEPT**.

The **ORDER BY** Clause

The optional **ORDER BY** clause has this general form:

```
ORDER BY expression [ASC | DESC | USING operator] [NULLS { FIRST | LAST}] [, ...,]
```

where `expression` can be the name or ordinal number of an output column (**SELECT** list item), or it can be an arbitrary expression formed from input-column values.

The **ORDER BY** clause causes the result rows to be sorted according to the specified expressions. If two rows are equal according to the left-most expression, they are compared according to the next expression and so on. If they are equal according to all specified expressions, they are returned in an implementation-dependent order.

The ordinal number refers to the ordinal (left-to-right) position of the result column. This feature makes it possible to define an ordering on the basis of a column that does not have a unique name. This is never
absolutely necessary because it is always possible to assign a name to a result column using the AS clause.

It is also possible to use arbitrary expressions in the ORDER BY clause, including columns that do not appear in the SELECT result list. Thus the following statement is valid:

```
SELECT name FROM distributors ORDER BY code;
```

A limitation of this feature is that an ORDER BY clause applying to the result of a UNION, INTERSECT, or EXCEPT clause may only specify an output column name or number, not an expression.

If an ORDER BY expression is a simple name that matches both a result column name and an input column name, ORDER BY will interpret it as the result column name. This is the opposite of the choice that GROUP BY will make in the same situation. This inconsistency is made to be compatible with the SQL standard.

Optionally one may add the key word ASC (ascending) or DESC (descending) after any expression in the ORDER BY clause. If not specified, ASC is assumed by default. Alternatively, a specific ordering operator name may be specified in the USING clause. ASC is usually equivalent to USING < and DESC is usually equivalent to USING >. (But the creator of a user-defined data type can define exactly what the default sort ordering is, and it might correspond to operators with other names.)

If NULLS LAST is specified, null values sort after all non-null values; if NULLS FIRST is specified, null values sort before all non-null values. If neither is specified, the default behavior is NULLS LAST when ASC is specified or implied, and NULLS FIRST when DESC is specified (thus, the default is to act as though nulls are larger than non-nulls). When USING is specified, the default nulls ordering depends upon whether the operator is a less-than or greater-than operator.

Note that ordering options apply only to the expression they follow; for example ORDER BY x, y DESC does not mean the same thing as ORDER BY x DESC, y DESC.

Character-string data is sorted according to the locale-specific collation order that was established when the Greenplum Database system was initialized.

**The DISTINCT Clause**

If DISTINCT is specified, all duplicate rows are removed from the result set (one row is kept from each group of duplicates). ALL specifies the opposite: all rows are kept. ALL is the default.

DISTINCT ON ( expression [, ...] ) keeps only the first row of each set of rows where the given expressions evaluate to equal. The DISTINCT ON expressions are interpreted using the same rules as for ORDER BY. Note that the 'first row' of each set is unpredictable unless ORDER BY is used to ensure that the desired row appears first. For example:

```
SELECT DISTINCT ON (location) location, time, report FROM weather_reports ORDER BY location, time DESC;
```

retrieves the most recent weather report for each location. But if we had not used ORDER BY to force descending order of time values for each location, we would have gotten a report from an unpredictable time for each location.

The DISTINCT ON expression(s) must match the left-most ORDER BY expression(s). The ORDER BY clause will normally contain additional expression(s) that determine the desired precedence of rows within each DISTINCT ON group.

When Greenplum Database processes queries that contain the DISTINCT clause, the queries are transformed into GROUP BY queries. In many cases, the transformation provides significant performance gains. However, when the number of distinct values is close to the total number of rows, the transformation might result in the generation of a multi-level grouping plan. In this case, there is an expected performance degradation because of the overhead introduced by the lower aggregation level.

**The LIMIT Clause**
The **LIMIT** clause consists of two independent sub-clauses:

```
LIMIT { count | ALL }
OFFSET start
```

where *count* specifies the maximum number of rows to return, while *start* specifies the number of rows to skip before starting to return rows. When both are specified, start rows are skipped before starting to count the count rows to be returned.

When using **LIMIT**, it is a good idea to use an **ORDER BY** clause that constrains the result rows into a unique order. Otherwise you will get an unpredictable subset of the query's rows — you may be asking for the tenth through twentieth rows, but tenth through twentieth in what ordering? You don't know what ordering unless you specify **ORDER BY**.

The query optimizer takes **LIMIT** into account when generating a query plan, so you are very likely to get different plans (yielding different row orders) depending on what you use for **LIMIT** and **OFFSET**. Thus, using different **LIMIT/OFFSET** values to select different subsets of a query result will give inconsistent results unless you enforce a predictable result ordering with **ORDER BY**. This is not a defect; it is an inherent consequence of the fact that SQL does not promise to deliver the results of a query in any particular order unless **ORDER BY** is used to constrain the order.

**The FOR UPDATE/FOR SHARE Clause**

The **FOR UPDATE** clause has this form:

```
FOR UPDATE [OF table_name [, ...]] [NOWAIT]
```

The closely related **FOR SHARE** clause has this form:

```
FOR SHARE [OF table_name [, ...]] [NOWAIT]
```

**FOR UPDATE** causes the tables accessed by the **SELECT** statement to be locked as though for update. This prevents the table from being modified or deleted by other transactions until the current transaction ends. That is, other transactions that attempt **UPDATE**, **DELETE**, or **SELECT** for **UPDATE** of this table will be blocked until the current transaction ends. Also, if an **UPDATE**, **DELETE**, or **SELECT** for **UPDATE** from another transaction has already locked a selected table, **SELECT** for **UPDATE** will wait for the other transaction to complete, and will then lock and return the updated table.

To prevent the operation from waiting for other transactions to commit, use the **NOWAIT** option. With **NOWAIT**, the statement reports an error, rather than waiting, if a selected row cannot be locked immediately. Note that **NOWAIT** only affects whether the **SELECT** statement waits to obtain row-level locks. A required table-level lock is always taken in the ordinary way. For example, a **SELECT** for **UPDATE** **NOWAIT** statement will always wait for the required table-level lock; it behaves as if **NOWAIT** was omitted. You can use **LOCK** with the **NOWAIT** option first, if you need to acquire the table-level lock without waiting.

**FOR SHARE** behaves similarly, except that it acquires a shared rather than exclusive lock on the table. A shared lock blocks other transactions from performing **UPDATE**, **DELETE**, or **SELECT** for **UPDATE** on the table, but it does not prevent them from performing **SELECT** for **SHARE**.

If specific tables are named in **FOR UPDATE** or **FOR SHARE**, then only those tables are locked; any other tables used in the **SELECT** are simply read as usual. A **FOR UPDATE** or **FOR SHARE** clause without a table list affects all tables used in the command. If **FOR UPDATE** or **FOR SHARE** is applied to a view or subquery, it affects all tables used in the view or subquery.

**FOR UPDATE** or **FOR SHARE** do not apply to a **with_query** referenced by the primary query. If you want row locking to occur within a **with_query**, specify **FOR UPDATE** or **FOR SHARE** within the **with_query**.

Multiple **FOR UPDATE** and **FOR SHARE** clauses can be written if it is necessary to specify different locking behavior for different tables. If the same table is mentioned (or implicitly affected) by both **FOR UPDATE** and **FOR SHARE** clauses, then it is processed as **FOR UPDATE**. Similarly, a table is processed as **NOWAIT** if that is specified in any of the clauses affecting it.
Examples

To join the table `films` with the table `distributors`:

```
SELECT f.title, f.did, d.name, f.date_prod, f.kind FROM distributors d, films f WHERE f.did = d.did
```

To sum the column `length` of all films and group the results by `kind`:

```
SELECT kind, sum(length) AS total FROM films GROUP BY kind;
```

To sum the column `length` of all films, group the results by `kind` and show those group totals that are less than 5 hours:

```
SELECT kind, sum(length) AS total FROM films GROUP BY kind HAVING sum(length) < interval '5 hours';
```

Calculate the subtotals and grand totals of all sales for movie `kind` and `distributor`:

```
SELECT kind, distributor, sum(prc*qty) FROM sales GROUP BY ROLLUP(kind, distributor) ORDER BY 1,2,3;
```

Calculate the rank of movie distributors based on total sales:

```
SELECT distributor, sum(prc*qty),
    rank() OVER (ORDER BY sum(prc*qty) DESC)
FROM sale GROUP BY distributor ORDER BY 2 DESC;
```

The following two examples are identical ways of sorting the individual results according to the contents of the second column (`name`):

```
SELECT * FROM distributors ORDER BY name;
SELECT * FROM distributors ORDER BY 2;
```

The next example shows how to obtain the union of the tables `distributors` and `actors`, restricting the results to those that begin with the letter `W` in each table. Only distinct rows are wanted, so the key word `ALL` is omitted:

```
SELECT distributors.name FROM distributors WHERE distributors.name LIKE 'W%' UNION SELECT actors.name FROM actors WHERE actors.name LIKE 'W%';
```

This example shows how to use a function in the `FROM` clause, both with and without a column definition list:

```
CREATE FUNCTION distributors(int) RETURNS SETOF distributors AS $$ SELECT * FROM distributors WHERE did = $1; $$ LANGUAGE SQL;
SELECT * FROM distributors(111);

CREATE FUNCTION distributors_2(int) RETURNS SETOF record AS $$ SELECT * FROM distributors WHERE did = $1; $$ LANGUAGE SQL;
SELECT * FROM distributors_2(111) AS (dist_id int, dist_name text);
```
This example uses a simple `WITH` clause:

```sql
WITH test AS (
    SELECT random() AS x FROM generate_series(1, 3)
) SELECT * FROM test
UNION ALL SELECT * FROM test;
```

This example uses the `WITH` clause to display per-product sales totals in only the top sales regions.

```sql
WITH regional_sales AS
    SELECT region, SUM(amount) AS total_sales
    FROM orders
    GROUP BY region
), top_regions AS (
    SELECT region
    FROM regional_sales
    WHERE total_sales > (SELECT SUM(total_sales) FROM regional_sales)
) SELECT region, product, SUM(quantity) AS product_units,
    SUM(amount) AS product_sales
FROM orders
WHERE region IN (SELECT region FROM top_regions)
GROUP BY region, product;
```

The example could have been written without the `WITH` clause but would have required two levels of nested sub-`SELECT` statements.

This example uses the `WITH RECURSIVE` clause to find all subordinates (direct or indirect) of the employee Mary, and their level of indirectness, from a table that shows only direct subordinates:

```sql
WITH RECURSIVE employee_recursive(distance, employee_name, manager_name) AS
    (SELECT 1, employee_name, manager_name
    FROM employee
    WHERE manager_name = 'Mary'
    UNION ALL
    SELECT er.distance + 1, e.employee_name, e.manager_name
    FROM employee_recursive er, employee e
    WHERE er.employee_name = e.manager_name
    ) SELECT distance, employee_name FROM employee_recursive;
```

The typical form of recursive queries: an initial condition, followed by `UNION [ALL]`, followed by the recursive part of the query. Be sure that the recursive part of the query will eventually return no tuples, or else the query will loop indefinitely. See `WITH Queries (Common Table Expressions)` in the Greenplum Database Administrator Guide for more examples.

## Compatibility

The `SELECT` statement is compatible with the SQL standard, but there are some extensions and some missing features.

### Omitted FROM Clauses

Greenplum Database allows one to omit the `FROM` clause. It has a straightforward use to compute the results of simple expressions. For example:

```sql
SELECT 2+2;
```
Some other SQL databases cannot do this except by introducing a dummy one-row table from which to do the `SELECT`.

Note that if a `FROM` clause is not specified, the query cannot reference any database tables. For compatibility with applications that rely on this behavior the `add_missing_from` configuration variable can be enabled.

**The AS Key Word**

In the SQL standard, the optional key word `AS` is just noise and can be omitted without affecting the meaning. The Greenplum Database parser requires this key word when renaming output columns because the type extensibility features lead to parsing ambiguities without it. `AS` is optional in `FROM` items, however.

**Namespace Available to GROUP BY and ORDER BY**

In the SQL-92 standard, an `ORDER BY` clause may only use result column names or numbers, while a `GROUP BY` clause may only use expressions based on input column names. Greenplum Database extends each of these clauses to allow the other choice as well (but it uses the standard's interpretation if there is ambiguity). Greenplum Database also allows both clauses to specify arbitrary expressions. Note that names appearing in an expression are always taken as input-column names, not as result-column names. SQL:1999 and later use a slightly different definition which is not entirely upward compatible with SQL-92. In most cases, however, Greenplum Database interprets an `ORDER BY` or `GROUP BY` expression the same way SQL:1999 does.

**Nonstandard Clauses**

The clauses `DISTINCT ON`, `LIMIT`, and `OFFSET` are not defined in the SQL standard.

**Limited Use of STABLE and VOLATILE Functions**

To prevent data from becoming out-of-sync across the segments in Greenplum Database, any function classified as `STABLE` or `VOLATILE` cannot be executed at the segment database level if it contains SQL or modifies the database in any way. See `CREATE FUNCTION` for more information.

**See Also**

`EXPLAIN`

**SELECT INTO**

Defines a new table from the results of a query.

**Synopsis**

```
[ WITH [ RECURSIVE# ] with_query [, ...] ]
SELECT [ALL | DISTINCT [ON ( expression [, ...] )]]
  * | expression [AS output_name] [, ...]
  INTO [TEMPORARY | TEMP] [TABLE] new_table
  [FROM from_item [, ...]]
  [WHERE condition]
  [GROUP BY expression [, ...]]
  [HAVING condition [, ...]]
  [(UNION | INTERSECT | EXCEPT) [ALL] select]  
  [ORDER BY expression [ASC | DESC | USING operator] [NULLS {FIRST | 
  LAST}] [, ...]]
  [LIMIT {count | ALL}]
  [OFFSET start]
  [FOR {UPDATE | SHARE} [OF table_name [, ...]] [NOWAIT]
   [, ...]]
```

**Note:** The `RECURSIVE` keyword is a Beta feature.
Description

`SELECT INTO` creates a new table and fills it with data computed by a query. The data is not returned to the client, as it is with a normal `SELECT`. The new table's columns have the names and data types associated with the output columns of the `SELECT`.

The `RECURSIVE` keyword can be enabled by setting the server configuration parameter `gp_recursive_cte_prototype` to `true`.

**Note:** The `RECURSIVE` keyword is a Beta feature.

Parameters

The majority of parameters for `SELECT INTO` are the same as `SELECT`.

- `TEMPORARY` or `TEMP`
  
  If specified, the table is created as a temporary table.

- `new_table`
  
  The name (optionally schema-qualified) of the table to be created.

Examples

Create a new table `films_recent` consisting of only recent entries from the table `films`:

```sql
SELECT * INTO films_recent FROM films WHERE date_prod >= '2016-01-01';
```

Compatibility

The SQL standard uses `SELECT INTO` to represent selecting values into scalar variables of a host program, rather than creating a new table. The Greenplum Database usage of `SELECT INTO` to represent table creation is historical. It is best to use `CREATE TABLE AS` for this purpose in new applications.

---

**SET**

Changes the value of a Greenplum Database configuration parameter.

Synopsis

```
SET [SESSION | LOCAL] configuration_parameter (TO | =) value |
     'value' | DEFAULT)
```

```
SET [SESSION | LOCAL] TIME_ZONE {timezone | LOCAL | DEFAULT}
```

Description

The `SET` command changes server configuration parameters. Any configuration parameter classified as a `session` parameter can be changed on-the-fly with `SET`. `SET` affects only the value used by the current session.

If `SET` or `SET SESSION` is issued within a transaction that is later aborted, the effects of the `SET` command disappear when the transaction is rolled back. Once the surrounding transaction is committed, the effects will persist until the end of the session, unless overridden by another `SET`. 
The effects of `SET LOCAL` last only till the end of the current transaction, whether committed or not. A special case is `SET` followed by `SET LOCAL` within a single transaction: the `SET LOCAL` value will be seen until the end of the transaction, but afterwards (if the transaction is committed) the `SET` value will take effect.

If `SET LOCAL` is used within a function that includes a `SET` option for the same configuration parameter (see `CREATE FUNCTION`), the effects of the `SET LOCAL` command disappear at function exit; the value in effect when the function was called is restored anyway. This allows `SET LOCAL` to be used for dynamic or repeated changes of a parameter within a function, while retaining the convenience of using the `SET` option to save and restore the caller's value. Note that a regular `SET` command overrides any surrounding function's `SET` option; its effects persist unless rolled back.

If you create a cursor with the `DECLARE` command in a transaction, you cannot use the `SET` command in the transaction until you close the cursor with the `CLOSE` command.

See `Server Configuration Parameters` for information about server parameters.

**Parameters**

**SESSION**
Specifies that the command takes effect for the current session. This is the default.

**LOCAL**
Specifies that the command takes effect for only the current transaction. After `COMMIT` or `ROLLBACK`, the session-level setting takes effect again. Note that `SET LOCAL` will appear to have no effect if it is executed outside of a transaction.

**configuration_parameter**
The name of a Greenplum Database configuration parameter. Only parameters classified as `session` can be changed with `SET`. See `Server Configuration Parameters` for details.

**value**
New value of parameter. Values can be specified as string constants, identifiers, numbers, or comma-separated lists of these. `DEFAULT` can be used to specify resetting the parameter to its default value. If specifying memory sizing or time units, enclose the value in single quotes.

**TIME ZONE**

`SET TIME ZONE value` is an alias for `SET timezone TO value`. The syntax `SET TIME ZONE` allows special syntax for the time zone specification. Here are examples of valid values:

- 'PST8PDT'
- 'Europe/Rome'
- -7 (time zone 7 hours west from UTC)
- `INTERVAL '-08:00' HOUR TO MINUTE` (time zone 8 hours west from UTC).

**LOCAL**

**DEFAULT**
Set the time zone to your local time zone (the one that the server's operating system defaults to). See the Time zone section of the PostgreSQL documentation for more information about time zones in Greenplum Database.

**Examples**

Set the schema search path:

```
SET search_path TO my_schema, public;
```
Increase the segment host memory per query to 200 MB:

```
SET statement_mem TO '200MB';
```

Set the style of date to traditional POSTGRES with "day before month" input convention:

```
SET datestyle TO postgres, dmy;
```

Set the time zone for San Mateo, California (Pacific Time):

```
SET TIME ZONE 'PST8PDT';
```

Set the time zone for Italy:

```
SET TIME ZONE 'Europe/Rome';
```

**Compatibility**

`SET TIME ZONE` extends syntax defined in the SQL standard. The standard allows only numeric time zone offsets while Greenplum Database allows more flexible time-zone specifications. All other `SET` features are Greenplum Database extensions.

**See Also**

`RESET`, `SHOW`

---

**SET ROLE**

Sets the current role identifier of the current session.

**Synopsis**

```
SET [SESSION | LOCAL] ROLE rolename
SET [SESSION | LOCAL] ROLE NONE
RESET ROLE
```

**Description**

This command sets the current role identifier of the current SQL-session context to be `rolename`. The role name may be written as either an identifier or a string literal. After `SET ROLE`, permissions checking for SQL commands is carried out as though the named role were the one that had logged in originally.

The specified `rolename` must be a role that the current session user is a member of. If the session user is a superuser, any role can be selected.

The `NONE` and `RESET` forms reset the current role identifier to be the current session role identifier. These forms may be executed by any user.

**Parameters**

**SESSION**

Specifies that the command takes effect for the current session. This is the default.

**LOCAL**
Specifies that the command takes effect for only the current transaction. After COMMIT or ROLLBACK, the session-level setting takes effect again. Note that SET LOCAL will appear to have no effect if it is executed outside of a transaction.

**rolename**

The name of a role to use for permissions checking in this session.

**NONE**

Reset the current role identifier to be the current session role identifier (that of the role used to log in).

**Notes**

Using this command, it is possible to either add privileges or restrict privileges. If the session user role has the INHERITS attribute, then it automatically has all the privileges of every role that it could SET ROLE to; in this case SET ROLE effectively drops all the privileges assigned directly to the session user and to the other roles it is a member of, leaving only the privileges available to the named role. On the other hand, if the session user role has the NOINHERITS attribute, SET ROLE drops the privileges assigned directly to the session user and instead acquires the privileges available to the named role.

In particular, when a superuser chooses to SET ROLE to a non-superuser role, she loses her superuser privileges.

SET ROLE has effects comparable to SET SESSION AUTHORIZATION, but the privilege checks involved are quite different. Also, SET SESSION AUTHORIZATION determines which roles are allowable for later SET ROLE commands, whereas changing roles with SET ROLE does not change the set of roles allowed to a later SET ROLE.

**Examples**

```sql
SELECT SESSION_USER, CURRENT_USER;
```

<table>
<thead>
<tr>
<th>session_user</th>
<th>current_user</th>
</tr>
</thead>
<tbody>
<tr>
<td>peter</td>
<td>peter</td>
</tr>
</tbody>
</table>

SET ROLE 'paul';

```sql
SELECT SESSION_USER, CURRENT_USER;
```

<table>
<thead>
<tr>
<th>session_user</th>
<th>current_user</th>
</tr>
</thead>
<tbody>
<tr>
<td>peter</td>
<td>paul</td>
</tr>
</tbody>
</table>

**Compatibility**

Greenplum Database allows identifier syntax (rolename), while the SQL standard requires the role name to be written as a string literal. SQL does not allow this command during a transaction; Greenplum Database does not make this restriction. The SESSION and LOCAL modifiers are a Greenplum Database extension, as is the RESET syntax.

**See Also**

SET SESSION AUTHORIZATION

**SET SESSION AUTHORIZATION**

Sets the session role identifier and the current role identifier of the current session.
Synopsis

- SET [SESSION | LOCAL] SESSION AUTHORIZATION rolename
- SET [SESSION | LOCAL] SESSION AUTHORIZATION DEFAULT
- RESET SESSION AUTHORIZATION

Description

This command sets the session role identifier and the current role identifier of the current SQL-session context to be `rolename`. The role name may be written as either an identifier or a string literal. Using this command, it is possible, for example, to temporarily become an unprivileged user and later switch back to being a superuser.

The session role identifier is initially set to be the (possibly authenticated) role name provided by the client. The current role identifier is normally equal to the session user identifier, but may change temporarily in the context of `setuid` functions and similar mechanisms; it can also be changed by `SET ROLE`. The current user identifier is relevant for permission checking.

The session user identifier may be changed only if the initial session user (the authenticated user) had the superuser privilege. Otherwise, the command is accepted only if it specifies the authenticated user name.

The `DEFAULT` and `RESET` forms reset the session and current role identifiers to be the originally authenticated user name. These forms may be executed by any user.

Parameters

**SESSION**
Specifies that the command takes effect for the current session. This is the default.

**LOCAL**
Specifies that the command takes effect for only the current transaction. After `COMMIT` or `ROLLBACK`, the session-level setting takes effect again. Note that `SET LOCAL` will appear to have no effect if it is executed outside of a transaction.

**rolename**
The name of the role to assume.

**NONE**
The `RESET` form resets the session and current role identifiers to be that of the role used to log in.

Examples

```
SELECT SESSION_USER, CURRENT_USER;
+---------------+-----+
| session_user  | current_user |
|---------------+-----+
| peter         | peter|

SET SESSION AUTHORIZATION 'paul';

SELECT SESSION_USER, CURRENT_USER;
+---------------+-----+
| session_user  | current_user |
|---------------+-----+
| paul          | paul|
```
Compatibility

The SQL standard allows some other expressions to appear in place of the literal rolename, but these options are not important in practice. Greenplum Database allows identifier syntax (rolename), which SQL does not. SQL does not allow this command during a transaction; Greenplum Database does not make this restriction. The SESSION and LOCAL modifiers are a Greenplum Database extension, as is the RESET syntax.

See Also

SET ROLE

SET TRANSACTION

Sets the characteristics of the current transaction.

Synopsis

```
SET TRANSACTION [transaction_mode] [READ ONLY | READ WRITE]
SET SESSION CHARACTERISTICS AS TRANSACTION transaction_mode
[READ ONLY | READ WRITE]
```

where transaction_mode is one of:

```
ISOLATION LEVEL {SERIALIZABLE | READ COMMITTED | READ UNCOMMITTED}
```

Description

The SET TRANSACTION command sets the characteristics of the current transaction. It has no effect on any subsequent transactions.

The available transaction characteristics are the transaction isolation level and the transaction access mode (read/write or read-only).

The isolation level of a transaction determines what data the transaction can see when other transactions are running concurrently.

- **READ COMMITTED** — A statement can only see rows committed before it began. This is the default.
- **SERIALIZABLE** — All statements of the current transaction can only see rows committed before the first query or data-modification statement was executed in this transaction.

The SQL standard defines two additional levels, **READ UNCOMMITTED** and **REPEATABLE READ**. In Greenplum Database **READ UNCOMMITTED** is treated as **READ COMMITTED**. **REPEATABLE READ** is not supported; use **SERIALIZABLE** if **REPEATABLE READ** behavior is required.

The transaction isolation level cannot be changed after the first query or data-modification statement (SELECT, INSERT, DELETE, UPDATE, FETCH, or COPY) of a transaction has been executed.

The transaction access mode determines whether the transaction is read/write or read-only. Read/write is the default. When a transaction is read-only, the following SQL commands are disallowed: INSERT, UPDATE, DELETE, and COPY FROM if the table they would write to is not a temporary table; all CREATE, ALTER, and DROP commands; GRANT, REVOKE, TRUNCATE; and EXPLAIN ANALYZE and EXECUTE if the command they would execute is among those listed. This is a high-level notion of read-only that does not prevent all writes to disk.

Parameters

**SESSION CHARACTERISTICS**

Sets the default transaction characteristics for subsequent transactions of a session.
The SQL standard defines four transaction isolation levels: READ COMMITTED, READ UNCOMMITTED, SERIALIZABLE, and REPEATABLE READ. The default behavior is that a statement can only see rows committed before it began (READ COMMITTED). In Greenplum Database READ UNCOMMITTED is treated the same as READ COMMITTED. REPEATABLE READ is not supported; use SERIALIZABLE instead. SERIALIZABLE is the strictest transaction isolation. This level emulates serial transaction execution, as if transactions had been executed one after another, serially, rather than concurrently. Applications using this level must be prepared to retry transactions due to serialization failures.

Determines whether the transaction is read/write or read-only. Read/write is the default. When a transaction is read-only, the following SQL commands are disallowed: INSERT, UPDATE, DELETE, and COPY FROM if the table they would write to is not a temporary table; all CREATE, ALTER, and DROP commands; GRANT, REVOKE, TRUNCATE; and EXPLAIN ANALYZE and EXECUTE if the command they would execute is among those listed.

If SET TRANSACTION is executed without a prior START TRANSACTION or BEGIN, it will appear to have no effect.

It is possible to dispense with SET TRANSACTION by instead specifying the desired transaction_modes in BEGIN or START TRANSACTION.

The session default transaction modes can also be set by setting the configuration parameters default_transaction_isolation and default_transaction_read_only.

Set the transaction isolation level for the current transaction:

```sql
BEGIN;
SET TRANSACTION ISOLATION LEVEL SERIALizable;
```

Both commands are defined in the SQL standard. SERIALizable is the default transaction isolation level in the standard. In Greenplum Database the default is READ COMMITTED. Because of lack of predicate locking, the SERIALizable level is not truly serializable. Essentially, a predicate-locking system prevents phantom reads by restricting what is written, whereas a multi-version concurrency control model (MVCC) as used in Greenplum Database prevents them by restricting what is read.

In the SQL standard, there is one other transaction characteristic that can be set with these commands: the size of the diagnostics area. This concept is specific to embedded SQL, and therefore is not implemented in the Greenplum Database server.

The SQL standard requires commas between successive transaction_modes, but for historical reasons Greenplum Database allows the commas to be omitted.

See Also

BEGIN, LOCK
**SHOW**

Shows the value of a system configuration parameter.

**Synopsis**

```
SHOW configuration_parameter
SHOW ALL
```

**Description**

**SHOW** displays the current settings of Greenplum Database system configuration parameters. You can set these parameters with the **SET** statement, or by editing the `postgresql.conf` configuration file of the Greenplum Database master. Note that some parameters viewable by **SHOW** are read-only — their values can be viewed but not set. See the Greenplum Database Reference Guide for details.

**Parameters**

- `configuration_parameter`
  - The name of a system configuration parameter.
- `ALL`
  - Shows the current value of all configuration parameters.

**Examples**

Show the current setting of the parameter `search_path`:

```
SHOW search_path;
```

Show the current setting of all parameters:

```
SHOW ALL;
```

**Compatibility**

**SHOW** is a Greenplum Database extension.

**See Also**

**SET, RESET**

**START TRANSACTION**

Starts a transaction block.

**Synopsis**

```
START TRANSACTION [SERIALIZABLE | READ COMMITTED | READ UNCOMMITTED]
[READ WRITE | READ ONLY]
```
Description

START TRANSACTION begins a new transaction block. If the isolation level or read/write mode is specified, the new transaction has those characteristics, as if SET TRANSACTION was executed. This is the same as the BEGIN command.

Parameters

- SERIALIZABLE
- READ COMMITTED
- READ UNCOMMITTED

The SQL standard defines four transaction isolation levels: READ COMMITTED, READ UNCOMMITTED, SERIALIZABLE, and REPEATABLE READ. The default behavior is that a statement can only see rows committed before it began (READ COMMITTED). In Greenplum Database READ UNCOMMITTED is treated the same as READ COMMITTED. REPEATABLE READ is not supported; use SERIALIZABLE if this behavior is required. SERIALIZABLE, wherein all statements of the current transaction can only see rows committed before the first statement was executed in the transaction, is the strictest transaction isolation. This level emulates serial transaction execution, as if transactions had been executed one after another, serially, rather than concurrently. Applications using this level must be prepared to retry transactions due to serialization failures.

READ WRITE

READ ONLY

Determines whether the transaction is read/write or read-only. Read/write is the default. When a transaction is read-only, the following SQL commands are disallowed: INSERT, UPDATE, DELETE, and COPY FROM if the table they would write to is not a temporary table; all CREATE, ALTER, and DROP commands; GRANT, REVOKE, TRUNCATE; and EXPLAIN ANALYZE and EXECUTE if the command they would execute is among those listed.

Examples

To begin a transaction block:

```
START TRANSACTION;
```

Compatibility

In the standard, it is not necessary to issue START TRANSACTION to start a transaction block: any SQL command implicitly begins a block. Greenplum Database behavior can be seen as implicitly issuing a COMMIT after each command that does not follow START TRANSACTION (or BEGIN), and it is therefore often called 'autocommit'. Other relational database systems may offer an autocommit feature as a convenience.

The SQL standard requires commas between successive transaction_modes, but for historical reasons Greenplum Database allows the commas to be omitted.

See also the compatibility section of SET TRANSACTION.

See Also

BEGIN, SET TRANSACTION

TRUNCATE

Empties a table of all rows.
Synopsis

TRUNCATE [TABLE] name [, ...] [CASCADE | RESTRICT]

Description

TRUNCATE quickly removes all rows from a table or set of tables. It has the same effect as an unqualified DELETE on each table, but since it does not actually scan the tables it is faster. This is most useful on large tables.

You must have the TRUNCATE privilege on the table to truncate table rows.

Parameters

name

The name (optionally schema-qualified) of a table to be truncated.

CASCADE

Since this key word applies to foreign key references (which are not supported in Greenplum Database) it has no effect.

RESTRICT

Since this key word applies to foreign key references (which are not supported in Greenplum Database) it has no effect.

Notes

TRUNCATE will not run any user-defined ON DELETE triggers that might exist for the tables.

TRUNCATE will not truncate any tables that inherit from the named table. Only the named table is truncated, not its child tables.

TRUNCATE will not truncate any sub-tables of a partitioned table. If you specify a sub-table of a partitioned table, TRUNCATE will not remove rows from the sub-table and its child tables.

Examples

Empty the table films:

TRUNCATE films;

Compatibility

There is no TRUNCATE command in the SQL standard.

See Also

DELETE, DROP TABLE

UPDATE

Updates rows of a table.

Synopsis

UPDATE [ONLY] table [[AS] alias]
  SET {column = {expression | DEFAULT} | 
  (column [, ...]) = ({{expression | DEFAULT} [, ...]}) [, ...] 
  [FROM fromlist]
**Description**

`UPDATE` changes the values of the specified columns in all rows that satisfy the condition. Only the columns to be modified need be mentioned in the `SET` clause; columns not explicitly modified retain their previous values.

By default, `UPDATE` will update rows in the specified table and all its subtables. If you wish to only update the specific table mentioned, you must use the `ONLY` clause.

There are two ways to modify a table using information contained in other tables in the database: using sub-selects, or specifying additional tables in the `FROM` clause. Which technique is more appropriate depends on the specific circumstances.

If the `WHERE CURRENT OF` clause is specified, the row that is updated is the one most recently fetched from the specified cursor.

You must have the `UPDATE` privilege on the table to update it, as well as the `SELECT` privilege to any table whose values are read in the expressions or condition.

**Outputs**

On successful completion, an `UPDATE` command returns a command tag of the form:

```
UPDATE count
```

where `count` is the number of rows updated. If `count` is 0, no rows matched the condition (this is not considered an error).

**Parameters**

`ONLY`

If specified, update rows from the named table only. When not specified, any tables inheriting from the named table are also processed.

`table`

The name (optionally schema-qualified) of an existing table.

`alias`

A substitute name for the target table. When an alias is provided, it completely hides the actual name of the table. For example, given `UPDATE foo AS f`, the remainder of the `UPDATE` statement must refer to this table as `f` not `foo`.

`column`

The name of a column in table. The column name can be qualified with a subfield name or array subscript, if needed. Do not include the table's name in the specification of a target column.

`expression`

An expression to assign to the column. The expression may use the old values of this and other columns in the table.

`DEFAULT`

Set the column to its default value (which will be NULL if no specific default expression has been assigned to it).

`fromlist`

A list of table expressions, allowing columns from other tables to appear in the `WHERE` condition and the update expressions. This is similar to the list of tables that can be specified in the `FROM` clause of a `SELECT` statement. Note that the target table must not
appear in the fromlist, unless you intend a self-join (in which case it must appear with an alias in the fromlist).

**condition**

An expression that returns a value of type boolean. Only rows for which this expression returns true will be updated.

**cursor_name**

The name of the cursor to use in a WHERE CURRENT OF condition. The row to be updated is the one most recently fetched from the cursor. The cursor must be a simple (non-join, non-aggregate) query on the UPDATE command target table. See DECLARE for more information about creating cursors.

WHERE CURRENT OF cannot be specified together with a Boolean condition.

The UPDATE...WHERE CURRENT OF statement can only be executed on the server, for example in an interactive psql session or a script. Language extensions such as PL/pgSQL do not have support for updatable cursors.

See DECLARE for more information about creating cursors.

**output_expression**

An expression to be computed and returned by the UPDATE command after each row is updated. The expression may use any column names of the table or table(s) listed in FROM. Write * to return all columns.

**output_name**

A name to use for a returned column.

**Notes**

**SET** is not allowed on the Greenplum distribution key columns of a table.

When a FROM clause is present, what essentially happens is that the target table is joined to the tables mentioned in the from list, and each output row of the join represents an update operation for the target table. When using FROM you should ensure that the join produces at most one output row for each row to be modified. In other words, a target row should not join to more than one row from the other table(s). If it does, then only one of the join rows will be used to update the target row, but which one will be used is not readily predictable.

Because of this indeterminacy, referencing other tables only within sub-selects is safer, though often harder to read and slower than using a join.

Executing UPDATE and DELETE commands directly on a specific partition (child table) of a partitioned table is not supported. Instead, execute these commands on the root partitioned table, the table created with the CREATE TABLE command.

For a partitioned table, all the child tables are locked during the UPDATE operation.

**Examples**

Change the word Drama to Dramatic in the column kind of the table films:

```sql
UPDATE films SET kind = 'Dramatic' WHERE kind = 'Drama';
```

Adjust temperature entries and reset precipitation to its default value in one row of the table weather:

```sql
UPDATE weather SET temp_lo = temp_lo+1, temp_hi = temp_lo+15, prcp = DEFAULT
WHERE city = 'San Francisco' AND date = '2016-07-03';
```
Use the alternative column-list syntax to do the same update:

```
UPDATE weather SET (temp_lo, temp_hi, prcp) = (temp_lo+1, temp_lo+15, DEFAULT)
WHERE city = 'San Francisco' AND date = '2016-07-03';
```

Increment the sales count of the salesperson who manages the account for Acme Corporation, using the `FROM` clause syntax (assuming both tables being joined are distributed in Greenplum Database on the `id` column):

```
UPDATE employees SET sales_count = sales_count + 1 FROM accounts
WHERE accounts.name = 'Acme Corporation'
AND employees.id = accounts.id;
```

Perform the same operation, using a sub-select in the `WHERE` clause:

```
UPDATE employees SET sales_count = sales_count + 1 WHERE id =
(SELECT id FROM accounts WHERE name = 'Acme Corporation');
```

Attempt to insert a new stock item along with the quantity of stock. If the item already exists, instead update the stock count of the existing item. To do this without failing the entire transaction, use savepoints.

```
BEGIN;
-- other operations
SAVEPOINT sp1;
INSERT INTO wines VALUES('Chateau Lafite 2003', '24');
-- Assume the above fails because of a unique key violation,
-- so now we issue these commands:
ROLLBACK TO sp1;
UPDATE wines SET stock = stock + 24 WHERE winename = 'Chateau
Lafite 2003';
-- continue with other operations, and eventually
COMMIT;
```

**Compatibility**

This command conforms to the SQL standard, except that the `FROM` clause is a Greenplum Database extension.

According to the standard, the column-list syntax should allow a list of columns to be assigned from a single row-valued expression, such as a sub-select:

```
UPDATE accounts SET (contact_last_name, contact_first_name) =
(SELECT last_name, first_name FROM salesmen
WHERE salesmen.id = accounts.sales_id);
```

This is not currently implemented — the source must be a list of independent expressions.

Some other database systems offer a `FROM` option in which the target table is supposed to be listed again within `FROM`. That is not how Greenplum Database interprets `FROM`. Be careful when porting applications that use this extension.

**See Also**

DECLARE, DELETE, SELECT, INSERT

**VACUUM**

Garbage-collects and optionally analyzes a database.
Synopsis

```
VACUUM [FULL] [FREEZE] [VERBOSE] [table]
VACUUM [FULL] [FREEZE] [VERBOSE] ANALYZE
    [table [(column [, ... ])]]
```

Description

`VACUUM` reclaims storage occupied by deleted tuples. In normal Greenplum Database operation, tuples that are deleted or obsoleted by an update are not physically removed from their table; they remain present on disk until a `VACUUM` is done. Therefore it is necessary to do `VACUUM` periodically, especially on frequently-updated tables.

**Note:** Starting in Greenplum 5.x, `VACUUM` is supported with persistent table system catalogs, and is required to manage free space.

With no parameter, `VACUUM` processes every table in the current database. With a parameter, `VACUUM` processes only that table.

`VACUUM ANALYZE` performs a `VACUUM` and then an `ANALYZE` for each selected table. This is a handy combination form for routine maintenance scripts. See `ANALYZE` for more details about its processing.

`VACUUM` (without `FULL`) marks deleted and obsoleted data in tables and indexes for future reuse and reclaims space for re-use only if the space is at the end of the table and an exclusive table lock can be easily obtained. Unused space at the start or middle of a table remains as is. With heap tables, this form of the command can operate in parallel with normal reading and writing of the table, as an exclusive lock is not obtained.

With append-optimized tables, `VACUUM` compacts a table by first vacuuming the indexes, then compacting each segment file in turn, and finally vacuuming auxiliary relations and updating statistics. On each segment, visible rows are copied from the current segment file to a new segment file, and then the current segment file is scheduled to be dropped and the new segment file is made available. Plain `VACUUM` of an append-optimized table allows scans, inserts, deletes, and updates of the table while a segment file is compacted. However, an Access Exclusive lock is taken briefly to drop the current segment file and activate the new segment file.

`VACUUM FULL` does more extensive processing, including moving of tuples across blocks to try to compact the table to the minimum number of disk blocks. This form is much slower and requires an Access Exclusive lock on each table while it is being processed. The Access Exclusive lock guarantees that the holder is the only transaction accessing the table in any way.

**Important:** For information on the use of `VACUUM`, `VACUUM FULL`, and `VACUUM ANALYZE`, see **Notes**

Outputs

When `VERBOSE` is specified, `VACUUM` emits progress messages to indicate which table is currently being processed. Various statistics about the tables are printed as well.

Parameters

**FULL**

Selects a full vacuum, which may reclaim more space, but takes much longer and exclusively locks the table.

**FREEZE**

Specifying `FREEZE` is equivalent to performing `VACUUM` with the `vacuum_freeze_min_age` server configuration parameter set to zero. See **Server Configuration Parameters** for information about `vacuum_freeze_min_age`.

**VERBOSE**
Prints a detailed vacuum activity report for each table.

**ANALYZE**

Updates statistics used by the planner to determine the most efficient way to execute a query.

**table**

The name (optionally schema-qualified) of a specific table to vacuum. Defaults to all tables in the current database.

**column**

The name of a specific column to analyze. Defaults to all columns.

**Notes**

**VACUUM** cannot be executed inside a transaction block.

Vacuum active databases frequently (at least nightly), in order to remove expired rows. After adding or deleting a large number of rows, running the **VACUUM ANALYZE** command for the affected table might be useful. This updates the system catalogs with the results of all recent changes, and allows the Greenplum Database query optimizer to make better choices in planning queries.

**Important:** PostgreSQL has a separate optional server process called the *autovacuum daemon*, whose purpose is to automate the execution of **VACUUM** and **ANALYZE** commands. Greenplum Database enables the autovacuum daemon to perform **VACUUM** operations only on the Greenplum Database template database *template0*. Autovacuum is enabled for *template0* because connections are not allowed to *template0*. The autovacuum daemon performs **VACUUM** operations on *template0* to manage transaction IDs (XIDs) and help avoid transaction ID wraparound issues in *template0*.

Manual **VACUUM** operations must be performed in user-defined databases to manage transaction IDs (XIDs) in those databases.

**VACUUM** causes a substantial increase in I/O traffic, which can cause poor performance for other active sessions. Therefore, it is advisable to vacuum the database at low usage times.

For heap tables, expired rows are held in what is called the *free space map*. The free space map must be sized large enough to cover the dead rows of all heap tables in your database. If not sized large enough, space occupied by dead rows that overflow the free space map cannot be reclaimed by a regular **VACUUM** command.

**VACUUM** commands skip external tables.

**VACUUM FULL** reclaims all expired row space, however it requires an exclusive lock on each table being processed, is a very expensive operation, and might take a long time to complete on large, distributed Greenplum Database tables. Perform **VACUUM FULL** operations during database maintenance periods.

As an alternative to **VACUUM FULL**, you can re-create the table with a **CREATE TABLE AS** statement and drop the old table.

Size the free space map appropriately. You configure the free space map using the following server configuration parameters:

- `max_fsm_pages`
- `max_fsm_relations`

For append-optimized tables, **VACUUM** requires enough available disk space to accommodate the new segment file during the **VACUUM** process. If the ratio of hidden rows to total rows in a segment file is less than a threshold value (10, by default), the segment file is not compacted. The threshold value can be configured with the `gp_appendonly_compaction_threshold` server configuration parameter. **VACUUM FULL** ignores the threshold and rewrites the segment file regardless of the ratio. **VACUUM** can be disabled for append-optimized tables using the `gp_appendonly_compaction` server configuration parameter. See [Server Configuration Parameters](#) for information about the server configuration parameters.
If a concurrent serializable transaction is detected when an append-optimized table is being vacuumed, the current and subsequent segment files are not compacted. If a segment file has been compacted but a concurrent serializable transaction is detected in the transaction that drops the original segment file, the drop is skipped. This could leave one or two segment files in an "awaiting drop" state after the vacuum has completed.

For more information about concurrency control in Greenplum Database, see “Routine System Maintenance Tasks” in Greenplum Database Administrator Guide.

Examples

Vacuum all tables in the current database:

```
VACUUM;
```

Vacuum a specific table only:

```
VACUUM mytable;
```

Vacuum all tables in the current database and collect statistics for the query optimizer:

```
VACUUM ANALYZE;
```

Compatibility

There is no VACUUM statement in the SQL standard.

ANALYZE

VALUES

Computes a set of rows.

Synopsis

```
VALUES ( expression [, ... ] ) [, ...]
    [ORDER BY sort_expression [ASC | DESC | USING operator] [, ...]]
    [LIMIT {count | ALL}] [OFFSET start]
```

Description

VALUES computes a row value or set of row values specified by value expressions. It is most commonly used to generate a "constant table" within a larger command, but it can be used on its own.

When more than one row is specified, all the rows must have the same number of elements. The data types of the resulting table's columns are determined by combining the explicit or inferred types of the expressions appearing in that column, using the same rules as for UNION.

Within larger commands, VALUES is syntactically allowed anywhere that SELECT is. Because it is treated like a SELECT by the grammar, it is possible to use the ORDERBY, LIMIT, and OFFSET clauses with a VALUES command.

Parameters

expression
A constant or expression to compute and insert at the indicated place in the resulting table (set of rows). In a VALUES list appearing at the top level of an INSERT, an expression can be replaced by DEFAULT to indicate that the destination column's default value should be inserted. DEFAULT cannot be used when VALUES appears in other contexts.

**sort_expression**

An expression or integer constant indicating how to sort the result rows. This expression may refer to the columns of the VALUES result as column1, column2, etc. For more details, see "The ORDER BY Clause" in the parameters for SELECT.

**operator**

A sorting operator. For more details, see "The ORDER BY Clause" in the parameters for SELECT.

**LIMIT count**

**OFFSET start**

The maximum number of rows to return. For more details, see "The LIMIT Clause" in the parameters for SELECT.

**Notes**

VALUES lists with very large numbers of rows should be avoided, as you may encounter out-of-memory failures or poor performance. VALUES appearing within INSERT is a special case (because the desired column types are known from the INSERT's target table, and need not be inferred by scanning the VALUES list), so it can handle larger lists than are practical in other contexts.

**Examples**

A bare VALUES command:

VALUES (1, 'one'), (2, 'two'), (3, 'three');

This will return a table of two columns and three rows. It is effectively equivalent to:

```
SELECT 1 AS column1, 'one' AS column2
UNION ALL
SELECT 2, 'two'
UNION ALL
SELECT 3, 'three';
```

More usually, VALUES is used within a larger SQL command. The most common use is in INSERT:

```
INSERT INTO films (code, title, did, date_prod, kind)
VALUES ('T_601', 'Yojimbo', 106, '1961-06-16', 'Drama');
```

In the context of INSERT, entries of a VALUES list can be DEFAULT to indicate that the column default should be used here instead of specifying a value:

```
INSERT INTO films VALUES
('UA502', 'Bananas', 105, DEFAULT, 'Comedy', '82 minutes'),
('T_601', 'Yojimbo', 106, DEFAULT, 'Drama', DEFAULT);
```

VALUES can also be used where a sub-SELECT might be written, for example in a FROM clause:

```
SELECT f.* FROM films f, (VALUES('MGM', 'Horror'), ('UA', 'Sci-Fi')) AS t (studio, kind) WHERE f.studio = t.studio AND f.kind = t.kind;
```

UPDATE employees SET salary = salary * v.increase FROM
VALUES (1, 200000, 1.2), (2, 400000, 1.4)) AS v (depno,
target, increase) WHERE employees.depno = v.depno AND
employees.sales >= v.target;

Note that an AS clause is required when VALUES is used in a FROM clause, just as is true for SELECT. It is not required that the AS clause specify names for all the columns, but it is good practice to do so. The default column names for VALUES are column1, column2, etc. in Greenplum Database, but these names might be different in other database systems.

When VALUES is used in INSERT, the values are all automatically coerced to the data type of the corresponding destination column. When it is used in other contexts, it may be necessary to specify the correct data type. If the entries are all quoted literal constants, coercing the first is sufficient to determine the assumed type for all:

```
SELECT * FROM machines WHERE ip_address IN
VALUES ('192.168.0.1'::inet), ('192.168.0.10'),
('192.0.2.43'));
```

**Note:** For simple IN tests, it is better to rely on the list-of-scalars form of IN than to write a VALUES query as shown above. The list of scalars method requires less writing and is often more efficient.

**Compatibility**

VALUES conforms to the SQL standard, except that LIMIT and OFFSET are Greenplum Database extensions.

INSERT, SELECT
The following table lists the features described in the 2008 SQL standard. Features that are supported in Greenplum Database are marked as YES in the 'Supported' column, features that are not implemented are marked as NO.

For information about Greenplum features and SQL compliance, see the *Greenplum Database Administrator Guide*.

Greenplum Environment Variables

This reference lists and describes the environment variables to set for Greenplum Database. Set these in your user’s startup shell profile (such as ~/.bashrc or ~/.bash_profile), or in /etc/profile if you want to set them for all users.

• Required Environment Variables
• Optional Environment Variables

Required Environment Variables

Note: GPHOME, PATH and LD_LIBRARY_PATH can be set by sourcing the greenplum_path.sh file from your Greenplum Database installation directory

GPHOME

This is the installed location of your Greenplum Database software. For example:

```
GPHOME=/usr/local/greenplum-db-<version>
export GPHOME
```

PATH

Your PATH environment variable should point to the location of the Greenplum Database bin directory. For example:

```
PATH=$GPHOME/bin:$PATH
export PATH
```

LD_LIBRARY_PATH

The LD_LIBRARY_PATH environment variable should point to the location of the Greenplum Database/PostgreSQL library files. For example:

```
LD_LIBRARY_PATH=$GPHOME/lib
export LD_LIBRARY_PATH
```

MASTER_DATA_DIRECTORY

This should point to the directory created by the gpinitsystem utility in the master data directory location. For example:

```
MASTER_DATA_DIRECTORY=/data/master/gpseg-1
export MASTER_DATA_DIRECTORY
```

Optional Environment Variables

The following are standard PostgreSQL environment variables, which are also recognized in Greenplum Database. You may want to add the connection-related environment variables to your profile for convenience, so you do not have to type so many options on the command line for client connections. Note that these environment variables should be set on the Greenplum Database master host only.
**PGAPPNAME**

The name of the application that is usually set by an application when it connects to the server. This name is displayed in the activity view and in log entries. The `PGAPPNAME` environmental variable behaves the same as the `application_name` connection parameter. The default value for `application_name` is `psql`. The name cannot be longer than 63 characters.

**PGDATABASE**

The name of the default database to use when connecting.

**PGHOST**

The Greenplum Database master host name.

**PGHOSTADDR**

The numeric IP address of the master host. This can be set instead of or in addition to `PGHOST` to avoid DNS lookup overhead.

**PGPASSWORD**

The password used if the server demands password authentication. Use of this environment variable is not recommended for security reasons (some operating systems allow non-root users to see process environment variables via `ps`). Instead consider using the `~/.pgpass` file.

**PGPASSFILE**

The name of the password file to use for lookups. If not set, it defaults to `~/.pgpass`. See the topic about `The Password File` in the PostgreSQL documentation for more information.

**PGOPTIONS**

Sets additional configuration parameters for the Greenplum Database master server.

**PGPORT**

The port number of the Greenplum Database server on the master host. The default port is 5432.

**PGUSER**

The Greenplum Database user name used to connect.

**PGDATESTYLE**

Sets the default style of date/time representation for a session. (Equivalent to `SET datestyle TO...`)

**PGTZ**

Sets the default time zone for a session. (Equivalent to `SET timezone TO...`)

**PGCLIENTENCODING**

Sets the default client character set encoding for a session. (Equivalent to `SET client_encoding TO...`
System Catalog Reference

This reference describes the Greenplum Database system catalog tables and views. System tables prefixed with `gp_` relate to the parallel features of Greenplum Database. Tables prefixed with `pg_` are either standard PostgreSQL system catalog tables supported in Greenplum Database, or are related to features Greenplum that provides to enhance PostgreSQL for data warehousing workloads. Note that the global system catalog for Greenplum Database resides on the master instance.

**Warning:** Changes to Pivotal Greenplum Database system catalog tables or views are not supported. If a catalog table or view is changed by the customer, the Pivotal Greenplum Database cluster is not supported. The cluster must be reinitialized and restored by the customer.

### System Views

Greenplum Database provides the following system views not available in PostgreSQL.

- gp_distributed_log
- gp_distributed_xacts
- gp_pgdatabase
- gp_resgroup_config
- gp_resgroup_status
- gp_resqueue_status
- gp_transaction_log
System Catalogs Definitions
System catalog table and view definitions in alphabetical order.

**gp_configuration_history**

The `gp_configuration_history` table contains information about system changes related to fault detection and recovery operations. The `fts_probe` process logs data to this table, as do certain related management utilities such as `gpcheck`, `gprecoverseg`, and `gpinitsystem`. For example, when you add a new segment and mirror segment to the system, records for these events are logged to `gp_configuration_history`.

The event descriptions stored in this table may be helpful for troubleshooting serious system issues in collaboration with Pivotal Support technicians.

This table is populated only on the master. This table is defined in the `pg_global` tablespace, meaning it is globally shared across all databases in the system.

**Table 106: pg_catalog gp_configuration_history**

<table>
<thead>
<tr>
<th>column</th>
<th>type</th>
<th>references</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>
<td>time</td>
<td>timestamp with time zone</td>
<td></td>
<td>Timestamp for the event recorded.</td>
</tr>
<tr>
<td>dbid</td>
<td>smallint</td>
<td><code>gp_segment_configuration.dbid</code></td>
<td>System-assigned ID. The unique identifier of a segment (or master) instance.</td>
</tr>
<tr>
<td>desc</td>
<td>text</td>
<td></td>
<td>Text description of the event.</td>
</tr>
</tbody>
</table>

For information about `gpcheck`, `gprecoverseg`, and `gpinitsystem`, see the Greenplum Database Utility Guide.
**gp_distributed_log**

The `gp_distributed_log` view contains status information about distributed transactions and their associated local transactions. A distributed transaction is a transaction that involves modifying data on the segment instances. Greenplum's distributed transaction manager ensures that the segments stay in synch. This view allows you to see the status of distributed transactions.

**Table 107: pg_catalog.gp_distributed_log**

<table>
<thead>
<tr>
<th>column</th>
<th>type</th>
<th>references</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>
<td>segment_id</td>
<td>smallint</td>
<td><code>gp_segment_configuration.content</code></td>
<td>The content id if the segment. The master is always -1 (no content).</td>
</tr>
<tr>
<td>dbid</td>
<td>small_int</td>
<td><code>gp_segment_configuration.dbid</code></td>
<td>The unique id of the segment instance.</td>
</tr>
<tr>
<td>distributed_xid</td>
<td>xid</td>
<td></td>
<td>The global transaction id.</td>
</tr>
<tr>
<td>distributed_id</td>
<td>text</td>
<td></td>
<td>A system assigned ID for a distributed transaction.</td>
</tr>
<tr>
<td>status</td>
<td>text</td>
<td></td>
<td>The status of the distributed transaction (Committed or Aborted).</td>
</tr>
<tr>
<td>local_transaction</td>
<td>xid</td>
<td></td>
<td>The local transaction ID.</td>
</tr>
</tbody>
</table>

**gp_distributed_xacts**

The `gp_distributed_xacts` view contains information about Greenplum Database distributed transactions. A distributed transaction is a transaction that involves modifying data on the segment instances. Greenplum's distributed transaction manager ensures that the segments stay in synch. This view allows you to see the currently active sessions and their associated distributed transactions.

**Table 108: pg_catalog.gp_distributed_xacts**

<table>
<thead>
<tr>
<th>column</th>
<th>type</th>
<th>references</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>
<td>distributed_xid</td>
<td>xid</td>
<td></td>
<td>The transaction ID used by the distributed transaction across the Greenplum Database array.</td>
</tr>
<tr>
<td>distributed_id</td>
<td>text</td>
<td></td>
<td>The distributed transaction identifier. It has 2 parts — a unique timestamp and the distributed transaction number.</td>
</tr>
<tr>
<td>state</td>
<td>text</td>
<td></td>
<td>The current state of this session with regards to distributed transactions.</td>
</tr>
<tr>
<td>column</td>
<td>type</td>
<td>references</td>
<td>description</td>
</tr>
<tr>
<td>---------------------</td>
<td>--------</td>
<td>------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>gp_session_id</td>
<td>int</td>
<td></td>
<td>The ID number of the Greenplum Database session associated with this transaction.</td>
</tr>
<tr>
<td>xmin_distributed_</td>
<td>xid</td>
<td></td>
<td>The minimum distributed transaction number found among all open transactions when this transaction was started. It is used for MVCC distributed snapshot purposes.</td>
</tr>
<tr>
<td>snapshot</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

### gp_distribution_policy

The `gp_distribution_policy` table contains information about Greenplum Database tables and their policy for distributing table data across the segments. This table is populated only on the master. This table is not globally shared, meaning each database has its own copy of this table.

**Table 109: pg_catalog.gp_distribution_policy**

<table>
<thead>
<tr>
<th>column</th>
<th>type</th>
<th>references</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>
<td>localoid</td>
<td>oid</td>
<td>pg_class.oid</td>
<td>The table object identifier (OID).</td>
</tr>
<tr>
<td>attrnums</td>
<td>smallint[]</td>
<td>pg_attribute.attnum</td>
<td>The column number(s) of the distribution column(s).</td>
</tr>
</tbody>
</table>

### gpexpand.expansion_progress

The `gpexpand.expansion_progress` view contains information about the status of a system expansion operation. The view provides calculations of the estimated rate of table redistribution and estimated time to completion.

Status for specific tables involved in the expansion is stored in `gpexpand.status_detail`.

**Table 110: gpexpand.expansion_progress**

<table>
<thead>
<tr>
<th>column</th>
<th>type</th>
<th>references</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>text</td>
<td></td>
<td>Name for the data field provided. Includes: Bytes Left, Bytes Done, Estimated Expansion Rate, Estimated Time to Completion, Tables Expanded, Tables Left</td>
</tr>
</tbody>
</table>
The value for the progress data. For example:
Estimated Expansion Rate - 9.75667095996092 MB/s

gpexpand.status

The `gpexpand.status` table contains information about the status of a system expansion operation. Status for specific tables involved in the expansion is stored in `gpexpand.status_detail`.

In a normal expansion operation it is not necessary to modify the data stored in this table.

Table 111: gpexpand.status

<table>
<thead>
<tr>
<th>column</th>
<th>type</th>
<th>references</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>
<td>status</td>
<td>text</td>
<td></td>
<td>Tracks the status of an expansion operation. Valid values are: SETUP, SETUP DONE, EXPANSION STARTED, EXPANSION STOPPED, COMPLETED</td>
</tr>
<tr>
<td>updated</td>
<td>timestamp with time zone</td>
<td></td>
<td>Timestamp of the last change in status.</td>
</tr>
</tbody>
</table>

gpexpand.status_detail

The `gpexpand.status_detail` table contains information about the status of tables involved in a system expansion operation. You can query this table to determine the status of tables being expanded, or to view the start and end time for completed tables.

This table also stores related information about the table such as the oid, disk size, and normal distribution policy and key. Overall status information for the expansion is stored in `gpexpand.status`.

In a normal expansion operation it is not necessary to modify the data stored in this table.

Table 112: gpexpand.status_detail

<table>
<thead>
<tr>
<th>column</th>
<th>type</th>
<th>references</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dbname</td>
<td>text</td>
<td></td>
<td>Name of the database to which the table belongs.</td>
</tr>
<tr>
<td>fq_name</td>
<td>text</td>
<td></td>
<td>Fully qualified name of the table.</td>
</tr>
<tr>
<td>column</td>
<td>type</td>
<td>references</td>
<td>description</td>
</tr>
<tr>
<td>-----------------------</td>
<td>------------------</td>
<td>------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>schema_oid</td>
<td>oid</td>
<td></td>
<td>OID for the schema of the database to which the table belongs.</td>
</tr>
<tr>
<td>table_oid</td>
<td>oid</td>
<td></td>
<td>OID of the table.</td>
</tr>
<tr>
<td>distribution_policy</td>
<td>smallint()</td>
<td></td>
<td>Array of column IDs for the distribution key of the table.</td>
</tr>
<tr>
<td>distribution_policy_names</td>
<td>text</td>
<td></td>
<td>Column names for the hash distribution key.</td>
</tr>
<tr>
<td>distribution_policy_coloids</td>
<td>text</td>
<td></td>
<td>Column IDs for the distribution keys of the table.</td>
</tr>
<tr>
<td>storage_options</td>
<td>text</td>
<td></td>
<td>Not enabled in this release. Do not update this field.</td>
</tr>
<tr>
<td>rank</td>
<td>int</td>
<td></td>
<td>Rank determines the order in which tables are expanded. The expansion utility will sort on rank and expand the lowest-ranking tables first.</td>
</tr>
<tr>
<td>status</td>
<td>text</td>
<td></td>
<td>Status of expansion for this table. Valid values are:</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>NOT STARTED</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>IN PROGRESS</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>COMPLETED</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>NO LONGER EXISTS</td>
</tr>
<tr>
<td>last updated</td>
<td>timestamp with time zone</td>
<td></td>
<td>Timestamp of the last change in status for this table.</td>
</tr>
<tr>
<td>expansion started</td>
<td>timestamp with time zone</td>
<td></td>
<td>Timestamp for the start of the expansion of this table. This field is only populated after a table is successfully expanded.</td>
</tr>
<tr>
<td>expansion finished</td>
<td>timestamp with time zone</td>
<td></td>
<td>Timestamp for the completion of expansion of this table.</td>
</tr>
</tbody>
</table>
The source_bytes column refers to the size of disk space associated with the source table. Due to table bloat in heap tables and differing numbers of segments after expansion, it is not expected that the final number of bytes will equal the source number. This information is tracked to help provide progress measurement to aid in duration estimation for the end-to-end expansion operation.

### gp_fastsequence

The gp_fastsequence table contains information about append-optimized and column-oriented tables. The last_sequence value indicates maximum row number currently used by the table.

<table>
<thead>
<tr>
<th>column</th>
<th>type</th>
<th>references</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>
<td>objid</td>
<td>oid</td>
<td>pg_class.oid</td>
<td>Object id of the pg_aoseg.pg_aocsseg_* table used to track append-optimized file segments.</td>
</tr>
<tr>
<td>objmod</td>
<td>bigint</td>
<td></td>
<td>Object modifier.</td>
</tr>
<tr>
<td>last_sequence</td>
<td>bigint</td>
<td></td>
<td>The last sequence number used by the object.</td>
</tr>
</tbody>
</table>

### gp_fault_strategy

The gp_fault_strategy table specifies the fault action.

<table>
<thead>
<tr>
<th>column</th>
<th>type</th>
<th>references</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>
<td>fault_strategy</td>
<td>char</td>
<td></td>
<td>The mirror failover action to take when a segment failure occurs: n = nothing f = file-based failover</td>
</tr>
</tbody>
</table>
**gp_global_sequence**

The *gp_global_sequence* table contains the log sequence number position in the transaction log, which is used by the file replication process to determine the file blocks to replicate from a primary to a mirror segment.

Table 115: pg_catalog.gp_global_sequence

<table>
<thead>
<tr>
<th>column</th>
<th>type</th>
<th>references</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sequence_num</td>
<td>bigint</td>
<td></td>
<td>Log sequence number position in the transaction log</td>
</tr>
</tbody>
</table>

**gp_id**

The *gp_id* system catalog table identifies the Greenplum Database system name and number of segments for the system. It also has local values for the particular database instance (segment or master) on which the table resides. This table is defined in the *pg_global* tablespace, meaning it is globally shared across all databases in the system.

Table 116: pg_catalog.gp_id

<table>
<thead>
<tr>
<th>column</th>
<th>type</th>
<th>references</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>
<td>gpname</td>
<td>name</td>
<td></td>
<td>The name of this Greenplum Database system.</td>
</tr>
<tr>
<td>numsegments</td>
<td>integer</td>
<td></td>
<td>The number of segments in the Greenplum Database system.</td>
</tr>
<tr>
<td>dbid</td>
<td>integer</td>
<td></td>
<td>The unique identifier of this segment (or master) instance.</td>
</tr>
<tr>
<td>content</td>
<td>integer</td>
<td></td>
<td>The ID for the portion of data on this segment instance. A primary and its mirror will have the same content ID. For a segment the value is from 0-N-1, where N is the number of segments in Greenplum Database. For the master, the value is -1.</td>
</tr>
</tbody>
</table>

**gp_persistent_database_node**

The *gp_persistent_database_node* table keeps track of the status of file system objects in relation to the transaction status of database objects. This information is used to make sure the state of the system catalogs and the file system files persisted to disk are synchronized. This information is used by the primary to mirror file replication process.
Table 117: pg_catalog.gp_persistent_database_node

<table>
<thead>
<tr>
<th>column</th>
<th>type</th>
<th>references</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>
<td>tablespace_oid</td>
<td>oid</td>
<td>pg_tablespace.oid</td>
<td>Table space object id.</td>
</tr>
<tr>
<td>database_oid</td>
<td>oid</td>
<td>pg_database.oid</td>
<td>Database object id.</td>
</tr>
</tbody>
</table>
| persistent_state      | smallint  |                    | 0 - free
|                       |           |                    | 1 - create pending
|                       |           |                    | 2 - created
|                       |           |                    | 3 - drop pending
|                       |           |                    | 4 - aborting create
|                       |           |                    | 5 - "Just in Time" create pending
|                       |           |                    | 6 - bulk load create pending                                               |
| mirror_existence_state| smallint  |                    | 0 - none
|                       |           |                    | 1 - not mirrored
|                       |           |                    | 2 - mirror create pending
|                       |           |                    | 3 - mirrorcreated
|                       |           |                    | 4 - mirror down before create
|                       |           |                    | 5 - mirror down during create
|                       |           |                    | 6 - mirror drop pending
|                       |           |                    | 7 - only mirror drop remains                                               |
| parent_xid            | integer   |                    | Global transaction id.                                                     |
| persistent_serial_num | bigint    |                    | Log sequence number position in the transaction log for a file block.      |
| previous_free_tid     | tid       |                    | Used by Greenplum Database to internally manage persistent representations of file system objects. |

**gp_persistent_filespace_node**

The `gp_persistent_filespace_node` table keeps track of the status of file system objects in relation to the transaction status of filesystem objects. This information is used to make sure the state of the system catalogs and the file system files persisted to disk are synchronized. This information is used by the primary to mirror file replication process.
### Table 118: pg_catalog.gp_persistent_filespace_node

</tbody>
</table>
gp_persistent_relation_node

The gp_persistent_relation_node table keeps track of the status of file system objects in relation to the transaction status of relation objects (tables, view, indexes, and so on). This information is used to make sure the state of the system catalogs and the file system files persisted to disk are synchronized. This information is used by the primary to mirror file replication process.

Table 119: pg_catalog.gp_persistent_relation_node

</tbody>
</table>

### gp_persistent_tablespace_node

The `gp_persistent_tablespace_node` table keeps track of the status of file system objects in relation to the transaction status of tablespace objects. This information is used to make sure the state of the system catalogs and the file system files persisted to disk are synchronized. This information is used by the primary to mirror file replication process.

Table 120: `pg_catalog.gp_persistent_tablespace_node`

<table>
<thead>
<tr>
<th>column</th>
<th>type</th>
<th>references</th>
<th>description</th>
</tr>
</thead>
<tbody>

### persistent_serial_num
- **Type**: bigint
- **References**: 
- **Description**: Log sequence number position in the transaction log for a file block.

### previous_free_tid
- **Type**: tid
- **References**: 
- **Description**: Used by Greenplum Database to internally manage persistent representations of file system objects.

### gp_pgdatabase

The `gp_pgdatabase` view shows status information about the Greenplum segment instances and whether they are acting as the mirror or the primary. This view is used internally by the Greenplum fault detection and recovery utilities to determine failed segments.

**Table 121: pg_catalog.gp_pgdatabase**

<table>
<thead>
<tr>
<th>column</th>
<th>type</th>
<th>references</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dbid</td>

</tr>
<tr>
<td>isprimary</td>
<td>boolean</td>
<td>gp_segment_configuration.role</td>
<td>Whether or not this instance is active. Is it currently acting as the primary segment (as opposed to the mirror).</td>
</tr>
<tr>
<td>content</td>
<td>smallint</td>
<td>gp_segment_configuration.content</td>
<td>The ID for the portion of data on an instance. A primary segment instance and its mirror will have the same content ID. For a segment the value is from 0-(N-1), where (N) is the number of segments in Greenplum Database. For the master, the value is -1.</td>
</tr>
<tr>
<td>definedprimary</td>
<td>boolean</td>
<td>gp_segment_configuration.preferred_role</td>
<td>Whether or not this instance was defined as the primary (as opposed to the mirror) at the time the system was initialized.</td>
</tr>
</tbody>
</table>
**gp_relation_node**

The `gp_relation_node` table contains information about the file system objects for a relation (table, view, index, and so on).

<table>
<thead>
<tr>
<th>column</th>
<th>type</th>
<th>references</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>
<td>relfilenode_oid</td>
<td>oid</td>

<td>Log sequence number position in the transaction log for a file block.</td>
</tr>
</tbody>
</table>

**gp_resgroup_config**

The `gp_toolkit.gp_resgroup_config` view allows administrators to see the current CPU, memory, and concurrency limits for a resource group. The view also displays proposed limit settings. A proposed limit will differ from a current limit when the limit has been altered, but the new value could not be immediately applied.

**Note:** The `gp_resgroup_config` view is valid only when resource group-based resource management is active.

<table>
<thead>
<tr>
<th>column</th>
<th>type</th>
<th>references</th>
<th>description</th>
</tr>
</thead>

<tr>
<td>proposed_memory_spill</td>
<td>text</td>
<td>pg_resgroupcapability. proposed for pg_resgroupcapability. reslimittype&gt; 5</td>
<td>The pending memory spill ratio value for the resource group.</td>
</tr>
</tbody>
</table>

**gp_resgroup_status**

The `gp_toolkit.gp_resgroup_status` view allows administrators to see status and activity for a resource group. It shows how many queries are waiting to run and how many queries are currently active in the system for each resource group. The view also displays current memory and CPU usage for the resource group.

**Note:** The `gp_resgroup_status` view is valid only when resource group-based resource management is active.

**Table 124: gp_toolkit.gp_resgroup_status**

<table>
<thead>
<tr>
<th>column</th>
<th>type</th>
<th>references</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>
<td>rsgname</td>
<td>name</td>
<td>pg_resgroup.rsgname</td>
<td>The name of the resource group.</td>
</tr>
<tr>
<td>groupid</td>
<td>oid</td>
<td>pg_resgroup.oid</td>
<td>The ID of the resource group.</td>
</tr>
<tr>
<td>column</td>
<td>type</td>
<td>references</td>
<td>description</td>
</tr>
<tr>
<td>----------------</td>
<td>---------</td>
<td>------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>num_running</td>
<td>integer</td>
<td></td>
<td>The number of transactions currently executing in the resource group.</td>
</tr>
<tr>
<td>num_queueing</td>
<td>integer</td>
<td></td>
<td>The number of currently queued transactions for the resource group.</td>
</tr>
<tr>
<td>num_queued</td>
<td>integer</td>
<td></td>
<td>The total number of queued transactions for the resource group since the Greenplum Database cluster was last started, excluding the num_queueing.</td>
</tr>
<tr>
<td>num_executed</td>
<td>integer</td>
<td></td>
<td>The total number of executed transactions in the resource group since the Greenplum Database cluster was last started, excluding the num_running.</td>
</tr>
<tr>
<td>total_queue_duration</td>
<td>interval</td>
<td></td>
<td>The total time any transaction was queued since the Greenplum Database cluster was last started.</td>
</tr>
<tr>
<td>cpu_usage</td>
<td>json</td>
<td></td>
<td>The real-time CPU usage of the resource group on each Greenplum Database segment's host.</td>
</tr>
<tr>
<td>memory_usage</td>
<td>json</td>
<td></td>
<td>The real-time memory usage of the resource group on each Greenplum Database segment's host.</td>
</tr>
</tbody>
</table>

The `cpu_usage` field is a JSON-formatted, key:value string that identifies, for each resource group, the per-segment CPU usage percentage. The key is segment id, the value is the percentage of CPU usage by the resource group on the segment host. The total CPU usage of all segments running on a segment host should not exceed the `gp_resource_group_cpu_limit`. Example `cpu_usage` column output:

```json
{"-1":0.01, "0":0.31, "1":0.31}
```

The `memory_usage` field is also a JSON-formatted, key:value string. The string contents differ depending upon the type of resource group. For each resource group that you assign to a role (default memory auditor vmtracker), this string identifies the used, available, granted, and proposed fixed and shared memory quota allocations on each segment. The key is segment id. The values are memory values.
displayed in MB units. The following example shows memory_usage column output for a single segment for a resource group that you assign to a role:

```
{"used":0, "available":76, "quota_used":-1, "quota_available":60, "quota_granted":60, "quota_proposed":60, "shared_used":0, "shared_available":16, "shared_granted":16, "shared_proposed":16}
```

For each resource group that you assign to an external component, the memory_usage JSON-formatted string identifies the memory used and the memory limit on each segment. The following example shows memory_usage column output for an external component resource group for a single segment:

```
{"used":11, "limit_granted":15}
```

**gp_resqueue_status**

The gp_toolkit.gp_resqueue_status view allows administrators to see status and activity for a resource queue. It shows how many queries are waiting to run and how many queries are currently active in the system from a particular resource queue.

**Note:** The gp_resqueue_status view is valid only when resource queue-based resource management is active.

**Table 125: gp_toolkit.gp_resqueue_status**

<table>
<thead>
<tr>
<th>column</th>
<th>type</th>
<th>references</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>
<td>queueid</td>

</tr>
</tbody>
</table>
### rsqwaiters
- **Type:** integer
- **References:** `gp_toolkit.gp_resqueue_rsqwaiter`
- **Description:** The number of statements currently waiting in the resource queue.

### rsqholders
- **Type:** integer
- **References:** `gp_toolkit.gp_resqueue_rsqholders`
- **Description:** The number of statements currently running on the system from this resource queue.

---

#### gp_segment_configuration

The gp_segment_configuration table contains information about mirroring and segment configuration.

**Table 126: pg_catalog.gp_segment_configuration**

<table>
<thead>
<tr>
<th>column</th>
<th>type</th>
<th>references</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dbid</td>
<td>smallint</td>
<td></td>
<td>The unique identifier of a segment (or master) instance.</td>
</tr>
<tr>
<td>content</td>
<td>smallint</td>
<td></td>
<td>The content identifier for a segment instance. A primary segment instance and its corresponding mirror will always have the same content identifier. For a segment the value is from 0- N-1, where N is the number of primary segments in the system. For the master, the value is always -1.</td>
</tr>
<tr>
<td>role</td>
<td>char</td>
<td></td>
<td>The role that a segment is currently running as. Values are p (primary) or m (mirror).</td>
</tr>
<tr>
<td>preferred_role</td>
<td>char</td>
<td></td>
<td>The role that a segment was originally assigned at initialization time. Values are p (primary) or m (mirror).</td>
</tr>
<tr>

<td>integer</td>
<td></td>
<td>The TCP port the database server listener process is using.</td>
</tr>
<tr>
<td>hostname</td>
<td>text</td>
<td></td>
<td>The hostname of a segment host.</td>
</tr>
<tr>
<td>address</td>
<td>text</td>
<td></td>
<td>The hostname used to access a particular segment on a segment host. This value may be the same as hostname in systems upgraded from 3.x or on systems that do not have per-interface hostnames configured.</td>
</tr>
<tr>
<td>replication_port</td>
<td>integer</td>
<td></td>
<td>The TCP port the file block replication process is using to keep primary and mirror segments synchronized.</td>
</tr>
</tbody>
</table>

**gp_transaction_log**

The gp_transaction_log view contains status information about transactions local to a particular segment. This view allows you to see the status of local transactions.

**Table 127: pg_catalog gp_transaction_log**

<table>
<thead>
<tr>
<th>column</th>
<th>type</th>
<th>references</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>
<td>segment_id</td>
<td>smallint</td>
<td>gp_segment_</td>
<td>The content id if the segment. The master is always -1 (no content).</td>
</tr>
<tr>
<td></td>
<td></td>
<td>configuration.content</td>
<td></td>
</tr>
<tr>
<td>dbid</td>
<td>smallint</td>
<td>gp_segment_</td>
<td>The unique id of the segment instance.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>configuration.dbid</td>
<td></td>
</tr>
<tr>
<td>transaction</td>
<td>xid</td>
<td></td>
<td>The local transaction ID.</td>
</tr>
<tr>
<td>status</td>
<td>text</td>
<td></td>
<td>The status of the local transaction (Committed or Aborted).</td>
</tr>
</tbody>
</table>

**gp_version_at_initdb**

The gp_version_at_initdb table is populated on the master and each segment in the Greenplum Database system. It identifies the version of Greenplum Database used when the system was first initialized. This table is defined in the pg_global tablespace, meaning it is globally shared across all databases in the system.
Table 128: pg_catalog.gp_version

<table>
<thead>
<tr>
<th>column</th>
<th>type</th>
<th>references</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>
<td>schemaversion</td>
<td>integer</td>
<td></td>
<td>Schema version number.</td>
</tr>
<tr>
<td>productversion</td>
<td>text</td>
<td></td>
<td>Product version number.</td>
</tr>
</tbody>
</table>

**pg_aggregate**

The `pg_aggregate` table stores information about aggregate functions. An aggregate function is a function that operates on a set of values (typically one column from each row that matches a query condition) and returns a single value computed from all these values. Typical aggregate functions are `sum`, `count`, and `max`. Each entry in `pg_aggregate` is an extension of an entry in `pg_proc`. The `pg_proc` entry carries the aggregate’s name, input and output data types, and other information that is similar to ordinary functions.

Table 129: pg_catalog.pg_aggregate

<table>
<thead>
<tr>
<th>column</th>
<th>type</th>
<th>references</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>
<td>aggfoid</td>

| columnstore      | boolean |            | 1 for column-oriented storage, 0 for row-oriented storage.                                    |
| segrelid         | oid     |            | Table on-disk segment file id.                                                                 |
| segidxid         | oid     |            | Index on-disk segment file id.                                                                  |
| blkdirrelid      | oid     |            | Block used for on-disk column-oriented table file.                                              |
| blkdiridridxid   | oid     |            | Block used for on-disk column-oriented index file.                                              |
| visimaprelid     | oid     |            | Visibility map for the table.                                                                   |
| visimapidxid     | oid     |            | B-tree index on the visibility map.                                                             |

**Note:** \(^1\)QuickLZ compression is available only in the commercial release of Pivotal Greenplum Database.

**pg_attrdef**

The `pg_attrdef` table stores column default values. The main information about columns is stored in `pg_attribute`. Only columns that explicitly specify a default value (when the table is created or the column is added) will have an entry here.
### Table 134: pg_catalog.pg_attrdef

<table>
<thead>
<tr>
<th>column</th>
<th>type</th>
<th>references</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>
<td>adrelid</td>
<td>oid</td>
<td>pg_class.oid</td>
<td>The table this column belongs to</td>
</tr>
<tr>
<td>adnum</td>
<td>int2</td>
<td>pg_attribute.attnum</td>
<td>The number of the column</td>
</tr>
<tr>
<td>adbin</td>
<td>text</td>
<td></td>
<td>The internal representation of the column default value</td>
</tr>
<tr>
<td>adsrc</td>
<td>text</td>
<td></td>
<td>A human-readable representation of the default value. This field is historical, and is best not used.</td>
</tr>
</tbody>
</table>

### pg_attribute

The `pg_attribute` table stores information about table columns. There will be exactly one `pg_attribute` row for every column in every table in the database. (There will also be attribute entries for indexes, and all objects that have `pg_class` entries.) The term attribute is equivalent to column.

### Table 135: pg_catalog.pg_attribute

<table>
<thead>
<tr>
<th>column</th>
<th>type</th>
<th>references</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>
<td>attrelid</td>
<td>oid</td>
<td>pg_class.oid</td>
<td>The table this column belongs to</td>
</tr>
<tr>
<td>attname</td>
<td>name</td>
<td></td>
<td>The column name</td>
</tr>
<tr>
<td>atttypid</td>
<td>oid</td>
<td>pg_type.oid</td>
<td>The data type of this column</td>
</tr>
<tr>
<td>attstattrtarget</td>
<td>int4</td>
<td></td>
<td>Controls the level of detail of statistics accumulated for this column by <code>ANALYZE</code>. A zero value indicates that no statistics should be collected. A negative value says to use the system default statistics target. The exact meaning of positive values is data type-dependent. For scalar data types, it is both the target number of &quot;most common values&quot; to collect, and the target number of histogram bins to create.</td>
</tr>
<tr>
<td>column</td>
<td>type</td>
<td>references</td>
<td>description</td>
</tr>
<tr>
<td>-----------</td>
<td>-----------</td>
<td>------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>attlen</td>
<td>int2</td>
<td></td>
<td>A copy of pg_type.typlen of this column's type.</td>
</tr>
<tr>
<td>attnum</td>
<td>int2</td>
<td></td>
<td>The number of the column. Ordinary columns are numbered from 1 up. System columns, such as oid, have (arbitrary) negative numbers.</td>
</tr>
<tr>
<td>attnums</td>
<td>int4</td>
<td></td>
<td>Number of dimensions, if the column is an array type; otherwise 0. (Presently, the number of dimensions of an array is not enforced, so any nonzero value effectively means it is an array)</td>
</tr>
<tr>
<td>attcacheoff</td>
<td>int4</td>
<td></td>
<td>Always –1 in storage, but when loaded into a row descriptor in memory this may be updated to cache the offset of the attribute within the row</td>
</tr>
<tr>
<td>atttypmod</td>
<td>int4</td>
<td></td>
<td>Records type-specific data supplied at table creation time (for example, the maximum length of a varchar column). It is passed to type-specific input functions and length coercion functions. The value will generally be –1 for types that do not need it.</td>
</tr>
<tr>
<td>attbyval</td>
<td>boolean</td>
<td></td>
<td>A copy of pg_type.tybyval of this column's type.</td>
</tr>
<tr>
<td>attstorage</td>
<td>char</td>
<td></td>
<td>Normally a copy of pg_type.typstorage of this column's type. For TOAST-able data types, this can be altered after column creation to control storage policy.</td>
</tr>
<tr>
<td>attalign</td>
<td>char</td>
<td></td>
<td>A copy of pg_type.typalign of this column's type.</td>
</tr>
<tr>
<td>column</td>
<td>type</td>
<td>references</td>
<td>description</td>
</tr>
<tr>
<td>-----------</td>
<td>---------</td>
<td>------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>attnotnull</td>
<td>boolean</td>
<td></td>
<td>This represents a not-null constraint. It is possible to change this column to enable or disable the constraint.</td>
</tr>
<tr>
<td>atthasdef</td>
<td>boolean</td>
<td></td>
<td>This column has a default value, in which case there will be a corresponding entry in the pg_attdf catalog that actually defines the value</td>
</tr>
<tr>
<td>attisdropped</td>
<td>boolean</td>
<td></td>
<td>This column has been dropped and is no longer valid. A dropped column is still physically present in the table, but is ignored by the parser and so cannot be accessed via SQL</td>
</tr>
<tr>
<td>attislocal</td>
<td>boolean</td>
<td></td>
<td>This column is defined locally in the relation. Note that a column may be locally defined and inherited simultaneously</td>
</tr>
<tr>
<td>attinhcount</td>
<td>int4</td>
<td></td>
<td>The number of direct ancestors this column has. A column with a nonzero number of ancestors cannot be dropped nor renamed</td>
</tr>
</tbody>
</table>

### pg_attribute_encoding

The `pg_attribute_encoding` system catalog table contains column storage information.

**Table 136: pg_catalog.pg_attribute_encoding**

<table>
<thead>
<tr>
<th>column</th>
<th>type</th>
<th>modifiers</th>
<th>storage</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>
<td>attrelid</td>
<td>oid</td>
<td>not null</td>
<td>plain</td>
<td>Foreign key to <code>pg_attribute</code>. <code>attrelid</code></td>
</tr>
<tr>
<td>attnum</td>
<td>smallint</td>
<td>not null</td>
<td>plain</td>
<td>Foreign key to <code>pg_attribute</code>. <code>attnum</code></td>
</tr>
<tr>
<td>attoptions</td>
<td>text [ ]</td>
<td></td>
<td>extended</td>
<td>The options</td>
</tr>
</tbody>
</table>
**pg_auth_members**

The `pg_auth_members` system catalog table shows the membership relations between roles. Any non-circular set of relationships is allowed. Because roles are system-wide, `pg_auth_members` is shared across all databases of a Greenplum Database system.

Table 137: `pg_catalog.pg_auth_members`

<table>
<thead>
<tr>
<th>column</th>
<th>type</th>
<th>references</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>
<td>roleid</td>
<td>oid</td>
<td>pg_authid.oid</td>
<td>ID of the parent-level (group) role</td>
</tr>
<tr>
<td>member</td>
<td>oid</td>
<td>pg_authid.oid</td>
<td>ID of a member role</td>
</tr>
<tr>
<td>grantor</td>
<td>oid</td>
<td>pg_authid.oid</td>
<td>ID of the role that granted this membership</td>
</tr>
<tr>
<td>admin_option</td>
<td>boolean</td>
<td></td>
<td>True if role member may grant membership to others</td>
</tr>
</tbody>
</table>

**pg_authid**

The `pg_authid` table contains information about database authorization identifiers (roles). A role subsumes the concepts of users and groups. A user is a role with the `rolcanlogin` flag set. Any role (with or without `rolcanlogin`) may have other roles as members. See `pg_auth_members`.

Since this catalog contains passwords, it must not be publicly readable. `pg_roles` is a publicly readable view on `pg_authid` that blanks out the password field.

Because user identities are system-wide, `pg_authid` is shared across all databases in a Greenplum Database system: there is only one copy of `pg_authid` per system, not one per database.

Table 138: `pg_catalog.pg_authid`

<table>
<thead>
<tr>
<th>column</th>
<th>type</th>
<th>references</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>

<td>Privilege to create write external tables with the gphdfs protocol (deprecated)</td>
</tr>
<tr>
<td>rolequeue</td>
<td>oid</td>
<td></td>
<td>Object ID of the associated resource group ID in <code>pg_resgroup</code></td>
</tr>
</tbody>
</table>
pg_available_extension_versions

The `pg_available_extension_versions` view lists the specific extension versions that are available for installation. The `pg_extension` system catalog table shows the extensions currently installed.

The view is read only.

Table 139: `pg_catalog.pg_available_extension_versions`

<table>
<thead>
<tr>
<th>column</th>
<th>type</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>name</td>
<td>Extension name.</td>

<tr>
<td>version</td>
<td>text</td>
<td>Version name.</td>
</tr>
<tr>
<td>installed</td>
<td>boolean</td>
<td>True if this version of this extension is currently installed, False otherwise.</td>
</tr>
<tr>
<td>superuser</td>
<td>boolean</td>
<td>True if only superusers are allowed to install the extension, False otherwise.</td>
</tr>
<tr>
<td>relocatable</td>
<td>boolean</td>
<td>True if extension can be relocated to another schema, False otherwise.</td>
</tr>
<tr>
<td>schema</td>
<td>name</td>
<td>Name of the schema that the extension must be installed into, or NULL if partially or fully relocatable.</td>
</tr>
<tr>
<td>requires</td>
<td>name[]</td>
<td>Names of prerequisite extensions, or NULL if none</td>
</tr>
<tr>
<td>comment</td>
<td>text</td>
<td>Comment string from the extension control file.</td>
</tr>
</tbody>
</table>

pg_available_extensions

The `pg_available_extensions` view lists the extensions that are available for installation. The `pg_extension` system catalog table shows the extensions currently installed.

The view is read only.

Table 140: `pg_catalog.pg_available_extensions`

<table>
<thead>
<tr>
<th>column</th>
<th>type</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>name</td>
<td>Extension name.</td>

<tr>
<td>default_version</td>
<td>text</td>
<td>Name of default version, or NULL if none is specified.</td>
</tr>
<tr>
<td>installed_version</td>
<td>text</td>
<td>Currently installed version of the extension, or NULL if not installed.</td>
</tr>
<tr>
<td>comment</td>
<td>text</td>
<td>Comment string from the extension control file.</td>
</tr>
</tbody>
</table>
**pg_cast**

The `pg_cast` table stores data type conversion paths, both built-in paths and those defined with `CREATE CAST`. The cast functions listed in `pg_cast` must always take the cast source type as their first argument type, and return the cast destination type as their result type. A cast function can have up to three arguments. The second argument, if present, must be type `integer`; it receives the type modifier associated with the destination type, or \(-1\) if there is none. The third argument, if present, must be type `boolean`; it receives `true` if the cast is an explicit cast, `false` otherwise.

It is legitimate to create a `pg_cast` entry in which the source and target types are the same, if the associated function takes more than one argument. Such entries represent 'length coercion functions' that coerce values of the type to be legal for a particular type modifier value. Note however that at present there is no support for associating non-default type modifiers with user-created data types, and so this facility is only of use for the small number of built-in types that have type modifier syntax built into the grammar.

When a `pg_cast` entry has different source and target types and a function that takes more than one argument, it represents converting from one type to another and applying a length coercion in a single step. When no such entry is available, coercion to a type that uses a type modifier involves two steps, one to convert between data types and a second to apply the modifier.

**Table 141: pg_catalog.pg_cast**

<table>
<thead>
<tr>
<th>column</th>
<th>type</th>
<th>references</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>

<td>OID of the target data type.</td>
</tr>
<tr>
<td>castfunc</td>
<td>oid</td>
<td>pg_proc.oid</td>
<td>The OID of the function to use to perform this cast. Zero is stored if the data types are binary compatible (that is, no run-time operation is needed to perform the cast).</td>
</tr>
<tr>
<td>castcontext</td>
<td>char</td>
<td></td>
<td>Indicates what contexts the cast may be invoked in. <code>e</code> means only as an explicit cast (using <code>CAST</code> or <code>::</code> syntax). <code>a</code> means implicitly in assignment to a target column, as well as explicitly. <code>i</code> means implicitly in expressions, as well as the other cases.</td>
</tr>
</tbody>
</table>

**pg_class**

The system catalog table `pg_class` catalogs tables and most everything else that has columns or is otherwise similar to a table (also known as `relations`). This includes indexes (see also `pg_index`), sequences, views, composite types, and TOAST tables. Not all columns are meaningful for all relation types.
Table 142: pg_catalog.pg_class

<table>
<thead>
<tr>
<th>column</th>

</tbody>
</table>

**pg_constraint**

The `pg_constraint` system catalog table stores check, primary key, unique, and foreign key constraints on tables. Column constraints are not treated specially. Every column constraint is equivalent to some table constraint. Not-null constraints are represented in the `pg_attribute` catalog table. Check constraints on domains are stored here, too.

**Table 144: pg_catalog.pg_constraint**

<table>
<thead>
<tr>
<th>column</th>
<th>type</th>
<th>references</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>

pg_database

The pg_database system catalog table stores information about the available databases. Databases are created with the CREATE DATABASE SQL command. Unlike most system catalogs, pg_database is shared across all databases in the system. There is only one copy of pg_database per system, not one per database.

Table 146: pg_catalog.pg_database

<table>
<thead>

</tbody>
</table>

**pg_depend**

The `pg_depend` system catalog table records the dependency relationships between database objects. This information allows `DROP` commands to find which other objects must be dropped by `DROP CASCADE`
or prevent dropping in the `DROP RESTRICT` case. See also `pg_shdepend`, which performs a similar function for dependencies involving objects that are shared across a Greenplum system.

In all cases, a `pg_depend` entry indicates that the referenced object may not be dropped without also dropping the dependent object. However, there are several subflavors identified by `deptype`:

- **DEPENDENCY_NORMAL** (n) — A normal relationship between separately-created objects. The dependent object may be dropped without affecting the referenced object. The referenced object may only be dropped by specifying `CASCADE`, in which case the dependent object is dropped, too. Example: a table column has a normal dependency on its data type.

- **DEPENDENCY_AUTO** (a) — The dependent object can be dropped separately from the referenced object, and should be automatically dropped (regardless of `RESTRICT` or `CASCADE` mode) if the referenced object is dropped. Example: a named constraint on a table is made autodependent on the table, so that it will go away if the table is dropped.

- **DEPENDENCY_INTERNAL** (i) — The dependent object was created as part of creation of the referenced object, and is really just a part of its internal implementation. A `DROP` of the dependent object will be disallowed outright (we’ll tell the user to issue a `DROP` against the referenced object, instead). A `DROP` of the referenced object will be propagated through to drop the dependent object whether `CASCADE` is specified or not.

- **DEPENDENCY_PIN** (p) — There is no dependent object; this type of entry is a signal that the system itself depends on the referenced object, and so that object must never be deleted. Entries of this type are created only by system initialization. The columns for the dependent object contain zeroes.

**Table 147: pg_catalog.pg_depend**

<table>
<thead>
<tr>
<th>column</th>
<th>type</th>
<th>references</th>
<th>description</th>
</tr>
</thead>
<tbody>

<td>int4</td>
<td></td>
<td>For a table column, this is the column number. For all other object types, this column is zero.</td>
</tr>
<tr>
<td>refclassid</td>
<td>oid</td>
<td>pg_class.oid</td>
<td>The OID of the system catalog the referenced object is in.</td>
</tr>
<tr>
<td>refobjid</td>
<td>oid</td>
<td>any OID column</td>
<td>The OID of the specific referenced object.</td>
</tr>
<tr>
<td>refobjsubid</td>
<td>int4</td>
<td></td>
<td>For a table column, this is the referenced column number. For all other object types, this column is zero.</td>
</tr>
<tr>
<td>deptype</td>
<td>char</td>
<td></td>
<td>A code defining the specific semantics of this dependency relationship.</td>
</tr>
</tbody>
</table>
**pg_description**

The `pg_description` system catalog table stores optional descriptions (comments) for each database object. Descriptions can be manipulated with the `COMMENT` command and viewed with `psql`'s `\d` meta-commands. Descriptions of many built-in system objects are provided in the initial contents of `pg_description`. See also `pg_shdescription`, which performs a similar function for descriptions involving objects that are shared across a Greenplum system.

<table>
<thead>
<tr>
<th><strong>Table 148: pg_catalog.pg_description</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>column</strong></td>
</tr>
<tr>
<td>objoid</td>
</tr>
<tr>
<td>classoid</td>
</tr>
<tr>
<td>objsubid</td>
</tr>
<tr>
<td>description</td>
</tr>
</tbody>
</table>

**pg_enum**

The `pg_enum` table contains entries matching enum types to their associated values and labels. The internal representation of a given enum value is actually the OID of its associated row in `pg_enum`. The OIDs for a particular enum type are guaranteed to be ordered in the way the type should sort, but there is no guarantee about the ordering of OIDs of unrelated enum types.

<table>
<thead>
<tr>
<th><strong>Table 149: pg_catalog.pg_enum</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Column</strong></td>
</tr>
<tr>
<td>enumtypid</td>
</tr>
<tr>
<td>enumlabel</td>
</tr>
</tbody>
</table>

**pg_extension**

The system catalog table `pg_extension` stores information about installed extensions.

<table>
<thead>
<tr>
<th><strong>Table 150: pg_catalog.pg_extension</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>column</strong></td>
</tr>
<tr>
<td>extname</td>
</tr>
</tbody>
</table>
### Greenplum Database Reference Guide

<table>
<thead>
<tr>
<th>column</th>
<th>type</th>
<th>references</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>
<td>extowner</td>
<td>oid</td>
<td>pg_authid.oid</td>
<td>Owner of the extension</td>
</tr>
<tr>
<td>extnamespace</td>
<td>oid</td>
<td>pg_namespace.oid</td>
<td>Schema containing the extension exported objects.</td>
</tr>
<tr>
<td>extrelocatable</td>
<td>boolean</td>
<td></td>
<td>True if the extension can be relocated to another schema.</td>
</tr>
<tr>
<td>extversion</td>
<td>text</td>
<td></td>
<td>Version name for the extension.</td>
</tr>
<tr>
<td>extconfig</td>
<td>oid[]</td>
<td>pg_class.oid</td>
<td>Array of regclass OIDs for the extension configuration tables, or NULL if none.</td>
</tr>
<tr>
<td>extcondition</td>
<td>text[]</td>
<td></td>
<td>Array of WHERE-clause filter conditions for the extension configuration tables, or NULL if none.</td>
</tr>
</tbody>
</table>

Unlike most catalogs with a namespace column, extnamespace does not imply that the extension belongs to that schema. Extension names are never schema-qualified. The extnamespace schema indicates the schema that contains most or all of the extension objects. If extrelocatable is true, then this schema must contain all schema-qualifiable objects that belong to the extension.

### pg_exttable

The pg_exttable system catalog table is used to track external tables and web tables created by the `CREATE EXTERNAL TABLE` command.

#### Table 151: pg_catalog.pg_exttable

</table>

pg_filespace

The pg_filespace table contains information about the file spaces created in a Greenplum Database system. Every system contains a default filespace, pg_system, which is a collection of all the data directory locations created at system initialization time.

A tablespace requires a file system location to store its database files. In Greenplum Database, the master and each segment (primary and mirror) needs its own distinct storage location. This collection of file system locations for all components in a Greenplum system is referred to as a filespace.

A tablespace requires a file system location to store its database files. In Greenplum Database, the master and each segment (primary and mirror) needs its own distinct storage location. <td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>indisvalid</td>
<td>boolean</td>
<td></td>
<td>If true, the index is currently valid for queries. False means the index is possibly incomplete: it must still be modified by INSERT/UPDATE operations, but it cannot safely be used for queries.</td>
</tr>
<tr>
<td>indkey</td>
<td>int2vector</td>
<td>pg_attribute.attnum</td>
<td>This is an array of indnatts values that indicate which table columns this index indexes. For example a value of 1 3 would mean that the first and the third table columns make up the index key. A zero in this array indicates that the corresponding index attribute is an expression over the table columns, rather than a simple column reference.</td>
</tr>
<tr>
<td>indclass</td>
<td>oidvector</td>
<td>pg_opclass.oid</td>
<td>For each column in the index key this contains the OID of the operator class to use.</td>
</tr>
<tr>
<td>indexprs</td>
<td>text</td>
<td></td>
<td>Expression trees (in nodeToString() representation) for index attributes that are not simple column references. This is a list with one element for each zero entry in indkey. NULL if all index attributes are simple references.</td>
</tr>
<tr>
<td>indpred</td>
<td>text</td>
<td></td>
<td>Expression tree (in nodeToString() representation) for partial index predicate. NULL if not a partial index.</td>
</tr>
</tbody>
</table>

**pg_inherits**

The pg_inherits system catalog table records information about table inheritance hierarchies. There is one entry for each direct child table in the database. (Indirect inheritance can be determined by following chains of entries.) In Greenplum Database, inheritance relationships are created by both the INHERITS
clause (standalone inheritance) and the PARTITION BY clause (partitioned child table inheritance) of CREATE TABLE.

Table 155: pg_catalog.pg_inherits

<table>
<thead>
<tr>
<th>column</th>
<th>type</th>
<th>references</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>
<td>inhrelid</td>
<td>oid</td>
<td>pg_class.oid</td>
<td>The OID of the child table.</td>

<td>boolean</td>
<td></td>
<td>True if this is a trusted language, which means that it is believed not to grant access to anything outside the normal SQL execution environment. Only superusers may create functions in untrusted languages.</td>
</tr>
</tbody>
</table>
### column
| lanplcallfoid  | oid       | pg_proc.oid | For noninternal languages this references the language handler, which is a special function that is responsible for executing all functions that are written in the particular language. |
| laninline      | oid       | pg_proc.oid | This references a function that is responsible for executing inline anonymous code blocks (see the `DO` command). Zero if anonymous blocks are not supported. |
| lanvalidator   | oid       | pg_proc.oid | This references a language validator function that is responsible for checking the syntax and validity of new functions when they are created. Zero if no validator is provided. |
| lanacl         | aclitem[] |             | Access privileges for the language. |

### pg_largeobject

The `pg_largeobject` system catalog table holds the data making up 'large objects'. A large object is identified by an OID assigned when it is created. Each large object is broken into segments or 'pages' small enough to be conveniently stored as rows in `pg_largeobject`. The amount of data per page is defined to be `LOBLKSIZE` (which is currently `BLCKSZ/4`, or typically 8K).

Each row of `pg_largeobject` holds data for one page of a large object, beginning at byte offset (`pageno * LOBLKSIZE`) within the object. The implementation allows sparse storage: pages may be missing, and may be shorter than `LOBLKSIZE` bytes even if they are not the last page of the object. Missing regions within a large object read as zeroes.

**Table 157: pg_catalog.pg_largeobject**

<table>
<thead>
<tr>
<th>column</th>
<th>type</th>
<th>references</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>
<td>loid</td>

</tbody>
</table>
| data     | bytea      |            | Actual data stored in the large object. This will never be more than LOBLKSIZ
|          |            |            | e bytes and may be less.                                                    |

**pg_listener**

The `pg_listener` system catalog table supports the `LISTEN` and `NOTIFY` commands. A listener creates an entry in `pg_listener` for each notification name it is listening for. A notifier scans and updates each matching entry to show that a notification has occurred. The notifier also sends a signal (using the PID recorded in the table) to awaken the listener from sleep.

This table is not currently used in Greenplum Database.

**Table 158: pg_catalog.pg_listener**

<table>
<thead>
<tr>
<th>column</th>
<th>type</th>
<th>references</th>
<th>description</th>
</tr>
</thead>
</table>

**pg_locks**

The `pg_locks` view provides access to information about the locks held by open transactions within Greenplum Database.

`pg_locks` contains one row per active lockable object, requested lock mode, and relevant transaction. Thus, the same lockable object may appear many times if multiple transactions are holding or waiting for locks on it. An object with no current locks on it will not appear in the view at all.

There are several distinct types of lockable objects: whole relations (such as tables), individual pages of relations, individual tuples of relations, transaction IDs (both virtual and permanent IDs), and general database objects. Also, the right to extend a relation is represented as a separate lockable object.
Table 159: pg_catalog.pg_locks

<table>
<thead>
<tr>
<th>column</th>
<th>type</th>

</tbody>
</table>

**pg_opclass**

The `pg_opclass` system catalog table defines index access method operator classes. Each operator class defines semantics for index columns of a particular data type and a particular index access method. Note that there can be multiple operator classes for a given data type/access method combination, thus supporting multiple behaviors. The majority of the information defining an operator class is actually not in its `pg_opclass` row, but in the associated rows in `pg_amop` and `pg_amproc`. Those rows are considered to be part of the operator class definition — this is not unlike the way that a relation is defined by a single `pg_class` row plus associated rows in `pg_attribute` and other tables.

Table 162: `pg_catalog.pg_opclass`

<table>
<thead>
<tr>
<th>column</th>
<th>type</th>
<th>references</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>
<td>opcamid</td>
<td>oid</td>
<td><code>pg_am.oid</code></td>
<td>Index access method operator class is for.</td>
</tr>
<tr>
<td>opcname</td>
<td>name</td>
<td></td>
<td>Name of this operator class</td>
</tr>
<tr>
<td>opcnamespace</td>
<td>oid</td>
<td><code>pg_namespace.oid</code></td>
<td>Namespace of this operator class</td>
</tr>
<tr>
<td>opcowner</td>
<td>oid</td>
<td><code>pg_authid.oid</code></td>
<td>Owner of the operator class</td>
</tr>
<tr>
<td>opcintype</td>
<td>oid</td>
<td><code>pg_type.oid</code></td>
<td>Data type that the operator class indexes.</td>
</tr>
<tr>
<td>opcdefault</td>
<td>boolean</td>
<td></td>
<td>True if this operator class is the default for the data type opcintype.</td>
</tr>
<tr>
<td>opckeytype</td>
<td>oid</td>
<td><code>pg_type.oid</code></td>
<td>Type of data stored in index, or zero if same as opcintype.</td>
</tr>
</tbody>
</table>
**pg_operator**

The `pg_operator` system catalog table stores information about operators, both built-in and those defined by `CREATE OPERATOR`. Unused columns contain zeroes. For example, `oprleft` is zero for a prefix operator.

<table>
<thead>
<tr>
<th>column</th>
<th>type</th>
<th>references</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>
<td>oprname</td>
<td>name</td>
<td></td>
<td>Name of the operator.</td>

<tr>
<td>oprjoin</td>
<td>regproc</td>
<td>pg_proc.oid</td>
<td>Join selectivity estimation function for this operator.</td>
</tr>
</tbody>
</table>

**pg_partition**

The `pg_partition` system catalog table is used to track partitioned tables and their inheritance level relationships. Each row of `pg_partition` represents either the level of a partitioned table in the partition hierarchy, or a subpartition template description. The value of the attribute `paristemplate` determines what a particular row represents.

**Table 164: pg_catalog.pg_partition**

<table>
<thead>
<tr>
<th>column</th>
<th>type</th>
<th>references</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>
<td>parrelid</td>
<td>oid</td>
<td>pg_class.oid</td>
<td>The object identifier of the table.</td>
</tr>
<tr>
<td>parkind</td>
<td>char</td>
<td></td>
<td>The partition type - R for range or L for list.</td>
</tr>
<tr>
<td>parlevel</td>
<td>smallint</td>
<td></td>
<td>The partition level of this row: 0 for the top-level parent table, 1 for the first level under the parent table, 2 for the second level, and so on.</td>
</tr>
<tr>
<td>paristemplate</td>
<td>boolean</td>
<td></td>
<td>Whether or not this row represents a subpartition template definition (true) or an actual partitioning level (false).</td>
</tr>
<tr>
<td>parnatts</td>
<td>smallint</td>
<td></td>
<td>The number of attributes that define this level.</td>
</tr>
<tr>
<td>column</td>
<td>type</td>
<td>references</td>
<td>description</td>
</tr>
<tr>
<td>---------</td>
<td>-------------</td>
<td>--------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>paratts</td>
<td>smallint()</td>
<td></td>
<td>An array of the attribute numbers (as in <code>pg_attribute.attnum</code>) of the attributes that participate in defining this level.</td>
</tr>
<tr>
<td>parclass</td>
<td>oidvector</td>
<td><code>pg_opclass.oid</code></td>
<td>The operator class identifier(s) of the partition columns.</td>
</tr>
</tbody>
</table>

**pg_partition_columns**

The `pg_partition_columns` system view is used to show the partition key columns of a partitioned table.

**Table 165: pg_catalog.pg_partition_columns**

<table>
<thead>
<tr>
<th>column</th>
<th>type</th>
<th>references</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>
<td>schemaname</td>
<td>name</td>
<td></td>
<td>The name of the schema the partitioned table is in.</td>
</tr>
<tr>
<td>tablename</td>
<td>name</td>
<td></td>
<td>The table name of the top-level parent table.</td>
</tr>
<tr>
<td>columnname</td>
<td>name</td>
<td></td>
<td>The name of the partition key column.</td>
</tr>
<tr>
<td>partitionlevel</td>
<td>smallint</td>
<td></td>
<td>The level of this subpartition in the hierarchy.</td>
</tr>
<tr>
<td>position_in_partition_key</td>
<td>integer</td>
<td></td>
<td>For list partitions you can have a composite (multi-column) partition key. This shows the position of the column in a composite key.</td>
</tr>
</tbody>
</table>

**pg_partition_encoding**

The `pg_partition_encoding` system catalog table describes the available column compression options for a partition template.

**Table 166: pg_catalog.pg_attribute_encoding**

<table>
<thead>
<tr>
<th>column</th>
<th>type</th>
<th>modifiers</th>
<th>storage</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>
<td>parencoid</td>
<td>oid</td>
<td>not null</td>
<td>plain</td>

</tr>
<tr>
<td>parencattnum</td>
<td>smallint</td>
<td>not null</td>
<td>plain</td>
<td></td>
</tr>
<tr>
<td>parencattoptions</td>
<td>text [ ]</td>
<td></td>
<td>extended</td>
<td></td>
</tr>
</tbody>
</table>
**pg_partition_rule**

The `pg_partition_rule` system catalog table is used to track partitioned tables, their check constraints, and data containment rules. Each row of `pg_partition_rule` represents either a leaf partition (the bottom level partitions that contain data), or a branch partition (a top or mid-level partition that is used to define the partition hierarchy, but does not contain any data).

**Table 167: pg_catalog.pg_partition_rule**

<table>
<thead>
<tr>
<th>column</th>
<th>type</th>
<th>references</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>
<td>paroid</td>
<td>oid</td>
<td>pg_partition.oid</td>
<td>Row identifier of the partitioning level (from <code>pg_partition</code>) to which this partition belongs. In the case of a branch partition, the corresponding table (identified by <code>pg_partition_rule</code>) is an empty container table. In case of a leaf partition, the table contains the rows for that partition containment rule.</td>
</tr>
<tr>
<td>parchildrelid</td>
<td>oid</td>
<td>pg_class.oid</td>
<td>The table identifier of the partition (child table).</td>
</tr>
<tr>
<td>parparentrule</td>
<td>oid</td>
<td>pg_partition_rule.paroid</td>

<td>name</td>
<td></td>
<td>The given name of this partition.</td>
</tr>
<tr>
<td>parisdefault</td>
<td>boolean</td>
<td></td>
<td>Whether or not this partition is a default partition.</td>
</tr>
<tr>
<td>parruleord</td>
<td>smallint</td>
<td></td>
<td>For range partitioned tables, the rank of this partition on this level of the partition hierarchy.</td>
</tr>
<tr>
<td>parrangestartincl</td>
<td>boolean</td>
<td></td>
<td>For range partitioned tables, whether or not the starting value is inclusive.</td>
</tr>
<tr>
<td>parrangeendincl</td>
<td>boolean</td>
<td></td>
<td>For range partitioned tables, whether or not the ending value is inclusive.</td>
</tr>
<tr>
<td>parrangestart</td>
<td>text</td>
<td></td>
<td>For range partitioned tables, the starting value of the range.</td>
</tr>
</tbody>
</table>
### pg_partition_templates

The `pg_partition_templates` system view is used to show the subpartitions that were created using a subpartition template.

**Table 168: pg_catalog.pg_partitionTemplates**

<table>
<thead>
<tr>
<th>column</th>
<th>type</th>
<th>references</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>
<td>schemaname</td>
<td>name</td>
<td></td>
<td>The name of the schema the partitioned table is in.</td>

</tr>
</tbody>
</table>
The `pg_pltemplate` system catalog table stores template information for procedural languages. A template for a language allows the language to be created in a particular database by a simple `CREATE LANGUAGE` command, with no need to specify implementation details. Unlike most system catalogs, `pg_pltemplate` is shared across all databases of Greenplum system: there is only one copy of `pg_pltemplate` per system, not one per database. This allows the information to be accessible in each database as it is needed.

There are not currently any commands that manipulate procedural language templates; to change the built-in information, a superuser must modify the table using ordinary `INSERT`, `DELETE`, or `UPDATE` commands.

### Table 170: `pg_catalog.pg_pltemplate`

<table>
<thead>
<tr>
<th>column</th>
<th>type</th>
<th>references</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>

<td>text</td>
<td></td>
<td>Path of shared library that implements language</td>
</tr>
<tr>
<td>tmplacl</td>
<td>aclitem[]</td>
<td></td>
<td>Access privileges for template (not yet implemented).</td>
</tr>
</tbody>
</table>

The `pg_proc` system catalog table stores information about functions (or procedures), both built-in functions and those defined by `CREATE FUNCTION`. The table contains data for aggregate and window functions as well as plain functions. If `proisagg` is true, there should be a matching row in `pg_aggregate`. If `proiswin` is true, there should be a matching row in `pg_window`.

For compiled functions, both built-in and dynamically loaded, `prosrc` contains the function's C-language name (link symbol). For all other currently-known language types, `prosrc` contains the function's source text. `probin` is unused except for dynamically-loaded C functions, for which it gives the name of the shared library file containing the function.

### Table 171: `pg_catalog.pg_proc`

<table>
<thead>
<tr>
<th>column</th>
<th>type</th>
<th>references</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>
<td>proname</td>
<td>name</td>

<tr>
<td>proargdefaults</td>
<td>text</td>
<td></td>
<td>Expression trees for default argument values. This is a list with proargdefaults elements, corresponding to the last $N$ input arguments (i.e., the last $N$ proargtypes positions). If none of the arguments have defaults, this field is empty.</td>
</tr>
<tr>
<td>prosrc</td>
<td>text</td>
<td></td>
<td>This tells the function handler how to invoke the function. It might be the actual source code of the function for interpreted languages, a link symbol, a file name, or just about anything else, depending on the implementation language/call convention.</td>
</tr>
<tr>
<td>probin</td>
<td>bytea</td>
<td></td>
<td>Additional information about how to invoke the function. Again, the interpretation is language-specific.</td>
</tr>
</tbody>
</table>
### pg_resgroup

**Note:** The `pg_resgroup` system catalog table is valid only when resource group-based resource management is active.

The `pg_resgroup` system catalog table contains information about Greenplum Database resource groups, which are used for managing concurrent statements, CPU, and memory resources. This table, defined in the `pg_global` tablespace, is globally shared across all databases in the system.

**Table 172: pg_catalog.pg_resgroup**

<table>
<thead>
<tr>
<th>column</th>
<th>type</th>
<th>references</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>
<td>rsgname</td>
<td>name</td>
<td></td>
<td>The name of the resource group.</td>
</tr>
<tr>
<td>parent</td>
<td>oid</td>
<td></td>
<td>Unused; reserved for future use.</td>
</tr>
</tbody>
</table>

### pg_resgroupcapability

**Note:** The `pg_resgroupcapability` system catalog table is valid only when resource group-based resource management is active.

The `pg_resgroupcapability` system catalog table contains information about the capabilities and limits of defined Greenplum Database resource groups. You can join this table to the `pg_resgroup` table by resource group object ID.

The `pg_resgroupcapability` table, defined in the `pg_global` tablespace, is globally shared across all databases in the system.

**Table 173: pg_catalog.pg_resgroupcapability**

<table>
<thead>
<tr>
<th>column</th>
<th>type</th>
<th>references</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>
<td>resgroupid</td>
<td>oid</td>
<td>pg_resgroup.oid</td>
<td>The object ID of the associated resource group.</td>
</tr>
</tbody>
</table>
### pg_resourcetype

The `pg_resourcetype` system catalog table contains information about the extended attributes that can be assigned to Greenplum Database resource queues. Each row details an attribute and inherent qualities such as its default setting, whether it is required, and the value to disable it (when allowed).

This table is populated only on the master. This table is defined in the `pg_global` tablespace, meaning it is globally shared across all databases in the system.

#### Table 174: pg_catalog.pg_resourcetype

<table>
<thead>
<tr>
<th>column</th>
<th>type</th>
<th>references</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>
<td>restypid</td>
<td>smallint</td>
<td></td>
<td>The resource type ID.</td>
</tr>
<tr>
<td>resname</td>
<td>name</td>
<td></td>
<td>The name of the resource type.</td>
</tr>
<tr>
<td>resrequired</td>
<td>boolean</td>
<td></td>
<td>Whether the resource type is required for a valid resource queue.</td>
</tr>
<tr>
<td>column</td>
<td>type</td>
<td>references</td>
<td>description</td>
</tr>
<tr>
<td>---------------</td>
<td>---------</td>

<tr>
<td>reshasdefault</td>
<td>boolean</td>
<td></td>
<td>Whether the resource type has a default value. When true, the default value is specified in reshasdefaultsetting.</td>
</tr>
<tr>
<td>rescandisable</td>
<td>boolean</td>
<td></td>
<td>Whether the type can be removed or disabled. When true, the default value is specified in rescandisablesetting.</td>
</tr>
<tr>
<td>resdefaultsetting</td>
<td>text</td>
<td></td>
<td>Default setting for the resource type, when applicable.</td>
</tr>
<tr>
<td>rescdisabledsetting</td>
<td>text</td>
<td></td>
<td>The value that disables this resource type (when allowed).</td>
</tr>
</tbody>
</table>

**pg_resqueue**

Note: The *pg_resqueue* system catalog table is valid only when resource queue-based resource management is active.

The *pg_resqueue* system catalog table contains information about Greenplum Database resource queues, which are used for the resource management feature. This table is populated only on the master. This table is defined in the *pg_global* tablespace, meaning it is globally shared across all databases in the system.

**Table 175: pg_catalog.pg_resqueue**

<table>
<thead>
<tr>
<th>column</th>
<th>type</th>
<th>references</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>
<td>rsqname</td>
<td>name</td>
<td></td>
<td>The name of the resource queue.</td>
</tr>
<tr>
<td>rsqcountlimit</td>
<td>real</td>
<td></td>
<td>The active query threshold of the resource queue.</td>
</tr>
<tr>
<td>rsqcostlimit</td>
<td>real</td>
<td></td>
<td>The query cost threshold of the resource queue.</td>
</tr>
<tr>
<td>rsqovercommit</td>
<td>boolean</td>
<td></td>
<td>Allows queries that exceed the cost threshold to run when the system is idle.</td>
</tr>
<tr>
<td>rsqignorecostlimit</td>
<td>real</td>
<td></td>
<td>The query cost limit of what is considered a 'small query'. Queries with a cost under this limit will not be queued and run immediately.</td>
</tr>
</tbody>
</table>
**pg_resqueue_attributes**

*Note:* The `pg_resqueue_attributes` view is valid only when resource queue-based resource management is active.

The `pg_resqueue_attributes` view allows administrators to see the attributes set for a resource queue, such as its active statement limit, query cost limits, and priority.

**Table 176: pg_catalog.pg_resqueue_attributes**

<table>
<thead>
<tr>
<th>column</th>
<th>type</th>
<th>references</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>
<td>rsqname</td>
<td>name</td>
<td>pg_resqueue.rsqname</td>
<td>The name of the resource queue.</td>
</tr>
<tr>
<td>resname</td>
<td>text</td>
<td></td>
<td>The name of the resource queue attribute.</td>
</tr>
<tr>
<td>ressetting</td>
<td>text</td>
<td></td>
<td>The current value of a resource queue attribute.</td>
</tr>
<tr>
<td>restypid</td>
<td>integer</td>
<td></td>
<td>System assigned resource type id.</td>
</tr>
</tbody>
</table>

**pg_resqueuecapability**

*Note:* The `pg_resqueuecapability` system catalog table is valid only when resource queue-based resource management is active.

The `pg_resqueuecapability` system catalog table contains information about the extended attributes, or capabilities, of existing Greenplum Database resource queues. Only resource queues that have been assigned an extended capability, such as a priority setting, are recorded in this table. This table is joined to the `pg_resqueue` table by resource queue object ID, and to the `pg_resourcetype` table by resource type ID (restypid).

This table is populated only on the master. This table is defined in the `pg_global` tablespace, meaning it is globally shared across all databases in the system.

**Table 177: pg_catalog.pg_resqueuecapability**

<table>
<thead>
<tr>
<th>column</th>
<th>type</th>
<th>references</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>
<td>rsqueueid</td>
<td>oid</td>
<td>pg_resqueue.oid</td>
<td>The object ID of the associated resource queue.</td>
</tr>
<tr>
<td>restypid</td>
<td>smallint</td>
<td>pg_resourcetype.</td>
<td>The resource type, derived from the <code>pg_resqueuecapability</code> system table.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>restypid</td>
<td></td>
</tr>
<tr>
<td>ressetting</td>
<td>opaque type</td>
<td></td>
<td>The specific value set for the capability referenced in this record. Depending on the actual resource type, this value may have different data types.</td>
</tr>
</tbody>
</table>
pg_rewrite

The pg_rewrite system catalog table stores rewrite rules for tables and views. pg_class.relhasrules must be true if a table has any rules in this catalog.

Table 178: pg_catalog.pg_rewrite

<table>
<thead>
<tr>
<th>column</th>
<th>type</th>
<th>references</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>
<td>rulename</td>
<td>name</td>
<td></td>
<td>Rule name.</td>
</tr>
<tr>

<td>int2</td>
<td></td>
<td>The column this rule is for (currently, always zero to indicate the whole table).</td>
</tr>
<tr>
<td>ev_type</td>
<td>char</td>
<td></td>
<td>Event type that the rule is for: 1 = SELECT, 2 = UPDATE, 3 = INSERT, 4 = DELETE.</td>
</tr>
<tr>
<td>is_instead</td>
<td>boolean</td>
<td></td>
<td>True if the rule is an INSTEAD rule.</td>
</tr>
<tr>
<td>ev_qual</td>
<td>text</td>
<td></td>
<td>Expression tree (in the form of a nodeToString() representation) for the rule's qualifying condition.</td>
</tr>
<tr>
<td>ev_action</td>
<td>text</td>
<td></td>
<td>Query tree (in the form of a nodeToString() representation) for the rule's action.</td>
</tr>
</tbody>
</table>

pg_roles

The view pg_roles provides access to information about database roles. This is simply a publicly readable view of pg_authid that blanks out the password field. This view explicitly exposes the OID column of the underlying table, since that is needed to do joins to other catalogs.

Table 179: pg_catalog.pg_roles

<table>
<thead>
<tr>
<th>column</th>
<th>type</th>
<th>references</th>
<th>description</th>
</tr>
</thead>

<td>pg_resgroup.oid</td>
<td>Object ID of the resource group to which this role is assigned.</td>
</tr>
</tbody>
</table>

### pg_shdepend

The `pg_shdepend` system catalog table records the dependency relationships between database objects and shared objects, such as roles. This information allows Greenplum Database to ensure that those objects are unreferenced before attempting to delete them. See also `pg_depend`, which performs a similar function for dependencies involving objects within a single database. Unlike most system catalogs, `pg_shdepend` is shared across all databases of Greenplum system: there is only one copy of `pg_shdepend` per system, not one per database.

In all cases, a `pg_shdepend` entry indicates that the referenced object may not be dropped without also dropping the dependent object. However, there are several subflavors identified by `deptype`:

- **SHARED_DEPENDENCY_OWNER (o)** — The referenced object (which must be a role) is the owner of the dependent object.
- **SHARED_DEPENDENCY_ACL (a)** — The referenced object (which must be a role) is mentioned in the ACL (access control list) of the dependent object.
- **SHARED_DEPENDENCY_PIN (p)** — There is no dependent object; this type of entry is a signal that the system itself depends on the referenced object, and so that object must never be deleted. Entries of this type are created only by system initialization. The columns for the dependent object contain zeroes.

#### Table 180: `pg_catalog.pg_shdepend`

<table>
<thead>
<tr>
<th>column</th>
<th>type</th>
<th>references</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dbid</td>
<td>oid</td>
<td>pg_database.oid</td>
<td>The OID of the database the dependent object is in, or zero for a shared object.</td>
</tr>
<tr>
<td>classid</td>
<td>oid</td>
<td>pg_class.oid</td>
<td>The OID of the system catalog the dependent object is in.</td>
</tr>
<tr>
<td>objid</td>
<td>oid</td>
<td>any OID column</td>
<td>The OID of the specific dependent object.</td>
</tr>
<tr>
<td>objsubid</td>
<td>int4</td>
<td></td>
<td>For a table column, this is the column number. For all other object types, this column is zero.</td>
</tr>
<tr>
<td>refclassid</td>
<td>oid</td>
<td>pg_class.oid</td>
<td>The OID of the system catalog the referenced object is in (must be a shared catalog).</td>
</tr>
</tbody>
</table>
### pg_shdescription

The `pg_shdescription` system catalog table stores optional descriptions (comments) for shared database objects. Descriptions can be manipulated with the `COMMENT` command and viewed with `psql`'s `\d` meta-commands. See also `pg_description`, which performs a similar function for descriptions involving objects within a single database. Unlike most system catalogs, `pg_shdescription` is shared across all databases of a Greenplum system: there is only one copy of `pg_shdescription` per system, not one per database.

**Table 181: pg_catalog.pg_shdescription**

<table>
<thead>
<tr>
<th>column</th>
<th>type</th>
<th>references</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>
<td>objoid</td>
<td>oid</td>
<td>any OID column</td>
<td>The OID of the object this description pertains to.</td>
</tr>
<tr>
<td>classoid</td>
<td>oid</td>
<td>pg_class.oid</td>
<td>The OID of the system catalog this object appears in.</td>
</tr>
<tr>
<td>description</td>
<td>text</td>
<td></td>
<td>Arbitrary text that serves as the description of this object.</td>
</tr>
</tbody>
</table>

### pg_stat_activity

The view `pg_stat_activity` shows one row per server process with details about the associated user session and query. The columns that report data on the current query are available unless the parameter `stats_command_string` has been turned off. Furthermore, these columns are only visible if the user examining the view is a superuser or the same as the user owning the process being reported on.

The maximum length of the query text string stored in the column `current_query` can be controlled with the server configuration parameter `pgstat_track_activity_query_size`.

**Table 182: pg_catalog.pg_stat_activity**

<table>
<thead>
<tr>
<th>column</th>
<th>type</th>
<th>references</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>
<td>datid</td>

<td>integer</td>
<td></td>
<td>Client port</td>
</tr>
<tr>
<td>application_name</td>
<td>text</td>
<td></td>
<td>Client application name</td>
</tr>
<tr>
<td>xact_start</td>
<td>timestamptz</td>
<td></td>
<td>Transaction start time</td>
</tr>
<tr>
<td>waiting_reason</td>
<td>text</td>
<td></td>
<td>Reason the server process is waiting. The value can be: lock, replication, or resgroup</td>
</tr>
<tr>
<td>rsgid</td>
<td>oid</td>
<td>pg_resgroup.oid</td>
<td>Resource group OID or 0</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>See Note.</td>
</tr>
<tr>
<td>rsgname</td>
<td>text</td>
<td>pg_resgroup.rsgname</td>
<td>Resource group name or unknown. See Note.</td>
</tr>
<tr>
<td>rsgqueueduration</td>
<td>interval</td>
<td></td>
<td>For a queued query, the total time the query has been queued.</td>
</tr>
</tbody>
</table>

Note: When resource groups are enabled. Only query dispatcher (QD) processes will have a rsgid and rsgname. Other server processes such as a query executer (QE) process or session connection processes will have a rsgid value of 0 and a rsgname value of unknown. QE processes are managed by the same resource group as the dispatching QD process.

**pg_stat_last_operation**

The pg_stat_last_operation table contains metadata tracking information about database objects (tables, views, etc.).
### Table 183: pg_catalog.pg_stat_last_operation

<table>
<thead>
<tr>
<th>column</th>
<th>type</th>
<th>references</th>
<th>description</th>
</tr>
</thead>
<tbody>

<td>WAL sender synchronization state. The value is sync.</td>
</tr>
</tbody>
</table>

### pg_statistic

The `pg_statistic` system catalog table stores statistical data about the contents of the database. Entries are created by `ANALYZE` and subsequently used by the query optimizer. There is one entry for each table column that has been analyzed. Note that all the statistical data is inherently approximate, even assuming that it is up-to-date.

`pg_statistic` also stores statistical data about the values of index expressions. These are described as if they were actual data columns; in particular, `starelid` references the index. No entry is made for
an ordinary non-expression index column, however, since it would be redundant with the entry for the underlying table column.

Since different kinds of statistics may be appropriate for different kinds of data, `pg_statistic` is designed not to assume very much about what sort of statistics it stores. Only extremely general statistics (such as nullness) are given dedicated columns in `pg_statistic`. Everything else is stored in slots, which are groups of associated columns whose content is identified by a code number in one of the slot's columns.

Statistical information about a table's contents should be considered sensitive (for example: minimum and maximum values of a salary column). `pg_stats` is a publicly readable view on `pg_statistic` that only exposes information about those tables that are readable by the current user.

**Warning:** Diagnostic tools such as `gpsd` and `minirepro` collect sensitive information from `pg_statistic`, such as histogram boundaries, in a clear, readable form. Always review the output files of these utilities to ensure that the contents are acceptable for transport outside of the database in your organization.

<table>
<thead>
<tr>
<th>column</th>
<th>type</th>
<th>references</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>
<td>starelid</td>
<td>oid</td>
<td>pg_class.oid</td>
<td>The table or index that the described column belongs to.</td>

<tr>
<td>staattnum</td>
<td>int2</td>
<td>pg_attribute.attnum</td>
<td>The number of the described column.</td>
</tr>
<tr>
<td>stanullfrac</td>
<td>float4</td>
<td></td>
<td>The fraction of the column's entries that are null.</td>
</tr>
<tr>
<td>stawidth</td>
<td>int4</td>
<td></td>
<td>The average stored width, in bytes, of nonnull entries.</td>
</tr>
<tr>
<td>stadistinct</td>
<td>float4</td>
<td></td>
<td>The number of distinct nonnull data values in the column. A value greater than zero is the actual number of distinct values. A value less than zero is the negative of a fraction of the number of rows in the table (for example, a column in which values appear about twice on the average could be represented by <code>stadistinct = -0.5</code>). A zero value means the number of distinct values is unknown.</td>
</tr>
<tr>
<td>column</td>
<td>type</td>
<td>references</td>
<td>description</td>
</tr>
<tr>
<td>----------</td>
<td>----------</td>
<td>------------</td>
<td>----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>stakindN</td>
<td>int2</td>

<td>float4[]</td>
<td></td>
<td>Numerical statistics of the appropriate kind for the Nth slot, or NULL if the slot kind does not involve numerical values.</td>
</tr>
<tr>
<td>stavaluesN</td>
<td>anyarray</td>
<td></td>
<td>Column data values of the appropriate kind for the Nth slot, or NULL if the slot kind does not store any data values. Each array's element values are actually of the specific column's data type, so there is no way to define these columns' type more specifically than anyarray.</td>
</tr>
</tbody>
</table>

**pg_stat_resqueues**

**Note:** The pg_stat_resqueues view is valid only when resource queue-based resource management is active.

The pg_stat_resqueues view allows administrators to view metrics about a resource queue's workload over time. To allow statistics to be collected for this view, you must enable the stats_queue_level server configuration parameter on the Greenplum Database master instance. Enabling the collection of these metrics does incur a small performance penalty, as each statement submitted through a resource queue must be logged in the system catalog tables.

**Table 189: pg_catalog.pg_stat_resqueues**

<table>
<thead>
<tr>
<th>column</th>
<th>type</th>
<th>references</th>
<th>description</th>

<td></td>
<td>Total elapsed execution time for statements submitted through this resource queue.</td>
</tr>
<tr>
<td>elapsed_wait</td>
<td>bigint</td>
<td></td>
<td>Total elapsed time that statements submitted through this resource queue had to wait before they were executed.</td>
</tr>
</tbody>
</table>

**pg_tablespace**

The `pg_tablespace` system catalog table stores information about the available tablespaces. Tables can be placed in particular tablespaces to aid administration of disk layout. Unlike most system catalogs, `pg_tablespace` is shared across all databases of a Greenplum system: there is only one copy of `pg_tablespace` per system, not one per database.

**Table 190: pg_catalog.pg_tablespace**

<table>
<thead>

<td>pg_filespace.oid</td>
<td>The object id of the filesystem used by this tablespace. A filesystem defines directory locations on the primary, mirror and master segments.</td>
</tr>
</tbody>
</table>
**pg_trigger**

The `pg_trigger` system catalog table stores triggers on tables.

**Note:** Greenplum Database does not support triggers.

### Table 191: `pg_catalog.pg_trigger`

<table>
<thead>
<tr>
<th>column</th>
<th>type</th>
<th>references</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>
<td>tgrelid</td>
<td>oid</td>
<td><code>pg_class.oid</code></td>
<td>The table this trigger is on.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Note that Greenplum Database does not enforce referential integrity.</td>
<td></td>
</tr>
<tr>
<td>tgname</td>
<td>name</td>
<td></td>
<td>Trigger name (must be unique among triggers of same table).</td>
</tr>
<tr>
<td>tgfoid</td>
<td>oid</td>
<td><code>pg_proc.oid</code></td>
<td>The function to be called.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Note that Greenplum Database does not enforce referential integrity.</td>
<td></td>
</tr>
<tr>
<td>tgttype</td>
<td>int2</td>
<td></td>
<td>Bit mask identifying trigger conditions.</td>
</tr>
<tr>
<td>tgenabled</td>
<td>boolean</td>
<td></td>
<td>True if trigger is enabled.</td>
</tr>
<tr>
<td>tgisconstraint</td>
<td>boolean</td>
<td></td>
<td>True if trigger implements a referential integrity constraint.</td>
</tr>
<tr>
<td>tgconstrname</td>
<td>name</td>
<td></td>
<td>Referential integrity constraint name.</td>
</tr>
<tr>

<td></td>
<td>Currently not used.</td>
</tr>
<tr>
<td>tgargs</td>
<td>bytea</td>
<td></td>
<td>Argument strings to pass to trigger, each NULL-terminated.</td>
</tr>
</tbody>
</table>
**pg_type**

The `pg_type` system catalog table stores information about data types. Base types (scalar types) are created with `CREATE TYPE`, and domains with `CREATE DOMAIN`. A composite type is automatically created for each table in the database, to represent the row structure of the table. It is also possible to create composite types with `CREATE TYPE AS`.

**Table 192: pg_catalog.pg_type**

<table>
<thead>
<tr>
<th>column</th>
<th>type</th>
<th>references</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>
<td>typname</td>
<td>name</td>
<td></td>
<td>Data type name.</td>
</tr>
<tr>

<tr>
<td>typanalyze</td>
<td>regproc</td>
<td>pg_proc.oid</td>
<td>Custom <strong>ANALYZE</strong> function, or 0 to use the standard function.</td>
</tr>
</tbody>
</table>
| typalign   | char   |            | The alignment required when storing a value of this type. It applies to storage on disk as well as most representations of the value inside Greenplum Database. When multiple values are stored consecutively, such as in the representation of a complete row on disk, padding is inserted before a datum of this type so that it begins on the specified boundary. The alignment reference is the beginning of the first datum in the sequence. Possible values are:  
  c = char alignment (no alignment needed).  
  s = short alignment (2 bytes on most machines).  
  i = int alignment (4 bytes on most machines).  
  d = double alignment (8 bytes on many machines, but not all). |

<td>User mapping specific options, as &quot;keyword=value&quot; strings.</td>
</tr>
</tbody>
</table>

pg_window

The pg_window table stores information about window functions. Window functions are often used to compose complex OLAP (online analytical processing) queries. Window functions are applied to partitioned result sets within the scope of a single query expression. A window partition is a subset of rows returned by a query, as defined in a special OVER() clause. Typical window functions are rank, dense_rank, and row_number. Each entry in pg_window is an extension of an entry in pg_proc. The pg_proc entry carries the window function’s name, input and output data types, and other information that is similar to ordinary functions.

Table 195: pg_catalog.pg_window

<table>
<thead>
<tr>
<th>column</th>
<th>type</th>
<th>references</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>

<td>char</td>
<td></td>
<td>A character indicating membership of the window function in a class of related functions: w - ordinary window functions n - NTILE functions f - FIRST_VALUE functions l - LAST_VALUE functions g - LAG functions d - LEAD functions</td>
</tr>
</tbody>
</table>
The gp_toolkit Administrative Schema

Greenplum Database provides an administrative schema called gp_toolkit that you can use to query the system catalogs, log files, and operating environment for system status information. The gp_toolkit schema contains a number of views that you can access using SQL commands. The gp_toolkit schema is accessible to all database users, although some objects may require superuser permissions. For convenience, you may want to add the gp_toolkit schema to your schema search path. For example:

```sql
=> ALTER ROLE myrole SET search_path TO myschema,gp_toolkit;
```

This documentation describes the most useful views in gp_toolkit. You may notice other objects (views, functions, and external tables) within the gp_toolkit schema that are not described in this documentation (these are supporting objects to the views described in this section).

**Warning:** Do not change database objects in the gp_toolkit schema. Do not create database objects in the schema. Changes to objects in the schema might affect the accuracy of administrative information returned by schema objects. Any changes made in the gp_toolkit schema are lost when the database is backed up and then restored with the gpbackup and gprestore utilities.

These are the categories for views in the gp_toolkit schema.

Checking for Tables that Need Routine Maintenance

The following views can help identify tables that need routine table maintenance (VACUUM and/or ANALYZE).

- **gp_bloat_diag**
- **gp_stats_missing**

The VACUUM or VACUUM FULL command reclaims disk space occupied by deleted or obsolete rows. Because of the MVCC transaction concurrency model used in Greenplum Database, data rows that are deleted or updated still occupy physical space on disk even though they are not visible to any new transactions. Expired rows increase table size on disk and eventually slow down scans of the table.

The ANALYZE command collects column-level statistics needed by the query optimizer. Greenplum Database uses a cost-based query optimizer that relies on database statistics. Accurate statistics allow the query optimizer to better estimate selectivity and the number of rows retrieved by a query operation in order to choose the most efficient query plan.

**gp_bloat_diag**

This view shows regular heap-storage tables that have bloat (the actual number of pages on disk exceeds the expected number of pages given the table statistics). Tables that are bloated require a VACUUM or a VACUUM FULL in order to reclaim disk space occupied by deleted or obsolete rows. This view is accessible to all users, however non-superusers will only be able to see the tables that they have permission to access.

**Note:** For diagnostic functions that return append-optimized table information, see Checking Append-Optimized Tables.

Table 196: gp_bloat_diag view

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>bdirelid</td>
<td>Table object id.</td>
</tr>
</tbody>
</table>
### Column Description

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>bdinspname</td>
<td>Schema name.</td>
</tr>
<tr>
<td>bdirelname</td>
<td>Table name.</td>
</tr>
<tr>
<td>bdirelpages</td>
<td>Actual number of pages on disk.</td>
</tr>
<tr>
<td>bdixppages</td>
<td>Expected number of pages given the table data.</td>
</tr>
<tr>
<td>bdidiag</td>
<td>Bloat diagnostic message.</td>
</tr>
</tbody>
</table>

### gp_stats_missing

This view shows tables that do not have statistics and therefore may require an `ANALYZE` be run on the table.

**Table 197: gp_stats_missing view**

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>smischema</td>
<td>Schema name.</td>
</tr>
<tr>
<td>smitable</td>
<td>Table name.</td>
</tr>
<tr>
<td>smisize</td>
<td>Does this table have statistics? False if the table does not have row count and row sizing statistics recorded in the system catalog, which may indicate that the table needs to be analyzed. This will also be false if the table does not contain any rows. For example, the parent tables of partitioned tables are always empty and will always return a false result.</td>
</tr>
<tr>
<td>smicols</td>
<td>Number of columns in the table.</td>
</tr>
<tr>
<td>smirecs</td>
<td>Number of rows in the table.</td>
</tr>
</tbody>
</table>

### Checking for Locks

When a transaction accesses a relation (such as a table), it acquires a lock. Depending on the type of lock acquired, subsequent transactions may have to wait before they can access the same relation. For more information on the types of locks, see "Managing Data" in the *Greenplum Database Administrator Guide*. Greenplum Database resource queues (used for resource management) also use locks to control the admission of queries into the system.

The `gp_locks_*` family of views can help diagnose queries and sessions that are waiting to access an object due to a lock.

- `gp_locks_on_relation`
- `gp_locks_on_resqueue`

### gp_locks_on_relation

This view shows any locks currently being held on a relation, and the associated session information about the query associated with the lock. For more information on the types of locks, see "Managing Data" in the *Greenplum Database Administrator Guide*. This view is accessible to all users, however non-superusers will only be able to see the locks for relations that they have permission to access.
## Table 198: gp_locks_on_relation view

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>lorlocktype</td>
<td>Type of the lockable object: relation, extend, page, tuple, transactionid, object, userlock, resource queue, or advisory</td>
</tr>
<tr>
<td>lordatabase</td>
<td>Object ID of the database in which the object exists, zero if the object is a shared object.</td>
</tr>
<tr>
<td>lorrelname</td>
<td>The name of the relation.</td>
</tr>
<tr>
<td>lorrelation</td>
<td>The object ID of the relation.</td>
</tr>
<tr>
<td>lortransaction</td>
<td>The transaction ID that is affected by the lock.</td>
</tr>
<tr>
<td>lorpid</td>
<td>Process ID of the server process holding or awaiting this lock. NULL if the lock is held by a prepared transaction.</td>
</tr>
<tr>
<td>lormode</td>
<td>Name of the lock mode held or desired by this process.</td>
</tr>
<tr>
<td>lorgranted</td>
<td>Displays whether the lock is granted (true) or not granted (false).</td>
</tr>
<tr>
<td>lorcurrentquery</td>
<td>The current query in the session.</td>
</tr>
</tbody>
</table>

## gp_locks_on_resqueue

Note: The `gp_locks_on_resqueue` view is valid only when resource queue-based resource management is active.

This view shows any locks currently being held on a resource queue, and the associated session information about the query associated with the lock. This view is accessible to all users, however non-superusers will only be able to see the locks associated with their own sessions.

## Table 199: gp_locks_on_resqueue view

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>lorusename</td>
<td>Name of the user executing the session.</td>
</tr>
<tr>

<td>The process ID of the transaction that is affected by the lock.</td>
</tr>
<tr>
<td>lormode</td>
<td>The name of the lock mode held or desired by this process.</td>
</tr>
<tr>
<td>lorgranted</td>
<td>Displays whether the lock is granted (true) or not granted (false).</td>
</tr>
<tr>
<td>lorwaiting</td>
<td>Displays whether or not the session is waiting.</td>
</tr>
</tbody>
</table>
Checking Append-Optimized Tables

The gp_toolkit schema includes a set of diagnostic functions you can use to investigate the state of append-optimized tables.

When an append-optimized table (or column-oriented append-optimized table) is created, another table is implicitly created, containing metadata about the current state of the table. The metadata includes information such as the number of records in each of the table's segments.

Append-optimized tables may have non-visible rows—rows that have been updated or deleted, but remain in storage until the table is compacted using VACUUM. The hidden rows are tracked using an auxiliary visibility map table, or visimap.

The following functions let you access the metadata for append-optimized and column-oriented tables and view non-visible rows. Some of the functions have two versions: one that takes the oid of the table, and one that takes the name of the table. The latter version has "_name" appended to the function name.

__gp_aovisimap_compaction_info(oid)

This function displays compaction information for an append-optimized table. The information is for the on-disk data files on Greenplum Database segments that store the table data. You can use the information to determine the data files that will be compacted by a VACUUM operation on an append-optimized table.

Note: Until a VACUUM operation deletes the row from the data file, deleted or updated data rows occupy physical space on disk even though they are hidden to new transactions. The configuration parameter gp_appendonly_compaction controls the functionality of the VACUUM command.

This table describes the __gp_aovisimap_compaction_info function output table.

Table 200: __gp_aovisimap_compaction_info output table

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>content</td>
<td>Greenplum Database segment ID.</td>
</tr>
<tr>
<td>datafile</td>
<td>ID of the data file on the segment.</td>
</tr>
<tr>
<td>compaction_possible</td>
<td>The value is either t or f. The value t indicates that the data in data file be compacted when a VACUUM operation is performed. The server configuration parameter gp_appendonly_compaction_threshold affects this value.</td>
</tr>
<tr>
<td>hidden_tupcount</td>
<td>In the data file, the number of hidden (deleted or updated) rows.</td>
</tr>
<tr>
<td>total_tupcount</td>
<td>In the data file, the total number of rows.</td>
</tr>
<tr>
<td>percent_hidden</td>
<td>In the data file, the ratio (as a percentage) of hidden (deleted or updated) rows to total rows.</td>
</tr>
</tbody>
</table>

__gp_aoseg_name('table_name')

This function returns metadata information contained in the append-optimized table's on-disk segment file.
**Table 201: __gp_aoseg_name output table**

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>segno</td>
<td>The file segment number.</td>
</tr>
<tr>
<td>eof</td>
<td>The effective end of file for this file segment.</td>
</tr>
<tr>
<td>tupcount</td>
<td>The total number of tuples in the segment, including invisible tuples.</td>
</tr>
<tr>
<td>varblockcount</td>
<td>The total number of varblocks in the file segment.</td>
</tr>
<tr>
<td>eof_uncompressed</td>
<td>The end of file if the file segment were uncompressed.</td>
</tr>
<tr>
<td>modcount</td>
<td>The number of data modification operations.</td>
</tr>
<tr>
<td>state</td>
<td>The state of the file segment. Indicates if the segment is active or ready to be dropped after compaction.</td>
</tr>
</tbody>
</table>

**__gp_aoseg_history(oid)**

This function returns metadata information contained in the append-optimized table's on-disk segment file. It displays all different versions (heap tuples) of the aoseg meta information. The data is complex, but users with a deep understanding of the system may find it useful for debugging.

The input argument is the oid of the append-optimized table.

Call __gp_aoseg_history_name("table_name") to get the same result with the table name as an argument.

**Table 202: __gp_aoseg_history output table**

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>

<td>The id of the query command.</td>
</tr>
<tr>
<td>gp_infomask</td>
<td>A bitmap containing state information.</td>
</tr>
<tr>
<td>gp_update_tid</td>
<td>The ID of the newer tuple if the row is updated.</td>
</tr>
<tr>
<td>gp_visibility</td>
<td>The tuple visibility status.</td>
</tr>
<tr>
<td>segno</td>
<td>The number of the segment in the segment file.</td>
</tr>
<tr>
<td>tupcount</td>
<td>The number of tuples, including hidden tuples.</td>
</tr>
<tr>
<td>eof</td>
<td>The effective end of file for the segment.</td>
</tr>
<tr>
<td>Column</td>
<td>Description</td>
</tr>
<tr>
<td>---------------</td>
<td>-----------------------------------------------------------</td>
</tr>
<tr>
<td>eof_uncompressed</td>
<td>The end of file for the segment if data were uncompressed.</td>
</tr>
<tr>
<td>modcount</td>
<td>A count of data modifications.</td>
</tr>
<tr>
<td>state</td>
<td>The status of the segment.</td>
</tr>
</tbody>
</table>

__gp_aocsseg(oid)__.  
This function returns metadata information contained in a column-oriented append-optimized table’s on-disk segment file, excluding non-visible rows. Each row describes a segment for a column in the table.

The input argument is the oid of a column-oriented append-optimized table. Call as __gp_aocsseg_name('table_name')__ to get the same result with the table name as an argument.

Table 203: __gp_aocsseg(oid) output table

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>gp_tid</td>
<td>The table id.</td>
</tr>
<tr>
<td>segno</td>
<td>The segment number.</td>
</tr>
<tr>
<td>column_num</td>
<td>The column number.</td>
</tr>
<tr>
<td>physical_segno</td>
<td>The number of the segment in the segment file.</td>
</tr>
<tr>
<td>tupcount</td>
<td>The number of rows in the segment, excluding hidden tuples.</td>
</tr>
<tr>
<td>eof</td>
<td>The effective end of file for the segment.</td>
</tr>
<tr>
<td>eof_uncompressed</td>
<td>The end of file for the segment if the data were uncompressed.</td>
</tr>
<tr>
<td>modcount</td>
<td>A count of data modification operations for the segment.</td>
</tr>
<tr>
<td>state</td>
<td>The status of the segment.</td>
</tr>
</tbody>
</table>

__gp_aocsseg_history(oid)__.  
This function returns metadata information contained in a column-oriented append-optimized table’s on-disk segment file. Each row describes a segment for a column in the table. The data is complex, but users with a deep understanding of the system may find it useful for debugging.

The input argument is the oid of a column-oriented append-optimized table. Call as __gp_aocsseg_history_name('table_name')__ to get the same result with the table name as argument.

Table 204: __gp_aocsseg_history output table

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>gp_tid</td>
<td>The oid of the tuple.</td>
</tr>
<tr>
<td>gp_xmin</td>
<td>The earliest transaction.</td>
</tr>
<tr>
<td>gp_xmin_status</td>
<td>The status of the gp_xmin transaction.</td>
</tr>
<tr>
<td>gp_xmin</td>
<td>Text representation of gp_xmin.</td>
</tr>
<tr>
<td>Column</td>
<td>Description</td>
</tr>
<tr>
<td>---------------------</td>
<td>--------------------------------------------------</td>
</tr>
<tr>
<td>gp_xmax</td>
<td>The latest transaction.</td>
</tr>
<tr>
<td>gp_xmax_status</td>
<td>The status of the gp_xmax transaction.</td>
</tr>
<tr>
<td>gp_xmax</td>
<td>Text representation of gp_max.</td>
</tr>
<tr>
<td>gp_command_id</td>
<td>ID of the command operating on the tuple.</td>
</tr>
<tr>
<td>gp_infomask</td>
<td>A bitmap containing state information.</td>
</tr>
<tr>
<td>gp_update_tid</td>
<td>The ID of the newer tuple if the row is updated.</td>
</tr>
<tr>
<td>gp_visibility</td>
<td>The tuple visibility status.</td>
</tr>
<tr>
<td>segno</td>
<td>The segment number in the segment file.</td>
</tr>
<tr>
<td>column_num</td>
<td>The column number.</td>
</tr>
<tr>
<td>physical_segno</td>
<td>The segment containing data for the column.</td>
</tr>
<tr>
<td>tupcount</td>
<td>The total number of tuples in the segment.</td>
</tr>
<tr>
<td>eof</td>
<td>The effective end of file for the segment.</td>
</tr>
<tr>
<td>eof_uncompressed</td>
<td>The end of file for the segment if the data were uncompressed.</td>
</tr>
<tr>
<td>modcount</td>
<td>A count of the data modification operations.</td>
</tr>
<tr>
<td>state</td>
<td>The state of the segment.</td>
</tr>
</tbody>
</table>

__gp_aovisimap(oid)__

This function returns the tuple id, the segment file, and the row number of each non-visible tuple according to the visibility map.

The input argument is the oid of an append-optimized table.

Use __gp_aovisimap_name('table_name') to get the same result with the table name as argument.

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>tid</td>
<td>The tuple id.</td>
</tr>
<tr>
<td>segno</td>
<td>The number of the segment file.</td>
</tr>
<tr>
<td>row_num</td>
<td>The row number of a row that has been deleted or updated.</td>
</tr>
</tbody>
</table>

__gp_aovisimap_hidden_info(oid)__

This function returns the numbers of hidden and visible tuples in the segment files for an append-optimized table.

The input argument is the oid of the append-optimized table.

Call __gp_aovisimap_hidden_info_name('table_name') to get the same result with a table name argument.

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>segno</td>
<td>The number of the segment file.</td>

<tr>
<td>hidden_tupcount</td>
<td>The number of hidden tuples in the segment file.</td>
</tr>
<tr>
<td>Column</td>
<td>Description</td>
</tr>
<tr>
<td>--------------</td>
<td>--------------------------------------------------</td>
</tr>
<tr>
<td>total_tupcount</td>
<td>The total number of tuples in the segment file.</td>
</tr>
</tbody>
</table>

__gp_aovisimap_entry(oid)\
This function returns information about each visibility map entry for the table.
The input argument is the oid of an append-optimized table.
Call __gp_aovisimap_entry_name('table_name') to get the same result with a table name argument.

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>segno</td>
<td>Segment number of the visibility map entry.</td>
</tr>
<tr>
<td>first_row_num</td>
<td>The first row number of the entry.</td>
</tr>
<tr>
<td>hidden_tupcount</td>
<td>The number of hidden tuples in the entry.</td>
</tr>
<tr>
<td>bitmap</td>
<td>A text representation of the visibility bitmap.</td>
</tr>
</tbody>
</table>

**Viewing Greenplum Database Server Log Files**

Each component of a Greenplum Database system (master, standby master, primary segments, and mirror segments) keeps its own server log files. The gp_log_* family of views allows you to issue SQL queries against the server log files to find particular entries of interest. The use of these views require superuser permissions.

- gp_log_command_timings
- gp_log_database
- gp_log_master_concise
- gp_log_system

**gp_log_command_timings**

This view uses an external table to read the log files on the master and report the execution time of SQL commands executed in a database session. The use of this view requires superuser permissions.

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>logsession</td>
<td>The session identifier (prefixed with &quot;con&quot;).</td>
</tr>
<tr>
<td>logcmdcount</td>
<td>The command number within a session (prefixed with &quot;cmd&quot;).</td>
</tr>
<tr>
<td>logdatabase</td>
<td>The name of the database.</td>
</tr>
<tr>
<td>loguser</td>
<td>The name of the database user.</td>
</tr>
<tr>
<td>logpid</td>
<td>The process id (prefixed with &quot;p&quot;).</td>
</tr>
<tr>
<td>logtimemin</td>
<td>The time of the first log message for this command.</td>
</tr>
<tr>
<td>logtimemax</td>
<td>The time of the last log message for this command.</td>
</tr>
<tr>
<td>logduration</td>
<td>Statement duration from start to end time.</td>
</tr>
</tbody>
</table>
gp_log_database

This view uses an external table to read the server log files of the entire Greenplum system (master, segments, and mirrors) and lists log entries associated with the current database. Associated log entries can be identified by the session id (logsession) and command id (logcmdcount). The use of this view requires superuser permissions.

**Table 207: gp_log_database view**

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>logtime</td>
<td>The timestamp of the log message.</td>
</tr>
<tr>
<td>loguser</td>
<td>The name of the database user.</td>
</tr>
<tr>
<td>logdatabase</td>
<td>The name of the database.</td>
</tr>
<tr>
<td>logpid</td>
<td>The associated process id (prefixed with &quot;p&quot;).</td>
</tr>
<tr>
<td>logthread</td>
<td>The associated thread count (prefixed with &quot;th&quot;).</td>
</tr>
<tr>
<td>loghost</td>
<td>The segment or master host name.</td>
</tr>
<tr>
<td>logport</td>
<td>The segment or master port.</td>
</tr>
<tr>
<td>logsessiontime</td>
<td>Time session connection was opened.</td>
</tr>
<tr>
<td>logtransaction</td>
<td>Global transaction id.</td>
</tr>
<tr>
<td>logsession</td>
<td>The session identifier (prefixed with &quot;con&quot;).</td>
</tr>
<tr>
<td>logcmdcount</td>
<td>The command number within a session (prefixed with &quot;cmd&quot;).</td>
</tr>
<tr>
<td>logsegment</td>
<td>The segment content identifier (prefixed with &quot;seg&quot; for primary or &quot;mir&quot; for mirror. The master always has a content id of -1).</td>
</tr>
<tr>
<td>logslice</td>
<td>The slice id (portion of the query plan being executed).</td>
</tr>
<tr>
<td>logdistxact</td>
<td>Distributed transaction id.</td>
</tr>
<tr>
<td>loglocalxact</td>
<td>Local transaction id.</td>
</tr>
<tr>
<td>logsubxact</td>
<td>Subtransaction id.</td>
</tr>
<tr>
<td>logseverity</td>
<td>LOG, ERROR, FATAL, PANIC, DEBUG1 or DEBUG2.</td>
</tr>
<tr>
<td>logstate</td>
<td>SQL state code associated with the log message.</td>
</tr>
<tr>
<td>logmessage</td>
<td>Log or error message text.</td>
</tr>
<tr>
<td>logdetail</td>
<td>Detail message text associated with an error message.</td>
</tr>
<tr>
<td>loghint</td>
<td>Hint message text associated with an error message.</td>
</tr>
<tr>
<td>logquery</td>
<td>The internally-generated query text.</td>
</tr>
<tr>
<td>logquerypos</td>
<td>The cursor index into the internally-generated query text.</td>
</tr>
<tr>
<td>Column</td>
<td>Description</td>
</tr>
<tr>
<td>-------------</td>
<td>-------------------------------------------------------</td>
</tr>
<tr>
<td>logcontext</td>
<td>The context in which this message gets generated.</td>
</tr>
<tr>
<td>logdebug</td>
<td>Query string with full detail for debugging.</td>
</tr>
<tr>
<td>logcursorpos</td>
<td>The cursor index into the query string.</td>
</tr>
<tr>
<td>logfunction</td>
<td>The function in which this message is generated.</td>
</tr>
<tr>
<td>logfile</td>
<td>The log file in which this message is generated.</td>
</tr>
<tr>
<td>logline</td>
<td>The line in the log file in which this message is generated.</td>
</tr>
<tr>
<td>logstack</td>
<td>Full text of the stack trace associated with this message.</td>
</tr>
</tbody>
</table>

**gp_log_master_concise**

This view uses an external table to read a subset of the log fields from the master log file. The use of this view requires superuser permissions.

**Table 208: gp_log_master_concise view**

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>logtime</td>
<td>The timestamp of the log message.</td>
</tr>
<tr>
<td>logdatabase</td>
<td>The name of the database.</td>
</tr>
<tr>
<td>logsession</td>
<td>The session identifier (prefixed with &quot;con&quot;).</td>
</tr>
<tr>
<td>logcmdcount</td>
<td>The command number within a session (prefixed with &quot;cmd&quot;).</td>
</tr>
<tr>
<td>logmessage</td>
<td>Log or error message text.</td>
</tr>
</tbody>
</table>

**gp_log_system**

This view uses an external table to read the server log files of the entire Greenplum system (master, segments, and mirrors) and lists all log entries. Associated log entries can be identified by the session id (logsession) and command id (logcmdcount). The use of this view requires superuser permissions.

**Table 209: gp_log_system view**

<table>
<thead>
<tr>

<td>Full text of the stack trace associated with this message.</td>
</tr>
</tbody>
</table>

**Checking Server Configuration Files**

Each component of a Greenplum Database system (master, standby master, primary segments, and mirror segments) has its own server configuration file (`postgresql.conf`). The following `gp_toolkit` objects can be used to check parameter settings across all primary `postgresql.conf` files in the system:

- `gp_param_setting('parameter_name')`
- `gp_param_settings_seg_value_diffs`
gp_param_setting('parameter_name')
This function takes the name of a server configuration parameter and returns the postgresql.conf value for the master and each active segment. This function is accessible to all users.

Table 210: gp_param_setting('parameter_name') function

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>paramsegment</td>
<td>The segment content id (only active segments are shown). The master content id is always -1.</td>
</tr>
<tr>
<td>paramname</td>
<td>The name of the parameter.</td>
</tr>
<tr>
<td>paramvalue</td>
<td>The value of the parameter.</td>
</tr>
</tbody>
</table>

Example:

```
SELECT * FROM gp_param_setting('max_connections');
```

gp_param_settings_seg_value_diffs
Server configuration parameters that are classified as local parameters (meaning each segment gets the parameter value from its own postgresql.conf file), should be set identically on all segments. This view shows local parameter settings that are inconsistent. Parameters that are supposed to have different values (such as port) are not included. This view is accessible to all users.

Table 211: gp_param_settings_seg_value_diffs view

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>psdname</td>
<td>The name of the parameter.</td>
</tr>
<tr>
<td>psdvalue</td>
<td>The value of the parameter.</td>
</tr>
<tr>
<td>psdcount</td>
<td>The number of segments that have this value.</td>
</tr>
</tbody>
</table>

Checking for Failed Segments
The gp_pgdatabase_invalid view can be used to check for down segments.

gp_pgdatabase_invalid
This view shows information about segments that are marked as down in the system catalog. This view is accessible to all users.

Table 212: gp_pgdatabase_invalid view

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pgdbidbid</td>
<td>The segment dbid. Every segment has a unique dbid.</td>
</tr>
<tr>
<td>pgdbiisprimary</td>
<td>Is the segment currently acting as the primary (active) segment? (t or f)</td>
</tr>
<tr>
<td>pgdbicontent</td>
<td>The content id of this segment. A primary and mirror will have the same content id.</td>
</tr>
</tbody>
</table>
Checking Resource Group Activity and Status

Note: The resource group activity and status views described in this section are valid only when resource group-based resource management is active.

Resource groups manage transactions to avoid exhausting system CPU and memory resources. Every database user is assigned a resource group. Greenplum Database evaluates every transaction submitted by a user against the limits configured for the user's resource group before running the transaction.

You can use the gp_resgroup_config view to check the configuration of each resource group. You can use the gp_resgroup_status view to display the current transaction status and resource usage of each resource group.

- gp_resgroup_config
- gp_resgroup_status

**gp_resgroup_config**

The gp_resgroup_config view allows administrators to see the current CPU, memory, and concurrency limits for a resource group. The view also displays proposed limit settings. A proposed limit will differ from the current limit when the limit has been altered, but the new value could not be immediately applied.

This view is accessible to all users.

**Table 213: gp_resgroup_config**

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>groupid</td>
<td>The ID of the resource group.</td>
</tr>
<tr>
<td>groupname</td>
<td>The name of the resource group.</td>
</tr>
<tr>
<td>concurrency</td>
<td>The concurrency (CONCURRENCY) value specified for the resource group.</td>
</tr>
<tr>
<td>proposed_concurrency</td>
<td>The pending concurrency value for the resource group.</td>
</tr>
<tr>
<td>cpu_rate_limit</td>
<td>The CPU limit (CPU_RATE_LIMIT) value specified for the resource group, or -1.</td>
</tr>
<tr>
<td>memory_limit</td>
<td>The memory limit (MEMORY_LIMIT) value specified for the resource group.</td>
</tr>
<tr>
<td>proposed_memory_limit</td>
<td>The pending memory limit value for the resource group.</td>
</tr>
<tr>
<td>memory_shared_quota</td>
<td>The shared memory quota (MEMORY_SHARED_QUOTA) value specified for the resource group.</td>
</tr>
<tr>
<td>proposed_memory_shared_quota</td>
<td>The pending shared memory quota value for the resource group.</td>
</tr>
<tr>
<td>memory_spill_ratio</td>
<td>The memory spill ratio (MEMORY_SPILL_RATIO) value specified for the resource group.</td>
</tr>
</tbody>
</table>
Column | Description
--- | ---
proposed_memory_spill_ratio | The pending memory spill ratio value for the resource group.
memory_auditor | The memory auditor for the resource group.
cpuset | The CPU cores reserved for the resource group, or -1.

**gp_resgroup_status**

The `gp_resgroup_status` view allows administrators to see status and activity for a resource group. It shows how many queries are waiting to run and how many queries are currently active in the system for each resource group. The view also displays current memory and CPU usage for the resource group.

**Note:** Resource groups use the Linux control groups (cgroups) configured on the host systems. The cgroups are used to manage host system resources. When resource groups use cgroups that are as part of a nested set of cgroups, resource group limits are relative to the parent cgroup allotment. For information about nested cgroups and Greenplum Database resource group limits, see *Understanding Role and Component Resource Groups*.

This view is accessible to all users.

**Table 214: gp_resgroup_status view**

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>rsgname</td>
<td>The name of the resource group.</td>
</tr>
<tr>
<td>groupid</td>
<td>The ID of the resource group.</td>
</tr>
<tr>
<td>num_running</td>
<td>The number of transactions currently executing in the resource group.</td>
</tr>
<tr>
<td>num_queueing</td>
<td>The number of currently queued transactions for the resource group.</td>
</tr>
<tr>
<td>num_queued</td>
<td>The total number of queued transactions for the resource group since the Greenplum Database cluster was last started, excluding the num_queueing.</td>
</tr>
<tr>
<td>num_executed</td>
<td>The total number of executed transactions in the resource group since the Greenplum Database cluster was last started, excluding the num_running.</td>
</tr>
<tr>
<td>total_queue_duration</td>
<td>The total time any transaction was queued since the Greenplum Database cluster was last started.</td>
</tr>
<tr>
<td>cpu_usage</td>
<td>The real-time CPU usage of the resource group on each Greenplum Database segment's host.</td>
</tr>
<tr>
<td>memory_usage</td>
<td>The real-time memory usage of the resource group on each Greenplum Database segment's host.</td>
</tr>
</tbody>
</table>

The `cpu_usage` field is a JSON-formatted, key:value string that identifies, for each resource group, the per-segment CPU usage percentage. The key is segment id, the value is the percentage of CPU usage by
the resource group on the segment host. The total CPU usage of all segments running on a segment host should not exceed the `gp_resource_group_cpu_limit`. Example `cpu_usage` column output:

```
{"-1":0.01, "0":0.31, "1":0.31}
```

In this example, segment 0 and segment 1 are running on the same host; their CPU usage is the same.

The `memory_usage` field is also a JSON-formatted, key:value string. The string contents differ depending upon the type of resource group. For each resource group that you assign to a role (default memory auditor, vmtracker), this string identifies the used, available, granted, and proposed fixed and shared memory quota allocations on each segment. The key is segment id. The values are memory values displayed in MB units. The following example shows `memory_usage` column output for a single segment for a resource group that you assign to a role:

```
"0":{
  "used":0,
  "available":76,
  "quota_used":-1,
  "quota_available":60,
  "quota_granted":60,
  "quota_proposed":60,
  "shared_used":0,
  "shared_available":16,
  "shared_granted":16,
  "shared_proposed":16
}
```

For each resource group that you assign to an external component, the `memory_usage` JSON-formatted string identifies the memory used and the memory limit on each segment. The following example shows `memory_usage` column output for an external component resource group for a single segment:

```
"1":{
  "used":11,
  "limit_granted":15
}
```

### Checking Resource Queue Activity and Status

**Note:** The resource queue activity and status views described in this section are valid only when resource queue-based resource management is active.

The purpose of resource queues is to limit the number of active queries in the system at any given time in order to avoid exhausting system resources such as memory, CPU, and disk I/O. All database users are assigned to a resource queue, and every statement submitted by a user is first evaluated against the resource queue limits before it can run. The `gp_resq_*` family of views can be used to check the status of statements currently submitted to the system through their respective resource queue. Note that statements issued by superusers are exempt from resource queuing.

- `gp_resq_activity`
- `gp_resq_activity_by_queue`
- `gp_resq_priority_statement`
- `gp_resq_role`
- `gp_resqueue_status`

### gp_resq_activity

For the resource queues that have active workload, this view shows one row for each active statement submitted through a resource queue. This view is accessible to all users.

#### Table 215: gp_resq_activity view

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>resqprocpid</td>
<td>Process ID assigned to this statement (on the master).</td>
</tr>
<tr>
<td>resqrole</td>
<td>User name.</td>
</tr>
<tr>
<td>Column</td>
<td>Description</td>
</tr>
<tr>
<td>----------------</td>
<td>--------------------------------------------------</td>
</tr>
<tr>
<td>resqoid</td>
<td>Resource queue object id.</td>
</tr>
<tr>
<td>resqname</td>
<td>Resource queue name.</td>
</tr>
<tr>
<td>resqstart</td>
<td>Time statement was issued to the system.</td>
</tr>
<tr>
<td>resqstatus</td>
<td>Status of statement: running, waiting or cancelled.</td>
</tr>
</tbody>
</table>

**gp_resq_activity_by_queue**

For the resource queues that have active workload, this view shows a summary of queue activity. This view is accessible to all users.

**Table 216: gp_resq_activity_by_queue Column**

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>resqoid</td>
<td>Resource queue object id.</td>
</tr>
<tr>
<td>resqname</td>
<td>Resource queue name.</td>
</tr>
<tr>
<td>resqlast</td>
<td>Time of the last statement issued to the queue.</td>
</tr>
<tr>
<td>resqstatus</td>
<td>Status of last statement: running, waiting or cancelled.</td>
</tr>
<tr>
<td>resqtotal</td>
<td>Total statements in this queue.</td>
</tr>
</tbody>
</table>

**gp_resq_priority_statement**

This view shows the resource queue priority, session ID, and other information for all statements currently running in the Greenplum Database system. This view is accessible to all users.

**Table 217: gp_resq_priority_statement view**

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>rqpdatname</td>
<td>The database name that the session is connected to.</td>
</tr>
<tr>
<td>rquusename</td>
<td>The user who issued the statement.</td>
</tr>
<tr>
<td>rqsessid</td>
<td>The session ID.</td>
</tr>
<tr>
<td>rqpcmd</td>
<td>The number of the statement within this session (the command id and session id uniquely identify a statement).</td>
</tr>
<tr>
<td>rqprio</td>
<td>The resource queue priority for this statement (MAX, HIGH, MEDIUM, LOW).</td>
</tr>
<tr>
<td>rqpweight</td>
<td>An integer value associated with the priority of this statement.</td>
</tr>
<tr>
<td>rqquery</td>
<td>The query text of the statement.</td>
</tr>
</tbody>
</table>

**gp_resq_role**

This view shows the resource queues associated with a role. This view is accessible to all users.
Table 218: gp_resq_role view

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>rrrolname</td>
<td>Role (user) name.</td>
</tr>
<tr>
<td>rrsqname</td>
<td>The resource queue name assigned to this role. If a role has not been</td>
</tr>
<tr>
<td></td>
<td>explicitly assigned to a resource queue, it will be in the default resource</td>
</tr>
<tr>
<td></td>
<td>queue (pg_default).</td>
</tr>
</tbody>
</table>

gp_resqueue_status

This view allows administrators to see status and activity for a resource queue. It shows how many queries are waiting to run and how many queries are currently active in the system from a particular resource queue.

Table 219: gp_resqueue_status view

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>queueid</td>
<td>The ID of the resource queue.</td>
</tr>
<tr>
<td>rsqname</td>
<td>The name of the resource queue.</td>
</tr>
<tr>
<td>rsqcountlimit</td>
<td>The active query threshold of the resource queue. A value of -1 means no</td>
</tr>
<tr>
<td></td>
<td>limit.</td>
</tr>
<tr>
<td>rsqcountvalue</td>
<td>The number of active query slots currently being used in the resource queue.</td>
</tr>
<tr>
<td>rsqcostlimit</td>
<td>The query cost threshold of the resource queue. A value of -1 means no</td>
</tr>
<tr>
<td></td>
<td>limit.</td>
</tr>
<tr>
<td>rsqcostvalue</td>
<td>The total cost of all statements currently in the resource queue.</td>
</tr>
<tr>
<td>rsqmemorylimit</td>
<td>The memory limit for the resource queue.</td>
</tr>
<tr>
<td>rsqmemoryvalue</td>

</tr>
</tbody>
</table>

Checking Query Disk Spill Space Usage

The gp_workfile_* views show information about all the queries that are currently using disk spill space. Greenplum Database creates work files on disk if it does not have sufficient memory to execute the query in memory. This information can be used for troubleshooting and tuning queries. The information in the views can also be used to specify the values for the Greenplum Database configuration parameters gp_workfile_limit_per_query and gp_workfile_limit_per_segment.

- gp_workfile_entries
- gp_workfile_usage_per_query
- gp_workfile_usage_per_segment
**gp_workfile_entries**

This view contains one row for each operator using disk space for workfiles on a segment at the current time. The view is accessible to all users, however non-superusers only to see information for the databases that they have permission to access.

Table 220: gp_workfile_entries

<table>
<thead>
<tr>
<th>Column</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>command_cnt</td>
<td>integer</td>

<tr>
<td>numfiles</td>
<td>bigint</td>
<td></td>
<td>The number of files created.</td>
</tr>
</tbody>
</table>

Viewing Users and Groups (Roles)

It is frequently convenient to group users (roles) together to ease management of object privileges: that way, privileges can be granted to, or revoked from, a group as a whole. In Greenplum Database this is done by creating a role that represents the group, and then granting membership in the group role to individual user roles.

The gp_roles_assigned view can be used to see all of the roles in the system, and their assigned members (if the role is also a group role).
**gp_roles_assigned**

This view shows all of the roles in the system, and their assigned members (if the role is also a group role). This view is accessible to all users.

**Table 223: gp_roles_assigned view**

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>raroleid</td>
<td>The role object ID. If this role has members (users), it is considered a group role.</td>
</tr>
<tr>
<td>rarolename</td>
<td>The role (user or group) name.</td>
</tr>
<tr>
<td>ramemberid</td>
<td>The role object ID of the role that is a member of this role.</td>
</tr>
<tr>
<td>ramembername</td>
<td>Name of the role that is a member of this role.</td>
</tr>
</tbody>
</table>

**Checking Database Object Sizes and Disk Space**

The `gp_size_*` family of views can be used to determine the disk space usage for a distributed Greenplum Database, schema, table, or index. The following views calculate the total size of an object across all primary segments (mirrors are not included in the size calculations).

- `gp_size_of_all_table_indexes`
- `gp_size_of_database`
- `gp_size_of_index`
- `gp_size_of_partition_and_indexes_disk`
- `gp_size_of_schema_disk`
- `gp_size_of_table_and_indexes_disk`
- `gp_size_of_table_and_indexes_licensing`
- `gp_size_of_table_disk`
- `gp_size_of_table_uncompressed`
- `gp_disk_free`

The table and index sizing views list the relation by object ID (not by name). To check the size of a table or index by name, you must look up the relation name (`relname`) in the `pg_class` table. For example:

```sql
SELECT relname as name, sotdsize as size, sotdtoastsize as toast, sotdadditionalsize as other
FROM gp_size_of_table_disk as sotd, pg_class
WHERE sotd.sotdoid=pg_class.oid ORDER BY relname;
```

**gp_size_of_all_table_indexes**

This view shows the total size of all indexes for a table. This view is accessible to all users, however non-superusers will only be able to see relations that they have permission to access.

**Table 224: gp_size_of_all_table_indexes view**

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>soatioid</td>
<td>The object ID of the table</td>
</tr>
<tr>
<td>soatisize</td>
<td>The total size of all table indexes in bytes</td>
</tr>
</tbody>
</table>
### gp_size_of_database

This view shows the total size of a database. This view is accessible to all users, however non-superusers will only be able to see databases that they have permission to access.

**Table 225: gp_size_of_database view**

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>soatischemaname</td>
<td>The schema name</td>
</tr>
<tr>
<td>soatitablename</td>
<td>The table name</td>
</tr>
</tbody>
</table>

### gp_size_of_index

This view shows the total size of an index. This view is accessible to all users, however non-superusers will only be able to see relations that they have permission to access.

**Table 226: gp_size_of_index view**

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sodddatname</td>
<td>The name of the database</td>
</tr>
<tr>

<td>The size of the database in bytes</td>
</tr>
<tr>
<td>soioid</td>
<td>The object ID of the index</td>
</tr>
<tr>
<td>soitableoid</td>
<td>The object ID of the table to which the index belongs</td>
</tr>
<tr>
<td>soisize</td>
<td>The size of the index in bytes</td>
</tr>
<tr>
<td>soiindexschemaname</td>
<td>The name of the index schema</td>
</tr>
<tr>
<td>soiindexname</td>
<td>The name of the index</td>
</tr>
<tr>
<td>soitableschemaname</td>
<td>The name of the table schema</td>
</tr>
<tr>
<td>soitablename</td>
<td>The name of the table</td>
</tr>
</tbody>
</table>

### gp_size_of_partition_and_indexes_disk

This view shows the size on disk of partitioned child tables and their indexes. This view is accessible to all users, however non-superusers will only be able to see relations that they have permission to access.

**Table 227: gp_size_of_partition_and_indexes_disk view**

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sopaidparentoid</td>
<td>The object ID of the parent table</td>
</tr>
<tr>
<td>sopaidpartitionoid</td>
<td>The object ID of the partition table</td>
</tr>
<tr>
<td>sopaidpartitiontablesizemeasure</td>
<td>The partition table size in bytes</td>
</tr>
<tr>
<td>sopaidpartitionindexessize</td>
<td>The total size of all indexes on this partition</td>
</tr>
<tr>
<td>Sopaidparentschemaname</td>
<td>The name of the parent schema</td>
</tr>
</tbody>
</table>
### Column & Description

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Sopaidparenttablename</td>
<td>The name of the parent table</td>
</tr>
<tr>
<td>Sopaidpartitionschemaname</td>
<td>The name of the partition schema</td>
</tr>
<tr>
<td>sopaidpartitiontablename</td>
<td>The name of the partition table</td>
</tr>
</tbody>
</table>

### gp_size_of_schema_disk

This view shows schema sizes for the public schema and the user-created schemas in the current database. This view is accessible to all users, however non-superusers will be able to see only the schemas that they have permission to access.

**Table 228: gp_size_of_schema_disk view**

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sosdnsp</td>
<td>The name of the schema</td>
</tr>
<tr>
<td>sosdschematablesize</td>
<td>The total size of tables in the schema in bytes</td>
</tr>
<tr>
<td>sosdschemaidxsize</td>
<td>The total size of indexes in the schema in bytes</td>
</tr>
</tbody>
</table>

### gp_size_of_table_and_indexes_disk

This view shows the size on disk of tables and their indexes. This view is accessible to all users, however non-superusers will only be able to see relations that they have permission to access.

**Table 229: gp_size_of_table_and_indexes_disk view**

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sotaidoid</td>
<td>The object ID of the parent table</td>
</tr>
<tr>
<td>sotaidtablesize</td>
<td>The disk size of the table</td>
</tr>
<tr>
<td>sotaididxsize</td>
<td>The total size of all indexes on the table</td>
</tr>
<tr>
<td>sotaidschemascename</td>
<td>The name of the schema</td>
</tr>
<tr>
<td>sotaidtablename</td>
<td>The name of the table</td>
</tr>
</tbody>
</table>

### gp_size_of_table_and_indexes_licensing

This view shows the total size of tables and their indexes for licensing purposes. The use of this view requires superuser permissions.

**Table 230: gp_size_of_table_and_indexes_licensing view**

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sotailoid</td>
<td>The object ID of the table</td>
</tr>
<tr>
<td>sotailtablesdisk</td>
<td>The total disk size of the table</td>
</tr>
<tr>
<td>sotailtablesizeuncompressed</td>
<td>If the table is a compressed append-optimized table, shows the uncompressed table size in bytes.</td>
</tr>
<tr>
<td>sotailindexesize</td>
<td>The total size of all indexes in the table</td>
</tr>
<tr>
<td>sotailschemascename</td>
<td>The schema name</td>
</tr>
<tr>
<td>Column</td>
<td>Description</td>
</tr>
<tr>
<td>----------------</td>
<td>------------------------------------------</td>
</tr>
<tr>
<td>sotailtablename</td>
<td>The table name</td>
</tr>
</tbody>
</table>

**gp_size_of_table_disk**

This view shows the size of a table on disk. This view is accessible to all users, however non-superusers will only be able to see tables that they have permission to access.

**Table 231: gp_size_of_table_disk view**

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sotoid</td>
<td>The object ID of the table</td>
</tr>
<tr>
<td>sotdsize</td>
<td>The size of the table in bytes. The size is only the main table size. The size does not include auxiliary objects such as oversized (toast) attributes, or additional storage objects for AO tables.</td>
</tr>
<tr>
<td>sotdtoastsize</td>
<td>The size of the TOAST table (oversized attribute storage), if there is one.</td>
</tr>
<tr>
<td>sotdadditionalsize</td>
<td>Reflects the segment and block directory table sizes for append-optimized (AO) tables.</td>
</tr>
<tr>
<td>sotschemaname</td>
<td>The schema name</td>
</tr>
<tr>
<td>sot tablename</td>
<td>The table name</td>
</tr>
</tbody>
</table>

**gp_size_of_table_uncompressed**

This view shows the uncompressed table size for append-optimized (AO) tables. Otherwise, the table size on disk is shown. The use of this view requires superuser permissions.

**Table 232: gp_size_of_table_uncompressed view**

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sotuoid</td>
<td>The object ID of the table</td>
</tr>
<tr>
<td>sotusize</td>
<td>The uncomressed size of the table in bytes if it is a compressed AO table. Otherwise, the table size on disk.</td>
</tr>
<tr>
<td>sotuschemaname</td>
<td>The schema name</td>
</tr>
<tr>
<td>souttablename</td>
<td>The table name</td>
</tr>
</tbody>
</table>

**gp_disk_free**

This external table runs the `df` (disk free) command on the active segment hosts and reports back the results. Inactive mirrors are not included in the calculation. The use of this external table requires superuser permissions.
Checking for Uneven Data Distribution

All tables in Greenplum Database are distributed, meaning their data is divided across all of the segments in the system. If the data is not distributed evenly, then query processing performance may suffer. The following views can help diagnose if a table has uneven data distribution:

- `gp_skew_coefficients`
- `gp_skew_idle_fractions`

**gp_skew_coefficients**

This view shows data distribution skew by calculating the coefficient of variation (CV) for the data stored on each segment. This view is accessible to all users, however non-superusers will only be able to see tables that they have permission to access.

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>skcoid</td>
<td>The object id of the table.</td>
</tr>
<tr>
<td>skcnamespace</td>
<td>The namespace where the table is defined.</td>
</tr>
<tr>
<td>skcrelname</td>
<td>The table name.</td>
</tr>
<tr>
<td>skccoeff</td>
<td>The coefficient of variation (CV) is calculated as the standard deviation divided by the average. It takes into account both the average and variability around the average of a data series. The lower the value, the better. Higher values indicate greater data skew.</td>
</tr>
</tbody>
</table>

**gp_skew_idle_fractions**

This view shows data distribution skew by calculating the percentage of the system that is idle during a table scan, which is an indicator of processing data skew. This view is accessible to all users, however non-superusers will only be able to see tables that they have permission to access.

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sifoid</td>
<td>The object id of the table.</td>
</tr>
<tr>
<td>sifnamespace</td>
<td>The namespace where the table is defined.</td>
</tr>
<tr>
<td>Column</td>
<td>Description</td>
</tr>
<tr>
<td>------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>sifrelname</td>
<td>The table name.</td>
</tr>
<tr>
<td>siffraction</td>
<td>The percentage of the system that is idle during a table scan, which is an indicator of uneven data distribution or query processing skew. For example, a value of 0.1 indicates 10% skew, a value of 0.5 indicates 50% skew, and so on. Tables that have more than 10% skew should have their distribution policies evaluated.</td>
</tr>
</tbody>
</table>
The gpperfmon Database

The gpperfmon database is a dedicated database where data collection agents on Greenplum segment hosts save query and system statistics. The optional Greenplum Command Center management tool depends upon the gpperfmon database for query history.

The gpperfmon database is created using the gpperfmon_install command-line utility. The utility creates the database and the gpmon database role and enables the data collection agents on the master and segment hosts. See the gpperfmon_install reference in the Greenplum Database Utility Guide for information about using the utility and configuring the data collection agents.

The gpperfmon database consists of three sets of tables that capture query and system status information at different stages.

- _now tables store current system metrics such as active queries.
- _tail tables are used to stage data before it is saved to the _history tables. The _tail tables are for internal use only and not to be queried by users.
- _history tables store historical metrics.

The data for _now and _tail tables are stored as text files on the master host file system, and are accessed in the gpperfmon database via external tables. The history tables are regular heap database tables in the gpperfmon database. History is saved only for queries that run for a minimum number of seconds, 20 by default. You can set this threshold to another value by setting the min_query_time parameter in the $MASTER_DATA_DIRECTORY/gpperfmon/conf/gpperfmon.conf configuration file. Setting the value to 0 saves history for all queries.

Note: gpperfmon does not support SQL ALTER commands. ALTER queries are not recorded in the gpperfmon query history tables.

The history tables are partitioned by month. See History Table Partition Retention for information about removing old partitions.

The database contains the following categories of tables:

- The database_* tables store query workload information for a Greenplum Database instance.
- The diskspace_* tables store diskspace metrics.
- The log_alert_* tables store error and warning messages from pg_log.
- The queries_* tables store high-level query status information.
- The segment_* tables store memory allocation statistics for the Greenplum Database segment instances.
- The socket_stats_* tables store statistical metrics about socket usage for a Greenplum Database instance. Note: These tables are in place for future use and are not currently populated.
- The system_* tables store system utilization metrics.

The gpperfmon database also contains the following views:

- The dynamic_memory_info view shows an aggregate of all the segments per host and the amount of dynamic memory used per host.
- The memory_info view shows per-host memory information from the system_history and segment_history tables.

History Table Partition Retention

The history tables in the gpperfmon database are partitioned by month. Partitions are automatically added in two month increments as needed.
The **partition_age** parameter in the `$MASTER_DATA_DIRECTORY/gpperfmon/conf/gpperfmon.conf` file can be set to the maximum number of monthly partitions to keep. Partitions older than the specified value are removed automatically when new partitions are added.

The default value for **partition_age** is 0, which means that administrators must manually remove unneeded partitions.

**Alert Log Processing and Log Rotation**

When the `gp_gpperfmon_enable` server configuration parameter is set to true, the Greenplum Database syslogger writes alert messages to a `.csv` file in the `$MASTER_DATA_DIRECTORY/gpperfmon/logs` directory.

The level of messages written to the log can be set to `none, warning, error, fatal, or panic` by setting the `gpperfmon_log_alert_level` server configuration parameter in `postgresql.conf`. The default message level is `warning`.

The directory where the log is written can be changed by setting the `log_location` configuration variable in the `$MASTER_DATA_DIRECTORY/gpperfmon/conf/gpperfmon.conf` configuration file.

The syslogger rotates the alert log every 24 hours or when the current log file reaches or exceeds 1MB.

A rotated log file can exceed 1MB if a single error message contains a large SQL statement or a large stack trace. Also, the syslogger processes error messages in chunks, with a separate chunk for each logging process. The size of a chunk is OS-dependent; on Red Hat Enterprise Linux, for example, it is 4096 bytes. If many Greenplum Database sessions generate error messages at the same time, the log file can grow significantly before its size is checked and log rotation is triggered.

**gpperfmon Data Collection Process**

When Greenplum Database starts up with gpperfmon support enabled, it forks a `gpmmon` agent process. `gpmmon` then starts a `gpsmon` agent process on the master host and every segment host in the Greenplum Database cluster. The Greenplum Database postmaster process monitors the `gpmmon` process and reverts it if needed, and the `gpmmon` process monitors and restarts `gpsmon` processes as needed.

The `gpmmon` process runs in a loop and at configurable intervals retrieves data accumulated by the `gpsmon` processes, adds it to the data files for the `_now` and `_tail` external database tables, and then into the `_history` regular heap database tables.

**Note:** The log_alert tables in the `gpperfmon` database follow a different process, since alert messages are delivered by the Greenplum Database system logger instead of through `gpsmon`. See Alert Log Processing and Log Rotation for more information.

Two configuration parameters in the `$MASTER_DATA_DIRECTORY/gpperfmon/conf/gpperfmon.conf` configuration file control how often `gpmmon` activities are triggered:

- The `quantum` parameter is how frequently, in seconds, `gpmmon` requests data from the `gpsmon` agents on the segment hosts and adds retrieved data to the `_now` and `_tail` external table data files. Valid values for the `quantum` parameter are 10, 15, 20, 30, and 60. The default is 15.
- The `harvest_interval` parameter is how frequently, in seconds, data in the `_tail` tables is moved to the `_history` tables. The `harvest_interval` must be at least 30. The default is 120.

See the `gpperfmon_install` management utility reference in the *Greenplum Database Utility Guide* for the complete list of `gpperfmon` configuration parameters.

The following steps describe the flow of data from Greenplum Database into the `gpperfmon` database when `gpperfmon` support is enabled.

1. While executing queries, the Greenplum Database query dispatcher and query executor processes send out query status messages in UDP datagrams. The `gp_gpperfmon_send_interval` server configuration variable determines how frequently the database sends these messages. The default is every second.
2. The `gpsmon` process on each host receives the UDP packets, consolidates and summarizes the data they contain, and adds additional host metrics, such as CPU and memory usage.

3. The `gpsmon` processes continue to accumulate data until they receive a dump command from `gpmmon`.

4. The `gpsmon` processes respond to a dump command by sending their accumulated status data and log alerts to a listening `gpmmon` event handler thread.

5. The `gpmmon` event handler saves the metrics to `.txt` files in the `$MASTER_DATA_DIRECTORY/gpperfmon/data` directory on the master host.

At each quantum interval (15 seconds by default), `gpmmon` performs the following steps:

1. Sends a dump command to the `gpsmon` processes.
2. Gathers and converts the `.txt` files saved in the `$MASTER_DATA_DIRECTORY/gpperfmon/data` directory into .dat external data files for the `_now` and `_tail` external tables in the `gpperfmon` database.
   For example, disk space metrics are added to the `diskspace_now.dat` and `diskspace_tail.dat` delimited text files. These text files are accessed via the `diskspace_now` and `diskspace_tail` tables in the `gpperfmon` database.

At each harvest_interval (120 seconds by default), `gpmmon` performs the following steps for each `_tail` file:

1. Renames the `_tail` file to a `_stage` file.
3. Appends data from the `_stage` file into the `_tail` file.
4. Runs a SQL command to insert the data from the `_tail` external table into the corresponding `_history` table.
   For example, the contents of the `_database_tail` external table is inserted into the `database_history` regular (heap) table.
5. Deletes the `_tail` file after its contents have been loaded into the database table.
6. Gathers all of the `gpdb-alert-*.csv` files in the `$MASTER_DATA_DIRECTORY/gpperfmon/logs` directory (except the most recent, which the syslogger has open and is writing to) into a single file, `alert_log_stage`.
7. Loads the `alert_log_stage` file into the `log_alert_history` table in the `gpperfmon` database.
8. Truncates the `alert_log_stage` file.

The following topics describe the contents of the tables in the `gpperfmon` database.

### database_*

The `database_*` tables store query workload information for a Greenplum Database instance. There are three database tables, all having the same columns:

- **database_now** is an external table whose data files are stored in `$MASTER_DATA_DIRECTORY/gpperfmon/data`. Current query workload data is stored in `database_now` during the period between data collection from the data collection agents and automatic commitment to the `database_history` table.

- **database_tail** is an external table whose data files are stored in `$MASTER_DATA_DIRECTORY/gpperfmon/data`. This is a transitional table for query workload data that has been cleared from `database_now` but has not yet been committed to `database_history`. It typically only contains a few minutes worth of data.

- **database_history** is a regular table that stores historical database-wide query workload data. It is pre-partitioned into monthly partitions. Partitions are automatically added in two month increments as needed.

<table>

<td>The number of active queries running at data collection time.</td>
</tr>
<tr>
<td>queries_queued</td>
<td>int</td>
<td>The number of queries waiting in a resource group or resource queue, depending upon which resource management scheme is active, at data collection time.</td>
</tr>
</tbody>
</table>

### diskspace_*

The diskspace_* tables store diskspace metrics.
- **diskspace_now** is an external table whose data files are stored in `$MASTER_DATA_DIRECTORY/gpperfmon/data`. Current diskspace metrics are stored in `database_now` during the period between data collection from the gpperfmon agents and automatic commitment to the `diskspace_history` table.
- **diskspace_tail** is an external table whose data files are stored in `$MASTER_DATA_DIRECTORY/gpperfmon/data`. This is a transitional table for diskspace metrics that have been cleared from `diskspace_now` but has not yet been committed to `diskspace_history`. It typically only contains a few minutes worth of data.
- **diskspace_history** is a regular table that stores historical diskspace metrics. It is pre-partitioned into monthly partitions. Partitions are automatically added in two month increments as needed.

<table>

</tr>
</tbody>
</table>

### interface_stats_*

The interface_stats_* tables store statistical metrics about communications over each active interface for a Greenplum Database instance.

These tables are in place for future use and are not currently populated.

There are three interface_stats tables, all having the same columns:
- **interface_stats_now** is an external table whose data files are stored in `$MASTER_DATA_DIRECTORY/gpperfmon/data`.
- **interface_stats_tail** is an external table whose data files are stored in `$MASTER_DATA_DIRECTORY/gpperfmon/data`. This is a transitional table for statistical interface
metrics that has been cleared from interface_stats_now but has not yet been committed to interface_stats_history. It typically only contains a few minutes worth of data.

- interface_stats_history is a regular table that stores statistical interface metrics. It is pre-partitioned into monthly partitions. Partitions are automatically added in one month increments as needed.

<table>
<thead>
<tr>
<th>Column</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>interface_name</td>
<td>string</td>
<td>Name of the interface. For example: eth0, eth1, lo.</td>

<tr>
<th>Column</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>transmit_compressed_packets</td>
<td>int</td>
<td>Number of packets transmitted in compressed format.</td>
</tr>
</tbody>
</table>

**log_alert_***

The log_alert_* tables store pg_log errors and warnings.

See Alert Log Processing and Log Rotation for information about configuring the system logger for gpperfmon.

There are three log_alert tables, all having the same columns:

- **log_alert_now** is an external table whose data is stored in .csv files in the $MASTER_DATA_DIRECTORY/gpperfmon/logs directory. Current pg_log errors and warnings data are available in log_alert_now during the period between data collection from the gpperfmon agents and automatic commitment to the log_alert_history table.

- **log_alert_tail** is an external table with data stored in $MASTER_DATA_DIRECTORY/gpperfmon/logs/alert_log_stage. This is a transitional table for data that has been cleared from log_alert_now but has not yet been committed to log_alert_history. The table includes records from all alert logs except the most recent. It typically contains only a few minutes' worth of data.

- **log_alert_history** is a regular table that stores historical database-wide errors and warnings data. It is pre-partitioned into monthly partitions. Partitions are automatically added in two month increments as needed.

<table>

</tr>
</tbody>
</table>
The `queries_*` tables store high-level query status information. The `tmid`, `ssid` and `ccnt` columns are the composite key that uniquely identifies a particular query.

There are three queries tables, all having the same columns:

- **queries_now** is an external table whose data files are stored in `$MASTER_DATA_DIRECTORY/gpperfmon/data`. Current query status is stored in `queries_now` during the period between data collection from the `gpperfmon` agents and automatic commitment to the `queries_history` table.
- **queries_tail** is an external table whose data files are stored in `$MASTER_DATA_DIRECTORY/gpperfmon/data`. This is a transitional table for query status data that has been cleared from `queries_now` but has not yet been committed to `queries_history`. It typically only contains a few minutes worth of data.
- **queries_history** is a regular table that stores historical query status data. It is pre-partitioned into monthly partitions. Partitions are automatically added in two month increments as needed.

<td>If the resource queue-based resource management scheme is active, this column specifies the name of the resource queue.</td>
</tr>
<tr>
<td>rqppriority</td>
<td>varchar(64)</td>
<td>If the resource queue-based resource management scheme is active, this column specifies the priority of the query -- max, high, med, low, or min.</td>
</tr>
</tbody>
</table>

**segment_**

The segment_ tables contain memory allocation statistics for the Greenplum Database segment instances. This tracks the amount of memory consumed by all postgres processes of a particular segment instance, and the remaining amount of memory available to a segment as per the settings configured by the currently active resource management scheme (resource group-based or resource queue-based). See the Greenplum Database Administrator Guide for more information about resource management schemes.

There are three segment tables, all having the same columns:

* segment_now is an external table whose data files are stored in $MASTER_DATA_DIRECTORY/gpperfmon/data. Current memory allocation data is stored in segment_now during the
Period between data collection from the `gpperfmon` agents and automatic commitment to the `segment_history` table.

- `segment_tail` is an external table whose data files are stored in `$MASTER_DATA_DIRECTORY/gpperfmon/data`. This is a transitional table for memory allocation data that has been cleared from `segment_now` but has not yet been committed to `segment_history`. It typically only contains a few minutes worth of data.

- `segment_history` is a regular table that stores historical memory allocation metrics. It is pre-partitioned into monthly partitions. Partitions are automatically added in two month increments as needed.

A particular segment instance is identified by its `hostname` and `dbid` (the unique segment identifier as per the `gp_segment_configuration` system catalog table).

<table>
<thead>
<tr>
<th>Column</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>ctime</code></td>
<td><code>timestamp(0)</code></td>
<td>The time the row was created.</td>
</tr>
<tr>
<td></td>
<td>(without time zone)</td>
<td></td>
</tr>
<tr>
<td><code>dbid</code></td>
<td><code>int</code></td>
<td>The segment ID (<code>dbid</code> from <code>gp_segment_configuration</code>).</td>
</tr>
<tr>
<td><code>hostname</code></td>
<td><code>charvar(64)</code></td>
<td>The segment hostname.</td>
</tr>
<tr>
<td><code>dynamic_memory_used</code></td>
<td><code>bigint</code></td>
<td>The amount of dynamic memory (in bytes) allocated to query processes running on this segment.</td>
</tr>
<tr>
<td><code>dynamic_memory_available</code></td>
<td><code>bigint</code></td>
<td>The amount of additional dynamic memory (in bytes) that the segment can request before reaching the limit set by the currently active resource management scheme (resource group-based or resource queue-based).</td>
</tr>
</tbody>
</table>

See also the views `memory_info` and `dynamic_memory_info` for aggregated memory allocation and utilization by host.

**socket_stats_***

The `socket_stats_*` tables store statistical metrics about socket usage for a Greenplum Database instance. There are three system tables, all having the same columns:

These tables are in place for future use and are not currently populated.

- `socket_stats_now` is an external table whose data files are stored in `$MASTER_DATA_DIRECTORY/gpperfmon/data`.
- `socket_stats_tail` is an external table whose data files are stored in `$MASTER_DATA_DIRECTORY/gpperfmon/data`. This is a transitional table for socket statistical metrics that has been cleared from `socket_stats_now` but has not yet been committed to `socket_stats_history`. It typically only contains a few minutes worth of data.
- `socket_stats_history` is a regular table that stores historical socket statistical metrics. It is pre-partitioned into monthly partitions. Partitions are automatically added in two month increments as needed.
### Column Type Description

<table>
<thead>
<tr>
<th>Column</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>total_sockets_used</td>
<td>int</td>
<td>Total sockets used in the system.</td>

<tr>
<td>frag_sockets_memusage_inbytes</td>
<td>int</td>
<td>Amount of memory consumed by FRAG sockets.</td>
</tr>
</tbody>
</table>

**system_**

The system_* tables store system utilization metrics. There are three system tables, all having the same columns:

- **system_now** is an external table whose data files are stored in `$MASTER_DATA_DIRECTORY/gpperfmon/data`. Current system utilization data is stored in `system_now` during the period between data collection from the gpperfmon agents and automatic commitment to the `system_history` table.
- **system_tail** is an external table whose data files are stored in `$MASTER_DATA_DIRECTORY/gpperfmon/data`. This is a transitional table for system utilization data that has been cleared from `system_now` but has not yet been committed to `system_history`. It typically only contains a few minutes worth of data.
- **system_history** is a regular table that stores historical system utilization metrics. It is pre-partitioned into monthly partitions. Partitions are automatically added in two month increments as needed.

### Column Type Description

<tr>
<td>Column</td>
<td>Type</td>
<td>Description</td>
</tr>
<tr>
<td>----------------</td>
<td>-----------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>net_wb_rate</td>
<td>bigint</td>
<td>Bytes per second on the system network for write operations.</td>
</tr>
</tbody>
</table>

**dynamic_memory_info**

The `dynamic_memory_info` view shows a sum of the used and available dynamic memory for all segment instances on a segment host. Dynamic memory refers to the maximum amount of memory that Greenplum Database instance will allow the query processes of a single segment instance to consume before it starts cancelling processes. This limit, determined by the currently active resource management scheme (resource group-based or resource queue-based), is evaluated on a per-segment basis.

<table>
<thead>
<tr>
<th>Column</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ctime</td>
<td>timestamp(0) without time zone</td>
<td>Time this row was created in the <code>segment_history</code> table.</td>
</tr>
<tr>
<td>hostname</td>
<td>varchar(64)</td>
<td>Segment or master hostname associated with these system memory metrics.</td>
</tr>
<tr>
<td>dynamic_memory_used_mb</td>
<td>numeric</td>
<td>The amount of dynamic memory in MB allocated to query processes running on this segment.</td>
</tr>
<tr>
<td>dynamic_memory_available_mb</td>
<td>numeric</td>
<td>The amount of additional dynamic memory (in MB) available to the query processes running on this segment host. Note that this value is a sum of the available memory for all segments on a host. Even though this value reports available memory, it is possible that one or more segments on the host have exceeded their memory limit.</td>
</tr>
</tbody>
</table>

**memory_info**

The `memory_info` view shows per-host memory information from the `system_history` and `segment_history` tables. This allows administrators to compare the total memory available on a segment host, total memory used on a segment host, and dynamic memory used by query processes.

<table>
<thead>
<tr>
<th>Column</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ctime</td>
<td>timestamp(0) without time zone</td>
<td>Time this row was created in the <code>segment_history</code> table.</td>
</tr>
<tr>
<td>hostname</td>
<td>varchar(64)</td>
<td>Segment or master hostname associated with these system memory metrics.</td>
</tr>
<tr>
<td>mem_total_mb</td>
<td>numeric</td>
<td>Total system memory in MB for this segment host.</td>
</tr>
<tr>
<td>mem_used_mb</td>
<td>numeric</td>
<td>Total system memory used in MB for this segment host.</td>

<tr>
<td>mem_actual_free_mb</td>
<td>numeric</td>
<td>Actual system memory free in MB for this segment host.</td>
</tr>
<tr>
<td>swap_total_mb</td>
<td>numeric</td>
<td>Total swap space in MB for this segment host.</td>
</tr>
<tr>
<td>swap_used_mb</td>
<td>numeric</td>
<td>Total swap space used in MB for this segment host.</td>
</tr>
<tr>
<td>dynamic_memory_used_mb</td>
<td>numeric</td>
<td>The amount of dynamic memory in MB allocated to query processes running on this segment.</td>
</tr>
<tr>
<td>dynamic_memory_available_mb</td>
<td>numeric</td>
<td>The amount of additional dynamic memory (in MB) available to the query processes running on this segment host. Note that this value is a sum of the available memory for all segments on a host. Even though this value reports available memory, it is possible that one or more segments on the host have exceeded their memory limit.</td>
</tr>
</tbody>
</table>
Greenplum Database Data Types

Greenplum Database has a rich set of native data types available to users. Users may also define new data types using the `CREATE TYPE` command. This reference shows all of the built-in data types. In addition to the types listed here, there are also some internally used data types, such as `oid` (object identifier), but those are not documented in this guide.

Optional modules in the `contrib` directory may also install new data types. The `hstore` module, for example, introduces a new data type and associated functions for working with key-value pairs. See `hstore Functions`. The `citext` module adds a case-insensitive text data type. See `citext Data Type`.

The following data types are specified by SQL: `bit`, `bit varying`, `boolean`, `character varying`, `varchar`, `character`, `char`, `date`, `double precision`, `integer`, `interval`, `numeric`, `decimal`, `real`, `smallint`, `time` (with or without time zone), and `timestamp` (with or without time zone).

Each data type has an external representation determined by its input and output functions. Many of the built-in types have obvious external formats. However, several types are either unique to PostgreSQL (and Greenplum Database), such as geometric paths, or have several possibilities for formats, such as the date and time types. Some of the input and output functions are not invertible. That is, the result of an output function may lose accuracy when compared to the original input.

### Table 236: Greenplum Database Built-in Data Types

<table>
<thead>
<tr>
<th>Name</th>
<th>Alias</th>
<th>Size</th>
<th>Range</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>bigint</td>
<td>int8</td>
<td>8 bytes</td>
<td>-922337203 to 922337203</td>
<td>large range integer</td>
</tr>
<tr>
<td>bigserial</td>
<td>serial8</td>
<td>8 bytes</td>
<td>1 to 922337203</td>
<td>large autoincrementing integer</td>
</tr>
<tr>
<td>bit [ (n) ]</td>
<td></td>
<td>n bits</td>
<td></td>
<td>fixed-length bit string</td>
</tr>
<tr>
<td>bit varying [ (n) ]</td>
<td>varbit</td>
<td></td>
<td>bit string constant</td>
<td>variable-length bit string</td>
</tr>
<tr>
<td>boolean</td>
<td>bool</td>
<td>1 byte</td>
<td>true/false, t/f, yes/no, y/n, 1/0</td>
<td>logical boolean (true/false)</td>
</tr>
<tr>
<td>box</td>
<td></td>
<td>32 bytes</td>
<td>((x1,y1),(x2,y2))</td>
<td>rectangular box in the plane - not allowed in distribution key columns.</td>
</tr>
<tr>
<td>bytea</td>
<td></td>
<td>1 byte + binary string</td>
<td>sequence of octets</td>
<td>variable-length binary string</td>
</tr>
<tr>
<td>character [ (n) ]</td>
<td>char [ (n) ]</td>
<td>1 byte + n</td>
<td>strings up to n characters in length</td>
<td>fixed-length, blank padded</td>
</tr>
</tbody>
</table>

9 For variable length data types, if the data is greater than or equal to 127 bytes, the storage overhead is 4 bytes instead of 1.

**Pseudo-Types**

Greenplum Database supports special-purpose data type entries that are collectively called *pseudo-types*. A pseudo-type cannot be used as a column data type, but it can be used to declare a function's argument or result type. Each of the available pseudo-types is useful in situations where a function's behavior does not correspond to simply taking or returning a value of a specific SQL data type.

Functions coded in procedural languages can use pseudo-types only as allowed by their implementation languages. The procedural languages all forbid use of a pseudo-type as an argument type, and allow only void and record as a result type.

A function with the pseudo-type record as a return data type returns an unspecified row type. The record represents an array of possibly-anonymous composite types. Since composite datums carry their own type identification, no extra knowledge is needed at the array level.

The pseudo-type void indicates that a function returns no value.

**Note:** Greenplum Database does not support triggers and the pseudo-type trigger.
The types `anyelement`, `anyarray`, `anynonarray`, and `anyenum` are pseudo-types called polymorphic types. Some procedural languages also support polymorphic functions using the types `anyarray`, `anyelement`, `anyenum`, and `anynonarray`.

The pseudo-type `anytable` is a Greenplum Database type that specifies a table expression—an expression that computes a table. Greenplum Database allows this type only as an argument to a user-defined function. See Table Value Expressions for more about the `anytable` pseudo-type.

For more information about pseudo-types, see the Postgres documentation about Pseudo-Types.

Polymorphic Types

Four pseudo-types of special interest are `anyelement`, `anyarray`, `anynonarray`, and `anyenum`, which are collectively called polymorphic types. Any function declared using these types is said to be a polymorphic function. A polymorphic function can operate on many different data types, with the specific data types being determined by the data types actually passed to it at runtime.

Polymorphic arguments and results are tied to each other and are resolved to a specific data type when a query calling a polymorphic function is parsed. Each position (either argument or return value) declared as `anyelement` is allowed to have any specific actual data type, but in any given call they must all be the same actual type. Each position declared as `anyarray` can have any array data type, but similarly they must all be the same type. If there are positions declared `anyarray` and others declared `anyelement`, the actual array type in the `anyarray` positions must be an array whose elements are the same type appearing in the `anyelement` positions. `anynonarray` is treated exactly the same as `anyelement`, but adds the additional constraint that the actual type must not be an array type. `anyenum` is treated exactly the same as `anyelement`, but adds the additional constraint that the actual type must be an enum type.

When more than one argument position is declared with a polymorphic type, the net effect is that only certain combinations of actual argument types are allowed. For example, a function declared as `equal(anyelement, anyelement)` takes any two input values, so long as they are of the same data type.

When the return value of a function is declared as a polymorphic type, there must be at least one argument position that is also polymorphic, and the actual data type supplied as the argument determines the actual result type for that call. For example, if there were not already an array subscripting mechanism, one could define a function that implements subscripting as `subscript(anyarray, integer) returns anyelement`. This declaration constrains the actual first argument to be an array type, and allows the parser to infer the correct result type from the actual first argument's type. Another example is that a function declared as `myfunc(anyarray) returns anyenum` will only accept arrays of enum types.

Note that `anynonarray` and `anyenum` do not represent separate type variables; they are the same type as `anyelement`, just with an additional constraint. For example, declaring a function as `myfunc(anyelement, anyenum)` is equivalent to declaring it as `myfunc(anyenum, anyenum)`: both actual arguments must be the same enum type.

A variadic function (one taking a variable number of arguments) is polymorphic when its last parameter is declared as `VARIADIC anyarray`. For purposes of argument matching and determining the actual result type, such a function behaves the same as if you had declared the appropriate number of `anynonarray` parameters.

For more information about polymorphic types, see the Postgres documentation about Polymorphic Arguments and Return Types.

Table Value Expressions

The `anytable` pseudo-type declares a function argument that is a table value expression. The notation for a table value expression is a `SELECT` statement enclosed in a `TABLE()` function. You can specify a distribution policy for the table by adding `SCATTER RANDOMLY`, or a `SCATTER BY` clause with a column list to specify the distribution key.
The **SELECT** statement is executed when the function is called and the result rows are distributed to segments so that each segment executes the function with a subset of the result table.

For example, this table expression selects three columns from a table named `customer` and sets the distribution key to the first column:

```
TABLE(SELECT cust_key, name, address FROM customer SCATTER BY 1)
```

The **SELECT** statement may include joins on multiple base tables, **WHERE** clauses, aggregates, and any other valid query syntax.

The `anytable` type is only permitted in functions implemented in the C or C++ languages. The body of the function can access the table using the Greenplum Database Server Programming Interface (SPI) or the Greenplum Partner Connector (GPPC) API.

The `anytable` type is used in some user-defined functions in the Pivotal GPText API. The following GPText example uses the `TABLE` function with the `SCATTER BY` clause in the GPText function `gptext.index()` to populate the index `mydb.mytest.articles` with data from the messages table:

```
SELECT * FROM gptext.index(TABLE(SELECT * FROM mytest.messages
  SCATTER BY distrib_id), 'mydb.mytest.messages');
```

For information about the function `gptext.index()`, see the Pivotal GPText documentation.
Character Set Support

The character set support in Greenplum Database allows you to store text in a variety of character sets, including single-byte character sets such as the ISO 8859 series and multiple-byte character sets such as EUC (Extended Unix Code), UTF-8, and Mule internal code. All supported character sets can be used transparently by clients, but a few are not supported for use within the server (that is, as a server-side encoding). The default character set is selected while initializing your Greenplum Database array using `gpinitsystem`. It can be overridden when you create a database, so you can have multiple databases each with a different character set.

Table 237: Greenplum Database Character Sets

<table>
<thead>
<tr>
<th>Name</th>

---

11 The SQL_ASCII setting behaves considerably differently from the other settings. Byte values 0-127 are interpreted according to the ASCII standard, while byte values 128-255 are taken as uninterpreted characters. If you are working with any non-ASCII data, it is unwise to use the SQL_ASCII setting as a client encoding. SQL_ASCII is not supported as a server encoding.
### Setting the Character Set

gpinitsystem defines the default character set for a Greenplum Database system by reading the setting of the ENCODING parameter in the gp_init_config file at initialization time. The default character set is UNICODE or UTF8.

You can create a database with a different character set besides what is used as the system-wide default. For example:

```
=> CREATE DATABASE korean WITH ENCODING 'EUC_KR';
```

**Important:** Although you can specify any encoding you want for a database, it is unwise to choose an encoding that is not what is expected by the locale you have selected. The LC_COLLATE and LC_CTYPE settings imply a particular encoding, and locale-dependent operations (such as sorting) are likely to misinterpret data that is in an incompatible encoding.

Since these locale settings are frozen by gpinitsystem, the apparent flexibility to use different encodings in different databases is more theoretical than real.

One way to use multiple encodings safely is to set the locale to C or POSIX during initialization time, thus disabling any real locale awareness.

### Character Set Conversion Between Server and Client

Greenplum Database supports automatic character set conversion between server and client for certain character set combinations. The conversion information is stored in the master pg_conversion system catalog table. Greenplum Database comes with some predefined conversions or you can create a new conversion using the SQL command `CREATE CONVERSION`.

#### Table 238: Client/Server Character Set Conversions

</tr>
</tbody>
</table>
To enable automatic character set conversion, you have to tell Greenplum Database the character set (encoding) you would like to use in the client. There are several ways to accomplish this:

- Using the `\encoding` command in `psql`, which allows you to change client encoding on the fly.
- Using `SET client_encoding TO`.

To set the client encoding, use the following SQL command:

```sql
=> SET CLIENT_ENCODING TO 'value';
```

To query the current client encoding:

```sql
=> SHOW client_encoding;
```

To return to the default encoding:

```sql
=> RESET client_encoding;
```

- Using the `PGCLIENTENCODING` environment variable. When `PGCLIENTENCODING` is defined in the client's environment, that client encoding is automatically selected when a connection to the server is made. (This can subsequently be overridden using any of the other methods mentioned above.)

- Setting the configuration parameter `client_encoding`. If `client_encoding` is set in the master `postgresql.conf` file, that client encoding is automatically selected when a connection to Greenplum Database is made. (This can subsequently be overridden using any of the other methods mentioned above.)

If the conversion of a particular character is not possible " suppose you chose `EUC_JP` for the server and `LATIN1` for the client, then some Japanese characters do not have a representation in `LATIN1 " then an error is reported.

If the client character set is defined as `SQL_ASCII`, encoding conversion is disabled, regardless of the server's character set. The use of `SQL_ASCII` is unwise unless you are working with all-ASCII data. `SQL_ASCII` is not supported as a server encoding.

Server Configuration Parameters

There are many Greenplum server configuration parameters that affect the behavior of the Greenplum Database system. Many of these configuration parameters have the same names, settings, and behaviors as in a regular PostgreSQL database system.

- **Parameter Types and Values** describes the parameter data types and values.
- **Setting Parameters** describes limitations on who can change them and where or when they can be set.
- **Parameter Categories** organizes parameters by functionality.
- **Configuration Parameters** lists the parameter descriptions in alphabetic order.

**Parameter Types and Values**

All parameter names are case-insensitive. Every parameter takes a value of one of four types: Boolean, integer, floating point, or string. Boolean values may be written as ON, OFF, TRUE, FALSE, YES, NO, 1, 0 (all case-insensitive).

Some settings specify a memory size or time value. Each of these has an implicit unit, which is either kilobytes, blocks (typically eight kilobytes), milliseconds, seconds, or minutes. Valid memory size units are kB (kilobytes), MB (megabytes), and GB (gigabytes). Valid time units are ms (milliseconds), s (seconds), min (minutes), h (hours), and d (days). Note that the multiplier for memory units is 1024, not 1000. A valid time expression contains a number and a unit. When specifying a memory or time unit using the SET command, enclose the value in quotes. For example:

```
SET statement_mem TO '200MB';
```

**Note:** There is no space between the value and the unit names.

**Setting Parameters**

Many of the configuration parameters have limitations on who can change them and where or when they can be set. For example, to change certain parameters, you must be a Greenplum Database superuser. Other parameters require a restart of the system for the changes to take effect. A parameter that is classified as session can be set at the system level (in the `postgresql.conf` file), at the database-level (using `ALTER DATABASE`), at the role-level (using `ALTER ROLE`), or at the session-level (using `SET`). System parameters can only be set in the `postgresql.conf` file.

In Greenplum Database, the master and each segment instance has its own `postgresql.conf` file (located in their respective data directories). Some parameters are considered local parameters, meaning that each segment instance looks to its own `postgresql.conf` file to get the value of that parameter. You must set local parameters on every instance in the system (master and segments). Others parameters are considered master parameters. Master parameters need only be set at the master instance.

This table describes the values in the Settable Classifications column of the table in the description of a server configuration parameter.
Table 239: Settable Classifications

<table>
<thead>
<tr>
<th>Set Classification</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>master or local</td>
<td>A <em>master</em> parameter only needs to be set in the <em>postgresql.conf</em> file of the Greenplum master instance. The value for this parameter is then either passed to (or ignored by) the segments at run time. A local parameter must be set in the <em>postgresql.conf</em> file of the master AND each segment instance. Each segment instance looks to its own configuration to get the value for the parameter. Local parameters always requires a system restart for changes to take effect.</td>
</tr>
<tr>
<td>session or system</td>
<td><em>Session</em> parameters can be changed on the fly within a database session, and can have a hierarchy of settings: at the system level (<em>postgresql.conf</em>), at the database level (<em>ALTER DATABASE...SET</em>), at the role level (<em>ALTER ROLE...SET</em>), or at the session level (<em>SET</em>). If the parameter is set at multiple levels, then the most granular setting takes precedence (for example, session overrides role, role overrides database, and database overrides system). A <em>system</em> parameter can only be changed via the <em>postgresql.conf</em> file(s).</td>
</tr>
<tr>
<td>restart or reload</td>
<td>When changing parameter values in the <em>postgresql.conf</em> file(s), some require a <em>restart</em> of Greenplum Database for the change to take effect. Other parameter values can be refreshed by just reloading the server configuration file (using <em>gpstop -u</em>), and do not require stopping the system.</td>
</tr>
<tr>
<td>superuser</td>
<td>These session parameters can only be set by a database superuser. Regular database users cannot set this parameter.</td>
</tr>
<tr>
<td>read only</td>
<td>These parameters are not settable by database users or superusers. The current value of the parameter can be shown but not altered.</td>
</tr>
</tbody>
</table>

**Parameter Categories**

Configuration parameters affect categories of server behaviors, such as resource consumption, query tuning, and authentication. The following topics describe Greenplum configuration parameter categories.

- Connection and Authentication Parameters
- System Resource Consumption Parameters
- GPORCA Parameters
- Query Tuning Parameters
- Error Reporting and Logging Parameters
- System Monitoring Parameters
- Runtime Statistics Collection Parameters
• Automatic Statistics Collection Parameters
• Client Connection Default Parameters
• Lock Management Parameters
• Resource Management Parameters (Resource Queues)
• Resource Management Parameters (Resource Groups)
• External Table Parameters
• Database Table Parameters
• Database and Tablespace/Filespace Parameters
• Past Version Compatibility Parameters
• Greenplum Database Array Configuration Parameters
• Greenplum Mirroring Parameters for Master and Segments
• Greenplum Database Extension Parameters

Connection and Authentication Parameters
These parameters control how clients connect and authenticate to Greenplum Database.

Connection Parameters

gp_connection_send_timeout
gp_vmem_idle_resource_timeout
listen_addresses
max_connections
max_prepared_transactions
superuser_reserved_connections
tcp_keepalives_count
tcp_keepalives_idle
tcp_keepalives_interval
unix_socket_directory
unix_socket_group
unix_socket_permissions

Security and Authentication Parameters

authentication_timeout
db_user_namespace
krb_caseins_users
krb_server_keyfile
krb_srvname
password_encryption
password_hash_algorithm
ssl
ssl_ciphers

System Resource Consumption Parameters
These parameters set the limits for system resources consumed by Greenplum Database.

Memory Consumption Parameters
These parameters control system memory usage.

gp_vmem_idle_resource_timeout
gp_resource_group_memory_limit (resource group-based resource management)
gp_vmem_protect_limit (resource queue-based resource management)
gp_vmem_protect_segworker_cache_limit
gp_workfile_limit_per_query
gp_workfile_limit_per_segment
max_stack_depth
shared_buffers
temp_buffers
Free Space Map Parameters
These parameters control the sizing of the free space map, which contains expired rows. Use VACUUM to reclaim the free space map disk space.

max_fsm_pages
max_fsm_relations

OS Resource Parameters

max_files_per_process
shared_preload_libraries

Cost-Based Vacuum Delay Parameters
Warning: Do not use cost-based vacuum delay because it runs asynchronously among the segment instances. The vacuum cost limit and delay is invoked at the segment level without taking into account the state of the entire Greenplum Database array.

You can configure the execution cost of VACUUM and ANALYZE commands to reduce the I/O impact on concurrent database activity. When the accumulated cost of I/O operations reaches the limit, the process performing the operation sleeps for a while, then resets the counter and continues execution.

vacuum_cost_delay
vacuum_cost_page_hit
vacuum_cost_page_limit
vacuum_cost_page_miss
vacuum_cost_page_dirty

Transaction ID Management Parameters

xid_stop_limit
xid_warn_limit

GPORCA Parameters
These parameters control the usage of GPORCA by Greenplum Database. For information about GPORCA, see About GPORCA in the Greenplum Database Administrator Guide.

gp_enable_relsize_collection
optimizer
optimizer_analyze_root_partition
optimizer_array_expansion_threshold
optimizer_cte_inlining_bound
optimizer_control
optimizer_enable_associativity
optimizer_enable_dml
optimizer_join_arity_for_associativity_commutativity
optimizer_join_order
optimizer_join_order_threshold
optimizer_mdcache_size
optimizer_metadata_caching
optimizer_parallel_union
optimizer_penalize_skew
optimizer_print_missing_stats
Query Tuning Parameters
These parameters control aspects of SQL query processing such as query operators and operator settings and statistics sampling.

Legacy Query Optimizer Operator Control Parameters
The following parameters control the types of plan operations the Postgres Planner can use. Enable or disable plan operations to force the Postgres Planner to choose a different plan. This is useful for testing and comparing query performance using different plan types.

- enable_bitmapscan
- enable_groupagg
- enable_hashagg
- enable_hashjoin
- enable_indexscan
- enable_mergejoin
- enable_nestloop
- enable_seqscan
- enable_sort
- enable_tidscan
- gp_enable_agg_distinct
- gp_enable_agg_distinct_pruning
- gp_enable_direct_dispatch
- gp_enable_fallback_plan
- gp_enable_fast_sri
- gp_enable_groupext_distinct_gather
- gp_enable_groupext_distinct_pruning
- gp_enable_multiphase_agg
- gp_enable_predicate_propagation
- gp_enable_preunique
- gp_enable_relsize_collection
- gp_enable_sequential_window_plans
- gp_enable_sort_distinct
- gp_enable_sort_limit

Legacy Query Optimizer Costing Parameters
Warning: Do not adjust these query costing parameters. They are tuned to reflect Greenplum Database hardware configurations and typical workloads. All of these parameters are related. Changing one without changing the others can have adverse affects on performance.

- cpu_index_tuple_cost
- cpu_operator_cost
- cpu_tuple_cost
- cursor_tuple_fraction
- effective_cache_size
- gp_motion_cost_per_row
- gp_segments_for_planner
- random_page_cost
- seq_page_cost
**Database Statistics Sampling Parameters**

These parameters adjust the amount of data sampled by an `ANALYZE` operation. Adjusting these parameters affects statistics collection system-wide. You can configure statistics collection on particular tables and columns by using the `ALTER TABLE SET STATISTICS` clause.

- `default_statistics_target`
- `gp_analyze_relative_error`

**Sort Operator Configuration Parameters**

- `gp_enable_sort_distinct`
- `gp_enable_sort_limit`

**Aggregate Operator Configuration Parameters**

- `gp_enable_agg_distinct`
- `gp_enable_agg_distinct_pruning`
- `gp_enable_multiphase_agg`
- `gp_enable_preunique`
- `gp_enable_groupext_distinct_gather`
- `gp_enable_groupext_distinct_pruning`
- `gp_workfile_compress_algorithm`

**Join Operator Configuration Parameters**

- `join_collapse_limit`
- `gp_adjust_selectivity_for_outerjoins`
- `gp_hashjoin_tuples_per_bucket`
- `gp_statistics_use_fkeys`
- `gp_workfile_compress_algorithm`

**Other Legacy Query Optimizer Configuration Parameters**

- `fromCollapse_limit`
- `gp_enable_predicate_propagation`
- `gp_max_plan_size`
- `gp_statistics_pullup_from_child_partition`

**Query Plan Execution**

Control the query plan execution.

- `gp_max_slices`

**Error Reporting and Logging Parameters**

These configuration parameters control Greenplum Database logging.
**Log Rotation**

- `log_rotation_age`
- `log_rotation_size`
- `log_truncate_on_rotation`

**When to Log**

- `client_min_messages`
- `gp_interconnect_debug_retry_interval`
- `log_error_verbosity`
- `log_min_duration_statement`
- `log_min_error_statement`
- `log_min_messages`
- `optimizer_minidump`

**What to Log**

- `debug_pretty_print`
- `debug_print_parse`
- `debug_print_plan`
- `debug_print_prelim_plan`
- `debug_print_rewritten`
- `debug_print_slice_table`
- `log_autostats`
- `log_connections`
- `log_disconnections`
- `log_dispatch_stats`
- `log_duration`
- `log_executor_stats`
- `log_hostname`
- `gp_log_interconnect`
- `log_parser_stats`
- `log_planner_stats`
- `log_statement`
- `log_statement_stats`
- `log_timezone`
- `gp_debug_linger`
- `gp_log_format`
- `gp_max_csv_line_length`
- `gp_reraise_signal`

**System Monitoring Parameters**

These configuration parameters control Greenplum Database data collection and notifications related to database monitoring.

**SNMP Alerts**

The following parameters send SNMP notifications when events occur.

- `gp_snmp_community`
- `gp_snmp_monitor_address`
- `gp_snmp_use_inform_or_trap`

**Email Alerts**

The following parameters configure the system to send email alerts for fatal error events, such as a segment going down or a server crash and reset.

- `gp_email_from`
- `gp_email_smtp_userid`
Greenplum Command Center Agent

The following parameters configure the data collection agents that populate the gpperfmon database for Greenplum Command Center.

- `gp_enable_gpperfmon`
- `gp_gpperfmon_send_interval`
- `gpperfmon_log_alert_level`
- `gpperfmon_port`

Runtime Statistics Collection Parameters

These parameters control the server statistics collection feature. When statistics collection is enabled, you can access the statistics data using the `pg_stat` family of system catalog views.

- `stats_queue_level`
- `update_process_title`

Automatic Statistics Collection Parameters

When automatic statistics collection is enabled, you can run `ANALYZE` automatically in the same transaction as an `INSERT`, `UPDATE`, `DELETE`, `COPY`, or `CREATE TABLE...AS SELECT` statement when a certain threshold of rows is affected (on_change), or when a newly generated table has no statistics (on_no_stats). To enable this feature, set the following server configuration parameters in your Greenplum Database master `postgresql.conf` file and restart Greenplum Database:

- `gp_autostats_mode`
- `gp_autostats_mode_in_functions`
- `gp_autostats_on_change_threshold`
- `log_autostats`

**Warning:** Depending on the specific nature of your database operations, automatic statistics collection can have a negative performance impact. Carefully evaluate whether the default setting of `on_no_stats` is appropriate for your system.

Client Connection Default Parameters

These configuration parameters set defaults that are used for client connections.

**Statement Behavior Parameters**

- `check_function_bodies`
- `default_tablespace`
- `default_transaction_isolation`
- `default_transaction_read_only`
- `search_path`
- `statement_timeout`
- `vacuum_freeze_min_age`

**Locale and Formatting Parameters**

- `client_encoding`
- `lc_messages`
Other Client Default Parameters

dynamic_library_path
explain_pretty_print

Lock Management Parameters
These configuration parameters set limits for locks and deadlocks.

deadlock_timeout
max_locks_per_transaction

Resource Management Parameters (Resource Queues)
The following configuration parameters configure the Greenplum Database resource management feature (resource queues), query prioritization, memory utilization and concurrency control.

Resource Management Parameters (Resource Groups)
The following parameters configure the Greenplum Database resource group workload management feature.
External Table Parameters
The following parameters configure the external tables feature of Greenplum Database.

- gp_external_enable_exec
- gp_external_enable_filter_pushdown
- gp_external_max_segs
- gp_initial_bad_row_limit
- gp_reject_percent_threshold
- readable_external_table_timeout
- writable_external_table_bufsize
- verify_gpfdists_cert

Database Table Parameters
The following parameter configures default option settings for Greenplum Database tables.

- gp_create_table_random_default_distribution
- gp_default_storage_options
- gp_enable_exchange_default_partition
- gp_enable_segment_copy_checking

Append-Optimized Table Parameters
The following parameters configure the append-optimized tables feature of Greenplum Database.

- max_appendonly_tables
- gp_appendonly_compaction
- gp_appendonly_compaction_threshold
- validate_previous_free_tid

Database and Tablespace/Filespace Parameters
The following parameters configure the maximum number of databases, tablespaces, and filespaces allowed in a system.

- gp_max_tablespaces
- gp_max_filespaces
- gp_max_databases

Past Version Compatibility Parameters
The following parameters provide compatibility with older PostgreSQL and Greenplum Database versions. You do not need to change these parameters in Greenplum Database.

**PostgreSQL**

- add_missing_from
- array_nulls
- regex_flavor
- standard_conforming_strings
Greenplum Database Array Configuration Parameters

The parameters in this topic control the configuration of the Greenplum Database array and its components: segments, master, distributed transaction manager, master mirror, and interconnect.

**Interconnect Configuration Parameters**

- `gp_interconnect_fc_method`
- `gp_interconnect_hash_multiplier`
- `gp_interconnect_queue_depth`
- `gp_interconnect_setup_timeout`
- `gp_interconnect_snd_queue_depth`
- `gp_interconnect_type`
- `gp_max_packet_size`

**Note:** Greenplum Database supports only the UDPIFC (default) and TCP interconnect types.

**Dispatch Configuration Parameters**

- `gp_cached_segworkers_threshold`
- `gp_connections_per_thread`
- `gp_enable_direct_dispatch`
- `gp_segment_connect_timeout`
- `gp_set_proc_affinity`

**Fault Operation Parameters**

- `gp_set_read_only`
- `gp_fts_probe_interval`
- `gp_fts_probe_retries`
- `gp_fts_probe_timeout`
- `gp_fts_probe_threadcount`
- `gp_log_fts`

**Distributed Transaction Management Parameters**

- `gp_max_local_distributed_cache`

**Read-Only Parameters**

- `gp_command_count`
- `gp_content`
- `gp_dbid`
- `gp_num_contents_in_cluster`
- `gp_role`
- `gp_session_id`
- `gp_server_version`
- `gp_server_version_num`
Greenplum Mirroring Parameters for Master and Segments

These parameters control the configuration of the replication between Greenplum Database primary master and standby master.

- `keep_wal_segments`
- `repl_catchup_within_range`
- `replication_timeout`
- `wal_receiver_status_interval`

This parameter controls validation between Greenplum Database primary segment and standby segment during incremental resynchronization.

- `filerep_mirrorvalidation_during_resync`

Greenplum Database Extension Parameters

The parameters in this topic control the configuration of Greenplum Database extensions.

- `pgcrypto.fips`
- `pljava_classpath`
- `pljava_classpath_insecure`
- `pljava_statement_cache_size`
- `pljava_release_lingering_savepoints`
- `pljava_vmoptions`

XML Data Parameters

The parameters in this topic control the configuration of the Greenplum Database XML data type.

- `xmlbinary`
- `xmloption`

Configuration Parameters

Descriptions of the Greenplum Database server configuration parameters listed alphabetically.

add_missing_from

Automatically adds missing table references to FROM clauses. Present for compatibility with releases of PostgreSQL prior to 8.1, where this behavior was allowed by default.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>off</td>
<td>master, session, reload</td>
</tr>
</tbody>
</table>
### application_name

Sets the application name for a client session. For example, if connecting via `psql`, this will be set to `psql`. Setting an application name allows it to be reported in log messages and statistics views.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>string</td>
<td></td>
<td>master</td>
</tr>
<tr>
<td></td>
<td></td>
<td>session</td>
</tr>
<tr>
<td></td>
<td></td>
<td>reload</td>
</tr>
</tbody>
</table>

### array_nulls

This controls whether the array input parser recognizes unquoted NULL as specifying a null array element. By default, this is on, allowing array values containing null values to be entered. Greenplum Database versions before 3.0 did not support null values in arrays, and therefore would treat NULL as specifying a normal array element with the string value 'NULL'.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>on</td>
<td>master</td>
</tr>
<tr>
<td></td>
<td></td>
<td>session</td>
</tr>
<tr>
<td></td>
<td></td>
<td>reload</td>
</tr>
</tbody>
</table>

### authentication_timeout

Maximum time to complete client authentication. This prevents hung clients from occupying a connection indefinitely.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>Any valid time expression (number and unit)</td>
<td>1min</td>
<td>local</td>
</tr>
<tr>
<td></td>
<td></td>
<td>system</td>
</tr>
<tr>
<td></td>
<td></td>
<td>restart</td>
</tr>
</tbody>
</table>

### backslash_quote

This controls whether a quote mark can be represented by `\` in a string literal. The preferred, SQL-standard way to represent a quote mark is by doubling it (`"`) but PostgreSQL has historically also accepted `\`. However, use of `\` creates security risks because in some client character set encodings, there are multibyte characters in which the last byte is numerically equivalent to ASCII `\`.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>on (allow <code>\</code> always)</td>
<td>safe_encoding</td>
<td>master</td>
</tr>
<tr>
<td>off (reject always)</td>
<td></td>
<td>session</td>
</tr>
<tr>
<td>safe_encoding (allow only if client encoding does not allow ASCII <code>\</code> within a multibyte character)</td>
<td>safe_encoding</td>
<td>reload</td>
</tr>
</tbody>
</table>
**block_size**
Reports the size of a disk block.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>number of bytes</td>
<td>32768</td>
<td>read only</td>
</tr>
</tbody>
</table>

**bonjour_name**
Specifies the Bonjour broadcast name. By default, the computer name is used, specified as an empty string. This option is ignored if the server was not compiled with Bonjour support.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>string</td>
<td>unset</td>
<td>master</td>
</tr>
<tr>
<td></td>
<td></td>
<td>system</td>
</tr>
<tr>
<td></td>
<td></td>
<td>restart</td>
</tr>
</tbody>
</table>

**check_function_bodies**
When set to off, disables validation of the function body string during `CREATE FUNCTION`. Disabling validation is occasionally useful to avoid problems such as forward references when restoring function definitions from a dump.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>on</td>
<td>master</td>
</tr>
<tr>
<td></td>
<td></td>
<td>session</td>
</tr>
<tr>
<td></td>
<td></td>
<td>reload</td>
</tr>
</tbody>
</table>

**client_encoding**
Sets the client-side encoding (character set). The default is to use the same as the database encoding. See Supported Character Sets in the PostgreSQL documentation.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>character set</td>
<td>UTF8</td>
<td>master</td>
</tr>
<tr>
<td></td>
<td></td>
<td>session</td>
</tr>
<tr>
<td></td>
<td></td>
<td>reload</td>
</tr>
</tbody>
</table>

**client_min_messages**
Controls which message levels are sent to the client. Each level includes all the levels that follow it. The later the level, the fewer messages are sent.
### Value Range | Default | Set Classifications
--- | --- | ---
DEBUG5 | NOTICE | master, session, reload
DEBUG4
DEBUG3
DEBUG2
DEBUG1
LOG
NOTICE
WARNING
ERROR
FATAL
PANIC

---

**cpu_index_tuple_cost**

For the legacy query optimizer (planner), sets the estimate of the cost of processing each index row during an index scan. This is measured as a fraction of the cost of a sequential page fetch.

Value Range | Default | Set Classifications
--- | --- | ---
floating point | 0.005 | master, session, reload

---

**cpu_operator_cost**

For the legacy query optimizer (planner), sets the estimate of the cost of processing each operator in a WHERE clause. This is measured as a fraction of the cost of a sequential page fetch.

Value Range | Default | Set Classifications
--- | --- | ---
floating point | 0.0025 | master, session, reload

---

**cpu_tuple_cost**

For the legacy query optimizer (planner), sets the estimate of the cost of processing each row during a query. This is measured as a fraction of the cost of a sequential page fetch.

Value Range | Default | Set Classifications
--- | --- | ---
floating point | 0.01 | master, session, reload
**cursor_tuple_fraction**

Tells the legacy query optimizer (planner) how many rows are expected to be fetched in a cursor query, thereby allowing the legacy optimizer to use this information to optimize the query plan. The default of 1 means all rows will be fetched.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>integer</td>
<td>1</td>
<td>master</td>
</tr>
<tr>
<td></td>
<td></td>
<td>session</td>
</tr>
<tr>
<td></td>
<td></td>
<td>reload</td>
</tr>
</tbody>
</table>

**custom_variable_classes**

Specifies one or several class names to be used for custom variables. A custom variable is a variable not normally known to the server but used by some add-on modules. Such variables must have names consisting of a class name, a dot, and a variable name.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>comma-separated list of class names</td>
<td>unset</td>
<td>local</td>
</tr>
<tr>
<td></td>
<td></td>
<td>system</td>
</tr>
<tr>
<td></td>
<td></td>
<td>restart</td>
</tr>
</tbody>
</table>

**data_checksums**

Reports whether checksums are enabled for heap data storage in the database system. Checksums for heap data are enabled or disabled when the database system is initialized and cannot be changed. Heap data pages store heap tables, catalog tables, indexes, and database metadata. Append-optimized storage has built-in checksum support that is unrelated to this parameter.

Greenplum Database uses checksums to prevent loading data corrupted in the file system into memory managed by database processes. When heap data checksums are enabled, Greenplum Database computes and stores checksums on heap data pages when they are written to disk. When a page is retrieved from disk, the checksum is verified. If the verification fails, an error is generated and the page is not permitted to load into managed memory.

If the `ignore_checksum_failure` configuration parameter has been set to on, a failed checksum verification generates a warning, but the page is allowed to be loaded into managed memory. If the page is then updated, it is flushed to disk and replicated to the mirror. This can cause data corruption to propagate to the mirror and prevent a complete recovery. Because of the potential for data loss, the `ignore_checksum_failure` parameter should only be enabled when needed to recover data. See `ignore_checksum_failure` for more information.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>on</td>
<td>read only</td>
</tr>
</tbody>
</table>

**DateStyle**

Sets the display format for date and time values, as well as the rules for interpreting ambiguous date input values. This variable contains two independent components: the output format specification and the input/output specification for year/month/day ordering.
### db_user_namespace

This enables per-database user names. If on, you should create users as `username@dbname`. To create ordinary global users, simply append @ when specifying the user name in the client.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>off</td>
<td>local</td>
</tr>
<tr>
<td></td>
<td></td>
<td>system</td>
</tr>
<tr>
<td></td>
<td></td>
<td>restart</td>
</tr>
</tbody>
</table>

### deadlock_timeout

The time to wait on a lock before checking to see if there is a deadlock condition. On a heavily loaded server you might want to raise this value. Ideally the setting should exceed your typical transaction time, so as to improve the odds that a lock will be released before the waiter decides to check for deadlock.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>Any valid time expression (number and unit)</td>
<td>1s</td>
<td>local</td>
</tr>
<tr>
<td></td>
<td></td>
<td>system</td>
</tr>
<tr>
<td></td>
<td></td>
<td>restart</td>
</tr>
</tbody>
</table>

### debug_assertions

Turns on various assertion checks.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>off</td>
<td>local</td>
</tr>
<tr>
<td></td>
<td></td>
<td>system</td>
</tr>
<tr>
<td></td>
<td></td>
<td>restart</td>
</tr>
</tbody>
</table>

### debug_pretty_print

Indents debug output to produce a more readable but much longer output format. `client_min_messages` or `log_min_messages` must be DEBUG1 or lower.
<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>off</td>
<td>master</td>
</tr>
<tr>
<td></td>
<td></td>
<td>session</td>
</tr>
<tr>
<td></td>
<td></td>
<td>reload</td>
</tr>
</tbody>
</table>

**debug_print_parse**

For each executed query, prints the resulting parse tree. `client_min_messages` or `log_min_messages` must be DEBUG1 or lower.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>off</td>
<td>master</td>
</tr>
<tr>
<td></td>
<td></td>
<td>session</td>
</tr>
<tr>
<td></td>
<td></td>
<td>reload</td>
</tr>
</tbody>
</table>

**debug_print_plan**

For each executed query, prints the Greenplum parallel query execution plan. `client_min_messages` or `log_min_messages` must be DEBUG1 or lower.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>off</td>
<td>master</td>
</tr>
<tr>
<td></td>
<td></td>
<td>session</td>
</tr>
<tr>
<td></td>
<td></td>
<td>reload</td>
</tr>
</tbody>
</table>

**debug_print_prelim_plan**

For each executed query, prints the preliminary query plan. `client_min_messages` or `log_min_messages` must be DEBUG1 or lower.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>off</td>
<td>master</td>
</tr>
<tr>
<td></td>
<td></td>
<td>session</td>
</tr>
<tr>
<td></td>
<td></td>
<td>reload</td>
</tr>
</tbody>
</table>

**debug_print_rewritten**

For each executed query, prints the query rewriter output. `client_min_messages` or `log_min_messages` must be DEBUG1 or lower.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>off</td>
<td>master</td>
</tr>
<tr>
<td></td>
<td></td>
<td>session</td>
</tr>
<tr>
<td></td>
<td></td>
<td>reload</td>
</tr>
</tbody>
</table>
debug_print_slice_table
For each executed query, prints the Greenplum query slice plan. client_min_messages or log_min_messages must be DEBUG1 or lower.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>off</td>
<td>master</td>
</tr>
<tr>
<td></td>
<td></td>
<td>session</td>
</tr>
<tr>
<td></td>
<td></td>
<td>reload</td>
</tr>
</tbody>
</table>

default_statistics_target
Sets the default statistics sampling target (the number of values that are stored in the list of common values) for table columns that have not had a column-specific target set via ALTER TABLE SET STATISTICS. Larger values may improve the quality of the legacy query optimizer (planner) estimates.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>0 &gt; Integer &gt; 10000</td>
<td>100</td>
<td>master</td>
</tr>
<tr>
<td></td>
<td></td>
<td>session</td>
</tr>
<tr>
<td></td>
<td></td>
<td>reload</td>
</tr>
</tbody>
</table>

default_tablespace
The default tablespace in which to create objects (tables and indexes) when a CREATE command does not explicitly specify a tablespace.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>name of a tablespace</td>
<td>unset</td>
<td>master</td>
</tr>
<tr>
<td></td>
<td></td>
<td>session</td>
</tr>
<tr>
<td></td>
<td></td>
<td>reload</td>
</tr>
</tbody>
</table>

default_transaction_isolation
Controls the default isolation level of each new transaction.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>read committed</td>
<td>read committed</td>
<td>master</td>
</tr>
<tr>
<td>read uncommitted</td>
<td></td>
<td>session</td>
</tr>
<tr>
<td>serializable</td>
<td></td>
<td>reload</td>
</tr>
</tbody>
</table>

default_transaction_read_only
Controls the default read-only status of each new transaction. A read-only SQL transaction cannot alter non-temporary tables.
### dynamic_library_path

If a dynamically loadable module needs to be opened and the file name specified in the `CREATE FUNCTION` or `LOAD` command does not have a directory component (i.e. the name does not contain a slash), the system will search this path for the required file. The compiled-in PostgreSQL package library directory is substituted for `$libdir`. This is where the modules provided by the standard PostgreSQL distribution are installed.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>a list of absolute directory paths separated by colons</td>
<td><code>$libdir</code></td>
<td>local, system, restart</td>
</tr>
</tbody>
</table>

### effective_cache_size

Sets the assumption about the effective size of the disk cache that is available to a single query for the legacy query optimizer (planner). This is factored into estimates of the cost of using an index; a higher value makes it more likely index scans will be used, a lower value makes it more likely sequential scans will be used. This parameter has no effect on the size of shared memory allocated by a Greenplum server instance, nor does it reserve kernel disk cache; it is used only for estimation purposes.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>floating point</td>
<td>512MB</td>
<td>master, session, reload</td>
</tr>
</tbody>
</table>

### enable_bitmapscan

Enables or disables the use of bitmap-scan plan types by the legacy query optimizer (planner). Note that this is different than a Bitmap Index Scan. A Bitmap Scan means that indexes will be dynamically converted to bitmaps in memory when appropriate, giving faster index performance on complex queries against very large tables. It is used when there are multiple predicates on different indexed columns. Each bitmap per column can be compared to create a final list of selected tuples.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>on</td>
<td>master, session, reload</td>
</tr>
</tbody>
</table>

### enable_groupagg

Enables or disables the use of group aggregation plan types by the legacy query optimizer (planner).
<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>on</td>
<td>master</td>
</tr>
<tr>
<td></td>
<td></td>
<td>session</td>
</tr>
<tr>
<td></td>
<td></td>
<td>reload</td>
</tr>
</tbody>
</table>

**enable_hashagg**
Enables or disables the use of hash aggregation plan types by the legacy query optimizer (planner).

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>on</td>
<td>master</td>
</tr>
<tr>
<td></td>
<td></td>
<td>session</td>
</tr>
<tr>
<td></td>
<td></td>
<td>reload</td>
</tr>
</tbody>
</table>

**enable_hashjoin**
Enables or disables the use of hash-join plan types by the legacy query optimizer (planner).

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>on</td>
<td>master</td>
</tr>
<tr>
<td></td>
<td></td>
<td>session</td>
</tr>
<tr>
<td></td>
<td></td>
<td>reload</td>
</tr>
</tbody>
</table>

**enable_indexscan**
Enables or disables the use of index-scan plan types by the legacy query optimizer (planner).

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>on</td>
<td>master</td>
</tr>
<tr>
<td></td>
<td></td>
<td>session</td>
</tr>
<tr>
<td></td>
<td></td>
<td>reload</td>
</tr>
</tbody>
</table>

**enable_mergejoin**
Enables or disables the use of merge-join plan types by the legacy query optimizer (planner). Merge join is based on the idea of sorting the left- and right-hand tables into order and then scanning them in parallel. So, both data types must be capable of being fully ordered, and the join operator must be one that can only succeed for pairs of values that fall at the 'same place' in the sort order. In practice this means that the join operator must behave like equality.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>off</td>
<td>master</td>
</tr>
<tr>
<td></td>
<td></td>
<td>session</td>
</tr>
<tr>
<td></td>
<td></td>
<td>reload</td>
</tr>
</tbody>
</table>
enable_nestloop
Enables or disables the use of nested-loop join plans by the legacy query optimizer (planner). It's not possible to suppress nested-loop joins entirely, but turning this variable off discourages the legacy optimizer from using one if there are other methods available.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>off</td>
<td>master</td>
</tr>
<tr>
<td></td>
<td></td>
<td>session</td>
</tr>
<tr>
<td></td>
<td></td>
<td>reload</td>
</tr>
</tbody>
</table>

enable_seqscan
Enables or disables the use of sequential scan plan types by the legacy query optimizer (planner). It's not possible to suppress sequential scans entirely, but turning this variable off discourages the legacy optimizer from using one if there are other methods available.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>on</td>
<td>master</td>
</tr>
<tr>
<td></td>
<td></td>
<td>session</td>
</tr>
<tr>
<td></td>
<td></td>
<td>reload</td>
</tr>
</tbody>
</table>

enable_sort
Enables or disables the use of explicit sort steps by the legacy query optimizer (planner). It's not possible to suppress explicit sorts entirely, but turning this variable off discourages the legacy optimizer from using one if there are other methods available.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>on</td>
<td>master</td>
</tr>
<tr>
<td></td>
<td></td>
<td>session</td>
</tr>
<tr>
<td></td>
<td></td>
<td>reload</td>
</tr>
</tbody>
</table>

enable_tidscan
Enables or disables the use of tuple identifier (TID) scan plan types by the legacy query optimizer (planner).

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>on</td>
<td>master</td>
</tr>
<tr>
<td></td>
<td></td>
<td>session</td>
</tr>
<tr>
<td></td>
<td></td>
<td>reload</td>
</tr>
</tbody>
</table>

escape_string_warning
When on, a warning is issued if a backslash (\) appears in an ordinary string literal ('...' syntax). Escape string syntax (E'...') should be used for escapes, because in future versions, ordinary strings will have the SQL standard-conforming behavior of treating backslashes literally.
**explain_pretty_print**

Determines whether EXPLAIN VERBOSE uses the indented or non-indented format for displaying detailed query-tree dumps.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>on</td>
<td>master session reload</td>
</tr>
</tbody>
</table>

**extra_float_digits**

Adjusts the number of digits displayed for floating-point values, including float4, float8, and geometric data types. The parameter value is added to the standard number of digits. The value can be set as high as 3, to include partially-significant digits; this is especially useful for dumping float data that needs to be restored exactly. Or it can be set negative to suppress unwanted digits.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>integer</td>
<td>0</td>
<td>master session reload</td>
</tr>
</tbody>
</table>

**filerep_mirrorvalidation_during_resync**

The default setting false improves Greenplum Database performance during incremental resynchronization of segment mirrors. Setting the value to true enables checking for the existence of files for all relations on the segment mirror during incremental resynchronization. Checking for files degrades performance of the incremental resynchronization process but provides a minimal check of database objects.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>false</td>
<td>master session reload</td>
</tr>
</tbody>
</table>

**fromCollapseLimit**

The legacy query optimizer (planner) will merge sub-queries into upper queries if the resulting FROM list would have no more than this many items. Smaller values reduce planning time but may yield inferior query plans.
### gp_adjust_selectivity_for_outerjoins
Enables the selectivity of NULL tests over outer joins.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>on</td>
<td>master, session, reload</td>
</tr>
</tbody>
</table>

### gp_analyze_relative_error
Sets the estimated acceptable error in the cardinality of the table. A value of 0.5 is supposed to be equivalent to an acceptable error of 50% (this is the default value used in PostgreSQL). If the statistics collected during `ANALYZE` are not producing good estimates of cardinality for a particular table attribute, decreasing the relative error fraction (accepting less error) tells the system to sample more rows.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>floating point &lt; 1.0</td>
<td>0.25</td>
<td>master, session, reload</td>
</tr>
</tbody>
</table>

### gp_appendonly_compaction
Enables compacting segment files during `VACUUM` commands. When disabled, `VACUUM` only truncates the segment files to the EOF value, as is the current behavior. The administrator may want to disable compaction in high I/O load situations or low space situations.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>on</td>
<td>master, session, reload</td>
</tr>
</tbody>
</table>

### gp_appendonly_compaction_threshold
Specifies the threshold ratio (as a percentage) of hidden rows to total rows that triggers compaction of the segment file when `VACUUM` is run without the `FULL` option (a lazy vacuum). If the ratio of hidden rows in a segment file on a segment is less than this threshold, the segment file is not compacted, and a log message is issued.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>on</td>
<td>master, session, reload</td>
</tr>
</tbody>
</table>
Value Range | Default | Set Classifications
---|---|---
integer (%) | 10 | master, session, reload

**gp_autostats_mode**

Specifies the mode for triggering automatic statistics collection with `ANALYZE`. The `on_no_stats` option triggers statistics collection for `CREATE TABLE AS SELECT`, `INSERT`, or `COPY` operations on any table that has no existing statistics.

The `on_change` option triggers statistics collection only when the number of rows affected exceeds the threshold defined by `gp_autostats_on_change_threshold`. Operations that can trigger automatic statistics collection with `on_change` are:

- `CREATE TABLE AS SELECT`
- `UPDATE`
- `DELETE`
- `INSERT`
- `COPY`

Default is `on_no_stats`.

*Note:* For partitioned tables, automatic statistics collection is not triggered if data is inserted from the top-level parent table of a partitioned table.

Automatic statistics collection is triggered if data is inserted directly in a leaf table (where the data is stored) of the partitioned table. Statistics are collected only on the leaf table.

**gp_autostats_mode_in_functions**

Specifies the mode for triggering automatic statistics collection with `ANALYZE` for statements in procedural language functions. The `none` option disables statistics collection. The `on_no_stats` option triggers statistics collection for `CREATE TABLE AS SELECT`, `INSERT`, or `COPY` operations that are executed in functions on any table that has no existing statistics.

The `on_change` option triggers statistics collection only when the number of rows affected exceeds the threshold defined by `gp_autostats_on_change_threshold`. Operations in functions that can trigger automatic statistics collection with `on_change` are:

- `CREATE TABLE AS SELECT`
- `UPDATE`
- `DELETE`
- `INSERT`
- `COPY`
gp_autostats_on_change_threshold

Specifies the threshold for automatic statistics collection when gp_autostats_mode is set to on_change. When a triggering table operation affects a number of rows exceeding this threshold, ANALYZE is added and statistics are collected for the table.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>integer</td>
<td>2147483647</td>
<td>master session reload</td>
</tr>
</tbody>
</table>

gp_backup_directIO

Direct I/O allows Greenplum Database to bypass the buffering of memory within the file system cache for backup. When Direct I/O is used for a file, data is transferred directly from the disk to the application buffer, without the use of the file buffer cache.

Direct I/O is supported only on Red Hat Enterprise Linux, CentOS, and SUSE.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>on, off</td>
<td>off</td>
<td>local session reload</td>
</tr>
</tbody>
</table>

gp_backup_directIO_read_chunk_mb

Sets the chunk size in MB when Direct I/O is enabled with gp_backup_directIO. The default chunk size is 20MB.

The default value is the optimal setting. Decreasing it will increase the backup time and increasing it will result in little change to backup time.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>1-200</td>
<td>20 MB</td>
<td>local session reload</td>
</tr>
</tbody>
</table>

gp_cached_segworkers_threshold

When a user starts a session with Greenplum Database and issues a query, the system creates groups or ‘gangs’ of worker processes on each segment to do the work. After the work is done, the segment worker processes are destroyed except for a cached number which is set by this parameter. A lower setting conserves system resources on the segment hosts, but a higher setting may improve performance for power-users that want to issue many complex queries in a row.
<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>integer &gt; 0</td>
<td>5</td>
<td>master, session, reload</td>
</tr>
</tbody>
</table>

### gp_command_count

Shows how many commands the master has received from the client. Note that a single SQL command might actually involve more than one command internally, so the counter may increment by more than one for a single query. This counter also is shared by all of the segment processes working on the command.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>integer &gt; 0</td>
<td>1</td>
<td>read only</td>
</tr>
</tbody>
</table>

### gp_connection_send_timeout

Timeout for sending data to unresponsive Greenplum Database user clients during query processing. A value of 0 disables the timeout, Greenplum Database waits indefinitely for a client. When the timeout is reached, the query is cancelled with this message:

```
Could not send data to client: Connection timed out.
```

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>number of seconds</td>
<td>3600 (1 hour)</td>
<td>master, system, reload</td>
</tr>
</tbody>
</table>

### gp_connections_per_thread

Controls the number of asynchronous threads (worker threads) that a Greenplum Database query dispatcher (QD) generates when dispatching work to query executor processes on segment instances when processing SQL queries. The value sets the number of primary segment instances that a worker thread connects to when processing a query. For example, when the value is 2 and there are 64 segment instances, a QD generates 32 worker threads to dispatch a query plan work. Each thread is assigned to two segments.

For the default value, 0, a query dispatcher generates two types of threads: a main thread that manages the dispatch of query plan work, and an interconnect thread. The main thread also acts as a worker thread.

For a value greater than 0, a QD generates three types of threads: a main thread, one or more worker threads, and an interconnect thread. When the value is equal to or greater than the number of segment instances, a QD generates three threads: a main thread, a single worker thread, and an interconnect thread.

The value does not need to be changed from the default unless there are known throughput performance issues.

This parameter is master only and changing it requires a server restart.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>integer &gt;= 0</td>
<td>0</td>
<td>master, restart</td>
</tr>
</tbody>
</table>
**gp_content**

The local content id if a segment.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>integer</td>
<td></td>
<td>read only</td>
</tr>
</tbody>
</table>

**gp_create_table_random_default_distribution**

Controls table creation when a Greenplum Database table is created with a `CREATE TABLE` or `CREATE TABLE AS` command that does not contain a `DISTRIBUTED BY` clause.

For `CREATE TABLE`, if the value of the parameter is off (the default), and the table creation command does not contain a `DISTRIBUTED BY` clause, Greenplum Database chooses the table distribution key based on the command. If the `LIKE` or `INHERITS` clause is specified in table creation command, the created table uses the same distribution key as the source or parent table.

If the value of the parameter is set to on, Greenplum Database follows these rules to create a table when the `DISTRIBUTED BY` clause is not specified:

- If `PRIMARY KEY` or `UNIQUE` columns are not specified, the distribution of the table is random (DISTRIBUTED RANDOMLY). Table distribution is random even if the table creation command contains the `LIKE` or `INHERITS` clause.
- If `PRIMARY KEY` or `UNIQUE` columns are specified, a `DISTRIBUTED BY` clause must also be specified. If a `DISTRIBUTED BY` clause is not specified as part of the table creation command, the command fails.

For a `CREATE TABLE AS` command that does not contain a distribution clause:

- If the legacy query optimizer creates the table, and the value of the parameter is off, the table distribution policy is determined based on the command.
- If the legacy query optimizer creates the table, and the value of the parameter is on, the table distribution policy is random.
- If GPORCA creates the table, the table distribution policy is random. The parameter value has no affect.

For information about the legacy query optimizer and GPORCA, see "Querying Data" in the Greenplum Database Administrator Guide.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>boolean</td>
<td>off</td>
<td>master system reload</td>
</tr>
</tbody>
</table>

**gp_dbid**

The local content dbid if a segment.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>integer</td>
<td></td>
<td>read only</td>
</tr>
</tbody>
</table>

**gp_debug_linger**

Number of seconds for a Greenplum process to linger after a fatal internal error.
<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>Any valid time expression</td>
<td>0</td>
<td>master, session, reload</td>
</tr>
</tbody>
</table>

**gp_default_storage_options**

Set the default values for the following table storage options when a table is created with the CREATE TABLE command.

- APPENDONLY
- BLOCKSIZE
- CHECKSUM
- COMPRESSTYPE
- COMPRESSLEVEL
- ORIENTATION

Specify multiple storage option values as a comma separated list.

You can set the storage options with this parameter instead of specifying the table storage options in the WITH of the CREATE TABLE command. The table storage options that are specified with the CREATE TABLE command override the values specified by this parameter.

Not all combinations of storage option values are valid. If the specified storage options are not valid, an error is returned. See the CREATE TABLE command for information about table storage options.

The defaults can be set for a database and user. If the server configuration parameter is set at different levels, this is the order of precedence, from highest to lowest, of the table storage values when a user logs into a database and creates a table:

1. The values specified in a CREATE TABLE command with the WITH clause or ENCODING clause
2. The value of gp_default_storage_options that set for the user with the ALTER ROLE...SET command
3. The value of gp_default_storage_options that is set for the database with the ALTER DATABASE...SET command
4. The value of gp_default_storage_options that is set for the Greenplum Database system with the gpconfig utility

The parameter value is not cumulative. For example, if the parameter specifies the APPENDONLY and COMPRESSTYPE options for a database and a user logs in and sets the parameter to specify the value for the ORIENTATION option, the APPENDONLY, and COMPRESSTYPE values set at the database level are ignored.

This example ALTER DATABASE command sets the default ORIENTATION and COMPRESSTYPE table storage options for the database mystest.

```
ALTER DATABASE mystest SET gp_default_storage_options = 'orientation=column, compressstype=rle_type'
```

To create an append-optimized table in the mystest database with column-oriented table and RLE compression. The user needs to specify only APPENDONLY=TRUE in the WITH clause.
This example `gpconfig` utility command sets the default storage option for a Greenplum Database system. If you set the defaults for multiple table storage options, the value must be enclosed in single quotes.

```
gpconfig -c 'gp_default_storage_options' -v 'appendonly=true, orientation=column'
```

This example `gpconfig` utility command shows the value of the parameter. The parameter value must be consistent across the Greenplum Database master and all segments.

```
gpconfig -s 'gp_default_storage_options'
```

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>APPENDONLY = TRUE</td>
<td>FALSE</td>
<td>APPENDONLY = FALSE</td>
</tr>
<tr>
<td>BLOCKSIZE = integer between 8192 and 2097152</td>
<td>BLOCKSIZE = 32768</td>
<td>BLOCKSIZE = 32768</td>
</tr>
<tr>
<td>CHECKSUM = TRUE</td>
<td>FALSE</td>
<td>CHECKSUM = TRUE</td>
</tr>
<tr>
<td>COMPRESSTYPE = ZLIB</td>
<td>RLE_TYPE</td>
<td>COMPRESSTYPE = none</td>
</tr>
<tr>
<td>COMPRESSLEVEL = integer between 0 and 19</td>
<td>COMPRESSLEVEL = 0</td>
<td>COMPRESSLEVEL = 0</td>
</tr>
<tr>
<td>ORIENTATION = ROW</td>
<td>COLUMN</td>
<td>ORIENTATION = ROW</td>
</tr>
</tbody>
</table>

**Note:** 1 The set classification when the parameter is set at the system level with the `gpconfig` utility.

**Note:** 2 QuickLZ compression is available only in the commercial release of Pivotal Greenplum Database.

**gp_dynamic_partition_pruning**

Enables plans that can dynamically eliminate the scanning of partitions.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>on/off</td>
<td>on</td>
<td>master</td>
</tr>
<tr>
<td></td>
<td></td>
<td>session</td>
</tr>
<tr>
<td></td>
<td></td>
<td>reload</td>
</tr>
</tbody>
</table>

**gp_email_from**

The email address used to send email alerts, in the format of:

'username@example.com'

or

'Name <username@example.com>'
### gp_email_smtp_password

The password/passphrase used to authenticate with the SMTP server.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>string</td>
<td></td>
<td>master system reload superuser</td>
</tr>
</tbody>
</table>

### gp_email_smtp_server

The fully qualified domain name or IP address and port of the SMTP server to use to send the email alerts. Must be in the format of:

smtp_servername.domain.com:port

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>string</td>
<td></td>
<td>master system reload superuser</td>
</tr>
</tbody>
</table>

### gp_email_smtp_userid

The user id used to authenticate with the SMTP server.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>string</td>
<td></td>
<td>master system reload superuser</td>
</tr>
</tbody>
</table>

### gp_email_to

A semi-colon (;) separated list of email addresses to receive email alert messages to in the format of:

'username@example.com'

or

'Name <username@example.com>'
If this parameter is not set, then email alerts are disabled.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>string</td>
<td></td>
<td>master</td>
</tr>
<tr>
<td></td>
<td></td>
<td>system</td>
</tr>
<tr>
<td></td>
<td></td>
<td>reload</td>
</tr>
<tr>
<td></td>
<td></td>
<td>superuser</td>
</tr>
</tbody>
</table>

### gp_enable_agg_distinct

Enables or disables two-phase aggregation to compute a single distinct-qualified aggregate. This applies only to subqueries that include a single distinct-qualified aggregate function.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>on</td>
<td>master</td>
</tr>
<tr>
<td></td>
<td></td>
<td>session</td>
</tr>
<tr>
<td></td>
<td></td>
<td>reload</td>
</tr>
</tbody>
</table>

### gp_enable_agg_distinct_pruning

Enables or disables three-phase aggregation and join to compute distinct-qualified aggregates. This applies only to subqueries that include one or more distinct-qualified aggregate functions.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>on</td>
<td>master</td>
</tr>
<tr>
<td></td>
<td></td>
<td>session</td>
</tr>
<tr>
<td></td>
<td></td>
<td>reload</td>
</tr>
</tbody>
</table>

### gp_enable_direct_dispatch

Enables or disables the dispatching of targeted query plans for queries that access data on a single segment. When on, queries that target rows on a single segment will only have their query plan dispatched to that segment (rather than to all segments). This significantly reduces the response time of qualifying queries as there is no interconnect setup involved. Direct dispatch does require more CPU utilization on the master.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>on</td>
<td>master</td>
</tr>
<tr>
<td></td>
<td></td>
<td>system</td>
</tr>
<tr>
<td></td>
<td></td>
<td>restart</td>
</tr>
</tbody>
</table>

### gp_enable_exchange_default_partition

Controls availability of the `EXCHANGE DEFAULT PARTITION` clause for `ALTER TABLE`. The default value for the parameter is `off`. The clause is not available and Greenplum Database returns an error if the clause is specified in an `ALTER TABLE` command.

If the value is `on`, Greenplum Database returns a warning stating that exchanging the default partition might result in incorrect results due to invalid data in the default partition.
**Warning:** Before you exchange the default partition, you must ensure the data in the table to be exchanged, the new default partition, is valid for the default partition. For example, the data in the new default partition must not contain data that would be valid in other leaf child partitions of the partitioned table. Otherwise, queries against the partitioned table with the exchanged default partition that are executed by GPORCA might return incorrect results.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>off</td>
<td>master</td>
</tr>
<tr>
<td></td>
<td></td>
<td>session</td>
</tr>
<tr>
<td></td>
<td></td>
<td>reload</td>
</tr>
</tbody>
</table>

**gp_enable_fallback_plan**

Allows use of disabled plan types when a query would not be feasible without them.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>on</td>
<td>master</td>
</tr>
<tr>
<td></td>
<td></td>
<td>session</td>
</tr>
<tr>
<td></td>
<td></td>
<td>reload</td>
</tr>
</tbody>
</table>

**gp_enable_fast_sri**

When set to on, the legacy query optimizer (planner) plans single row inserts so that they are sent directly to the correct segment instance (no motion operation required). This significantly improves performance of single-row-insert statements.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>on</td>
<td>master</td>
</tr>
<tr>
<td></td>
<td></td>
<td>session</td>
</tr>
<tr>
<td></td>
<td></td>
<td>reload</td>
</tr>
</tbody>
</table>

**gp_enable_gpperfmon**

Enables or disables the data collection agents that populate the gpperfmon database for Greenplum Command Center.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>off</td>
<td>local</td>
</tr>
<tr>
<td></td>
<td></td>
<td>system</td>
</tr>
<tr>
<td></td>
<td></td>
<td>restart</td>
</tr>
</tbody>
</table>

**gp_enable_groupext_distinct_gather**

Enables or disables gathering data to a single node to compute distinct-qualified aggregates on grouping extension queries. When this parameter and gp_enable_groupext_distinct_pruning are both enabled, the legacy query optimizer (planner) uses the cheaper plan.
<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>on</td>
<td>master</td>
</tr>
<tr>
<td></td>
<td></td>
<td>session</td>
</tr>
<tr>
<td></td>
<td></td>
<td>reload</td>
</tr>
</tbody>
</table>

**gp_enable_groupext_distinct_pruning**

Enables or disables three-phase aggregation and join to compute distinct-qualified aggregates on grouping extension queries. Usually, enabling this parameter generates a cheaper query plan that the legacy query optimizer (planner) will use in preference to existing plan.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>on</td>
<td>master</td>
</tr>
<tr>
<td></td>
<td></td>
<td>session</td>
</tr>
<tr>
<td></td>
<td></td>
<td>reload</td>
</tr>
</tbody>
</table>

**gp_enable_multiphase_agg**

Enables or disables the use of two or three-stage parallel aggregation plans legacy query optimizer (planner). This approach applies to any subquery with aggregation. If gp_enable_multiphase_agg is off, then gp_enable_agg_distinct and gp_enable_agg_distinct_pruning are disabled.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>on</td>
<td>master</td>
</tr>
<tr>
<td></td>
<td></td>
<td>session</td>
</tr>
<tr>
<td></td>
<td></td>
<td>reload</td>
</tr>
</tbody>
</table>

**gp_enable_predicate_propagation**

When enabled, the legacy query optimizer (planner) applies query predicates to both table expressions in cases where the tables are joined on their distribution key column(s). Filtering both tables prior to doing the join (when possible) is more efficient.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>on</td>
<td>master</td>
</tr>
<tr>
<td></td>
<td></td>
<td>session</td>
</tr>
<tr>
<td></td>
<td></td>
<td>reload</td>
</tr>
</tbody>
</table>

**gp_enable_preunique**

Enables two-phase duplicate removal for SELECT DISTINCT queries (not SELECT COUNT(DISTINCT)). When enabled, it adds an extra SORT DISTINCT set of plan nodes before motioning. In cases where the distinct operation greatly reduces the number of rows, this extra SORT DISTINCT is much cheaper than the cost of sending the rows across the Interconnect.
<table>
<thead>
<tr>
<th><strong>Value Range</strong></th>
<th><strong>Default</strong></th>
<th><strong>Set Classifications</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>on</td>
<td>master session reload</td>
</tr>
</tbody>
</table>

**gp_enable_relsize_collection**

Enables GPORCA and the legacy query optimizer (planner) to use the estimated size of a table (pg_relation_size function) if there are no statistics for the table. By default, GPORCA and the planner use a default value to estimate the number of rows if statistics are not available. The default behavior improves query optimization time and reduces resource queue usage in heavy workloads, but can lead to suboptimal plans.

This parameter is ignored for a root partition of a partitioned table. When GPORCA is enabled and the root partition does not have statistics, GPORCA always uses the default value. You can use **ANALYZE** **ROOTPARTITION** to collect statistics on the root partition. See **ANALYZE**.

<table>
<thead>
<tr>
<th><strong>Value Range</strong></th>
<th><strong>Default</strong></th>
<th><strong>Set Classifications</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>off</td>
<td>master session reload</td>
</tr>
</tbody>
</table>

**gp_enable_sequential_window_plans (Beta)**

If on, enables non-parallel (sequential) query plans for queries containing window function calls. If off, evaluates compatible window functions in parallel and rejoins the results. This is a Beta feature.

<table>
<thead>
<tr>
<th><strong>Value Range</strong></th>
<th><strong>Default</strong></th>
<th><strong>Set Classifications</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>on</td>
<td>master session reload</td>
</tr>
</tbody>
</table>

**gp_enable_segment_copy_checking**

Controls whether the distribution policy for a table (from the table DISTRIBUTED clause) is checked when data is copied into the table with the COPY FROM...ON SEGMENT command. The default is true, check the policy when copying data into the table. An error is returned in these situations.

- For a table that is not a partitioned table, an error is returned if the row of data violates the distribution policy for a segment instance.
- For a partitioned table, an error is returned if either of the following is true.
  - If the distribution policy of the child leaf partitioned table is the same as the root table and the row of data violates the distribution policy for a segment instance.
  - If the distribution policy of the child leaf partitioned table is not the same as the root table.

If the value is false, the distribution policy is not checked. The data added to the table might violate the table distribution policy for the segment instance. Manual redistribution of table data might be required. See the **ALTER TABLE** clause **WITH REORGANIZE**.

The parameter can be set for a database system or a session. The parameter cannot be set for a specific database.
### gp_enable_sort_distinct

Enable duplicates to be removed while sorting.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>true</td>
<td>master, session, reload</td>
</tr>
</tbody>
</table>

### gp_enable_sort_limit

Enable **LIMIT** operation to be performed while sorting. Sorts more efficiently when the plan requires the first **limit_number** of rows at most.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>on</td>
<td>master, session, reload</td>
</tr>
</tbody>
</table>

### gp_external_enable_exec

Enables or disables the use of external tables that execute OS commands or scripts on the segment hosts (**CREATE EXTERNAL TABLE EXECUTE** syntax). Must be enabled if using the Command Center or MapReduce features.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>on</td>
<td>master, system, restart</td>
</tr>
</tbody>
</table>

### gp_external_max_segs

Sets the number of segments that will scan external table data during an external table operation, the purpose being not to overload the system with scanning data and take away resources from other concurrent operations. This only applies to external tables that use the **gpfdist:**// protocol to access external table data.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>integer</td>
<td>64</td>
<td>master, session, reload</td>
</tr>
</tbody>
</table>
**gp_external_enable_filter_pushdown**

Enable filter pushdown when reading data from external tables. If pushdown fails, a query is executed without pushing filters to the external data source (instead, Greenplum Database applies the same constraints to the result). See *Defining External Tables* for more information.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>on</td>
<td>master session reload</td>
</tr>
</tbody>
</table>

**gp_filerep_tcp_keepalives_count**

How many keepalives may be lost before the connection is considered dead. A value of 0 uses the system default. If TCP_KEEPCNT is not supported, this parameter must be 0.

Use this parameter for all connections that are between a primary and mirror segment. Use `tcp_keepalives_count` for settings that are not between a primary and mirror segment.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>number of lost keepalives</td>
<td>2</td>
<td>local system restart</td>
</tr>
</tbody>
</table>

**gp_filerep_tcp_keepalives_idle**

Number of seconds between sending keepalives on an otherwise idle connection. A value of 0 uses the system default. If TCP_KEEPIDLE is not supported, this parameter must be 0.

Use this parameter for all connections that are between a primary and mirror segment. Use `tcp_keepalives_idle` for settings that are not between a primary and mirror segment.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>number of seconds</td>
<td>1 min</td>
<td>local system restart</td>
</tr>
</tbody>
</table>

**gp_filerep_tcp_keepalives_interval**

How many seconds to wait for a response to a keepalive before retransmitting. A value of 0 uses the system default. If TCP_KEEPINTVL is not supported, this parameter must be 0.

Use this parameter for all connections that are between a primary and mirror segment. Use `tcp_keepalives_interval` for settings that are not between a primary and mirror segment.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>number of seconds</td>
<td>30 sec</td>
<td>local system restart</td>
</tr>
</tbody>
</table>
**gp_fts_probe_interval**

Specifies the polling interval for the fault detection process (*ftsprobe*). The *ftsprobe* process will take approximately this amount of time to detect a segment failure.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>10 - 3600 seconds</td>
<td>1min</td>
<td>master, system, restart</td>
</tr>
</tbody>
</table>

**gp_fts_probe_retries**

Specifies the number of times the fault detection process (*ftsprobe*) attempts to connect to a segment before reporting segment failure.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>integer</td>
<td>5</td>
<td>master, system, restart</td>
</tr>
</tbody>
</table>

**gp_fts_probe_threadcount**

Specifies the number of *ftsprobe* threads to create. This parameter should be set to a value equal to or greater than the number of segments per host.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>1 - 128</td>
<td>16</td>
<td>master, system, restart</td>
</tr>
</tbody>
</table>

**gp_fts_probe_timeout**

Specifies the allowed timeout for the fault detection process (*ftsprobe*) to establish a connection to a segment before declaring it down.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>10 - 3600 seconds</td>
<td>20 secs</td>
<td>master, system, restart</td>
</tr>
</tbody>
</table>

**gp_log_fts**

Controls the amount of detail the fault detection process (*ftsprobe*) writes to the log file.
**gp_log_interconnect**

Controls the amount of information that is written to the log file about communication between Greenplum Database segment instance worker processes. The default value is **terse**. The log information is written to both the master and segment instance logs.

Increasing the amount of logging could affect performance and increase disk space usage.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>OFF</td>
<td>TERSE</td>
<td>master</td>
</tr>
<tr>
<td>TERSE</td>
<td></td>
<td>system</td>
</tr>
<tr>
<td>VERBOSE</td>
<td></td>
<td>restart</td>
</tr>
<tr>
<td>DEBUG</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**gp_log_gang**

Controls the amount of information that is written to the log file about query worker process creation and query management. The default value is **OFF**, do not log information.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>OFF</td>
<td></td>
<td>master</td>
</tr>
<tr>
<td>TERSE</td>
<td>terse</td>
<td>session</td>
</tr>
<tr>
<td>VERBOSE</td>
<td></td>
<td>reload</td>
</tr>
<tr>
<td>DEBUG</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**gp_gpperfmon_send_interval**

Sets the frequency that the Greenplum Database server processes send query execution updates to the data collection agent processes used to populate the **gpperfmon** database for Command Center. Query operations executed during this interval are sent through UDP to the segment monitor agents. If you find that an excessive number of UDP packets are dropped during long-running, complex queries, you may consider increasing this value.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>Any valid time expression (number and unit)</td>
<td>1sec</td>
<td>master</td>
</tr>
<tr>
<td></td>
<td></td>
<td>system</td>
</tr>
<tr>
<td></td>
<td></td>
<td>restart</td>
</tr>
<tr>
<td></td>
<td></td>
<td>superuser</td>
</tr>
</tbody>
</table>
**gpperfmon_log_alert_level**

Controls which message levels are written to the gpperfmon log. Each level includes all the levels that follow it. The later the level, the fewer messages are sent to the log.

**Note:** If the gpperfmon database is installed and is monitoring the database, the default value is warning.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>none</td>
<td>none</td>
<td>local</td>
</tr>
<tr>
<td>warning</td>
<td></td>
<td>system</td>
</tr>
<tr>
<td>error</td>
<td></td>
<td>restart</td>
</tr>
<tr>
<td>fatal</td>
<td></td>
<td></td>
</tr>
<tr>
<td>panic</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**gp_hadoop_home**

Specifies the installation directory for the Greenplum Database gphdfs protocol (deprecated) Hadoop target.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>Valid directory name</td>
<td>Value of HADOOP_HOME</td>
<td>local</td>
</tr>
<tr>
<td></td>
<td></td>
<td>session</td>
</tr>
<tr>
<td></td>
<td></td>
<td>reload</td>
</tr>
</tbody>
</table>

**gp_hadoop_target_version**

The installed version of the Greenplum Database gphdfs protocol (deprecated) Hadoop target.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>cdh</td>
<td>hadoop</td>
<td>local</td>
</tr>
<tr>
<td>hadoop</td>
<td></td>
<td>session</td>
</tr>
<tr>
<td>hdp</td>
<td></td>
<td>reload</td>
</tr>
<tr>
<td>mpr</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**gp_hashjoin_tuples_per_bucket**

Sets the target density of the hash table used by HashJoin operations. A smaller value will tend to produce larger hash tables, which can increase join performance.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>integer</td>
<td>5</td>
<td>master</td>
</tr>
<tr>
<td></td>
<td></td>
<td>session</td>
</tr>
<tr>
<td></td>
<td></td>
<td>reload</td>
</tr>
</tbody>
</table>
**gp_idf_deduplicate**

Changes the strategy to compute and process MEDIAN, and PERCENTILE_DISC.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>auto</td>
<td>auto</td>
<td>master</td>
</tr>
<tr>
<td>none</td>
<td></td>
<td>session</td>
</tr>
<tr>
<td>force</td>
<td></td>
<td>reload</td>
</tr>
</tbody>
</table>

**gp_ignore_error_table**

Controls Greenplum Database behavior when the INTO ERROR TABLE clause is specified in a CREATE EXTERNAL TABLE or COPY command. The INTO ERROR TABLE clause was removed in Greenplum Database 5.

The default value is false, Greenplum Database returns an error if the INTO ERROR TABLE clause is specified in a command.

If the value is true, Greenplum Database ignores the clause, issues a warning, and executes the command without the INTO ERROR TABLE clause. In Greenplum Database 5.x and later, you access the error log information with built-in SQL functions. See the CREATE EXTERNAL TABLE or COPY command.

You can set this value to true to avoid the Greenplum Database error when you run applications that execute CREATE EXTERNAL TABLE or COPY commands that include the Greenplum Database 4.3.x INTO ERROR TABLE clause.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>false</td>
<td>master</td>
</tr>
<tr>
<td></td>
<td></td>
<td>session</td>
</tr>
<tr>
<td></td>
<td></td>
<td>reload</td>
</tr>
</tbody>
</table>

**gp_initial_bad_row_limit**

For the parameter value \( n \), Greenplum Database stops processing input rows when you import data with the COPY command or from an external table if the first \( n \) rows processed contain formatting errors. If a valid row is processed within the first \( n \) rows, Greenplum Database continues processing input rows.

Setting the value to 0 disables this limit.

The SEGMENT REJECT LIMIT clause can also be specified for the COPY command or the external table definition to limit the number of rejected rows.

\( INT\_MAX \) is the largest value that can be stored as an integer on your system.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>integer 0 – INT_MAX</td>
<td>1000</td>
<td>master</td>
</tr>
<tr>
<td></td>
<td></td>
<td>session</td>
</tr>
<tr>
<td></td>
<td></td>
<td>reload</td>
</tr>
</tbody>
</table>

**gp_interconnect_debug_retry_interval**

Specifies the interval, in seconds, to log Greenplum Database interconnect debugging messages when the server configuration parameter `gp_log_interconnect` is set to `DEBUG`. The default is 10 seconds.
The log messages contain information about the interconnect communication between Greenplum Database segment instance worker processes. The information can be helpful when debugging network issues between segment instances.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>1 &lt;= Integer &lt; 4096</td>
<td>10</td>
<td>master session reload</td>
</tr>
</tbody>
</table>

**gp_interconnect_fc_method**

Specifies the flow control method used for the default Greenplum Database UDPIFC interconnect.

For capacity based flow control, senders do not send packets when receivers do not have the capacity. Loss based flow control is based on capacity based flow control, and also tunes the sending speed according to packet losses.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>CAPACITY</td>
<td>LOSS</td>
<td>master session reload</td>
</tr>
<tr>
<td>LOSS</td>
<td>LOSS</td>
<td>master session reload</td>
</tr>
</tbody>
</table>

**gp_interconnect_hash_multiplier**

Sets the size of the hash table used by the Greenplum Database to track interconnect connections with the default UDPIFC interconnect. This number is multiplied by the number of segments to determine the number of buckets in the hash table. Increasing the value may increase interconnect performance for complex multi-slice queries (while consuming slightly more memory on the segment hosts).

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>2-25</td>
<td>2</td>
<td>master session reload</td>
</tr>
</tbody>
</table>

**gp_interconnect_queue_depth**

Sets the amount of data per-peer to be queued by the Greenplum Database interconnect on receivers (when data is received but no space is available to receive it the data will be dropped, and the transmitter will need to resend it) for the default UDPIFC interconnect. Increasing the depth from its default value will cause the system to use more memory, but may increase performance. It is reasonable to set this value between 1 and 10. Queries with data skew potentially perform better with an increased queue depth. Increasing this may radically increase the amount of memory used by the system.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>1-2048</td>
<td>4</td>
<td>master session reload</td>
</tr>
</tbody>
</table>
**gp_interconnect_setup_timeout**

Specifies the amount of time to wait for the Greenplum Database interconnect to complete setup before it times out.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>Any valid time expression</td>
<td>2 hours</td>
<td>master, session, reload</td>
</tr>
<tr>
<td>(number and unit)</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**gp_interconnect_snd_queue_depth**

Sets the amount of data per-peer to be queued by the default UDPIFC interconnect on senders. Increasing the depth from its default value will cause the system to use more memory, but may increase performance. Reasonable values for this parameter are between 1 and 4. Increasing the value might radically increase the amount of memory used by the system.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>1 - 4096</td>
<td>2</td>
<td>master, session, reload</td>
</tr>
</tbody>
</table>

**gp_interconnect_type**

Sets the networking protocol used for Greenplum Database interconnect traffic. UDPIFC specifies using UDP with flow control for interconnect traffic, and is the only value supported.

UDPIFC (the default) specifies using UDP with flow control for interconnect traffic. Specify the interconnect flow control method with `gp_interconnect_fc_method`.

With TCP as the interconnect protocol, Greenplum Database has an upper limit of 1000 segment instances - less than that if the query workload involves complex, multi-slice queries.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>UDPIFC</td>
<td>UDPIFC</td>
<td>local, system, restart</td>
</tr>
<tr>
<td>TCP</td>
<td>UDPIFC</td>
<td></td>
</tr>
</tbody>
</table>

**gp_log_format**

Specifies the format of the server log files. If using `gp_toolkit` administrative schema, the log files must be in CSV format.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>csv</td>
<td>csv</td>
<td>local, system, restart</td>
</tr>
<tr>
<td>text</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
**gp_max_csv_line_length**

The maximum length of a line in a CSV formatted file that will be imported into the system. The default is 1MB (1048576 bytes). Maximum allowed is 1GB (1073741824 bytes). The default may need to be increased if using the `gp_toolkit` administrative schema to read Greenplum Database log files.

**Note:** This parameter is deprecated and will be removed in a future release.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>number of bytes</td>
<td>1048576</td>
<td>local system restart</td>
</tr>
</tbody>
</table>

**gp_max_databases**

The maximum number of databases allowed in a Greenplum Database system.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>integer</td>
<td>16</td>
<td>master system restart</td>
</tr>
</tbody>
</table>

**gp_max_filespaces**

The maximum number of filespaces allowed in a Greenplum Database system.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>integer</td>
<td>8</td>
<td>master system restart</td>
</tr>
</tbody>
</table>

**gp_max_local_distributed_cache**

Sets the maximum number of distributed transaction log entries to cache in the backend process memory of a segment instance.

The log entries contain information about the state of rows that are being accessed by an SQL statement. The information is used to determine which rows are visible to an SQL transaction when executing multiple simultaneous SQL statements in an MVCC environment. Caching distributed transaction log entries locally improves transaction processing speed by improving performance of the row visibility determination process.

The default value is optimal for a wide variety of SQL processing environments.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>integer</td>
<td>1024</td>
<td>local system restart</td>
</tr>
</tbody>
</table>
**gp_max_packet_size**

Sets the tuple-serialization chunk size for the Greenplum Database interconnect.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>512-65536</td>
<td>8192</td>
<td>master, system, restart</td>
</tr>
</tbody>
</table>

**gp_max_plan_size**

Specifies the total maximum uncompressed size of a query execution plan multiplied by the number of Motion operators (slices) in the plan. If the size of the query plan exceeds the value, the query is cancelled and an error is returned. A value of 0 means that the size of the plan is not monitored.

You can specify a value in kB, MB, or GB. The default unit is kB. For example, a value of 200 is 200kB. A value of 1GB is the same as 1024MB or 1048576kB.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>integer</td>
<td>0</td>
<td>master, superuser, session</td>
</tr>
</tbody>
</table>

**gp_max_slices**

Specifies the maximum number of slices (portions of a query plan that are executed on segment instances) that can be generated by a query. If the query generates more than the specified number of slices, Greenplum Database returns an error and does not execute the query. The default value is 0, no maximum value.

Executing a query that generates a large number of slices might affect Greenplum Database performance. For example, a query that contains UNION or UNION ALL operators over several complex views can generate a large number of slices. You can run EXPLAIN ANALYZE on the query to view slice statistics for the query.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>0 - INT_MAX</td>
<td>0</td>
<td>master, session, reload</td>
</tr>
</tbody>
</table>

**gp_max_tablespaces**

The maximum number of tablespaces allowed in a Greenplum Database system.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>integer</td>
<td>16</td>
<td>master, system, restart</td>
</tr>
</tbody>
</table>
**gp_motion_cost_per_row**
Sets the legacy query optimizer (planner) cost estimate for a Motion operator to transfer a row from one segment to another, measured as a fraction of the cost of a sequential page fetch. If 0, then the value used is two times the value of `cpu_tuple_cost`.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>floating point</td>
<td>0</td>
<td>master</td>
</tr>
<tr>
<td></td>
<td></td>
<td>session</td>
</tr>
<tr>
<td></td>
<td></td>
<td>reload</td>
</tr>
</tbody>
</table>

**gp_num_contents_in_cluster**
The number of primary segments in the Greenplum Database system.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>read only</td>
</tr>
</tbody>
</table>

**gp_recursive_cte_prototype**
Controls the availability of the `RECURSIVE` keyword (Beta) in the `WITH` clause of a `SELECT[ INTO]` command. The keyword allows a subquery in the `WITH` clause of a `SELECT[ INTO]` command to reference itself. The default value is `false`, the keyword is not allowed in the `WITH` clause a `SELECT[ INTO]` command.

*Note:* The `RECURSIVE` keyword is a Beta feature.

For information about the `RECURSIVE` keyword (Beta), see the `SELECT` command.

The parameter can be set for a database system, an individual database, or a session or query.

*Note:* This parameter will be removed if the `RECURSIVE` keyword is promoted from Beta or if the keyword is removed from Greenplum Database.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>false</td>
<td>master</td>
</tr>
<tr>
<td></td>
<td></td>
<td>session</td>
</tr>
<tr>
<td></td>
<td></td>
<td>restart</td>
</tr>
</tbody>
</table>

**gp_reject_percent_threshold**
For single row error handling on `COPY` and external table `SELECTs`, sets the number of rows processed before `SEGMENT REJECT LIMIT n PERCENT` starts calculating.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>1-n</td>
<td>300</td>
<td>master</td>
</tr>
<tr>
<td></td>
<td></td>
<td>session</td>
</tr>
<tr>
<td></td>
<td></td>
<td>reload</td>
</tr>
</tbody>
</table>
**gp_reraise_signal**

If enabled, will attempt to dump core if a fatal server error occurs.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>on</td>
<td>master</td>
</tr>
<tr>
<td></td>
<td></td>
<td>session</td>
</tr>
<tr>
<td></td>
<td></td>
<td>reload</td>
</tr>
</tbody>
</table>

**gp_resgroup_memory_policy**

*Note:* The `gp_resgroup_memory_policy` server configuration parameter is enforced only when resource group-based resource management is active.

Used by a resource group to manage memory allocation to query operators.

When set to `auto`, Greenplum Database uses resource group memory limits to distribute memory across query operators, allocating a fixed size of memory to non-memory-intensive operators and the rest to memory-intensive operators.

When you specify `eager_free`, Greenplum Database distributes memory among operators more optimally by re-allocating memory released by operators that have completed their processing to operators in a later query stage.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>

</tbody>
</table>

**gp_resource_group_bypass**

*Note:* The `gp_resource_group_bypass` server configuration parameter is enforced only when resource group-based resource management is active.

Enables or disables the enforcement of resource group concurrent transaction limits on Greenplum Database resources. The default value is `false`, which enforces resource group transaction limits. Resource groups manage resources such as CPU, memory, and the number of concurrent transactions that are used by queries and external components such as PL/Container.

You can set this parameter to `true` to bypass resource group concurrent transaction limitations so that a query can run immediately. For example, you can set the parameter to `true` for a session to run a system catalog query or a similar query that requires a minimal amount of resources.

When you set this parameter to `true` and run a query, the query runs in this environment:

- The query runs inside a resource group. The resource group assignment for the query does not change.
- The query memory quota is approximately 10 MB per query. The memory is allocated from resource group shared memory or global shared memory. The query fails if there is not enough shared memory available to fulfill the memory allocation request.

This parameter can be set for a session. The parameter cannot be set within a transaction or a function.
<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>false</td>
<td>session</td>
</tr>
</tbody>
</table>

**gp_resource_group_cpu_limit**

*Note:* The `gp_resource_group_cpu_limit` server configuration parameter is enforced only when resource group-based resource management is active.

Identifies the maximum percentage of system CPU resources to allocate to resource groups on each Greenplum Database segment node.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>0.1 - 1.0</td>
<td>0.9</td>
<td>local system restart</td>
</tr>
</tbody>
</table>

**gp_resource_group_memory_limit**

*Note:* The `gp_resource_group_memory_limit` server configuration parameter is enforced only when resource group-based resource management is active.

Identifies the maximum percentage of system memory resources to allocate to resource groups on each Greenplum Database segment node.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>0.1 - 1.0</td>
<td>0.7</td>
<td>local system restart</td>
</tr>
</tbody>
</table>

*Note:* When resource group-based resource management is active, the memory allotted to a segment host is equally shared by active primary segments. Greenplum Database assigns memory to primary segments when the segment takes the primary role. The initial memory allotment to a primary segment does not change, even in a failover situation. This may result in a segment host utilizing more memory than the `gp_resource_group_memory_limit` setting permits.

For example, suppose your Greenplum Database cluster is utilizing the default `gp_resource_group_memory_limit` of 0.7 and a segment host named seghost1 has 4 primary segments and 4 mirror segments. Greenplum Database assigns each primary segment on seghost1 (0.7 / 4 = 0.175%) of overall system memory. If failover occurs and two mirrors on seghost1 fail over to become primary segments, each of the original 4 primaries retain their memory allotment of 0.175, and the two new primary segments are each allotted (0.7 / 6 = 0.116%) of system memory. seghost1’s overall memory allocation in this scenario is

\[
0.7 + (0.116 * 2) = 0.932\%
\]

which is above the percentage configured in the `gp_resource_group_memory_limit` setting.

**gp_resource_manager**

Identifies the resource management scheme currently enabled in the Greenplum Database cluster. The default scheme is to use resource queues. For information about Greenplum Database resource management, see *Managing Resources.*
gp_resqueue_memory_policy

**Note:** The `gp_resqueue_memory_policy` server configuration parameter is enforced only when resource queue-based resource management is active.

Enables Greenplum memory management features. The distribution algorithm `eager_free` takes advantage of the fact that not all operators execute at the same time (in Greenplum Database 4.2 and later). The query plan is divided into stages and Greenplum Database eagerly frees memory allocated to a previous stage at the end of that stage's execution, then allocates the eagerly freed memory to the new stage.

When set to `none`, memory management is the same as in Greenplum Database releases prior to 4.1.

When set to `auto`, query memory usage is controlled by `statement_mem` and resource queue memory limits.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>none, auto, eager_free</td>
<td>eager_free</td>
<td>local, system, restart/reload</td>
</tr>
</tbody>
</table>

gp_resqueue_priority

**Note:** The `gp_resqueue_priority` server configuration parameter is enforced only when resource queue-based resource management is active.

Enables or disables query prioritization. When this parameter is disabled, existing priority settings are not evaluated at query run time.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>on</td>
<td>local, system, restart</td>
</tr>
</tbody>
</table>

gp_resqueue_priority_cpucores_per_segment

**Note:** The `gp_resqueue_priority_cpucores_per_segment` server configuration parameter is enforced only when resource queue-based resource management is active.

Specifies the number of CPU units allocated per segment instance. For example, if a Greenplum Database cluster has 10-core segment hosts that are configured with four segments, set the value for the segment instances to 2.5. For the master instance, the value would be 10. A master host typically has only the master instance running on it, so the value for the master should reflect the usage of all available CPU cores.

Incorrect settings can result in CPU under-utilization or query prioritization not working as designed.

The default values for the Greenplum Data Computing Appliance are 4 for segments and 4 for the master.
### gp_resqueue_priority_sweeper_interval

**Note:** The `gp_resqueue_priority_sweeper_interval` server configuration parameter is enforced only when resource queue-based resource management is active.

Specifies the interval at which the sweeper process evaluates current CPU usage. When a new statement becomes active, its priority is evaluated and its CPU share determined when the next interval is reached.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>500 - 15000 ms</td>
<td>1000</td>
<td>local system restart</td>
</tr>
</tbody>
</table>

### gp_role

The role of this server process " set to `dispatch` for the master and `execute` for a segment.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>dispatch</td>
<td></td>
<td>read only</td>
</tr>
<tr>
<td>execute</td>
<td></td>
<td></td>
</tr>
<tr>
<td>utility</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

### gp_safefswritesize

Specifies a minimum size for safe write operations to append-optimized tables in a non-mature file system. When a number of bytes greater than zero is specified, the append-optimized writer adds padding data up to that number in order to prevent data corruption due to file system errors. Each non-mature file system has a known safe write size that must be specified here when using Greenplum Database with that type of file system. This is commonly set to a multiple of the extent size of the file system; for example, Linux ext3 is 4096 bytes, so a value of 32768 is commonly used.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>integer</td>
<td>0</td>
<td>local system restart</td>
</tr>
</tbody>
</table>

### gp_segment_connect_timeout

Time that the Greenplum interconnect will try to connect to a segment instance over the network before timing out. Controls the network connection timeout between master and primary segments, and primary to mirror segment replication processes.
**gp_segments_for_planner**

Sets the number of primary segment instances for the legacy query optimizer (planner) to assume in its cost and size estimates. If 0, then the value used is the actual number of primary segments. This variable affects the legacy optimizer's estimates of the number of rows handled by each sending and receiving process in Motion operators.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>Any valid time expression (number and unit)</td>
<td>10min</td>
<td>local system reload</td>
</tr>
</tbody>
</table>

**gp_server_version**

Reports the version number of the server as a string. A version modifier argument might be appended to the numeric portion of the version string, example: 5.0.0 beta.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>String. Examples: 5.0.0</td>
<td>n/a</td>
<td>read only</td>
</tr>
</tbody>
</table>

**gp_server_version_num**

Reports the version number of the server as an integer. The number is guaranteed to always be increasing for each version and can be used for numeric comparisons. The major version is represented as is, the minor and patch versions are zero-padded to always be double digit wide.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>Mmmpp where M is the major version, mm is the minor version zero-padded and pp is the patch version zero-padded. Example: 50000</td>
<td>n/a</td>
<td>read only</td>
</tr>
</tbody>
</table>

**gp_session_id**

A system assigned ID number for a client session. Starts counting from 1 when the master instance is first started.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>1-n</td>
<td>14</td>
<td>read only</td>
</tr>
</tbody>
</table>

**gp_set_proc_affinity**

If enabled, when a Greenplum server process (postmaster) is started it will bind to a CPU.
<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>off</td>
<td>master, system, restart</td>
</tr>
</tbody>
</table>

**gp_set_read_only**

Set to on to disable writes to the database. Any in progress transactions must finish before read-only mode takes affect.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>off</td>
<td>master, system, restart</td>
</tr>
</tbody>
</table>

**gp_snmp_community**

Set to the community name you specified for your environment.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>SNMP community name</td>
<td>public</td>
<td>master, system, reload</td>
</tr>
</tbody>
</table>

**gp_snmp_monitor_address**

The hostname:port of your network monitor application. Typically, the port number is 162. If there are multiple monitor addresses, separate them with a comma.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>hostname:port</td>
<td></td>
<td>master, system, reload</td>
</tr>
</tbody>
</table>

**gp_snmp_use_inform_or_trap**

Trap notifications are SNMP messages sent from one application to another (for example, between Greenplum Database and a network monitoring application). These messages are unacknowledged by the monitoring application, but generate less network overhead.

Inform notifications are the same as trap messages, except that the application sends an acknowledgement to the application that generated the alert.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>inform</td>
<td>trap</td>
<td>master, system, reload</td>
</tr>
<tr>
<td>trap</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
**gp_statistics_pullup_from_child_partition**

Enables the use of statistics from child tables when planning queries on the parent table by the legacy query optimizer (planner).

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>on</td>
<td>master, session, reload</td>
</tr>
</tbody>
</table>

**gp_statistics_use_fkeys**

When enabled, allows the legacy query optimizer (planner) to use foreign key information stored in the system catalog to optimize joins between foreign keys and primary keys.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>off</td>
<td>master, session, reload</td>
</tr>
</tbody>
</table>

**gp_vmem_idle_resource_timeout**

If a database session is idle for longer than the time specified, the session will free system resources (such as shared memory), but remain connected to the database. This allows more concurrent connections to the database at one time.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>Any valid time expression (number and unit)</td>
<td>18s</td>
<td>master, system, reload</td>
</tr>
</tbody>
</table>

**gp_vmem_protect_limit**

*Note*: The `gp_vmem_protect_limit` server configuration parameter is enforced only when resource queue-based resource management is active.

Sets the amount of memory (in number of MBs) that all postgres processes of an active segment instance can consume. If a query causes this limit to be exceeded, memory will not be allocated and the query will fail. Note that this is a local parameter and must be set for every segment in the system (primary and mirrors). When setting the parameter value, specify only the numeric value. For example, to specify 4096MB, use the value 4096. Do not add the units MB to the value.

To prevent over-allocation of memory, these calculations can estimate a safe `gp_vmem_protect_limit` value.

First calculate the value `gp_vmem`. This is the Greenplum Database memory available on a host

\[
gp_vmem = \frac{((SWAP + RAM) - (7.5GB + 0.05 * RAM))}{1.7}
\]

where `SWAP` is the host swap space and `RAM` is the RAM on the host in GB.
Next, calculate the `max_acting_primary_segments`. This is the maximum number of primary segments that can be running on a host when mirror segments are activated due to a failure. With mirrors arranged in a 4-host block with 8 primary segments per host, for example, a single segment host failure would activate two or three mirror segments on each remaining host in the failed host's block. The `max_acting_primary_segments` value for this configuration is 11 (8 primary segments plus 3 mirrors activated on failure).

This is the calculation for `gp_vmem_protect_limit`. The value should be converted to MB.

```
gp_vmem_protect_limit = gp_vmem / acting_primary_segments
```

For scenarios where a large number of workfiles are generated, this is the calculation for `gp_vmem` that accounts for the workfiles.

```
gp_vmem = ((SWAP + RAM) - (7.5GB + 0.05 * RAM - (300KB * total_#_workfiles))) / 1.7
```

For information about monitoring and managing workfile usage, see the Greenplum Database Administrator Guide.

Based on the `gp_vmem` value you can calculate the value for the `vm.overcommit_ratio` operating system kernel parameter. This parameter is set when you configure each Greenplum Database host.

```
vm.overcommit_ratio = (RAM - (0.026 * gp_vmem)) / RAM
```

**Note:** The default value for the kernel parameter `vm.overcommit_ratio` in Red Hat Enterprise Linux is 50.

For information about the kernel parameter, see the Greenplum Database Installation Guide.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>integer</td>
<td>8192</td>
<td>local system restart</td>
</tr>
</tbody>
</table>

**gp_vmem_protect_segworker_cache_limit**

If a query executor process consumes more than this configured amount, then the process will not be cached for use in subsequent queries after the process completes. Systems with lots of connections or idle processes may want to reduce this number to free more memory on the segments. Note that this is a local parameter and must be set for every segment.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>number of megabytes</td>
<td>500</td>
<td>local system restart</td>
</tr>
</tbody>
</table>

**gp_workfilechecksumming**

Adds a checksum value to each block of a work file (or spill file) used by `HashAgg` and `HashJoin` query operators. This adds an additional safeguard from faulty OS disk drivers writing corrupted blocks to disk. When a checksum operation fails, the query will cancel and rollback rather than potentially writing bad data to disk.
### gp_workfile_compress_algorithm

When a hash aggregation or hash join operation spills to disk during query processing, specifies the compression algorithm to use on the spill files. If using zlib, the zlib library must be installed on all hosts in the Greenplum Database cluster.

If your Greenplum Database installation uses serial ATA (SATA) disk drives, setting the value of this parameter to `zlib` might help to avoid overloading the disk subsystem with IO operations.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>boolean</td>
<td>on</td>
<td>master session reload</td>
</tr>
</tbody>
</table>

### gp_workfile_limit_files_per_query

Sets the maximum number of temporary spill files (also known as workfiles) allowed per query per segment. Spill files are created when executing a query that requires more memory than it is allocated. The current query is terminated when the limit is exceeded.

Set the value to 0 (zero) to allow an unlimited number of spill files.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>integer</td>
<td>100000</td>
<td>master session reload</td>
</tr>
</tbody>
</table>

### gp_workfile_limit_per_query

Sets the maximum disk size an individual query is allowed to use for creating temporary spill files at each segment. The default value is 0, which means a limit is not enforced.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>kilobytes</td>
<td>0</td>
<td>master session reload</td>
</tr>
</tbody>
</table>

### gp_workfile_limit_per_segment

Sets the maximum total disk size that all running queries are allowed to use for creating temporary spill files at each segment. The default value is 0, which means a limit is not enforced.
### gpperfmon_port

Sets the port on which all data collection agents (for Command Center) communicate with the master.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>integer</td>
<td>8888</td>
<td>master</td>
</tr>
</tbody>
</table>

### ignore_checksum_failure

Only has effect if `data_checkums` is enabled.

Greenplum Database uses checksums to prevent loading data that has been corrupted in the file system into memory managed by database processes.

By default, when a checksum verify error occurs when reading a heap data page, Greenplum Database generates an error and prevents the page from being loaded into managed memory. When `ignore_checksum_failure` is set to on and a checksum verify failure occurs, Greenplum Database generates a warning, and allows the page to be read into managed memory. If the page is then updated it is saved to disk and replicated to the mirror. If the page header is corrupt an error is reported even if this option is enabled.

**Warning:** Setting `ignore_checksum_failure` to on may propagate or hide data corruption or lead to other serious problems. However, if a checksum failure has already been detected and the page header is uncorrupted, setting `ignore_checksum_failure` to on may allow you to bypass the error and recover undamaged tuples that may still be present in the table.

The default setting is off, and it can only be changed by a superuser.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>off</td>
<td>local</td>
</tr>
</tbody>
</table>

### integer_datetimes

Reports whether PostgreSQL was built with support for 64-bit-integer dates and times.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>on</td>
<td>read only</td>
</tr>
</tbody>
</table>

### IntervalStyle

Sets the display format for interval values. The value `sql_standard` produces output matching SQL standard interval literals. The value `postgres` produces output matching PostgreSQL releases prior to 8.4 when the `DateStyle` parameter was set to ISO.
The value `postgres_verbose` produces output matching Greenplum releases prior to 3.3 when the `DateStyle` parameter was set to non-ISO output.

The value `iso_8601` will produce output matching the time interval `format with designators` defined in section 4.4.3.2 of ISO 8601. See the PostgreSQL 8.4 documentation for more information.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>postgres</td>
<td>postgres</td>
<td>master</td>
</tr>
<tr>
<td>postgres_verbose</td>
<td></td>
<td>session</td>
</tr>
<tr>
<td>sql_standard</td>
<td></td>
<td>reload</td>
</tr>
<tr>
<td>iso_8601</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**join Collapse Limit**

The legacy query optimizer (planner) will rewrite explicit inner JOIN constructs into lists of FROM items whenever a list of no more than this many items in total would result. By default, this variable is set the same as `fromCollapseLimit`, which is appropriate for most uses. Setting it to 1 prevents any reordering of inner JOINs. Setting this variable to a value between 1 and `fromCollapseLimit` might be useful to trade off planning time against the quality of the chosen plan (higher values produce better plans).

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>1-(n)</td>
<td>20</td>
<td>master</td>
</tr>
<tr>
<td></td>
<td></td>
<td>session</td>
</tr>
<tr>
<td></td>
<td></td>
<td>reload</td>
</tr>
</tbody>
</table>

**keep Wal Segments**

For Greenplum Database master mirroring, sets the maximum number of processed WAL segment files that are saved by the by the active Greenplum Database master if a checkpoint operation occurs. The segment files are used to synchronize the active master on the standby master.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>integer</td>
<td>5</td>
<td>master</td>
</tr>
<tr>
<td></td>
<td></td>
<td>system</td>
</tr>
<tr>
<td></td>
<td></td>
<td>reload</td>
</tr>
<tr>
<td></td>
<td></td>
<td>superuser</td>
</tr>
</tbody>
</table>

**krb Caseins Users**

Sets whether Kerberos user names should be treated case-insensitively. The default is case sensitive (off).

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>off</td>
<td>master</td>
</tr>
<tr>
<td></td>
<td></td>
<td>system</td>
</tr>
<tr>
<td></td>
<td></td>
<td>restart</td>
</tr>
</tbody>
</table>
**krb_server_keyfile**

Sets the location of the Kerberos server key file.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>path and file name</td>
<td>unset</td>
<td>master system restart</td>
</tr>
</tbody>
</table>

**krb_srvname**

Sets the Kerberos service name.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>service name</td>
<td>postgres</td>
<td>master system restart</td>
</tr>
</tbody>
</table>

**lc_collate**

Reports the locale in which sorting of textual data is done. The value is determined when the Greenplum Database array is initialized.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt;system dependent&gt;</td>
<td></td>
<td>read only</td>
</tr>
</tbody>
</table>

**lc_ctype**

Reports the locale that determines character classifications. The value is determined when the Greenplum Database array is initialized.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt;system dependent&gt;</td>
<td></td>
<td>read only</td>
</tr>
</tbody>
</table>

**lc_messages**

Sets the language in which messages are displayed. The locales available depends on what was installed with your operating system - use `locale -a` to list available locales. The default value is inherited from the execution environment of the server. On some systems, this locale category does not exist. Setting this variable will still work, but there will be no effect. Also, there is a chance that no translated messages for the desired language exist. In that case you will continue to see the English messages.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt;system dependent&gt;</td>
<td></td>
<td>local system restart</td>
</tr>
</tbody>
</table>
**lc_monetary**

Sets the locale to use for formatting monetary amounts, for example with the `to_char` family of functions. The locales available depends on what was installed with your operating system - use `locale -a` to list available locales. The default value is inherited from the execution environment of the server.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt;system dependent&gt;</td>
<td></td>
<td>local</td>
</tr>
<tr>
<td></td>
<td></td>
<td>system</td>
</tr>
<tr>
<td></td>
<td></td>
<td>restart</td>
</tr>
</tbody>
</table>

**lc_numeric**

Sets the locale to use for formatting numbers, for example with the `to_char` family of functions. The locales available depends on what was installed with your operating system - use `locale -a` to list available locales. The default value is inherited from the execution environment of the server.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt;system dependent&gt;</td>
<td></td>
<td>local</td>
</tr>
<tr>
<td></td>
<td></td>
<td>system</td>
</tr>
<tr>
<td></td>
<td></td>
<td>restart</td>
</tr>
</tbody>
</table>

**lc_time**

This parameter currently does nothing, but may in the future.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt;system dependent&gt;</td>
<td></td>
<td>local</td>
</tr>
<tr>
<td></td>
<td></td>
<td>system</td>
</tr>
<tr>
<td></td>
<td></td>
<td>restart</td>
</tr>
</tbody>
</table>

**listen_addresses**

Specifies the TCP/IP address(es) on which the server is to listen for connections from client applications - a comma-separated list of host names and/or numeric IP addresses. The special entry * corresponds to all available IP interfaces. If the list is empty, only UNIX-domain sockets can connect.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>localhost,</td>
<td>*</td>
<td>master</td>
</tr>
<tr>
<td>host names,</td>
<td></td>
<td></td>
</tr>
<tr>
<td>IP addresses,</td>
<td></td>
<td></td>
</tr>
<tr>
<td>* (all available IP interfaces)</td>
<td></td>
<td>master</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**local_preload_libraries**

Comma separated list of shared library files to preload at the start of a client session.
### log_autostats

Logs information about automatic `ANALYZE` operations related to `gp_autostats_mode` and `gp_autostats_on_change_threshold`.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>off</td>
<td>master</td>
</tr>
<tr>
<td></td>
<td></td>
<td>session</td>
</tr>
<tr>
<td></td>
<td></td>
<td>reload</td>
</tr>
<tr>
<td></td>
<td></td>
<td>superuser</td>
</tr>
</tbody>
</table>

### log_connections

This outputs a line to the server log detailing each successful connection. Some client programs, like `psql`, attempt to connect twice while determining if a password is required, so duplicate "connection received" messages do not always indicate a problem.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>off</td>
<td>local</td>
</tr>
<tr>
<td></td>
<td></td>
<td>system</td>
</tr>
<tr>
<td></td>
<td></td>
<td>restart</td>
</tr>
</tbody>
</table>

### log_disconnections

This outputs a line in the server log at termination of a client session, and includes the duration of the session.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>off</td>
<td>local</td>
</tr>
<tr>
<td></td>
<td></td>
<td>system</td>
</tr>
<tr>
<td></td>
<td></td>
<td>restart</td>
</tr>
</tbody>
</table>

### log_dispatch_stats

When set to "on," this parameter adds a log message with verbose information about the dispatch of the statement.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>off</td>
<td>local</td>
</tr>
<tr>
<td></td>
<td></td>
<td>system</td>
</tr>
<tr>
<td></td>
<td></td>
<td>restart</td>
</tr>
</tbody>
</table>
**log_duration**
Causes the duration of every completed statement which satisfies log_statement to be logged.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>off</td>
<td>master, session, reload, superuser</td>
</tr>
</tbody>
</table>

**log_error_verbosity**
Controls the amount of detail written in the server log for each message that is logged.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>TERSE</td>
<td>DEFAULT</td>
<td>master, session, reload, superuser</td>
</tr>
<tr>
<td>DEFAULT</td>
<td></td>
<td></td>
</tr>
<tr>
<td>VERBOSE</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**log_executor_stats**
For each query, write performance statistics of the query executor to the server log. This is a crude profiling instrument. Cannot be enabled together with log_statement_stats.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>off</td>
<td>local, system, restart</td>
</tr>
</tbody>
</table>

**log_hostname**
By default, connection log messages only show the IP address of the connecting host. Turning on this option causes logging of the IP address and host name of the Greenplum Database master. Note that depending on your host name resolution setup this might impose a non-negligible performance penalty.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>off</td>
<td>master, system, restart</td>
</tr>
</tbody>
</table>

**log_min_duration_statement**
Logs the statement and its duration on a single log line if its duration is greater than or equal to the specified number of milliseconds. Setting this to 0 will print all statements and their durations. -1 disables the feature. For example, if you set it to 250 then all SQL statements that run 250ms or longer will be logged. Enabling this option can be useful in tracking down unoptimized queries in your applications.
**log_min_error_statement**

Controls whether or not the SQL statement that causes an error condition will also be recorded in the server log. All SQL statements that cause an error of the specified level or higher are logged. The default is ERROR. To effectively turn off logging of failing statements, set this parameter to PANIC.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>number of milliseconds, 0, -1</td>
<td>-1</td>
<td>master, session, reload, superuser</td>
</tr>
</tbody>
</table>

**log_min_messages**

Controls which message levels are written to the server log. Each level includes all the levels that follow it. The later the level, the fewer messages are sent to the log.

If the Greenplum Database PL/Container extension is installed. This parameter also controls the PL/Container log level. For information about the extension, see *PL/Container Language*. 

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>DEBUG5</td>
<td>ERROR</td>
<td>master, session, reload, superuser</td>

</tr>
</tbody>
</table>

**log_parser_stats**

For each query, write performance statistics of the query parser to the server log. This is a crude profiling instrument. Cannot be enabled together with **log_statement_stats**.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>off</td>
<td>master</td>
</tr>
<tr>
<td></td>

<td>session</td>
</tr>
<tr>
<td></td>
<td></td>
<td>reload</td>
</tr>
<tr>
<td></td>
<td></td>
<td>superuser</td>
</tr>
</tbody>
</table>

**log_planner_stats**

For each query, write performance statistics of the legacy query optimizer (planner) to the server log. This is a crude profiling instrument. Cannot be enabled together with **log_statement_stats**.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>off</td>
<td>master</td>
</tr>
<tr>
<td></td>
<td></td>
<td>session</td>
</tr>
<tr>
<td></td>
<td></td>
<td>reload</td>
</tr>
<tr>
<td></td>
<td></td>
<td>superuser</td>
</tr>
</tbody>
</table>

**log_rotation_age**

Determines the maximum lifetime of an individual log file. After this time has elapsed, a new log file will be created. Set to zero to disable time-based creation of new log files.
### log_rotation_size

Determines the maximum size of an individual log file. After this many kilobytes have been emitted into a log file, a new log file will be created. Set to zero to disable size-based creation of new log files.

The maximum value is INT_MAX/1024. If an invalid value is specified, the default value is used. INT_MAX is the largest value that can be stored as an integer on your system.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>number of kilobytes</td>
<td>0</td>
<td>local, system, restart</td>
</tr>
</tbody>
</table>

### log_statement

Controls which SQL statements are logged. DDL logs all data definition commands like CREATE, ALTER, and DROP commands. MOD logs all DDL statements, plus INSERT, UPDATE, DELETE, TRUNCATE, and COPY FROM. PREPARE and EXPLAIN ANALYZE statements are also logged if their contained command is of an appropriate type.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>NONE</td>
<td>ALL</td>
<td>master, session, reload, superuser</td>
</tr>
<tr>
<td>DDL</td>
<td>ALL</td>
<td>master, session, reload, superuser</td>
</tr>
<tr>
<td>MOD</td>
<td>ALL</td>
<td>master, session, reload, superuser</td>
</tr>
<tr>
<td>ALL</td>
<td>ALL</td>
<td>master, session, reload, superuser</td>
</tr>
</tbody>
</table>

### log_statement_stats

For each query, write total performance statistics of the query parser, planner, and executor to the server log. This is a crude profiling instrument.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>off</td>
<td>master, session, reload, superuser</td>
</tr>
</tbody>
</table>

### log_temp_files

Controls logging of temporary file names and sizes. Temporary files can be created for sorts, hashes, temporary query results and spill files. A log entry is made in `pg_log` for each temporary file when it is deleted. Depending on the source of the temporary files, the log entry could be created on either the master and/or segments. A `log_temp_files` value of zero logs all temporary file information, while
positive values log only files whose size is greater than or equal to the specified number of kilobytes. The default setting is $-1$, which disables logging. Only superusers can change this setting.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>Integer</td>
<td>-1</td>
<td>local system restart</td>
</tr>
</tbody>
</table>

**log_timezone**

Sets the time zone used for timestamps written in the log. Unlike `TimeZone`, this value is system-wide, so that all sessions will report timestamps consistently. The default is `unknown`, which means to use whatever the system environment specifies as the time zone.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>string</td>
<td>unknown</td>
<td>local system restart</td>
</tr>
</tbody>
</table>

**log_truncate_on_rotation**

Truncates (overwrites), rather than appends to, any existing log file of the same name. Truncation will occur only when a new file is being opened due to time-based rotation. For example, using this setting in combination with a log_filename such as `gpseg#-%H.log` would result in generating twenty-four hourly log files and then cyclically overwriting them. When off, pre-existing files will be appended to in all cases.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>off</td>
<td>local system restart</td>
</tr>
</tbody>
</table>

**max_appendonly_tables**

Sets the maximum number of concurrent transactions that can write to or update append-optimized tables. Transactions that exceed the maximum return an error.

Operations that are counted are `INSERT`, `UPDATE`, `COPY`, and `VACUUM` operations. The limit is only for in-progress transactions. Once a transaction ends (either aborted or committed), it is no longer counted against this limit.

For operations against a partitioned table, each subpartition (child table) that is an append-optimized table is counted as a single table towards the maximum. For example, a partitioned table `p_tbl` is defined with three subpartitions that are append-optimized tables `p_tbl_ao1`, `p_tbl_ao2`, and `p_tbl_ao3`. An `INSERT` or `UPDATE` command against the partitioned table `p_tbl` that changes append-optimized tables `p_tbl_ao1` and `p_tbl_ao2` is counted as two transactions.

Increasing the limit allocates more shared memory on the master host at server start.
**max_connections**

The maximum number of concurrent connections to the database server. In a Greenplum Database system, user client connections go through the Greenplum master instance only. Segment instances should allow 5-10 times the amount as the master. When you increase this parameter, `max_prepared_transactions` must be increased as well. For more information about limiting concurrent connections, see "Configuring Client Authentication" in the Greenplum Database Administrator Guide.

Increasing this parameter might cause Greenplum Database to request more shared memory. See `shared_buffers` for information about Greenplum server instance shared memory buffers. If this value is increased, `shared_buffers` and the kernel parameter `SHMMAX` might also need to be increased. Also, parameters that depend on shared memory such as `max_fsm_pages` might need to be changed.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>integer &gt; 0</td>
<td>10000</td>
<td>master, system, restart</td>
</tr>
</tbody>
</table>

**max_files_per_process**

Sets the maximum number of simultaneously open files allowed to each server subprocess. If the kernel is enforcing a safe per-process limit, you don't need to worry about this setting. Some platforms such as BSD, the kernel will allow individual processes to open many more files than the system can really support.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>integer</td>
<td>1000</td>
<td>local, system, restart</td>
</tr>
</tbody>
</table>

**max fsm_pages**

Sets the maximum number of disk pages for which free space will be tracked in the shared free-space map. Six bytes of shared memory are consumed for each page slot. If this value is increased, `shared_buffers` and the kernel parameter `SHMMAX` might also need to be increased. Also, parameters that depend on shared memory such as `max_connections` might need to be changed.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>integer &gt; 16 * <code>max_fsm_relations</code></td>
<td>200000</td>
<td>local, system, restart</td>
</tr>
</tbody>
</table>
max_fsm_relations
Sets the maximum number of relations for which free space will be tracked in the shared memory free-space map. Should be set to a value larger than the total number of:
\[ \text{tables} + \text{indexes} + \text{system tables} \]
It costs about 60 bytes of memory for each relation per segment instance. It is better to allow some room for overhead and set too high rather than too low.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>integer</td>
<td>1000</td>
<td>local, system, restart</td>
</tr>
</tbody>
</table>

max_function_args
Reports the maximum number of function arguments.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>integer</td>
<td>100</td>
<td>read only</td>
</tr>
</tbody>
</table>

max_identifier_length
Reports the maximum identifier length.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>integer</td>
<td>63</td>
<td>read only</td>
</tr>
</tbody>
</table>

max_index_keys
Reports the maximum number of index keys.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>integer</td>
<td>32</td>
<td>read only</td>
</tr>
</tbody>
</table>

max_locks_per_transaction
The shared lock table is created with room to describe locks on \( \text{max_locks_per_transaction} * (\text{max_connections} + \text{max_prepared_transactions}) \) objects, so no more than this many distinct objects can be locked at any one time. This is not a hard limit on the number of locks taken by any one transaction, but rather a maximum average value. You might need to raise this value if you have clients that touch many different tables in a single transaction.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>integer</td>
<td>128</td>
<td>local, system, restart</td>
</tr>
</tbody>
</table>
max_prepared_transactions

Sets the maximum number of transactions that can be in the prepared state simultaneously. Greenplum uses prepared transactions internally to ensure data integrity across the segments. This value must be at least as large as the value of max_connections on the master. Segment instances should be set to the same value as the master.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>integer &lt;= 1000</td>
<td>250 on master 250 on segments</td>
<td>local system restart</td>
</tr>
</tbody>
</table>

max_resource_portals_per_transaction

Note: The max_resource_portals_per_transaction server configuration parameter is enforced only when resource queue-based resource management is active.

Sets the maximum number of simultaneously open user-declared cursors allowed per transaction. Note that an open cursor will hold an active query slot in a resource queue. Used for resource management.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>integer</td>
<td>64</td>
<td>master system restart</td>
</tr>
</tbody>
</table>

max_resource_queues

Note: The max_resource_queues server configuration parameter is enforced only when resource queue-based resource management is active.

Sets the maximum number of resource queues that can be created in a Greenplum Database system. Note that resource queues are system-wide (as are roles) so they apply to all databases in the system.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>integer</td>
<td>9</td>
<td>master system restart</td>
</tr>
</tbody>
</table>

max_stack_depth

Specifies the maximum safe depth of the server's execution stack. The ideal setting for this parameter is the actual stack size limit enforced by the kernel (as set by ulimit -s or local equivalent), less a safety margin of a megabyte or so. Setting the parameter higher than the actual kernel limit will mean that a runaway recursive function can crash an individual backend process.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>number of kilobytes</td>
<td>2MB</td>
<td>local system restart</td>
</tr>
</tbody>
</table>
max_statement_mem

Sets the maximum memory limit for a query. Helps avoid out-of-memory errors on a segment host during query processing as a result of setting `statement_mem` too high.

Taking into account the configuration of a single segment host, calculate `max_statement_mem` as follows:

\[
\text{(seghost_physical_memory)} / \text{(average_number_concurrent_queries)}
\]

When changing both `max_statement_mem` and `statement_mem`, `max_statement_mem` must be changed first, or listed first in the `postgresql.conf` file.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>number of kilobytes</td>
<td>2000MB</td>
<td>master</td>
</tr>
<tr>
<td></td>
<td></td>
<td>session</td>
</tr>
<tr>
<td></td>
<td></td>
<td>reload</td>
</tr>
<tr>
<td></td>
<td></td>
<td>superuser</td>
</tr>
</tbody>
</table>

memory_spill_ratio

Note: The `memory_spill_ratio` server configuration parameter is enforced only when resource group-based resource management is active.

Sets the memory usage threshold percentage for memory-intensive operators in a transaction. When a transaction reaches this threshold, it spills to disk.

The default `memory_spill_ratio` percentage is the value defined for the resource group assigned to the currently active role. You can set `memory_spill_ratio` at the session level to selectively set this limit on a per-query basis. For example, if you have a specific query that spills to disk and requires more memory, you may choose to set a larger `memory_spill_ratio` to increase the initial memory allocation.

When you set `memory_spill_ratio` at the session level, Greenplum Database does not perform semantic validation on the new value until you next perform a query.

You can specify an integer percentage value from 0 to 100 inclusive. If you specify a value of 0, Greenplum Database uses the `statement_mem` server configuration parameter value to control the initial query operator memory amount.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>0 - 100</td>
<td>20</td>
<td>master</td>
</tr>
<tr>
<td></td>
<td></td>
<td>session</td>
</tr>
<tr>
<td></td>
<td></td>
<td>reload</td>
</tr>
</tbody>
</table>

optimizer

Enables or disables GPORCA when running SQL queries. The default is on. If you disable GPORCA, Greenplum Database uses only the legacy query optimizer.

GPORCA co-exists with the legacy query optimizer. With GPORCA enabled, Greenplum Database uses GPORCA to generate an execution plan for a query when possible. If GPORCA cannot be used, then the legacy query optimizer is used.

The `optimizer` parameter can be set for a database system, an individual database, or a session or query.
For information about the legacy query optimizer and GPORCA, see *Querying Data* in the *Greenplum Database Administrator Guide*.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>on</td>
<td>master</td>
</tr>
<tr>
<td></td>
<td></td>
<td>session</td>
</tr>
<tr>
<td></td>
<td></td>
<td>reload</td>
</tr>
</tbody>
</table>

**optimizer_analyze_root_partition**

For a partitioned table, controls whether the `ROOTPARTITION` keyword is required to collect root partition statistics when the `ANALYZE` command is run on the table. GPORCA uses the root partition statistics when generating a query plan. The legacy query optimizer does not use these statistics.

The default setting for the parameter is `on`, the `ANALYZE` command can collect root partition statistics without the `ROOTPARTITION` keyword. Root partition statistics are collected when you run `ANALYZE` on the root partition, or when you run `ANALYZE` on a child leaf partition of the partitioned table and the other child leaf partitions have statistics. When the value is `off`, you must run `ANALYZE ROOTPARTITION` to collect root partition statistics.

When the value of the server configuration parameter `optimizer` is `on` (the default), the value of this parameter should also be `on`. For information about collecting table statistics on partitioned tables, see `ANALYZE`.

For information about the legacy query optimizer and GPORCA, see *Querying Data* in the *Greenplum Database Administrator Guide*.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>on</td>
<td>master</td>
</tr>
<tr>
<td></td>
<td></td>
<td>session</td>
</tr>
<tr>
<td></td>
<td></td>
<td>reload</td>
</tr>
</tbody>
</table>

**optimizer_array_expansion_threshold**

When GPORCA is enabled (the default) and is processing a query that contains a predicate with a constant array, the `optimizer_array_expansion_threshold` parameter limits the optimization process based on the number of constants in the array. If the array in the query predicate contains more than the number elements specified by parameter, GPORCA disables the transformation of the predicate into its disjunctive normal form during query optimization.

The default value is 100.

For example, when GPORCA is executing a query that contains an `IN` clause with more than 100 elements, GPORCA does not transform the predicate into its disjunctive normal form during query optimization to reduce optimization time consume less memory. The difference in query processing can be seen in the filter condition for the `IN` clause of the query `EXPLAIN` plan.

Changing the value of this parameter changes the trade-off between a shorter optimization time and lower memory consumption, and the potential benefits from constraint derivation during query optimization, for example conflict detection and partition elimination.

The parameter can be set for a database system, an individual database, or a session or query.
### optimizer_control

Controls whether the server configuration parameter `optimizer` can be changed with `SET`, the `RESET` command, or the Greenplum Database utility `gpconfig`. If the `optimizer_control` parameter value is `on`, users can set the `optimizer` parameter. If the `optimizer_control` parameter value is `off`, the `optimizer` parameter cannot be changed.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>Integer &gt; 0</td>
<td>100</td>
<td>master</td>
</tr>
<tr>

<td>on</td>
<td>master</td>
</tr>
<tr>
<td></td>
<td></td>
<td>system</td>
</tr>
<tr>
<td></td>
<td></td>
<td>restart</td>
</tr>
<tr>
<td></td>
<td></td>
<td>superuser</td>
</tr>
</tbody>
</table>

### optimizer_cte_inlining_bound

When GPORCA is enabled (the default), this parameter controls the amount of inlining performed for common table expression (CTE) queries (queries that contain a `WHERE` clause). The default value, 0, disables inlining.

The parameter can be set for a database system, an individual database, or a session or query.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>Decimal &gt;= 0</td>
<td>0</td>
<td>master</td>
</tr>
<tr>
<td></td>
<td></td>
<td>session</td>
</tr>
<tr>
<td></td>
<td></td>
<td>reload</td>
</tr>
</tbody>
</table>

### optimizer_enable_associativity

When GPORCA is enabled (the default), this parameter controls whether the join associativity transform is enabled during query optimization. The transform analyzes join orders. For the default value `off`, only the GPORCA dynamic programming algorithm for analyzing join orders is enabled. The join associativity transform largely duplicates the functionality of the newer dynamic programming algorithm.

If the value is `on`, GPORCA can use the associativity transform during query optimization.

The parameter can be set for a database system, an individual database, or a session or query.

For information about GPORCA, see *About GPORCA* in the *Greenplum Database Administrator Guide*.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>off</td>
<td>master</td>
</tr>
<tr>
<td></td>
<td></td>
<td>session</td>
</tr>
<tr>
<td></td>
<td></td>
<td>reload</td>
</tr>
</tbody>
</table>
**optimizer_enable_dml**

When GPORCA is enabled (the default) and this parameter is `true` (the default), GPORCA attempts to execute DML commands such as `INSERT`, `UPDATE`, and `DELETE`. If GPORCA cannot execute the command, Greenplum Database falls back to the Postgres Planner.

When set to `false`, Greenplum Database always falls back to the Postgres Planner when performing DML commands.

The parameter can be set for a database system, an individual database, or a session or query.

For information about GPORCA, see *About GPORCA* in the *Greenplum Database Administrator Guide*.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>true</td>
<td>master, session, reload</td>
</tr>
</tbody>
</table>

**optimizer_enable_master_only_queries**

When GPORCA is enabled (the default), this parameter allows GPORCA to execute catalog queries that run only on the Greenplum Database master. For the default value `off`, only the Postgres Planner can execute catalog queries that run only on the Greenplum Database master.

The parameter can be set for a database system, an individual database, or a session or query.

*Note:* Enabling this parameter decreases performance of short running catalog queries. To avoid this issue, set this parameter only for a session or a query.

For information about GPORCA, see *About GPORCA* in the *Greenplum Database Administrator Guide*.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>off</td>
<td>master, session, reload</td>
</tr>
</tbody>
</table>

**optimizer_force_agg_skew_avoidance**

When GPORCA is enabled (the default), this parameter affects the query plan alternatives that GPORCA considers when 3 stage aggregate plans are generated. When the value is `true`, the default, GPORCA considers only 3 stage aggregate plans where the intermediate aggregation uses the `GROUP BY` and `DISTINCT` columns for distribution to reduce the effects of processing skew.

If the value is `false`, GPORCA can also consider a plan that uses `GROUP BY` columns for distribution. These plans might perform poorly when processing skew is present.

For information about GPORCA, see *About GPORCA* in the *Greenplum Database Administrator Guide*.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>true</td>
<td>master, session, reload</td>
</tr>
</tbody>
</table>
**optimizer_force_multistage_agg**

For the default settings, GPORCA is enabled and this parameter is `true`, GPORCA chooses a 3 stage aggregate plan for scalar distinct qualified aggregate when such a plan alternative is generated. When the value is `false`, GPORCA makes a cost based choice rather than a heuristic choice.

The parameter can be set for a database system, an individual database, or a session or query.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>true</td>
<td>master, session, reload</td>

</tbody>
</table>

**optimizer_force_three_stage_scalar_dqa**

For the default settings, GPORCA is enabled and this parameter is `true`, GPORCA chooses a plan with multistage aggregates when such a plan alternative is generated. When the value is `false`, GPORCA makes a cost based choice rather than a heuristic choice.

The parameter can be set for a database system, an individual database, or a session, or query.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>true</td>
<td>master, session, reload</td>
</tr>
</tbody>
</table>

**optimizer_join_arity_for_associativity_commutativity**

The value is an optimization hint to limit the number of join associativity and join commutativity transformations explored during query optimization. The limit controls the alternative plans that GPORCA considers during query optimization. For example, the default value of 18 is an optimization hint for GPORCA to stop exploring join associativity and join commutativity transformations when an n-ary join operator has more than 18 children during optimization.

For a query with a large number of joins, specifying a lower value improves query performance by limiting the number of alternate query plans that GPORCA evaluates. However, setting the value too low might cause GPORCA to generate a query plan that performs sub-optimally.

This parameter has no effect when the `optimizer_join_order` parameter is set to `query` or `greedy`.

This parameter can be set for a database system or a session.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>integer &gt; 0</td>
<td>18</td>
<td>local, system, reload</td>
</tr>
</tbody>
</table>

**optimizer_join_order**

When GPORCA is enabled, this parameter sets the optimization level for join ordering during query optimization by specifying which types of join ordering alternatives to evaluate.

- `query` - Uses the join order specified in the query.
- **greedy** - Evaluates the join order specified in the query and alternatives based on minimum cardinalities of the relations in the joins.
- **exhaustive** - Applies transformation rules to find and evaluate all join ordering alternatives.

The default value is **exhaustive**. Setting this parameter to **query** or **greedy** can generate a suboptimal query plan. However, if the administrator is confident that a satisfactory plan is generated with the **query** or **greedy** setting, query optimization time can be improved by setting the parameter to the lower optimization level.

Setting this parameter to **query** or **greedy** overrides the **optimizer_join_order_threshold** and **optimizer_join_arity_for_associativity_commutativity** parameters.

This parameter can be set for an individual database, a session, or a query.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>query</td>
<td>exhaustive</td>
<td>master</td>
</tr>
<tr>
<td>greedy</td>
<td></td>
<td>session</td>
</tr>
<tr>
<td>exhaustive</td>
<td></td>
<td>reload</td>
</tr>
</tbody>
</table>

### optimizer_join_order_threshold

When GPORCA is enabled (the default), this parameter sets the maximum number of join children for which GPORCA will use the dynamic programming-based join ordering algorithm. You can set this value for a single query or for an entire session.

This parameter has no effect when the **optimizer_join_query** parameter is set to **query** or **greedy**.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>0 - 12</td>
<td>10</td>
<td>master</td>
</tr>
<tr>
<td></td>
<td></td>
<td>session</td>
</tr>
<tr>
<td></td>
<td></td>
<td>reload</td>
</tr>
</tbody>
</table>

### optimizer_mdcache_size

Sets the maximum amount of memory on the Greenplum Database master that GPORCA uses to cache query metadata (optimization data) during query optimization. The memory limit session based. GPORCA caches query metadata during query optimization with the default settings: GPORCA is enabled and **optimizer_metadata_caching** is on.

The default value is 16384 (16MB). This is an optimal value that has been determined through performance analysis.

You can specify a value in KB, MB, or GB. The default unit is KB. For example, a value of 16384 is 16384KB. A value of 1GB is the same as 1024MB or 1048576KB. If the value is 0, the size of the cache is not limited.

This parameter can be set for a database system, an individual database, or a session or query.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>Integer &gt;= 0</td>
<td>16384</td>
<td>master</td>
</tr>
<tr>
<td></td>
<td></td>
<td>session</td>
</tr>
<tr>
<td></td>
<td></td>
<td>reload</td>
</tr>
</tbody>
</table>
**optimizer_metadata_caching**

When GPORCA is enabled (the default), this parameter specifies whether GPORCA caches query metadata (optimization data) in memory on the Greenplum Database master during query optimization. The default for this parameter is *on*, enable caching. The cache is session based. When a session ends, the cache is released. If the amount of query metadata exceeds the cache size, then old, unused metadata is evicted from the cache.

If the value is *off*, GPORCA does not cache metadata during query optimization.

This parameter can be set for a database system, an individual database, or a session or query.

The server configuration parameter `optimizer_mdcache_size` controls the size of the query metadata cache.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>on</td>
<td>master</td>
</tr>
<tr>
<td></td>
<td></td>
<td>session</td>
</tr>
<tr>
<td></td>
<td></td>
<td>reload</td>
</tr>
</tbody>
</table>

**optimizer_minidump**

GPORCA generates minidump files to describe the optimization context for a given query. The information in the file is not in a format that can be easily used for debugging or troubleshooting. The minidump file is located under the master data directory and uses the following naming format:

`Minidump_`*date_time*.mdp

The minidump file contains this query related information:

- Catalog objects including data types, tables, operators, and statistics required by GPORCA
- An internal representation (DXL) of the query
- An internal representation (DXL) of the plan produced by GPORCA
- System configuration information passed to GPORCA such as server configuration parameters, cost and statistics configuration, and number of segments
- A stack trace of errors generated while optimizing the query

Setting this parameter to `ALWAYS` generates a minidump for all queries. Set this parameter to `ONERROR` to minimize total optimization time.

For information about GPORCA, see *About GPORCA* in the *Greenplum Database Administrator Guide*.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>ONERROR</td>
<td>ONERROR</td>
<td>master</td>
</tr>
<tr>
<td>ALWAYS</td>
<td></td>
<td>session</td>
</tr>
<tr>
<td></td>
<td></td>
<td>reload</td>
</tr>
</tbody>
</table>

**optimizer_nestloop_factor**

This parameter adds a costing factor to GPORCA to prioritize hash joins instead of nested loop joins during query optimization. The default value of 1024 was chosen after evaluating numerous workloads with uniformly distributed data. 1024 should be treated as the practical upper bound setting for this parameter.

If you find the GPORCA selects hash joins more often than it should, reduce the value to shift the costing factor in favor of nested loop joins.

The parameter can be set for a database system, an individual database, or a session or query.
### optimizer_parallel_union

When GPORCA is enabled (the default), `optimizer_parallel_union` controls the amount of parallelization that occurs for queries that contain a `UNION` or `UNION ALL` clause.

When the value is *off*, the default, GPORCA generates a query plan where each child of an `APPEND(UNION)` operator is in the same slice as the `APPEND` operator. During query execution, the children are executed in a sequential manner.

When the value is *on*, GPORCA generates a query plan where a redistribution motion node is under an `APPEND(UNION)` operator. During query execution, the children and the parent `APPEND` operator are on different slices, allowing the children of the `APPEND(UNION)` operator to execute in parallel on segment instances.

The parameter can be set for a database system, an individual database, or a session or query.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>boolean</td>
<td>off</td>
<td>master</td>
</tr>
<tr>
<td></td>
<td></td>
<td>session</td>
</tr>
<tr>
<td></td>
<td></td>
<td>reload</td>
</tr>
</tbody>
</table>

### optimizer_penalize_skew

When GPORCA is enabled (the default), this parameter allows GPORCA to penalize the local cost of a HashJoin with a skewed Redistribute Motion as child to favor a Broadcast Motion during query optimization. The default value is *true*.

GPORCA determines there is skew for a Redistribute Motion when the NDV (number of distinct values) is less than the number of segments.

The parameter can be set for a database system, an individual database, or a session or query.

For information about GPORCA, see *About GPORCA* in the *Greenplum Database Administrator Guide*.

### optimizer_print_missing_stats

When GPORCA is enabled (the default), this parameter controls the display of table column information about columns with missing statistics for a query. The default value is *true*, display the column information to the client. When the value is *false*, the information is not sent to the client.

The information is displayed during query execution, or with the `EXPLAIN` or `EXPLAIN ANALYZE` commands.

The parameter can be set for a database system, an individual database, or a session.
<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>true</td>
<td>master</td>
</tr>
<tr>
<td></td>
<td></td>
<td>session</td>
</tr>
<tr>
<td></td>
<td></td>
<td>reload</td>
</tr>
</tbody>
</table>

**optimizer_print_optimization_stats**

When GPORCA is enabled (the default), this parameter enables logging of GPORCA query optimization statistics for various optimization stages for a query. The default value is off, do not log optimization statistics. To log the optimization statistics, this parameter must be set to on and the parameter client_min_messages must be set to log.

- set optimizer_print_optimization_stats = on;
- set client_min_messages = 'log';

The information is logged during query execution, or with the EXPLAIN or EXPLAIN ANALYZE commands. This parameter can be set for a database system, an individual database, or a session or query.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>off</td>
<td>master</td>
</tr>
<tr>
<td></td>
<td></td>
<td>session</td>
</tr>
<tr>
<td></td>
<td></td>
<td>reload</td>
</tr>
</tbody>
</table>

**optimizer_sort_factor**

When GPORCA is enabled (the default), optimizer_sort_factor controls the cost factor to apply to sorting operations during query optimization. The default value 1 specifies the default sort cost factor. The value is a ratio of increase or decrease from the default factor. For example, a value of 2.0 sets the cost factor at twice the default, and a value of 0.5 sets the factor at half the default.

The parameter can be set for a database system, an individual database, or a session or query.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>Decimal &gt; 0</td>
<td>1</td>
<td>master</td>
</tr>
<tr>
<td></td>
<td></td>
<td>session</td>
</tr>
<tr>
<td></td>
<td></td>
<td>reload</td>
</tr>
</tbody>
</table>

**optimizer_use_gpdb Allocators**

When GPORCA is enabled (the default) and this parameter is true, GPORCA uses Greenplum Database memory management when executing queries. The default is false, GPORCA uses GPORCA-specific memory management. Greenplum Database memory management allows for faster optimization, reduced memory usage during optimization, and improves GPORCA support of vmem limits when compared to GPORCA-specific memory management.

For information about GPORCA, see *About GPORCA* in the *Greenplum Database Administrator Guide*.
value_range

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>false</td>
<td>master, system, restart</td>
</tr>
</tbody>
</table>

**password_encryption**

When a password is specified in `CREATE USER` or `ALTER USER` without writing either `ENCRYPTED` or `UNENCRYPTED`, this option determines whether the password is to be encrypted.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>on</td>
<td>master, session, reload</td>
</tr>
</tbody>
</table>

**password_hash_algorithm**

Specifies the cryptographic hash algorithm that is used when storing an encrypted Greenplum Database user password. The default algorithm is MD5.

For information about setting the password hash algorithm to protect user passwords, see “Protecting Passwords in Greenplum Database” in the *Greenplum Database Administrator Guide*.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>MD5</td>
<td>MD5</td>
<td>master, session, reload, superuser</td>
</tr>
<tr>
<td>SHA-256</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**pgcrypto.fips**

Before enabling this parameter, ensure that FIPS is enabled on the Greenplum Database system hosts.

When this parameter is enabled, these changes occur:

- FIPS mode is initialized in the OpenSSL library
- The functions `digest()` and `hmac()` allow only the SHA encryption algorithm (MD5 is not allowed)
- The functions for the crypt and `gen_salt` algorithms are disabled
- PGP encryption and decryption functions support only AES and 3DES encryption algorithms (other algorithms such as blowfish are not allowed)
- RAW encryption and decryption functions support only AES and 3DES (other algorithms such as blowfish are not allowed)

To enable `pgcrypto.fips`
1. Enable the \texttt{pgcrypto} functions as an extension if it is not enabled. See \texttt{pgcrypto Cryptographic Functions}. This example \texttt{psql} command creates the \texttt{pgcrypto} extension in the database \texttt{testdb}.

\begin{verbatim}
psql -d testdb -c 'CREATE EXTENSION pgcrypto'
\end{verbatim}

2. Configure the Greenplum Database server configuration parameter \texttt{shared_preload_libraries} to load the \texttt{pgcrypto} library. This example uses the \texttt{gpconfig} utility to update the parameter in the Greenplum Database \texttt{postgresql.conf} files.

\begin{verbatim}
gpconfig -c shared_preload_libraries -v '${libdir}/pgcrypto'
\end{verbatim}

This command displays the value of \texttt{shared_preload_libraries}.

\begin{verbatim}
gpconfig -s shared_preload_libraries
\end{verbatim}

3. Restart the Greenplum Database system.

\begin{verbatim}
gpstop -ra
\end{verbatim}

4. Set the \texttt{pgcrypto.fips} server configuration parameter to \texttt{on} for each database that uses FIPS encryption. For example, this command sets the parameter to \texttt{on} for the database \texttt{testdb}.

\begin{verbatim}
ALTER DATABASE testdb SET pgcrypto.fips TO on;
\end{verbatim}

\textbf{Important:} You must use the \texttt{ALTER DATABASE} command to set the parameter. You cannot use the \texttt{SET} command that updates the parameter for a session, or use the \texttt{gpconfig} utility that updates \texttt{postgresql.conf} files.

5. After setting the parameter, reconnect to the database to enable encryption support for a session. This example uses the \texttt{psql} meta command \texttt{\c} to connect to the \texttt{testdb} database.

\begin{verbatim}
\c testdb
\end{verbatim}

\section*{To disable \texttt{pgcrypto.fips}}

1. If the database does not use \texttt{pgcrypto} functions, disable the \texttt{pgcrypto} extension. See \texttt{pgcrypto Cryptographic Functions}. This example \texttt{psql} command drops the \texttt{pgcrypto} extension in the database \texttt{testdb}.

\begin{verbatim}
psql -d testdb -c 'DROP EXTENSION pgcrypto'
\end{verbatim}

2. Remove \texttt{${libdir}/pgcrypto} from the \texttt{shared_preload_libraries} parameter, and restart Greenplum Database. This \texttt{gpconfig} command displays the value of the parameter from the Greenplum Database \texttt{postgresql.conf} files.

\begin{verbatim}
gpconfig -s shared_preload_libraries
\end{verbatim}

Use the \texttt{gpconfig} utility with the \texttt{-c} and \texttt{-v} options to change the value of the parameter. Use the \texttt{-r} option to remove the parameter.

3. Restart the Greenplum Database system.

\begin{verbatim}
gpstop -ra
\end{verbatim}

\begin{tabular}{|l|l|l|}
\hline
\textbf{Value Range} & \textbf{Default} & \textbf{Set Classifications} \\
\hline
Boolean & off & see description. \\
\hline
\end{tabular}
**pgstat_track_activity_query_size**

Sets the maximum length limit for the query text stored in `current_query` column of the system catalog view `pg_stat_activity`. The minimum length is 1024 characters.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>integer</td>
<td>1024</td>
<td>local system restart</td>
</tr>
</tbody>
</table>

**pljava_classpath**

A colon (:) separated list of jar files or directories containing jar files needed for PL/Java functions. The full path to the jar file or directory must be specified, except the path can be omitted for jar files in the `$GPHOME/lib/postgresql/java` directory. The jar files must be installed in the same locations on all Greenplum hosts and readable by the `gpadmin` user.

The `pljava_classpath` parameter is used to assemble the PL/Java classpath at the beginning of each user session. Jar files added after a session has started are not available to that session.

If the full path to a jar file is specified in `pljava_classpath` it is added to the PL/Java classpath. When a directory is specified, any jar files the directory contains are added to the PL/Java classpath. The search does not descend into subdirectories of the specified directories. If the name of a jar file is included in `pljava_classpath` with no path, the jar file must be in the `$GPHOME/lib/postgresql/java` directory.

**Note:** Performance can be affected if there are many directories to search or a large number of jar files.

If `pljava_classpath_insecure` is false, setting the `pljava_classpath` parameter requires superuser privilege. Setting the classpath in SQL code will fail when the code is executed by a user without superuser privilege. The `pljava_classpath` parameter must have been set previously by a superuser or in the `postgresql.conf` file. Changing the classpath in the `postgresql.conf` file requires a reload (gpstop -u).

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>string</td>
<td></td>
<td>master session reload superuser</td>
</tr>
</tbody>
</table>

**pljava_classpath_insecure**

Controls whether the server configuration parameter `pljava_classpath` can be set by a user without Greenplum Database superuser privileges. When true, `pljava_classpath` can be set by a regular user. Otherwise, `pljava_classpath` can be set only by a database superuser. The default is false.

**Warning:** Enabling this parameter exposes a security risk by giving non-administrator database users the ability to run unauthorized Java methods.
<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>false</td>
<td>master, session, restart, superuser</td>
</tr>
</tbody>
</table>

**pljava_statement_cache_size**
Sets the size in KB of the JRE MRU (Most Recently Used) cache for prepared statements.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>number of kilobytes</td>
<td>10</td>
<td>master, system, restart, superuser</td>
</tr>
</tbody>
</table>

**pljava_release_lingering_savepoints**
If true, lingering savepoints used in PL/Java functions will be released on function exit. If false, savepoints will be rolled back.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>true</td>
<td>master, system, restart, superuser</td>
</tr>
</tbody>
</table>

**pljava_vmoptions**
Defines the startup options for the Java VM. The default value is an empty string (""").

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>string</td>
<td></td>
<td>master, system, reload, superuser</td>
</tr>
</tbody>
</table>

**port**
The database listener port for a Greenplum instance. The master and each segment has its own port. Port numbers for the Greenplum system must also be changed in the gp_segment_configuration catalog. You must shut down your Greenplum Database system before changing port numbers.
### random_page_cost

Sets the estimate of the cost of a nonsequentially fetched disk page for the legacy query optimizer (planner). This is measured as a multiple of the cost of a sequential page fetch. A higher value makes it more likely a sequential scan will be used, a lower value makes it more likely an index scan will be used.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>floating point</td>
<td>100</td>
<td>master, session, reload</td>
</tr>
</tbody>
</table>

### readable_external_table_timeout

When an SQL query reads from an external table, the parameter value specifies the amount of time in seconds that Greenplum Database waits before cancelling the query when data stops being returned from the external table.

The default value of 0, specifies no time out. Greenplum Database does not cancel the query.

If queries that use gpfdist run a long time and then return the error "intermittent network connectivity issues", you can specify a value for readable_external_table_timeout. If no data is returned by gpfdist for the specified length of time, Greenplum Database cancels the query.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>integer &gt;= 0</td>
<td>0</td>
<td>master, system, reload</td>
</tr>
</tbody>
</table>

### repl_catchup_within_range

For Greenplum Database master mirroring, controls updates to the active master. If the number of WAL segment files that have not been processed by the walsender exceeds this value, Greenplum Database updates the active master.

If the number of segment files does not exceed the value, Greenplum Database blocks updates to the to allow the walsender process the files. If all WAL segments have been processed, the active master is updated.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>0 - 64</td>
<td>1</td>
<td>master, system, reload, superuser</td>
</tr>
</tbody>
</table>
replication_timeout

For Greenplum Database master mirroring, sets the maximum time in milliseconds that the walsender process on the active master waits for a status message from the walreceiver process on the standby master. If a message is not received, the walsender logs an error message.

The wal_receiver_status_interval controls the interval between walreceiver status messages.

<table>
<thead>
<tr>

<tr>
<td>basic</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

resource_cleanup_gangs_on_wait

Note: The resource_cleanup_gangs_on_wait server configuration parameter is enforced only when resource queue-based resource management is active.

If a statement is submitted through a resource queue, clean up any idle query executor worker processes before taking a lock on the resource queue.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>on</td>
<td>master, system, restart</td>
</tr>
</tbody>
</table>

resource_select_only

Note: The resource_select_only server configuration parameter is enforced only when resource queue-based resource management is active.

Sets the types of queries managed by resource queues. If set to on, then SELECT, SELECT INTO, CREATE TABLE AS SELECT, and DECLARE CURSOR commands are evaluated. If set to off INSERT, UPDATE, and DELETE commands will be evaluated as well.
### runaway_detector_activation_percent

For queries that are managed by resource queues or resource groups, this parameter determines when Greenplum Database terminates running queries based on the amount of memory the queries are using. A value of 100 disables the automatic termination of queries based on the percentage of memory that is utilized.

Either the resource queue or the resource group management scheme can be active in Greenplum Database; both schemes cannot be active at the same time. The server configuration parameter `gp_resource_manager` controls which scheme is active.

**When resource queues are enabled** - This parameter sets the percent of utilized Greenplum Database vmem memory that triggers the termination of queries. If the percentage of vmem memory that is utilized for a Greenplum Database segment exceeds the specified value, Greenplum Database terminates queries managed by resource queues based on memory usage, starting with the query consuming the largest amount of memory. Queries are terminated until the percentage of utilized vmem is below the specified percentage.

Specify the maximum vmem value for active Greenplum Database segment instances with the server configuration parameter `gp_vmem_protect_limit`.

For example, if vmem memory is set to 10GB, and this parameter is 90 (90%), Greenplum Database starts terminating queries when the utilized vmem memory exceeds 9 GB.

For information about resource queues, see [*Using Resource Queues*](#).

**When resource groups are enabled** - This parameter sets the percent of utilized resource group global shared memory that triggers the termination of queries that are managed by resource groups that are configured to use the `vmtracker` memory auditor, such as `admin_group` and `default_group`. For information about memory auditors, see [*Memory Auditor*](#).

Resource groups have a global shared memory pool when the sum of the `MEMORY_LIMIT` attribute values configured for all resource groups is less than 100. For example, if you have 3 resource groups configured with `memory_limit` values of 10, 20, and 30, then global shared memory is 40% = 100% - (10% + 20% + 30%). See [*Global Shared Memory*](#).

If the percentage of utilized global shared memory exceeds the specified value, Greenplum Database terminates queries based on memory usage, selecting from queries managed by the resource groups that are configured to use the `vmtracker` memory auditor. Greenplum Database starts with the query consuming the largest amount of memory. Queries are terminated until the percentage of utilized global shared memory is below the specified percentage.

For example, if global shared memory is 10GB, and this parameter is 90 (90%), Greenplum Database starts terminating queries when the utilized global shared memory exceeds 9 GB.

For information about resource groups, see [*Using Resource Groups*](#).

**Set Classifications**

- `master`
- `system`
- `restart`
**search_path**

Specifies the order in which schemas are searched when an object is referenced by a simple name with no schema component. When there are objects of identical names in different schemas, the one found first in the search path is used. The system catalog schema, `pg_catalog`, is always searched, whether it is mentioned in the path or not. When objects are created without specifying a particular target schema, they will be placed in the first schema listed in the search path. The current effective value of the search path can be examined via the SQL function `current_schemas()`. `current_schemas()` shows how the requests appearing in `search_path` were resolved.

</table>

**server_encoding**

Reports the database encoding (character set). It is determined when the Greenplum Database array is initialized. Ordinarily, clients need only be concerned with the value of `client_encoding`.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt;system dependent&gt;</td>
<td>UTF8</td>
<td>read only</td>
</tr>
</tbody>
</table>

**server_version**

Reports the version of PostgreSQL that this release of Greenplum Database is based on.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>string</td>
<td>8.3.23</td>
<td>read only</td>
</tr>
</tbody>
</table>

**server_version_num**

Reports the version of PostgreSQL that this release of Greenplum Database is based on as an integer.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>integer</td>
<td>80323</td>
<td>read only</td>
</tr>
</tbody>
</table>
**shared_buffers**

Sets the amount of memory a Greenplum Database segment instance uses for shared memory buffers. This setting must be at least 128KB and at least 16KB times `max_connections`.

Each Greenplum Database segment instance calculates and attempts to allocate certain amount of shared memory based on the segment configuration. The value of `shared_buffers` is significant portion of this shared memory calculation, but is not all it. When setting `shared_buffers`, the values for the operating system parameters `SHMMAX` or `SHMALL` might also need to be adjusted.

The operating system parameter `SHMMAX` specifies maximum size of a single shared memory allocation. The value of `SHMMAX` must be greater than this value:

```
shared_buffers + other_seg_shmem
```

The value of `other_seg_shmem` is the portion the Greenplum Database shared memory calculation that is not accounted for by the `shared_buffers` value. The `other_seg_shmem` value will vary based on the segment configuration.

With the default Greenplum Database parameter values, the value for `other_seg_shmem` is approximately 111MB for Greenplum Database segments and approximately 79MB for the Greenplum Database master.

The operating system parameter `SHMALL` specifies the maximum amount of shared memory on the host. The value of `SHMALL` must be greater than this value:

```
(num_instances_per_host * ( shared_buffers + other_seg_shmem ))
+ other_app_shared_mem
```

The value of `other_app_shared_mem` is the amount of shared memory that is used by other applications and processes on the host.

When shared memory allocation errors occur, possible ways to resolve shared memory allocation issues are to increase `SHMMAX` or `SHMALL`, or decrease `shared_buffers` or `max_connections`.

See the *Greenplum Database Installation Guide* for information about the Greenplum Database values for the parameters `SHMMAX` and `SHMALL`.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>integer &gt; 16K * <code>max_connections</code></td>
<td>125MB</td>
<td>local system restart</td>
</tr>
</tbody>
</table>

**shared_preload_libraries**

A comma-separated list of shared libraries that are to be preloaded at server start. PostgreSQL procedural language libraries can be preloaded in this way, typically by using the syntax `$libdir/plXXX` where `XXX` is `pgsql`, `perl`, `tcl`, or `python`. By preloading a shared library, the library startup time is avoided when the library is first used. If a specified library is not found, the server will fail to start.

**Note:** When you add a library to `shared_preload_libraries`, be sure to retain any previous setting of the parameter.
<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td>local system restart</td>
</tr>
</tbody>
</table>

ssl

Enables SSL connections.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>off</td>
<td>master system restart</td>
</tr>
</tbody>
</table>

ssl_ciphers

Specifies a list of SSL ciphers that are allowed to be used on secure connections. See the openssl manual page for a list of supported ciphers.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>string</td>
<td>ALL</td>
<td>master system restart</td>
</tr>
</tbody>
</table>

standard_conforming_strings

Determines whether ordinary string literals (‘...’) treat backslashes literally, as specified in the SQL standard. The default value is on. Turn this parameter off to treat backslashes in string literals as escape characters instead of literal backslashes. Applications may check this parameter to determine how string literals are processed. The presence of this parameter can also be taken as an indication that the escape string syntax (E‘...’) is supported.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>on</td>
<td>master session reload</td>
</tr>
</tbody>
</table>

statement_mem

Allocates segment host memory per query. The amount of memory allocated with this parameter cannot exceed `max_statement_mem` or the memory limit on the resource queue or resource group through which the query was submitted. If additional memory is required for a query, temporary spill files on disk are used.

*If you are using resource groups to control resource allocation in your Greenplum Database cluster:*

- Greenplum Database uses `statement_mem` to control query memory usage when the resource group `MEMORY_SPILL_RATIO` is set to 0.
You can use the following calculation to estimate a reasonable `statement_mem` value:

\[
\text{rg_perseg_mem} = \frac{(\text{RAM} \times (\text{vm.overcommit\_ratio} / 100) + \text{SWAP}) \times \text{gp\_resource\_group\_memory\_limit}}{\text{num\_active\_primary\_segments\_per\_host}}
\]
\[
\text{statement_mem} = \frac{\text{rg_perseg_mem}}{\text{max\_expected\_concurrent\_queries}}
\]

If you are using resource queues to control resource allocation in your Greenplum Database cluster:

- When `gp\_resqueue\_memory\_policy` = auto, `statement_mem` and resource queue memory limits control query memory usage.
- You can use the following calculation to estimate a reasonable `statement_mem` value for a wide variety of situations:

\[
(\text{gp\_vmem\_protect\_limitGB} \times 0.9) / \text{max\_expected\_concurrent\_queries}
\]

For example, with a `gp\_vmem\_protect\_limit` set to 8192MB (8GB) and assuming a maximum of 40 concurrent queries with a 10% buffer, you would use the following calculation to determine the `statement_mem` value:

\[
(8\text{GB} \times 0.9) / 40 = 0.18\text{GB} = 184\text{MB}
\]

When changing both `max\_statement\_mem` and `statement\_mem`, `max\_statement\_mem` must be changed first, or listed first in the `postgresql.conf` file.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>number of kilobytes</td>
<td>128MB</td>
<td>master, session, reload</td>
</tr>
</tbody>
</table>

**statement_timeout**

Abort any statement that takes over the specified number of milliseconds. 0 turns off the limitation.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>number of milliseconds</td>
<td>0</td>
<td>master, session, reload</td>
</tr>
</tbody>
</table>

**stats_queue_level**

Note: The `stats_queue_level` server configuration parameter is enforced only when resource queue-based resource management is active.

Collects resource queue statistics on database activity.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>off</td>
<td>master, session, reload</td>
</tr>
</tbody>
</table>
**superuser_reserved_connections**

Determines the number of connection slots that are reserved for Greenplum Database superusers.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>integer &lt; max_connections</code></td>
<td>3</td>
<td>local</td>
</tr>
<tr>
<td></td>
<td></td>
<td>system</td>
</tr>
<tr>
<td></td>
<td></td>
<td>restart</td>
</tr>
</tbody>
</table>

**tcp_keepalives_count**

How many keepalives may be lost before the connection is considered dead. A value of 0 uses the system default. If TCP_KEEPCNT is not supported, this parameter must be 0.

Use this parameter for all connections that are not between a primary and mirror segment. Use `gp_filerep_tcp_keepalives_count` for settings that are between a primary and mirror segment.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>number of lost keepalives</code></td>
<td>0</td>
<td>local</td>
</tr>
<tr>
<td></td>
<td></td>
<td>system</td>
</tr>
<tr>
<td></td>
<td></td>
<td>restart</td>
</tr>
</tbody>
</table>

**tcp_keepalives_idle**

Number of seconds between sending keepalives on an otherwise idle connection. A value of 0 uses the system default. If TCP_KEEPIDLE is not supported, this parameter must be 0.

Use this parameter for all connections that are not between a primary and mirror segment. Use `gp_filerep_tcp_keepalives_idle` for settings that are between a primary and mirror segment.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>number of seconds</code></td>
<td>0</td>
<td>local</td>
</tr>
<tr>
<td></td>
<td></td>
<td>system</td>
</tr>
<tr>
<td></td>
<td></td>
<td>restart</td>
</tr>
</tbody>
</table>

**tcp_keepalives_interval**

How many seconds to wait for a response to a keepalive before retransmitting. A value of 0 uses the system default. If TCP_KEEPINTVL is not supported, this parameter must be 0.

Use this parameter for all connections that are not between a primary and mirror segment. Use `gp_filerep_tcp_keepalives_interval` for settings that are between a primary and mirror segment.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>number of seconds</code></td>
<td>0</td>
<td>local</td>
</tr>
<tr>
<td></td>
<td></td>
<td>system</td>
</tr>
<tr>
<td></td>
<td></td>
<td>restart</td>
</tr>
</tbody>
</table>
**temp_buffers**

Sets the maximum number of temporary buffers used by each database session. These are session-local buffers used only for access to temporary tables. The setting can be changed within individual sessions, but only up until the first use of temporary tables within a session. The cost of setting a large value in sessions that do not actually need a lot of temporary buffers is only a buffer descriptor, or about 64 bytes, per increment. However if a buffer is actually used, an additional 8192 bytes will be consumed.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>integer</td>
<td>1024</td>
<td>master</td>
</tr>
<tr>
<td></td>
<td></td>
<td>session</td>
</tr>
<tr>
<td></td>
<td></td>
<td>reload</td>
</tr>
</tbody>
</table>

**TimeZone**

Sets the time zone for displaying and interpreting time stamps. The default is to use whatever the system environment specifies as the time zone. See *Date/Time Keywords* in the PostgreSQL documentation.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>time zone abbreviation</td>
<td></td>
<td>local</td>
</tr>
<tr>
<td></td>
<td></td>
<td>restart</td>
</tr>
</tbody>
</table>

**timezone_abbreviations**

Sets the collection of time zone abbreviations that will be accepted by the server for date time input. The default is *Default*, which is a collection that works in most of the world. *Australia* and *India*, and other collections can be defined for a particular installation. Possible values are names of configuration files stored in `$GPHOME/share/postgresql/timezonesets/`.

To configure Greenplum Database to use a custom collection of timezones, copy the file that contains the timezone definitions to the directory `$GPHOME/share/postgresql/timezonesets/` on the Greenplum Database master and segment hosts. Then set value of the server configuration parameter *timezone_abbreviations* to the file. For example, to use a file *custom* that contains the default timezones and the WIB (Waktu Indonesia Barat) timezone.

1. Copy the file *Default* from the directory `$GPHOME/share/postgresql/timezonesets/` to the file *custom*. Add the WIB timezone information from the file *Asia.txt* to the *custom*.
2. Copy the file *custom* to the directory `$GPHOME/share/postgresql/timezonesets/` on the Greenplum Database master and segment hosts.
3. Set value of the server configuration parameter *timezone_abbreviations* to *custom*.
4. Reload the server configuration file (`gpstop -u`).

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>string</td>
<td>Default</td>
<td>master</td>
</tr>
<tr>
<td></td>
<td></td>
<td>session</td>
</tr>
<tr>
<td></td>
<td></td>
<td>reload</td>
</tr>
</tbody>
</table>

**track_activity_query_size**

Sets the maximum length limit for the query text stored in *current_query* column of the system catalog view *pg_stat_activity*. The minimum length is 1024 characters.
### transaction_isolation

Sets the current transaction's isolation level.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>read committed</td>
<td>read committed</td>
<td>master</td>
</tr>
<tr>
<td>serializable</td>
<td></td>
<td>session</td>
</tr>
<tr>
<td></td>
<td></td>
<td>reload</td>
</tr>
</tbody>
</table>

### transaction_read_only

Sets the current transaction's read-only status.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>off</td>
<td>master</td>
</tr>
<tr>
<td></td>
<td></td>
<td>session</td>
</tr>
<tr>
<td></td>
<td></td>
<td>reload</td>
</tr>
</tbody>
</table>

### transform_null_equals

When on, expressions of the form expr = NULL (or NULL = expr) are treated as expr IS NULL, that is, they return true if expr evaluates to the null value, and false otherwise. The correct SQL-spec-compliant behavior of expr = NULL is to always return null (unknown).

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>off</td>
<td>master</td>
</tr>
<tr>
<td></td>
<td></td>
<td>session</td>
</tr>
<tr>
<td></td>
<td></td>
<td>reload</td>
</tr>
</tbody>
</table>

### unix_socket_directory

Specifies the directory of the UNIX-domain socket on which the server is to listen for connections from client applications. The default is an empty string which is the directory `/tmp/`.

**Important:** Do not change the value of this parameter. The default location is required for Greenplum Database utilities.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>directory path</td>
<td>unset</td>
<td>local</td>
</tr>
<tr>
<td></td>
<td></td>
<td>system</td>
</tr>
<tr>
<td></td>
<td></td>
<td>restart</td>
</tr>
</tbody>
</table>
**unix_socket_group**

Sets the owning group of the UNIX-domain socket. By default this is an empty string, which uses the default group for the current user.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>UNIX group name</td>
<td>unset</td>
<td>local system restart</td>
</tr>
</tbody>
</table>

**unix_socket_permissions**

Sets the access permissions of the UNIX-domain socket. UNIX-domain sockets use the usual UNIX file system permission set. Note that for a UNIX-domain socket, only write permission matters.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>numeric UNIX file permission mode (as accepted by the chmod or umask commands)</td>
<td>511</td>
<td>local system restart</td>
</tr>
</tbody>
</table>

**update_process_title**

Enables updating of the process title every time a new SQL command is received by the server. The process title is typically viewed by the `ps` command.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>on</td>
<td>local system restart</td>
</tr>
</tbody>
</table>

**vacuum_cost_delay**

The length of time that the process will sleep when the cost limit has been exceeded. 0 disables the cost-based vacuum delay feature.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>milliseconds &lt; 0 (in multiples of 10)</td>
<td>0</td>
<td>local system restart</td>
</tr>
</tbody>
</table>

**vacuum_cost_limit**

The accumulated cost that will cause the vacuuming process to sleep.
vacuum_cost_page_dirty

The estimated cost charged when vacuum modifies a block that was previously clean. It represents the extra I/O required to flush the dirty block out to disk again.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>integer &gt; 0</td>
<td>200</td>
<td>local, system, restart</td>
</tr>
</tbody>
</table>

vacuum_cost_page_hit

The estimated cost for vacuuming a buffer found in the shared buffer cache. It represents the cost to lock the buffer pool, lookup the shared hash table and scan the content of the page.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>integer &gt; 0</td>
<td>1</td>
<td>local, system, restart</td>
</tr>
</tbody>
</table>

vacuum_cost_page_miss

The estimated cost for vacuuming a buffer that has to be read from disk. This represents the effort to lock the buffer pool, lookup the shared hash table, read the desired block in from the disk and scan its content.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>integer &gt; 0</td>
<td>10</td>
<td>local, system, restart</td>
</tr>
</tbody>
</table>

vacuum_freeze_min_age

Specifies the cutoff age (in transactions) that vacuum should use to decide whether to replace transaction IDs with FrozenXID while scanning a table.

For information about vacuum and transaction ID management, see "Managing Data" in the Greenplum Database Administrator Guide and the PostgreSQL documentation.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>integer 0-1000000000000</td>
<td>100000000</td>
<td>local, system, restart</td>
</tr>
</tbody>
</table>
**validate_previous_free_tid**

Enables a test that validates the free tuple ID (TID) list. The list is maintained and used by Greenplum Database. Greenplum Database determines the validity of the free TID list by ensuring the previous free TID of the current free tuple is a valid free tuple. The default value is `true`, enable the test.

If Greenplum Database detects a corruption in the free TID list, the free TID list is rebuilt, a warning is logged, and a warning is returned by queries for which the check failed. Greenplum Database attempts to execute the queries.

**Note:** If a warning is returned, please contact Pivotal Support.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>true</td>
<td>master</td>
</tr>
<tr>
<td></td>
<td></td>
<td>session</td>
</tr>
<tr>
<td></td>
<td></td>
<td>reload</td>
</tr>
</tbody>
</table>

**verify_gpfdists_cert**

When a Greenplum Database external table is defined with the `gpfdists` protocol to use SSL security, this parameter controls whether SSL certificate authentication is enabled. The default is `true`, SSL authentication is enabled when Greenplum Database communicates with the `gpfdist` utility to either read data from or write data to an external data source.

The value `false` disables SSL certificate authentication. These SSL exceptions are ignored:

- The self-signed SSL certificate that is used by `gpfdist` is not trusted by Greenplum Database.
- The host name contained in the SSL certificate does not match the host name that is running `gpfdist`.

You can set the value to `false` to disable authentication when testing the communication between the Greenplum Database external table and the `gpfdist` utility that is serving the external data.

**Warning:** Disabling SSL certificate authentication exposes a security risk by not validating the `gpfdists` SSL certificate.

For information about the `gpfdists` protocol, see `gpfdists:// Protocol`. For information about running the `gpfdist` utility, see `gpfdist`.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>true</td>
<td>master</td>
</tr>
<tr>
<td></td>
<td></td>
<td>session</td>
</tr>
<tr>
<td></td>
<td></td>
<td>reload</td>
</tr>
</tbody>
</table>

**vmem_process_interrupt**

Enables checking for interrupts before reserving vmem memory for a query during Greenplum Database query execution. Before reserving further vmem for a query, check if the current session for the query has a pending query cancellation or other pending interrupts. This ensures more responsive interrupt processing, including query cancellation requests. The default is `off`.
### wal_receiver_status_interval

For Greenplum Database master mirroring, sets the interval in seconds between `walreceiver` process status messages that are sent to the active master. Under heavy loads, the time might be longer.

The value of `replication_timeout` controls the time that the `walsender` process waits for a `walreceiver` message.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>integer 0- INT_MAX/1000</td>
<td>10 sec</td>
<td>master, system, reload, superuser</td>
</tr>
</tbody>
</table>

### writable_external_table_bufsize

Size of the buffer (in KB) that Greenplum Database uses for network communication, such as the `gpfdist` utility and external web tables (that use http). Greenplum Database stores data in the buffer before writing the data out. For information about `gpfdist`, see the [Greenplum Database Utility Guide](#).

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>integer 32 - 131072 (32KB - 128MB)</td>
<td>64</td>
<td>local, session, reload</td>
</tr>
</tbody>
</table>

### xid_stop_limit

The number of transaction IDs prior to the ID where transaction ID wraparound occurs. When this limit is reached, Greenplum Database stops creating new transactions to avoid data loss due to transaction ID wraparound.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>integer 10000000 - 2000000000</td>
<td>1000000000</td>
<td>local, system, restart</td>
</tr>
</tbody>
</table>

### xid_warn_limit

The number of transaction IDs prior to the limit specified by `xid_stop_limit`. When Greenplum Database reaches this limit, it issues a warning to perform a VACUUM operation to avoid data loss due to transaction ID wraparound.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>integer 10000000 - 2000000000</td>
<td>1000000000</td>
<td>local, system, restart</td>
</tr>
</tbody>
</table>
xmlbinary

Specifies how binary values are encoded in XML data. For example, when `bytea` values are converted to XML. The binary data can be converted to either base64 encoding or hexadecimal encoding. The default is base64.

The parameter can be set for a database system, an individual database, or a session.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>integer 10000000 - 2000000000</td>
<td>5000000000</td>
<td>local system restart</td>
</tr>
</tbody>
</table>

xmloption

Specifies whether XML data is to be considered as an XML document (`document`) or XML content fragment (`content`) for operations that perform implicit parsing and serialization. The default is `content`.

This parameter affects the validation performed by `xml_is_well_formed()`. If the value is `document`, the function checks for a well-formed XML document. If the value is `content`, the function checks for a well-formed XML content fragment.

**Note:** An XML document that contains a document type declaration (DTD) is not considered a valid XML content fragment. If `xmloption` set to `content`, XML that contains a DTD is not considered valid XML.

To cast a character string that contains a DTD to the `xml` data type, use the `xmlparse` function with the `document` keyword, or change the `xmloption` value to `document`.

The parameter can be set for a database system, an individual database, or a session. The SQL command to set this option for a session is also available in Greenplum Database.

```
SET XML OPTION { DOCUMENT | CONTENT }
```

<table>

</tr>
<tr>
<td>content</td>
<td>content</td>
<td></td>
</tr>
</tbody>
</table>
Summary of Built-in Functions

Greenplum Database supports built-in functions and operators including analytic functions and window functions that can be used in window expressions. For information about using built-in Greenplum Database functions see, "Using Functions and Operators" in the Greenplum Database Administrator Guide.

- Greenplum Database Function Types
- Built-in Functions and Operators
- JSON Functions and Operators
- Window Functions
- Advanced Aggregate Functions

Greenplum Database Function Types

Greenplum Database evaluates functions and operators used in SQL expressions. Some functions and operators are only allowed to execute on the master since they could lead to inconsistencies in Greenplum Database segment instances. This table describes the Greenplum Database Function Types.

Table 240: Functions in Greenplum Database

<table>
<thead>
<tr>
<th>Function Type</th>
<th>Greenplum Support</th>
<th>Description</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>IMMUTABLE</td>
<td>Yes</td>
<td>Relies only on information directly in its argument list. Given the same argument values, always returns the same result.</td>
<td></td>
</tr>
<tr>
<td>STABLE</td>
<td>Yes, in most cases</td>
<td>Within a single table scan, returns the same result for same argument values, but results change across SQL statements.</td>
<td>Results depend on database lookups or parameter values. current_timestamp family of functions is STABLE; values do not change within an execution.</td>
</tr>
<tr>
<td>VOLATILE</td>
<td>Restricted</td>
<td>Function values can change within a single table scan. For example: random(), gettimeofday().</td>
<td>Any function with side effects is volatile, even if its result is predictable. For example: setval().</td>
</tr>
</tbody>
</table>

In Greenplum Database, data is divided up across segments — each segment is a distinct PostgreSQL database. To prevent inconsistent or unexpected results, do not execute functions classified as VOLATILE at the segment level if they contain SQL commands or modify the database in any way. For example, functions such as setval() are not allowed to execute on distributed data in Greenplum Database because they can cause inconsistent data between segment instances.

To ensure data consistency, you can safely use VOLATILE and STABLE functions in statements that are evaluated on and run from the master. For example, the following statements run on the master (statements without a FROM clause):

```sql
SELECT setval('myseq', 201);
SELECT foo();
```
If a statement has a `FROM` clause containing a distributed table and the function in the `FROM` clause returns a set of rows, the statement can run on the segments:

```
SELECT * from foo();
```

Greenplum Database does not support functions that return a table reference (rangeFuncs) or functions that use the refCursor datatype.

**Built-in Functions and Operators**

The following table lists the categories of built-in functions and operators supported by PostgreSQL. All functions and operators are supported in Greenplum Database as in PostgreSQL with the exception of STABLE and VOLATILE functions, which are subject to the restrictions noted in Greenplum Database Function Types. See the Functions and Operators section of the PostgreSQL documentation for more information about these built-in functions and operators.

**Table 241: Built-in functions and operators**

### JSON Functions and Operators

Built-in functions and operators that create and manipulate JSON data.

- **JSON Operators**
- **JSON Creation Functions**
- **JSON Processing Functions**

**Note:** For `json` values, all key/value pairs are kept even if a JSON object contains duplicate key/value pairs. The processing functions consider the last value as the operative one.

OpenTopic

JSON Processing Functions
This table describes the functions that process json values.
Table 244: JSON Processing Functions
Function

Return Type

Description

Example

json_
each(json)

setof key
text, value
json

Expands the
outermost JSON
object into a set of
key/value pairs.

select *
key | value
from json_
-----+------| "foo"
each('{"a":"foo", a
b
| "bar"
"b":"bar"}')

setof key
text, value
jsonb

Example Result

json_each_
text(json)

setof key
text, value
text

Expands the
outermost JSON
object into a set
of key/value pairs.
The returned
values are of type
text.

select * from
key | value
json_each_
-----+------| foo
text('{"a":"foo", a
b
| bar
"b":"bar"}')

json_extract_
path(from_json
json, VARIADIC
path_elems
text[])

json

Returns the JSON
value specified to
by path_elems.
Equivalent to #>
operator.

json_extract_
{"f5":99,"f6":"foo"}
path('{"f2":
{"f3":1},"f4":
{"f5":99,"f6":"foo"}}','f4')

json_
extract_path_
text(from_json
json, VARIADIC
path_elems
text[])

text

Returns the JSON
value specified to
by path_elems
as text. Equivalent
to #>> operator.

json_extract_
foo
path_text('{"f2":
{"f3":1},"f4":
{"f5":99,"f6":"foo"}}','f4',
'f6')

json_object_
keys(json)

setof text

Returns set
of keys in the
outermost JSON
object.

json_object_
json_object_
keys('{"f1":"abc","f2":
keys
-----------------{"f3":"a",
f1
"f4":"b"}}')
f2

json_populate_
record(base
anyelement,
from_json
json)

anyelement

Expands the
object in from_
json to a row
whose columns
match the record
type defined by
base. See Note.

select * from
a | b
json_populate_
---+--1 | 2
record(null::myrowtype,
'{"a":1,"b":2}')

1530


### Function

<table>
<thead>
<tr>
<th>Function</th>
<th>Return Type</th>
<th>Description</th>
<th>Example</th>
<th>Example Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>json_populate_recordset (base anyelement, from_json json)</td>
<td>setof anyelement</td>
<td>Expands the outermost array of objects in from_json to a set of rows whose columns match the record type defined by base. See Note.</td>
<td>select * from json_populate_recordset(null::myrowtype, '[{&quot;a&quot;:1,&quot;b&quot;:2},{&quot;a&quot;:3,&quot;b&quot;:4}]')</td>
<td>a</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td>1</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td>3</td>
</tr>
<tr>
<td>json_array_elements (json)</td>
<td>setof json</td>
<td>Expands a JSON array to a set of JSON values.</td>
<td>select * from json_array_elements('[1,true,[2,false]]')</td>
<td>value</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td>1</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td>[2,false]</td>
</tr>
</tbody>
</table>

**Note:** Many of these functions and operators convert Unicode escapes in JSON strings to regular characters. The functions throw an error for characters that cannot be represented in the database encoding.

For json_populate_record and json_populate_recordset, type coercion from JSON is best effort and might not result in desired values for some types. JSON keys are matched to identical column names in the target row type. JSON fields that do not appear in the target row type are omitted from the output, and target columns that do not match any JSON field return NULL.

### Window Functions

The following built-in window functions are Greenplum extensions to the PostgreSQL database. All window functions are immutable. For more information about window functions, see "Window Expressions" in the Greenplum Database Administrator Guide.

**Table 245: Window functions**

<table>
<thead>
<tr>
<th>Function</th>
<th>Return Type</th>
<th>Full Syntax</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>cume_dist()</td>
<td>double precision</td>
<td>CUME_DIST() OVER ( [PARTITION BY expr ] ORDER BY expr )</td>
<td>Calculates the cumulative distribution of a value in a group of values. Rows with equal values always evaluate to the same cumulative distribution value.</td>
</tr>
<tr>
<td>dense_rank()</td>
<td>bigint</td>
<td>DENSE_RANK () OVER ( [PARTITION BY expr ] ORDER BY expr )</td>
<td>Computes the rank of a row in an ordered group of rows without skipping rank values. Rows with equal values are given the same rank value.</td>
</tr>
<tr>
<td>first_value(expr)</td>
<td>same as input expr type</td>
<td>FIRST_VALUE(expr) OVER ( [PARTITION BY expr ] ORDER BY expr [ROWS</td>
<td>RANGE frame_expr ] )</td>
</tr>
<tr>

<td>Full Syntax</td>
<td>Description</td>
</tr>
<tr>
<td>--------------------------</td>
<td>-------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td><code>lag(expr [,offset] [,default])</code></td>
<td>same as input expr type</td>
<td><code>LAG(expr [,offset] [,default]) OVER ( [PARTITION BY expr] ORDER BY expr )</code></td>
<td>Provides access to more than one row of the same table without doing a self join. Given a series of rows returned from a query and a position of the cursor, <code>LAG</code> provides access to a row at a given physical offset prior to that position. The default offset is 1. <code>default</code> sets the value that is returned if the offset goes beyond the scope of the window. If <code>default</code> is not specified, the default value is null.</td>
</tr>
<tr>
<td><code>last_value(expr)</code></td>
<td>same as input expr type</td>
<td>`LAST_VALUE(expr) OVER ( [PARTITION BY expr] ORDER BY expr [ROWS</td>
<td>RANGE frame_expr] )`</td>
</tr>
<tr>
<td><code>lead(expr [,offset] [,default])</code></td>
<td>same as input expr type</td>
<td><code>LEAD(expr [,offset] [,expr default]) OVER ( [PARTITION BY expr] ORDER BY expr )</code></td>
<td>Provides access to more than one row of the same table without doing a self join. Given a series of rows returned from a query and a position of the cursor, <code>lead</code> provides access to a row at a given physical offset after that position. If <code>offset</code> is not specified, the default offset is 1. <code>default</code> sets the value that is returned if the offset goes beyond the scope of the window. If <code>default</code> is not specified, the default value is null.</td>
</tr>
<tr>
<td><code>ntile(expr)</code></td>
<td>bigint</td>
<td><code>NTILE(expr) OVER ( [PARTITION BY expr] ORDER BY expr )</code></td>
<td>Divides an ordered data set into a number of buckets (as defined by <code>expr</code>) and assigns a bucket number to each row.</td>
</tr>
<tr>
<td><code>percent_rank()</code></td>
<td>double precision</td>
<td><code>PERCENT_RANK () OVER ( [PARTITION BY expr] ORDER BY expr )</code></td>
<td>Calculates the rank of a hypothetical row R minus 1, divided by 1 less than the number of rows being evaluated (within a window partition).</td>
</tr>
</tbody>
</table>
### Advanced Aggregate Functions

The following built-in advanced analytic functions are Greenplum extensions of the PostgreSQL database. Analytic functions are immutable.

**Note:** The Greenplum MADlib Extension for Analytics provides additional advanced functions to perform statistical analysis and machine learning with Greenplum Database data. See Greenplum MADlib Extension for Analytics.

#### Table 246: Advanced Aggregate Functions

<table>
<thead>
<tr>
<th>Function</th>
<th>Return Type</th>
<th>Full Syntax</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>rank()</td>
<td>bigint</td>
<td>RANK () OVER ( [PARTITION BY expr] ORDER BY expr )</td>
<td>Calculates the rank of a row in an ordered group of values. Rows with equal values for the ranking criteria receive the same rank. The number of tied rows are added to the rank number to calculate the next rank value. Ranks may not be consecutive numbers in this case.</td>
</tr>
<tr>
<td>row_number()</td>
<td>bigint</td>
<td>ROW_NUMBER () OVER ( [PARTITION BY expr] ORDER BY expr )</td>
<td>Assigns a unique number to each row to which it is applied (either each row in a window partition or each row of the query).</td>
</tr>
<tr>
<td>MEDIAN (expr)</td>
<td>timestamp, timestamptz, interval, float</td>
<td>MEDIAN (expression)</td>
<td>Can take a two-dimensional array as input. Treats such arrays as matrices.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>SELECT department_id, MEDIAN(salary) FROM employees GROUP BY department_id;</td>
<td></td>
</tr>
<tr>
<td>PERCENTILE_CONT (expr) WITHIN GROUP (ORDER BY expr [DESC/ASC])</td>
<td>timestamp, timestamptz, interval, float</td>
<td>PERCENTILE_CONT(percentage) WITHIN GROUP (ORDER BY expression)</td>
<td>Performs an inverse distribution function that assumes a continuous distribution model. It takes a percentile value and a sort specification and returns the same datatype as the numeric datatype of the argument. This returned value is a computed result after performing linear interpolation. Null are ignored in this calculation.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>SELECT department_id, PERCENTILE_CONT (0.5) WITHIN GROUP (ORDER BY salary DESC) &quot;Median_cont&quot;; FROM employees GROUP BY department_id;</td>
<td></td>
</tr>
<tr>
<td>Function</td>
<td>Return Type</td>
<td>Full Syntax</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------------</td>
<td>-------------------</td>
<td>----------------------------------------------------------------------------</td>
<td>----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>PERCENTILE_DISC</td>
<td>timestamp,</td>
<td>PERCENTILE_DISC(percentage) WITHIN GROUP (ORDER BY expression)</td>
<td>Performs an inverse distribution function that assumes a discrete distribution model. It takes a percentile value and a sort specification. This returned value is an element from the set. Null are ignored in this calculation.</td>
</tr>
<tr>
<td>(expr) WITHIN GROUP</td>
<td>interval, float</td>
<td></td>
<td></td>
</tr>
<tr>
<td>(ORDER BY expr [DESC/ASC])</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>sum(array[])</td>
<td>smallint[], bigint[], float[]</td>
<td>sum(array[[1,2],[3,4]])</td>
<td>Performs matrix summation. Can take as input a two-dimensional array that is treated as a matrix.</td>
</tr>
<tr>
<td>pivot_sum</td>
<td>int[], bigint[], float[]</td>
<td>pivot_sum( array['A1','A2'], attr, value)</td>
<td>A pivot aggregation using sum to resolve duplicate entries.</td>
</tr>
<tr>
<td>(label[], label, expr)</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>unnest</td>
<td>set of anyelement</td>
<td>unnest( array['one', 'row', 'per', 'item'])</td>
<td>Transforms a one dimensional array into rows. Returns a set of anyelement, a polymorphic pseudotype in PostgreSQL.</td>
</tr>
<tr>
<td>(array[])</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
Greenplum MapReduce Specification

This specification describes the document format and schema for defining Greenplum MapReduce jobs. MapReduce is a programming model developed by Google for processing and generating large data sets on an array of commodity servers. Greenplum MapReduce allows programmers who are familiar with the MapReduce model to write map and reduce functions and submit them to the Greenplum Database parallel engine for processing.

To enable Greenplum to process MapReduce functions, define the functions in a document, then pass the document to the Greenplum MapReduce program, `gpmapreduce`, for execution by the Greenplum Database parallel engine. The Greenplum Database system distributes the input data, executes the program across a set of machines, handles machine failures, and manages the required inter-machine communication.

See the Greenplum Database Utility Guide for information about `gpmapreduce`.

Greenplum MapReduce Document Format

This section explains some basics of the Greenplum MapReduce document format to help you get started creating your own Greenplum MapReduce documents. Greenplum uses the YAML 1.1 document format and then implements its own schema for defining the various steps of a MapReduce job.

All Greenplum MapReduce files must first declare the version of the YAML specification they are using. After that, three dashes (---) denote the start of a document, and three dots (...), indicate the end of a document without starting a new one. Comment lines are prefixed with a pound symbol (#). It is possible to declare multiple Greenplum MapReduce documents in the same file:

```
%YAML 1.1
---
# Begin Document 1
# ...
---
# Begin Document 2
# ...
```

Within a Greenplum MapReduce document, there are three basic types of data structures or nodes: scalars, sequences, and mappings.

A scalar is a basic string of text indented by a space. If you have a scalar input that spans multiple lines, a preceding pipe ( | ) denotes a literal style, where all line breaks are significant. Alternatively, a preceding angle bracket ( > ) folds a single line break to a space for subsequent lines that have the same indentation level. If a string contains characters that have reserved meaning, the string must be quoted or the special character must be escaped with a backslash ( \ ).

```
# Read each new line literally
somekey: |  this value contains two lines
          and each line is read literally
# Treat each new line as a space
anotherkey: >
    this value contains two lines
    but is treated as one continuous line
# This quoted string contains a special character
ThirdKey: "This is a string: not a mapping"
```

A sequence is a list with each entry in the list on its own line denoted by a dash and a space ( - ). Alternatively, you can specify an inline sequence as a comma-separated list within square brackets.

```
```
A sequence provides a set of data and gives it an order. When you load a list into the Greenplum MapReduce program, the order is kept.

```bash
# list sequence
- this
- is
- a list
- with
- five scalar values
# inline sequence
[this, is, a list, with, five scalar values]
```

A mapping is used to pair up data values with identifiers called keys. Mappings use a colon and space (:) for each key: value pair, or can also be specified inline as a comma-separated list within curly braces. The key is used as an index for retrieving data from a mapping.

```bash
# a mapping of items
title: War and Peace
author: Leo Tolstoy
date: 1865
# same mapping written inline
title: War and Peace, author: Leo Tolstoy, date: 1865
```

Keys are used to associate meta information with each node and specify the expected node type (scalar, sequence or mapping). See Greenplum MapReduce Document Schema for the keys expected by the Greenplum MapReduce program.

The Greenplum MapReduce program processes the nodes of a document in order and uses indentation (spaces) to determine the document hierarchy and the relationships of the nodes to one another. The use of white space is significant. White space should not be used simply for formatting purposes, and tabs should not be used at all.

**Greenplum MapReduce Document Schema**

Greenplum MapReduce uses the YAML document framework and implements its own YAML schema. The basic structure of a Greenplum MapReduce document is:

```yaml
---
VERSION: 1.0.0.2
DATABASE: dbname
USER: db_username
HOST: master_hostname
PORT: master_port

DEFINE:
- INPUT:
  NAME: input_name

  TARGET: output_name
  MAP: map_function_name
  REDUCE: reduce_function_name...
**VERSION**

Required. The version of the Greenplum MapReduce YAML specification. Current versions are 1.0.0.1.

**DATABASE**

Optional. Specifies which database in Greenplum to connect to. If not specified, defaults to the default database or $PGDATABASE if set.

**USER**

Optional. Specifies which database role to use to connect. If not specified, defaults to the current user or $PGUSER if set. You must be a Greenplum superuser to run functions written in untrusted Python and Perl. Regular database users can run functions written in trusted Perl. You also must be a database superuser to run MapReduce jobs that contain FILE, GPFDIST and EXEC input types.

**HOST**

Optional. Specifies Greenplum master host name. If not specified, defaults to localhost or $PGHOST if set.

**PORT**

Optional. Specifies Greenplum master port. If not specified, defaults to 5432 or $PGPORT if set.

**DEFINE**

Required. A sequence of definitions for this MapReduce document. The DEFINE section must have at least one INPUT definition.

**INPUT**

Required. Defines the input data. Every MapReduce document must have at least one input defined. Multiple input definitions are allowed in a document, but each input definition can specify only one of these access types: a file, a gpfdist file distribution program, a table in the database, an SQL command, or an operating system command. See the Greenplum Database Utility Guide for information about gpfdist.

**NAME**

A name for this input. Names must be unique with regards to the names of other objects in this MapReduce job (such as map function, task, reduce function and output names). Also, names cannot conflict with existing objects in the database (such as tables, functions or views).

**FILE**

A sequence of one or more input files in the format: seghostname:/path/to/filename. You must be a Greenplum Database superuser to run MapReduce jobs with FILE input. The file must reside on a Greenplum segment host.

**GPFDIST**

A sequence of one or more running gpfdist file distribution programs in the format: hostname[:port]/file_pattern. You must be a Greenplum Database superuser to run MapReduce jobs with GPFDIST input, unless the server configuration parameter Server Configuration Parameters is set to on.

**TABLE**

The name of an existing table in the database.

**QUERY**

A SQL SELECT command to run within the database.

**EXEC**

An operating system command to run on the Greenplum segment hosts. The command is run by all segment instances in the system by default. For example, if you have four
segment instances per segment host, the command will be run four times on each host. You must be a Greenplum Database superuser to run MapReduce jobs with EXEC input and the server configuration parameter Server Configuration Parameters is set to on.

**COLUMNS**

Optional. Columns are specified as: column_name [data_type]. If not specified, the default is value text. The DELIMITER character is what separates two data value fields (columns). A row is determined by a line feed character (0x0a).

**FORMAT**

Optional. Specifies the format of the data - either delimited text (TEXT) or comma separated values (CSV) format. If the data format is not specified, defaults to TEXT.

**DELIMITER**

Optional for FILE, GPFDIST and EXEC inputs. Specifies a single character that separates data values. The default is a tab character in TEXT mode, a comma in CSV mode. The delimiter character must only appear between any two data value fields. Do not place a delimiter at the beginning or end of a row.

**ESCAPE**

Optional for FILE, GPFDIST and EXEC inputs. Specifies the single character that is used for C escape sequences (such as \n, \t, \100, and so on) and for escaping data characters that might otherwise be taken as row or column delimiters. Make sure to choose an escape character that is not used anywhere in your actual column data. The default escape character is a \ (backslash) for text-formatted files and a " (double quote) for csv-formatted files, however it is possible to specify another character to represent an escape. It is also possible to disable escaping by specifying the value 'OFF' as the escape value. This is very useful for data such as text-formatted web log data that has many embedded backslashes that are not intended to be escapes.

**NULL**

Optional for FILE, GPFDIST and EXEC inputs. Specifies the string that represents a null value. The default is \N in TEXT format, and an empty value with no quotations in CSV format. You might prefer an empty string even in TEXT mode for cases where you do not want to distinguish nulls from empty strings. Any input data item that matches this string will be considered a null value.

**QUOTE**

Optional for FILE, GPFDIST and EXEC inputs. Specifies the quotation character for CSV formatted files. The default is a double quote ("). In CSV formatted files, data value fields must be enclosed in double quotes if they contain any commas or embedded new lines. Fields that contain double quote characters must be surrounded by double quotes, and the embedded double quotes must each be represented by a pair of consecutive double quotes. It is important to always open and close quotes correctly in order for data rows to be parsed correctly.

**ERROR_LIMIT**

If the input rows have format errors they will be discarded provided that the error limit count is not reached on any Greenplum segment instance during input processing. If the error limit is not reached, all good rows will be processed and any error rows discarded.

**ENCODING**

Character set encoding to use for the data. Specify a string constant (such as 'SQL_ASCII'), an integer encoding number, or DEFAULT to use the default client encoding. See Character Set Support for more information.

**OUTPUT**
Optional. Defines where to output the formatted data of this MapReduce job. If output is not defined, the default is `STDOUT` (standard output of the client). You can send output to a file on the client host or to an existing table in the database.

**NAME**

A name for this output. The default output name is `STDOUT`. Names must be unique with regards to the names of other objects in this MapReduce job (such as map function, task, reduce function and input names). Also, names cannot conflict with existing objects in the database (such as tables, functions or views).

**FILE**

Specifies a file location on the MapReduce client machine to output data in the format: `/path/to/filename`.

**TABLE**

Specifies the name of a table in the database to output data. If this table does not exist prior to running the MapReduce job, it will be created using the distribution policy specified with `KEYS`.

**KEYS**

Optional for `TABLE` output. Specifies the column(s) to use as the Greenplum Database distribution key. If the `EXECUTE` task contains a `REDUCE` definition, then the `REDUCE` keys will be used as the table distribution key by default. Otherwise, the first column of the table will be used as the distribution key.

**MODE**

Optional for `TABLE` output. If not specified, the default is to create the table if it does not already exist, but error out if it does exist. Declaring `APPEND` adds output data to an existing table (provided the table schema matches the output format) without removing any existing data. Declaring `REPLACE` will drop the table if it exists and then recreate it. Both `APPEND` and `REPLACE` will create a new table if one does not exist.

**MAP**

Required. Each `MAP` function takes data structured in `(key, value)` pairs, processes each pair, and generates zero or more output `(key, value)` pairs. The Greenplum MapReduce framework then collects all pairs with the same key from all output lists and groups them together. This output is then passed to the `REDUCE` task, which is comprised of `TRANSITION | CONSOLIDATE | FINALIZE` functions. There is one predefined `MAP` function named `IDENTITY` that returns `(key, value)` pairs unchanged. Although `(key, value)` are the default parameters, you can specify other prototypes as needed.

**TRANSITION | CONSOLIDATE | FINALIZE**

`TRANSITION`, `CONSOLIDATE` and `FINALIZE` are all component pieces of `REDUCE`. A `TRANSITION` function is required. `CONSOLIDATE` and `FINALIZE` functions are optional. By default, all take `state` as the first of their input `PARAMETERS`, but other prototypes can be defined as well.

A `TRANSITION` function iterates through each value of a given key and accumulates values in a `state` variable. When the transition function is called on the first value of a key, the `state` is set to the value specified by `INITIALIZE` of a `REDUCE` job (or the default state value for the data type). A transition takes two arguments as input; the current state of the key reduction, and the next value, which then produces a new `state`.

If a `CONSOLIDATE` function is specified, `TRANSITION` processing is performed at the segment-level before redistributing the keys across the Greenplum interconnect for final aggregation (two-phase aggregation). Only the resulting `state` value for a given key is redistributed, resulting in lower interconnect traffic and greater parallelism. `CONSOLIDATE` is handled like a `TRANSITION`, except that instead of `state + value` => `state`, it is `(state + state)` => `state`. 
If a **FINALIZE** function is specified, it takes the final state produced by **CONSOLIDATE** (if present) or **TRANSITION** and does any final processing before emitting the final result. **TRANSITION** and **CONSOLIDATE** functions cannot return a set of values. If you need a **REDUCE** job to return a set, then a **FINALIZE** is necessary to transform the final state into a set of output values.

**NAME**

Required. A name for the function. Names must be unique with regards to the names of other objects in this MapReduce job (such as function, task, input and output names). You can also specify the name of a function built-in to Greenplum Database. If using a built-in function, do not supply **LANGUAGE** or a **FUNCTION** body.

**FUNCTION**

Optional. Specifies the full body of the function using the specified **LANGUAGE**. If **FUNCTION** is not specified, then a built-in database function corresponding to **NAME** is used.

**LANGUAGE**

Required when **FUNCTION** is used. Specifies the implementation language used to interpret the function. This release has language support for **perl**, **python**, and **C**. If calling a built-in database function, **LANGUAGE** should not be specified.

**LIBRARY**

Required when **LANGUAGE** is **C** (not allowed for other language functions). To use this attribute, **VERSION** must be 1.0.0.2. The specified library file must be installed prior to running the MapReduce job, and it must exist in the same file system location on all Greenplum hosts (master and segments).

**PARAMETERS**

Optional. Function input parameters. The default type is **text**.

- **MAP** default - key text, value text
- **TRANSITION** default - state text, value text
- **CONSOLIDATE** default - state1 text, state2 text (must have exactly two input parameters of the same data type)
- **FINALIZE** default - state text (single parameter only)

**RETURNS**

Optional. The default return type is **text**.

- **MAP** default - key text, value text
- **TRANSITION** default - state text (single return value only)
- **CONSOLIDATE** default - state text (single return value only)
- **FINALIZE** default - value text

**OPTIMIZE**

Optional optimization parameters for the function:

- **STRICT** - function is not affected by **NULL** values
- **IMMUTABLE** - function will always return the same value for a given input

**MODE**

Optional. Specifies the number of rows returned by the function.

- **MULTI** - returns 0 or more rows per input record. The return value of the function must be an array of rows to return, or the function must be written as an iterator using **yield**
in Python or `return_next` in Perl. **MULTI** is the default mode for **MAP** and **FINALIZE** functions. 

**SINGLE** - returns exactly one row per input record. **SINGLE** is the only mode supported for **TRANSITION** and **CONSOLIDATE** functions. When used with **MAP** and **FINALIZE** functions, **SINGLE** mode can provide modest performance improvement. 

**REDUCE**

Required. A **REDUCE** definition names the **TRANSITION**, **CONSOLIDATE**, or **FINALIZE** functions that comprise the reduction of (key, value) pairs to the final result set. There are also several predefined **REDUCE** jobs you can execute, which all operate over a column named value:

- **IDENTITY** - returns (key, value) pairs unchanged
- **SUM** - calculates the sum of numeric data
- **AVG** - calculates the average of numeric data
- **COUNT** - calculates the count of input data
- **MIN** - calculates minimum value of numeric data
- **MAX** - calculates maximum value of numeric data

**NAME**

Required. The name of this **REDUCE** job. Names must be unique with regards to the names of other objects in this MapReduce job (function, task, input and output names). Also, names cannot conflict with existing objects in the database (such as tables, functions or views). 

**TRANSITION**

Required. The name of the **TRANSITION** function. 

**CONSOLIDATE**

Optional. The name of the **CONSOLIDATE** function.

**FINALIZE**

Optional. The name of the **FINALIZE** function.

**INITIALIZE**

Optional for **text** and **float** data types. Required for all other data types. The default value for **text** is `' '`. The default value for **float** is `0.0`. Sets the initial state value of the **TRANSITION** function. 

**KEYS**

Optional. Defaults to `[key, *]`. When using a multi-column reduce it may be necessary to specify which columns are key columns and which columns are value columns. By default, any input columns that are not passed to the **TRANSITION** function are key columns, and a column named `key` is always a key column even if it is passed to the **TRANSITION** function. The special indicator `*` indicates all columns not passed to the **TRANSITION** function. If this indicator is not present in the list of keys then any unmatched columns are discarded. 

**TASK**

Optional. A **TASK** defines a complete end-to-end **INPUT**/**MAP**/**REDUCE** stage within a Greenplum MapReduce job pipeline. It is similar to **EXECUTE** except it is not immediately executed. A task object can be called as **INPUT** to further processing stages.

**NAME**

Required. The name of this task. Names must be unique with regards to the names of other objects in this MapReduce job (such as map function, reduce function, input and
output names). Also, names cannot conflict with existing objects in the database (such as tables, functions or views).

**SOURCE**

The name of an *INPUT* or another *TASK*.

**MAP**

Optional. The name of a *MAP* function. If not specified, defaults to *IDENTITY*.

**REDUCE**

Optional. The name of a *REDUCE* function. If not specified, defaults to *IDENTITY*.

**EXECUTE**

Required. *EXECUTE* defines the final *INPUT/MAP/REDUCE* stage within a Greenplum MapReduce job pipeline.

**RUN**

**SOURCE**

Required. The name of an *INPUT* or *TASK*.

**TARGET**

Optional. The name of an *OUTPUT*. The default output is *STDOUT*.

**MAP**

Optional. The name of a *MAP* function. If not specified, defaults to *IDENTITY*.

**REDUCE**

Optional. The name of a *REDUCE* function. Defaults to *IDENTITY*.

---

**Example Greenplum MapReduce Document**

```yaml
# This example MapReduce job processes documents and looks for keywords in
# them.
# It takes two database tables as input:
# - documents (doc_id integer, url text, data text)
# - keywords (keyword_id integer, keyword text)
# The documents data is searched for occurrences of keywords and returns
# results of
# url, data and keyword (a keyword can be multiple words, such as "high
# performance # computing")
YAML 1.1
---

VERSION: 1.0.0.1

# Connect to Greenplum Database using this database and role
DATABASE: webdata
USER: jsmith

# Begin definition section
DEFINE:

# Declare the input, which selects all columns and rows from the
# 'documents' and 'keywords' tables.
- INPUT:
  NAME: doc
  TABLE: documents
- INPUT:
  NAME: kw
  TABLE: keywords

# Define the map functions to extract terms from documents and keyword
# This example simply splits on white space, but it would be possible
# to make use of a python library like nltk (the natural language toolkit)
# to perform more complex tokenization and word stemming.
- MAP:
  NAME:doc_map
  LANGUAGE:python
  FUNCTION: |
  i = 0 # the index of a word within the document
terms = {}# a hash of terms and their indexes within the document

# Lower-case and split the text string on space
for term in data.lower().split():
i = i + 1# increment i (the index)

    # Check for the term in the terms list:
    # If stem word already exists, append the i value to the array
    entry # corresponding to the term. This counts multiple occurrences of the
    word.
    # If stem word does not exist, add it to the dictionary with
    position i.
    # For example:
    # data: "a computer is a machine that manipulates data"
    # "a" [1, 4]
    # "computer" [2]
    # "machine" [3]
    # ...
    if term in terms:
        terms[term] += ','+str(i)
    else:
        terms[term] = str(i)

# Return multiple lines for each document. Each line consists of
# the doc_id, a term and the positions in the data where the term appeared.
# For example:
#   (doc_id => 100, term => "a", [1,4]
#   (doc_id => 100, term => "computer", [2]
#   ...
for term in terms:
yield((doc_id, term, terms[term]))

OPTIMIZE:STRICT IMMUTABLE
PARAMETERS:
- doc_id integer
  - data text

RETURNS:
- doc_id integer
  - term text
  - positions text

# The map function for keywords is almost identical to the one for
documents
# but it also counts of the number of terms in the keyword.
- MAP:
  NAME:kw_map

# A TASK is an object that defines an entire INPUT/MAP/REDUCE stage
# within a Greenplum MapReduce pipeline. It is like EXECUTION, but it is
# executed only when called as input to other processing stages.
# Identify a task called 'doc_prep' which takes in the 'doc' INPUT defined
# earlier
# and runs the 'doc_map' MAP function which returns doc_id, term,
# [term_position]
- TASK:
  NAME:doc_prep
  SOURCE:doc
  MAP:doc_map

# Identify a task called 'kw_prep' which takes in the 'kw' INPUT defined
# earlier
# and runs the kw_map MAP function which returns kw_id, term,
# [term_position]
- TASK:
  NAME:kw_prep
  SOURCE:kw
  MAP:kw_map

# One advantage of Greenplum MapReduce is that MapReduce tasks can be
# used as input to SQL operations and SQL can be used to process a MapReduce
task.
# This INPUT defines a SQL query that joins the output of the 'doc_prep'
# TASK to that of the 'kw_prep' TASK. Matching terms are output to the
# 'candidate'
# list (any keyword that shares at least one term with the document).
- INPUT:
  NAME: term_join
  QUERY: |
    SELECT doc.doc_id, kw.keyword_id, kw.term, kw.nterms,
    doc.positions as doc_positions,
    kw.positions as kw_positions
    FROM doc_prep doc INNER JOIN kw_prep kw ON (doc.term = kw.term)

# In Greenplum MapReduce, a REDUCE function is comprised of one or more
functions.
# A REDUCE has an initial 'state' variable defined for each grouping key.
that is
# A TRANSITION function adjusts the state for every value in a key grouping.
# If present, an optional CONSOLIDATE function combines multiple
# 'state' variables. This allows the TRANSITION function to be executed
locally at
# the segment-level and only redistribute the accumulated 'state' over
# the network. If present, an optional FINALIZE function can be used to
perform
# final computation on a state and emit one or more rows of output from the
state.
#
# This REDUCE function is called 'term_reducer' with a TRANSITION function
called 'term_transition' and a FINALIZE function called 'term_finalizer'
- REDUCE:
  NAME: term_reducer
  TRANSITION: term_transition
  FINALIZE: term_finalizer

- TRANSITION:
  NAME: term_transition
  LANGUAGE: python
  PARAMETERS:
  - state text
  - term text
  - nterms integer
  - doc_positions text
  - kw_positions text
  FUNCTION: |

  # 'state' has an initial value of '' and is a colon delimited set
  # of keyword positions. keyword positions are comma delimited sets
  # of integers. For example, '1,3,2:4:'
  # If there is an existing state, split it into the set of keyword
  # positions
  # otherwise construct a set of 'nterms' keyword positions - all empty
  if state:
    kw_split = state.split(':')
  else:
    kw_split = []
    for i in range(0, nterms):
      kw_split.append('')

  # 'kw_positions' is a comma delimited field of integers indicating
  # position a single term occurs within a given keyword.
  # Splitting based on ',' converts the string into a python list.
  # add doc_positions for the current term
  for kw_p in kw_positions.split(', '):
    kw_split[int(kw_p) - 1] = doc_positions

  # This section takes each element in the 'kw_split' array and
  # strings them together placing a ':' in between each element from the
  # array.
  # For example: for the keyword "computer software computer hardware",
  # the 'kw_split' array matched up to the document data of
  # "in the business of computer software software engineers"
  # would look like: ['5', '6,7', '5', '']
  # and the outstate would look like: 5:6,7:5:
  outstate = kw_split[0]
  for s in kw_split[1:]:
    outstate = outstate + ':' + s
  return outstate

- FINALIZE:
  NAME: term_finalizer
  LANGUAGE: python
  RETURNS:
  - count integer
  MODE: MULTI
  FUNCTION: |
  if not state:
    return 0
  kw_split = state.split(':')

  # This function does the following:
# 1) Splits 'kw_split' on ':'
#   for example, 1,5,7:2,8 creates '1,5,7' and '2,8'
# 2) For each group of positions in 'kw_split', splits the set on ','
#   to create ['1','5','7'] from Set 0: 1,5,7 and
#   eventually ['2', '8'] from Set 1: 2,8
# 3) Checks for empty strings
# 4) Adjusts the split sets by subtracting the position of the set
#    in the 'kw_split' array
#   ['1','5','7'] - 0 from each element = ['1','5','7']
#   ['2', '8'] - 1 from each element = ['1', '7']
# 5) Resulting arrays after subtracting the offset in step 4 are
#    intersected and their overlapping values kept:
#   ['1','5','7'].intersect['1', '7'] = [1,7]
# 6) Determines the length of the intersection, which is the number
#    of
#    times that an entire keyword (with all its pieces) matches in the
#    document data.

Flow Diagram for MapReduce Example

The following diagram shows the job flow of the MapReduce job defined in the example:
**TASK: doc_prep**

**INPUT:** doc

**TABLE:** documents

**EXAMPLE ROW:**
<doc_id=100, data="A mapreduce tutorial for keyword matching in Greenplum mapreduce">

**MAP FUNCTION: doc_map**

**EXAMPLE:**
- <doc_id=100, term="A", positions=[1]>
- <doc_id=100, term="mapreduce", positions=[2,9]>

**RETURN:** doc_id int
term text
positions [text]

**TASK: kw_prep**

**INPUT:** kw

**TABLE:** keywords

**EXAMPLE ROW:**
<keyword_id=1, keyword="mapreduce tutorial"/>

**MAP FUNCTION: kw_map**

**EXAMPLE:**
- <keyword_id=1, term="mapreduce", positions=[1]>
- <keyword_id=1, term="tutorial", positions=[2]>

**RETURN:** keyword_id int
nterms int
term text
positions [text]

**TASK: term_match**

**INPUT:** term_join

**QUERY:**
```
SELECT doc.doc_id, kw.keyword_id, kw.term, kw.nterms, doc.positions as doc_positions, kw.positions as kw_positions
FROM doc_prep doc INNER JOIN kw_prep kw ON (doc.term = kw.term)
```

**EXAMPLE:**
- <doc_id=100, keyword_id=1, term="mapreduce", nterms=2, doc_positions="2,9", kw_positions="1"/>
- <doc_id=100, keyword_id=1, term="tutorial", nterms=2, doc_positions="3", kw_positions="2"/>

**REDUCE FUNCTION: term_reducer**

**KEYS:** [doc_id, keyword_id]

**TRANSITION FUNCTION: term_transition**

**RETURN:** state text

**EXAMPLE:** 
- <state="2,9:3"/>

**EXECUTE:**

**FINALIZE FUNCTION: term_finalizer**

**RETURN:** count integer

**EXAMPLE:**
- <count=1>

**INPUT:** final_output

**QUERY:**
```
SELECT doc.*, kw.*, tm.count FROM documents doc, keywords kw, term_match tm
WHERE doc.doc_id = tm.doc_id AND kw.keyword_id = tm.keyword_id AND tm.count > 0
```

**EXAMPLE:**

Greenplum Database PL/pgSQL Procedural Language

This section contains an overview of the Greenplum Database PL/pgSQL language.

- About Greenplum Database PL/pgSQL
- PL/pgSQL Plan Caching
- PL/pgSQL Examples
- References

About Greenplum Database PL/pgSQL

Greenplum Database PL/pgSQL is a loadable procedural language that is installed and registered by default with Greenplum Database. You can create user-defined functions using SQL statements, functions, and operators.

With PL/pgSQL you can group a block of computation and a series of SQL queries inside the database server, thus having the power of a procedural language and the ease of use of SQL. Also, with PL/pgSQL you can use all the data types, operators and functions of Greenplum Database SQL.

The PL/pgSQL language is a subset of Oracle PL/SQL. Greenplum Database PL/pgSQL is based on Postgres PL/pgSQL. The Postgres PL/pgSQL documentation is at https://www.postgresql.org/docs/8.3/static/plpgsql.html

When using PL/pgSQL functions, function attributes affect how Greenplum Database creates query plans. You can specify the attribute IMMUTABLE, STABLE, or VOLATILE as part of the LANGUAGE clause to classify the type of function. For information about the creating functions and function attributes, see the CREATE FUNCTION command in the Greenplum Database Reference Guide.

You can run PL/SQL code blocks as anonymous code blocks. See the DO command in the Greenplum Database Reference Guide.

Greenplum Database SQL Limitations

When using Greenplum Database PL/pgSQL, limitations include

- Triggers are not supported
- Cursors are forward moving only (not scrollable)
- Updatable cursors (UPDATE...WHERE CURRENT OF and DELETE...WHERE CURRENT OF) are not supported.

For information about Greenplum Database SQL conformance, see Summary of Greenplum Features in the Greenplum Database Reference Guide.

The PL/pgSQL Language

PL/pgSQL is a block-structured language. The complete text of a function definition must be a block. A block is defined as:

```sql
[ label ]
[ DECLARE declarations ]
BEGIN
  statements
END [ label ];
```
Each declaration and each statement within a block is terminated by a semicolon (;). A block that appears within another block must have a semicolon after `END`, as shown in the previous block. The `END` that concludes a function body does not require a semicolon.

**Important:** Do not confuse the use of the `BEGIN` and `END` keywords for grouping statements in PL/pgSQL with the database commands for transaction control. The PL/pgSQL `BEGIN` and `END` keywords are only for grouping; they do not start or end a transaction. Functions are always executed within a transaction established by an outer query — they cannot start or commit that transaction, since there would be no context for them to execute in. However, a PL/pgSQL block that contains an `EXCEPTION` clause effectively forms a subtransaction that can be rolled back without affecting the outer transaction. For more about the `EXCEPTION` clause, see the post the Postgres documentation on error trapping at https://www.postgresql.org/docs/8.3/static/plpgsql-control-structures.html#PLPGSQL-ERROR-TRAPPING.

All key words and identifiers can be written in mixed upper and lower case. Identifiers are implicitly converted to lowercase unless enclosed in double-quotes (" ).

You can add comments in PL/pgSQL in the following ways:

- A double dash (--) starts a comment that extends to the end of the line.
- A /* starts a block comment that extends to the next occurrence of */.

Block comments cannot be nested, but double dash comments can be enclosed into a block comment and a double dash can hide the block comment delimiters /* and */.

Any statement in the statement section of a block can be a subblock. Subblocks can be used for logical grouping or to localize variables to a small group of statements.

The variables declared in the declarations section preceding a block are initialized to their default values every time the block is entered, not only once per function call. For example declares the variable `quantity` several times:

```sql
CREATE FUNCTION testfunc() RETURNS integer AS $$
DECLARE
    quantity integer := 30;
BEGIN
    RAISE NOTICE 'Quantity here is %', quantity;
    -- Quantity here is 30
    quantity := 50;
    --
    -- Create a subblock
    --
    DECLARE
        quantity integer := 80;
    BEGIN
        RAISE NOTICE 'Quantity here is %', quantity;
        -- Quantity here is 80
        END;
    RAISE NOTICE 'Quantity here is %', quantity;
    -- Quantity here is 50
    RETURN quantity;
END;
$$ LANGUAGE plpgsql;
```

### Executing SQL Commands

You can execute SQL commands with PL/pgSQL statements such as `EXECUTE`, `PERFORM`, and `SELECT ... INTO`. For information about the PL/pgSQL statements, see https://www.postgresql.org/docs/8.3/static/plpgsql-statements.html.

**Note:** The PL/pgSQL statement `SELECT INTO` is not supported in the `EXECUTE` statement.
**PL/pgSQL Plan Caching**

A PL/pgSQL function's volatility classification has implications on how Greenplum Database caches plans that reference the function. Refer to Function Volatility and Plan Caching in the Greenplum Database Administrator Guide for information on plan caching considerations for Greenplum Database function volatility categories.

When a PL/pgSQL function executes for the first time in a database session, the PL/pgSQL interpreter parses the function's SQL expressions and commands. The interpreter creates a prepared execution plan as each expression and SQL command is first executed in the function. The PL/pgSQL interpreter reuses the execution plan for a specific expression and SQL command for the life of the database connection. While this reuse substantially reduces the total amount of time required to parse and generate plans, errors in a specific expression or command cannot be detected until run time when that part of the function is executed.

Greenplum Database will automatically re-plan a saved query plan if there is any schema change to any relation used in the query, or if any user-defined function used in the query is redefined. This makes the re-use of a prepared plan transparent in most cases.

The SQL commands that you use in a PL/pgSQL function must refer to the same tables and columns on every execution. You cannot use a parameter as the name of a table or a column in an SQL command.

PL/pgSQL caches a separate query plan for each combination of actual argument types in which you invoke a polymorphic function to ensure that data type differences do not cause unexpected failures.

Refer to the PostgreSQL Plan Caching documentation for a detailed discussion of plan caching considerations in the PL/pgSQL language.

**PL/pgSQL Examples**

The following are examples of PL/pgSQL user-defined functions.

**Example: Aliases for Function Parameters**

Parameters passed to functions are named with identifiers such as $1, $2. Optionally, aliases can be declared for $n parameter names for increased readability. Either the alias or the numeric identifier can then be used to refer to the parameter value.

There are two ways to create an alias. The preferred way is to give a name to the parameter in the CREATE FUNCTION command, for example:

```sql
CREATE FUNCTION sales_tax(subtotal real) RETURNS real AS $$
BEGIN
    RETURN subtotal * 0.06;
END;
$$ LANGUAGE plpgsql;
```

You can also explicitly declare an alias, using the declaration syntax:

```sql
name ALIAS FOR $n;
```

This example, creates the same function with the DECLARE syntax.

```sql
CREATE FUNCTION sales_tax(real) RETURNS real AS $$
DECLARE
    subtotal ALIAS FOR $1;
BEGIN
    RETURN subtotal * 0.06;
END;
$$
```
Example: Using the Data Type of a Table Column

When declaring a variable, you can use %TYPE to specify the data type of a variable or table column. This is the syntax for declaring a variable with the data type of a table column:

```
name table.column_name%TYPE;
```

You can use this to declare variables that will hold database values. For example, if you have a column named `user_id` in your `users` table. To declare the variable `my_userid` with the same data type as the `users.user_id` column:

```
my_userid users.user_id%TYPE;
```

%TYPE is particularly valuable in polymorphic functions, since the data types needed for internal variables may change from one call to the next. Appropriate variables can be created by applying %TYPE to the function’s arguments or result placeholders.

Example: Composite Type Based on a Table Row

The following syntax declares a composite variable based on table row:

```
name table_name%ROWTYPE;
```

Such a row variable can hold a whole row of a SELECT or FOR query result, so long as that query column set matches the declared type of the variable. The individual fields of the row value are accessed using the usual dot notation, for example `rowvar.column`.

Parameters to a function can be composite types (complete table rows). In that case, the corresponding identifier $n will be a row variable, and fields can be selected from it, for example $1.user_id.

Only the user-defined columns of a table row are accessible in a row-type variable, not the OID or other system columns. The fields of the row type inherit the table’s field size or precision for data types such as `char(n)`.

The next example function uses a row variable composite type. Before creating the function, create the table that is used by the function with this command:

```
CREATE TABLE table1 (  
  f1 text,  
  f2 numeric,  
  f3 integer  
) distributed by (f1);
```

This INSERT command adds data to the table.

```
INSERT INTO table1 values  
  ('test1', 14.1, 3),  
  ('test2', 52.5, 2),  
  ('test3', 32.22, 6),  
  ('test4', 12.1, 4) ;
```

This function uses a variable and %ROWTYPE composite variable based on `table1`.

```
CREATE OR REPLACE FUNCTION t1_calc( name text) RETURNS integer  
AS $$  
DECLARE  
  t1_row  table1%ROWTYPE;
$$
```
calc_int table1.f3%TYPE;
BEGIN
    SELECT * INTO t1_row FROM table1 WHERE table1.f1 = $1 ;
calc_int = (t1_row.f2 * t1_row.f3)::integer ;
    RETURN calc_int ;
END;
$$ LANGUAGE plpgsql VOLATILE;

**Note:** The previous function is classified as a **VOLATILE** function because function values could change within a single table scan.

The following **SELECT** command uses the function.

```
select t1_calc( 'test1' );
```

**Note:** The example PL/pgSQL function uses **SELECT** with the **INTO** clause. It is different from the SQL command **SELECT INTO**. If you want to create a table from a **SELECT** result inside a PL/pgSQL function, use the SQL command **CREATE TABLE AS**.

**Example: Using a Variable Number of Arguments**

You can declare a PL/pgSQL function to accept variable numbers of arguments, as long as all of the optional arguments are of the same data type. You must mark the last argument of the function as **VARIADIC** and declare the argument using an array type. You can refer to a function that includes **VARIADIC** arguments as a variadic function.

For example, this variadic function returns the minimum value of a variable array of numerics:

```
CREATE FUNCTION mleast (VARIADIC numeric[]) RETURNS numeric AS $$
DECLARE minval numeric;
BEGIN
    SELECT min($1[i]) FROM generate_subscripts( $1, 1) g(i) INTO minval;
    RETURN minval;
END;
$$ LANGUAGE plpgsql;
```

```
CREATE FUNCTION
SELECT mleast(10, -1, 5, 4.4);
mleast
--------
-1
(1 row)
```

Effectively, all of the actual arguments at or beyond the **VARIADIC** position are gathered up into a one-dimensional array.

You can pass an already-constructed array into a variadic function. This is particularly useful when you want to pass arrays between variadic functions. Specify **VARIADIC** in the function call as follows:

```
SELECT mleast(VARIADIC ARRAY[10, -1, 5, 4.4]);
```

This prevents PL/pgSQL from expanding the function's variadic parameter into its element type.

**Example: Using Default Argument Values**

You can declare PL/pgSQL functions with default values for some or all input arguments. The default values are inserted whenever the function is called with fewer than the declared number of arguments. Because arguments can only be omitted from the end of the actual argument list, you must provide default values for all arguments after an argument defined with a default value.
For example:

```sql
CREATE FUNCTION use_default_args(a int, b int DEFAULT 2, c int DEFAULT 3)
RETURNS int AS $$
DECLARE
  sum int;
BEGIN
  sum := $1 + $2 + $3;
  RETURN sum;
END;
$$ LANGUAGE plpgsql;

SELECT use_default_args(10, 20, 30);
use_default_args
------------------
   60
(1 row)

SELECT use_default_args(10, 20);
use_default_args
------------------
   33
(1 row)

SELECT use_default_args(10);
use_default_args
------------------
   15
(1 row)
```

You can also use the = sign in place of the keyword DEFAULT.

**Example: Using Polymorphic Data Types**

PL/pgSQL supports the polymorphic `anyelement`, `anyarray`, `anyenum`, and `anynonarray` types. Using these types, you can create a single PL/pgSQL function that operates on multiple data types. Refer to Greenplum Database Data Types for additional information on polymorphic type support in Greenplum Database.

A special parameter named $0 is created when the return type of a PL/pgSQL function is declared as a polymorphic type. The data type of $0 identifies the return type of the function as deduced from the actual input types.

In this example, you create a polymorphic function that returns the sum of two values:

```sql
CREATE FUNCTION add_two_values(v1 anyelement,v2 anyelement)
RETURNS anyelement AS $$
DECLARE
  sum ALIAS FOR $0;
BEGIN
  sum := v1 + v2;
  RETURN sum;
END;
$$ LANGUAGE plpgsql;

Execute add_two_values() providing integer input values:

SELECT add_two_values(1, 2);
   add_two_values
------------------
         3
(1 row)
```
The return type of `add_two_values()` is integer, the type of the input arguments. Now execute `add_two_values()` providing float input values:

```
SELECT add_two_values (1.1, 2.2);
  add_two_values
----------------
    3.3
(1 row)
```

The return type of `add_two_values()` in this case is float.

You can also specify `VARIADIC` arguments in polymorphic functions.

**Example: Anonymous Block**

This example executes the function in the previous example as an anonymous block with the `DO` command. In the example, the anonymous block retrieves the input value from a temporary table.

```
CREATE TEMP TABLE list AS VALUES ('test1') DISTRIBUTED RANDOMLY;

DO $$
DECLARE
  t1_row   table1%ROWTYPE;
  calc_int table1.f3%TYPE;
BEGIN
  SELECT * INTO t1_row FROM table1, list WHERE table1.f1 = list.column1;
  calc_int = (t1_row.f2 * t1_row.f3)::integer;
  RAISE NOTICE 'calculated value is %', calc_int;
END $$ LANGUAGE plpgsql;
```

**References**

For a summary of built-in Greenplum Database functions, see Summary of Built-in Functions in the *Greenplum Database Reference Guide*. For information about using Greenplum Database functions see “Querying Data” in the *Greenplum Database Administrator Guide*.

Greenplum PostGIS Extension

This chapter contains the following information:

- About PostGIS
- Greenplum PostGIS Extension
- Enabling and Removing PostGIS Support
- Usage
- PostGIS Extension Support and Limitations
- PostGIS Support Scripts

About PostGIS

PostGIS is a spatial database extension for PostgreSQL that allows GIS (Geographic Information Systems) objects to be stored in the database. The Greenplum Database PostGIS extension includes support for GiST-based R-Tree spatial indexes and functions for analysis and processing of GIS objects.

The Greenplum Database PostGIS extension supports the optional PostGIS raster data type and most PostGIS Raster functions. With the PostGIS Raster objects, PostGIS geometry data type offers a single set of overlay SQL functions (such as ST_Intersects) operating seamlessly on vector and raster geospatial data. PostGIS Raster uses the GDAL (Geospatial Data Abstraction Library) translator library for raster geospatial data formats that presents a single raster abstract data model to a calling application.

For information about Greenplum Database PostGIS extension support, see PostGIS Extension Support and Limitations.

For information about PostGIS, see http://postgis.refractions.net/

For information about GDAL, see http://www.gdal.org.

Greenplum PostGIS Extension

The Greenplum Database PostGIS extension package is available from Pivotal Network. You can install the package using the Greenplum Package Manager (gppkg). For details, see gppkg in the Greenplum Database Utility Guide.

Greenplum Database supports the PostGIS extension with these component versions.

- PostGIS 2.1.5
- Proj 4.8.0
- Geos 3.4.2
- GDAL 1.11.1
- Json 0.12
- Expat 2.1.0

For the information about supported extension packages and software versions see the Greenplum Database Release Notes.

Major enhancements and changes in PostGIS 2.1.5 from 2.0.3 include new PostGIS Raster functions. For a list of new and enhanced functions in PostGIS 2.1, see the PostGIS documentation PostGIS Functions new or enhanced in 2.1.

For a list of breaking changes in PostGIS 2.1, see PostGIS functions breaking changes in 2.1.

For a comprehensive list of PostGIS changes in PostGIS 2.1.5 and earlier, see PostGIS 2.1 Appendix A Release 2.1.5.
Greenplum Database PostGIS Limitations

The Greenplum Database PostGIS extension does not support the following features:

- Topology
- A small number of user defined functions and aggregates
- PostGIS long transaction support
- Geometry and geography type modifier

For information about Greenplum Database PostGIS support, see PostGIS Extension Support and Limitations.

Enabling and Removing PostGIS Support

The Greenplum Database PostGIS extension contains the `postgis_manager.sh` script that installs or removes both the PostGIS and PostGIS Raster features in a database. After the PostGIS extension package is installed, the script is in `$GPHOME/share/postgresql/contrib/postgis-2.1/`. The `postgis_manager.sh` script runs SQL scripts that install or remove PostGIS and PostGIS Raster from a database.

For information about the PostGIS and PostGIS Raster SQL scripts, and required PostGIS Raster environment variables, see PostGIS Support Scripts.

Enabling PostGIS Support

Run the `postgis_manager.sh` script specifying the database and with the `install` option to install PostGIS and PostGIS Raster. This example installs PostGIS and PostGIS Raster objects in the database `mydatabase`.

```
postgis_manager.sh mydatabase install
```

The script runs all the PostGIS SQL scripts that enable PostGIS in a database: `install/postgis.sql`, `install/rtpostgis.sql`, `install/spatial_ref_sys.sql`, `install/postgis_comments.sql`, and `install/raster_comments.sql`.

The `postGIS` package installation adds these lines to the `greenplum_path.sh` file for PostGIS Raster support.

```
export GDAL_DATA=$GPHOME/share/gdal
export POSTGIS_ENABLE_OUTDB_RASTERS=0
export POSTGIS_GDAL_ENABLED_DRIVERS=DISABLE_ALL
```

Enabling GDAL Raster Drivers

PostGIS uses GDAL raster drivers when processing raster data with commands such as `ST_AsJPEG()`. As the default, PostGIS disables all raster drivers. You enable raster drivers by setting the value of the `POSTGIS_GDAL_ENABLED_DRIVERS` environment variable in the `greenplum_path.sh` file on all Greenplum Database hosts.

To see the list of supported GDAL raster drivers for a Greenplum Database system, run the `raster2pgsql` utility with the `-G` option on the Greenplum Database master.

```
raster2pgsql -G
```

The command lists the driver long format name. The GDAL Raster Formats table at `http://www.gdal.org/formats_list.html` lists the long format names and the corresponding codes that you specify as the value of
the environment variable. For example, the code for the long name Portable Network Graphics is PNG. This example export line enables four GDAL raster drivers.

```bash
export POSTGIS_GDAL_ENABLED_DRIVERS="GTiff PNG JPEG GIF"
```

The `gpstop -r` command restarts the Greenplum Database system to use the updated settings in the `greenplum_path.sh` file.

After you have updated the `greenplum_path.sh` file on all hosts, and have restarted the Greenplum Database system, you can display the enabled raster drivers with the `ST_GDALDrivers()` function. This `SELECT` command lists the enabled raster drivers.

```sql
SELECT short_name, long_name FROM ST_GDALDrivers();
```

### Removing PostGIS Support

Run the `postgis_manager.sh` script specifying the database and with the `uninstall` option to remove PostGIS and PostGIS Raster. This example removes PostGIS and PostGIS Raster support from the database `mydatabase`.

```bash
postgis_manager.sh mydatabase uninstall
```

The script runs both the PostGIS SQL scripts that remove PostGIS and PostGIS Raster from a database: `uninstall_rtpostgis.sql` and `uninstall_postgis.sql`.

The `postgis_manager.sh` script does not remove these PostGIS Raster environment variables the `greenplum_path.sh` file: `GDAL_DATA`, `POSTGIS_ENABLE_OUTDB_RASTERS`, `POSTGIS_GDAL_ENABLED_DRIVERS`. The environment variables are removed when you uninstall the PostGIS extension package with the `gppkg` utility.

### Usage

The following example SQL statements create non-OpenGIS tables and geometries.

```sql
CREATE TABLE geom_test ( gid int4, geom geometry, 
  name varchar(25) );
INSERT INTO geom_test ( gid, geom, name ) 
  VALUES ( 1, 'POLYGON((0 0 0,0 5 0,5 5 0,5 0 0,0 0 0))', '3D Square');
INSERT INTO geom_test ( gid, geom, name )
  VALUES ( 2, 'LINESTRING(1 1 1,5 5 5,7 7 5)', '3D Line' );
INSERT INTO geom_test ( gid, geom, name )
  VALUES ( 3, 'MULTIPOINT(3 4,8 9)', '2D Aggregate Point' );
SELECT * from geom_test WHERE geom &&
  Box3D(ST_GeomFromEWKT('LINESTRING(2 2 0, 3 3 0)'));
```

The following example SQL statements create a table and add a geometry column to the table with a SRID integer value that references an entry in the `SPATIAL_REF_SYS` table. The `INSERT` statements add two geopoints to the table.

```sql
CREATE TABLE geotest (id INT4, name VARCHAR(32) );
SELECT AddGeometryColumn('geotest','geopoint', 4326,'POINT',2);
INSERT INTO geotest (id, name, geopoint) 
  VALUES (1, 'Olympia', ST_GeometryFromText('POINT(-122.90 46.97)', 4326));
INSERT INTO geotest (id, name, geopoint) 
  VALUES (2, 'Renton', ST_GeometryFromText('POINT(-122.22 47.50)', 4326));
SELECT name,ST_AsText(geopoint) FROM geotest;
```
Spatial Indexes

PostgreSQL provides support for GiST spatial indexing. The GiST scheme offers indexing even on large objects. It uses a system of lossy indexing in which smaller objects act as proxies for larger ones in the index. In the PostGIS indexing system, all objects use their bounding boxes as proxies in the index.

Building a Spatial Index

You can build a GiST index as follows:

```
CREATE INDEX indexname
    ON tablename
    USING GIST ( geometryfield );
```

PostGIS Extension Support and Limitations

This section describes Greenplum PostGIS extension feature support and limitations.

- Supported PostGIS Data Types
- Supported PostGIS Index
- Supported PostGIS Raster Data Types
- PostGIS Extension Limitations

The Greenplum Database PostGIS extension does not support the following features:

- Topology
- Some Raster Functions

Supported PostGIS Data Types

Greenplum Database PostGIS extension supports these PostGIS data types:

- box2d
- box3d
- geometry
- geography

For a list of PostGIS data types, operators, and functions, see the PostGIS reference documentation.

Supported PostGIS Raster Data Types

Greenplum Database PostGIS supports these PostGIS Raster data types.

- geomval
- addbandarg
- rastbandarg
- raster
- reclassarg
- summarystats
- unionarg

For information about PostGIS Raster data Management, queries, and applications see http://postgis.net/docs/manual-2.1/using_raster_dataman.html

For a list of PostGIS Raster data types, operators, and functions, see the PostGIS Raster reference documentation.
**Supported PostGIS Index**

Greenplum Database PostGIS extension supports the GiST (Generalized Search Tree) index.

**PostGIS Extension Limitations**

This section lists the Greenplum Database PostGIS extension limitations for user-defined functions (UDFs), data types, and aggregates.

- Data types and functions related to PostGIS topology functionality, such as TopoGeometry, are not supported by Greenplum Database.
- Functions that perform ANALYZE operations for user-defined data types are not supported. For example, the ST_Estimated_Extent function is not supported. The function requires table column statistics for user defined data types that are not available with Greenplum Database.
- These PostGIS aggregates are not supported by Greenplum Database:
  - ST_MemCollect
  - ST_MakeLine

On a Greenplum Database with multiple segments, the aggregate might return different answers if it is called several times repeatedly.

- Greenplum Database does not support PostGIS long transactions.
  
  PostGIS relies on triggers and the PostGIS table `public.authorization_table` for long transaction support. When PostGIS attempts to acquire locks for long transactions, Greenplum Database reports errors citing that the function cannot access the relation, `authorization_table`.

- Greenplum Database does not support type modifiers for user defined types.

  The workaround is to use the AddGeometryColumn function for PostGIS geometry. For example, a table with PostGIS geometry cannot be created with the following SQL command:

  ```sql
  CREATE TABLE geometries(id INTEGER, geom geometry(LINestring));
  ```

  Use the AddGeometryColumn function to add PostGIS geometry to a table. For example, these following SQL statements create a table and add PostGIS geometry to the table:

  ```sql
  CREATE TABLE geometries(id INTEGER);
  SELECT AddGeometryColumn('public', 'geometries', 'geom', 0, 'LINestring', 2);
  ```

**PostGIS Support Scripts**

After installing the PostGIS extension package, you enable PostGIS support for each database that requires its use. To enable or remove PostGIS support in your database, you can run SQL scripts that are supplied with the PostGIS package in `$GPHOME/share/postgresql/contrib/postgis-2.1/`.

- **Scripts that Enable PostGIS and PostGIS Raster Support**
- **Scripts that Remove PostGIS and PostGIS Raster Support**

Instead of running the scripts individually, you can use the `postgis_manager.sh` script to run SQL scripts that enable or remove PostGIS support. See Enabling and Removing PostGIS Support.

You can run the PostGIS SQL scripts individually to enable or remove PostGIS support. For example, these commands run the SQL scripts `postgis.sql`, `rtpostgis.sql`, and `spatial_ref_sys.sql` in the database `mydatabase`.

```bash
psql -d mydatabase -f
$GPHOME/share/postgresql/contrib/postgis-2.1/install/postgis.sql
psql -d mydatabase -f
```
After running the scripts, the database is enabled with both PostGIS and PostGIS Raster.

**Scripts that Enable PostGIS and PostGIS Raster Support**

These scripts enable PostGIS, and the optional PostGIS Raster in a database.

- `install/postgis.sql` - Load the PostGIS objects and function definitions.
- `install/rtpostgis.sql` - Load the PostGIS raster object and function definitions.

**Note:** If you are installing PostGIS Raster, PostGIS objects must be installed before PostGIS Raster. PostGIS Raster depends on PostGIS objects. Greenplum Database returns an error if `rtpostgis.sql` is run before `postgis.sql`.

These SQL scripts add data and comments to a PostGIS enabled database.

- `install/spatial_ref_sys.sql` - Populate the `spatial_ref_sys` table with a complete set of EPSG coordinate system definition identifiers. With the definition identifiers you can perform `ST_Transform()` operations on geometries.

**Note:** If you have overridden standard entries and want to use those overrides, do not load the `spatial_ref_sys.sql` file when creating the new database.

- `install/postgis_comments.sql` - Add comments to the PostGIS functions.
- `install/raster_comments.sql` - Add comments to the PostGIS Raster functions.

You can view comments with the `psql` meta-command `\dd function_name` or from any tool that can show Greenplum Database function comments.

**PostGIS Raster Environment Variables**

The postGIS package installation adds these lines to the `greenplum_path.sh` file for PostGIS Raster support.

```bash
export GDAL_DATA=$GPHOME/share/gdal
export POSTGIS_ENABLE_OUTDB_RASTERS=0
export POSTGIS_GDAL_ENABLED_DRIVERS=DISABLE_ALL
```

**GDAL_DATA** specifies the location of GDAL utilities and support files used by the GDAL library. For example, the directory contains EPSG support files such as `gcs.csv` and `pcs.csv` (so called dictionaries, mostly in CSV format). The GDAL library requires the support files to properly evaluate EPSG codes.

**POSTGIS_GDAL_ENABLED_DRIVERS** sets the enabled GDAL drivers in the PostGIS environment.

**POSTGIS_ENABLE_OUTDB_RASTERS** is a boolean configuration option to enable access to out of database raster bands.

**Scripts that Remove PostGIS and PostGIS Raster Support**

To remove PostGIS support from a database, run SQL scripts that are supplied with the PostGIS extension package in `$GPHOME/share/postgresql/contrib/postgis-2.1/`.

**Note:** If you installed PostGIS Raster, you must uninstall PostGIS Raster before you uninstall the PostGIS objects. PostGIS Raster depends on PostGIS objects. Greenplum Database returns an error if PostGIS objects are removed before PostGIS Raster.

These scripts remove PostGIS and PostGIS Raster objects from a database.

- `uninstall/uninstall_rtpostgis.sql` - Removes the PostGIS Raster object and function definitions.
• `uninstall/uninstall_postgis.sql` - Removes the PostGIS objects and function definitions. After PostGIS support has been removed from all databases in the Greenplum Database system, you can remove the PostGIS extension package. For example this `gppkg` command removes the PostGIS extension package.

```
gppkg -r postgis-2.1.5+pivotal.2
```

Restart Greenplum Database after removing the package.

```
gpstop -r
```

Ensure that these lines for PostGIS Raster support are removed from the `greenplum_path.sh` file.

```
export GDAL_DATA=$GPHOME/share/gdal
export POSTGIS_ENABLE_OUTDB_RASTERS=0
export POSTGIS_GDAL_ENABLED_DRIVERS=DISABLE_ALL
```
Greenplum PL/R Language Extension

This chapter contains the following information:

- About Greenplum Database PL/R
- Installing PL/R
- Uninstalling PL/R
- Enabling PL/R Language Support
- Examples
- Downloading and Installing R Packages
- Displaying R Library Information
- References

About Greenplum Database PL/R

PL/R is a procedural language. With the Greenplum Database PL/R extension you can write database functions in the R programming language and use R packages that contain R functions and data sets.

For information about supported PL/R versions, see the Greenplum Database Release Notes.

Installing PL/R

The PL/R extension is available as a package. Download the package from Pivotal Network and install it with the Greenplum Package Manager (gppkg).

The gppkg utility installs Greenplum Database extensions, along with any dependencies, on all hosts across a cluster. It also automatically installs extensions on new hosts in the case of system expansion and segment recovery.

For information about gppkg, see the Greenplum Database Utility Guide.

Installing the Extension Package

Before you install the PL/R extension, make sure that your Greenplum Database is running, you have sourced greenplum_path.sh, and that the $MASTER_DATA_DIRECTORY and $GPHOME variables are set.

1. Download the PL/R extension package from Pivotal Network.
2. Copy the PL/R package to the Greenplum Database master host.
3. Install the software extension package by running the gppkg command. This example installs the PL/R extension on a Linux system:
   
   ```bash
   $ gppkg -i plr-2.3.1-gp5-rhel6-x86_64.gppkg
   ```

4. Source the file $GPHOME/greenplum_path.sh.
5. Restart the database.
   
   ```bash
   $ gpstop -r
   ```

The extension and the R environment is installed in this directory:

$GPHOME/ext/R-3.3.3/

Note: The version of some shared libraries installed with the operating system might not be compatible with the Greenplum Database PL/R extension.
If a shared library is not compatible, edit the file $GPHOME/greenplum_path.sh in all Greenplum Database master and segment hosts and set environment variable `LD_LIBRARY_PATH` to specify the location that is installed with the PL/R extension.

```
export LD_LIBRARY_PATH=
    $GPHOME/ext/R-3.3.3/lib:$LD_LIBRARY_PATH
```

### Enabling PL/R Language Support

For each database that requires its use, register the PL/R language with the SQL command `CREATE EXTENSION`. Because PL/R is an untrusted language, only superusers can register PL/R with a database. For example, run this command as the `gpadmin` user to register the language with the database named `testdb`:

```
$ psql -d testdb -c 'CREATE EXTENSION plr;'  
```

PL/R is registered as an untrusted language.

### Uninstalling PL/R

- **Remove PL/R Support for a Database**
- **Uninstall the Extension Package**

When you remove PL/R language support from a database, the PL/R routines that you created in the database will no longer work.

#### Remove PL/R Support for a Database

For a database that no longer requires the PL/R language, remove support for PL/R with the SQL command `DROP EXTENSION`. Because PL/R is an untrusted language, only superusers can remove support for the PL/R language from a database. For example, run this command as the `gpadmin` user to remove support for PL/R from the database named `testdb`:

```
$ psql -d testdb -c 'DROP EXTENSION plr;'  
```

The default command fails if any existing objects (such as functions) depend on the language. Specify the `CASCADE` option to also drop all dependent objects, including functions that you created with PL/R.

#### Uninstall the Extension Package

If no databases have PL/R as a registered language, uninstall the Greenplum PL/R extension with the `gppkg` utility. This example uninstalls PL/R package version 2.3.1

```
$ gppkg -r plr-2.3.1
```

You can run the `gppkg` utility with the options `-q` `--all` to list the installed extensions and their versions. Restart the database.

```
$ gpstop -r
```

### Examples

The following are simple PL/R examples.
**Example 1: Using PL/R for single row operators**

This function generates an array of numbers with a normal distribution using the R function `rnorm()`.

```sql
CREATE OR REPLACE FUNCTION r_norm(n integer, mean float8, std_dev float8) RETURNS float8[] AS $$
x<-rnorm(n,mean,std_dev)
return(x)
$$ LANGUAGE 'plr';
```

The following CREATE TABLE command uses the `r_norm` function to populate the table. The `r_norm` function creates an array of 10 numbers.

```sql
CREATE TABLE test_norm_var
    AS SELECT id, r_norm(10,0,1) as x
    FROM (SELECT generate_series(1,30:: bigint) AS ID) foo
    DISTRIBUTED BY (id);
```

**Example 2: Returning PL/R data.frames in Tabular Form**

Assuming your PL/R function returns an R `data.frame` as its output, unless you want to use arrays of arrays, some work is required to see your `data.frame` from PL/R as a simple SQL table:

- Create a `TYPE` in a Greenplum database with the same dimensions as your R `data.frame`:

```sql
CREATE TYPE t1 AS ...;
```

- Use this `TYPE` when defining your PL/R function

```sql
... RETURNS SET OF t1 AS ...;
```

Sample SQL for this is given in the next example.

**Example 3: Hierarchical Regression using PL/R**

The SQL below defines a `TYPE` and runs hierarchical regression using PL/R:

```sql
--Create TYPE to store model results
DROP TYPE IF EXISTS wj_model_results CASCADE;
CREATE TYPE wj_model_results AS (   cs text, coefext float, ci_95_lower float, ci_95_upper float,   ci_90_lower, float, ci_90_upper float, ci_80_lower, float, ci_80_upper float);

--Create PL/R function to run model in R
DROP FUNCTION wj.plr.RE(response float [], cs text [])
RETURNS SETOF wj_model_results AS $$
library(arm)
y<- log(response)
cs<- cs
d_temp<- data.frame(y,cs)
m0 <- lmer (y ~ 1 + (1 | cs), data=d_temp)
cs_unique<- sort(unique(cs))
n_cs_unique<- length(cs_unique)
temp_m0<- data.frame(matrix0,n_cs_unique, 7))
for (i in 1:n_cs_unique)
{temp_m0[i,]<-
  c(exp(coef(m0)$cs[i,1]) + c(0,-1.96,1.96,-1.65,1.65
```r
-1.28,1.28)*se.ranef(m0)$cs[i])})
names(temp_m0)<- c("Coefest", "CI_95_Lower",
   "CI_95_Upper", "CI_90_Lower", "CI_90_Upper",
   "CI_80_Lower", "CI_80_Upper")
temp_m0_v2<- data.frames(cs_unique, temp_m0)
return(temp_m0_v2)
```

```
LANGUAGE 'plr';

--Run modeling plr function and store model results in a
table
DROP TABLE IF EXISTS wj_model_results_roi;
CREATE TABLE wj_model_results_roi AS SELECT *
FROM wj.plr_RE((SELECT wj.droi2_array),
(SELECT cs FROM wj.droi2_array));
```

## Downloading and Installing R Packages

R packages are modules that contain R functions and data sets. You can install R packages to extend R
and PL/R functionality in Greenplum Database.

Greenplum Database provides a collection of data science-related R libraries that can be used with the
Greenplum Database PL/R language. You can download these libraries in .gppkg format from Pivotal
Network. For information about the libraries, see R Data Science Library Package.

**Note:** If you expand Greenplum Database and add segment hosts, you must install the R
packages in the R installation of the new hosts.

1. For an R package, identify all dependent R packages and each package web URL. The information can
be found by selecting the given package from the following navigation page:

   [http://cran.r-project.org/web/packages/available_packages_by_name.html](http://cran.r-project.org/web/packages/available_packages_by_name.html)

   As an example, the page for the R package arm indicates that the package requires the following R
   libraries: Matrix, lattice, lme4, R2WinBUGS, coda, abind, foreign, and MASS.

   You can also try installing the package with `R CMD INSTALL` command to determine the dependent
   packages.

   For the R installation included with the Greenplum Database PL/R extension, the required R packages
   are installed with the PL/R extension. However, the Matrix package requires a newer version.

2. From the command line, use the `wget` utility to download the `tar.gz` files for the arm package to the
   Greenplum Database master host:

   ```
wget http://cran.r-project.org/src/contrib/Archive/arm/arm_1.5-03.tar.gz
   wget http://cran.r-project.org/src/contrib/Archive/Matrix/
   Matrix_0.9996875-1.tar.gz
   ```

3. Use the `gpscp` utility and the `hosts_all` file to copy the `tar.gz` files to the same directory on all
   nodes of the Greenplum Database cluster. The `hosts_all` file contains a list of all the Greenplum
   Database segment hosts. You might require root access to do this.

   ```
gpscp -f hosts_all Matrix_0.9996875-1.tar.gz =:/home/gpadmin
   gpscp -f /hosts_all arm_1.5-03.tar.gz =:/home/gpadmin
   ```

4. Use the `gpssh` utility in interactive mode to log into each Greenplum Database segment host (`gpssh -f all_hosts`). Install the packages from the command prompt using the `R CMD INSTALL` command.
Note that this may require root access. For example, this R install command installs the packages for the arm package.

```
$R_HOME/bin/R CMD INSTALL Matrix_0.9996875-1.tar.gz   arm_1.5-03.tar.gz
```

5. Ensure that the package is installed in the `$R_HOME/library` directory on all the segments (the `gpssh` can be use to install the package). For example, this `gpssh` command list the contents of the R library directory.

```
gpssh -s -f all_hosts "ls $R_HOME/library"
```

The `gpssh` option `-s` sources the `greenplum_path.sh` file before running commands on the remote hosts.

6. Test if the R package can be loaded.

This function performs a simple test to if an R package can be loaded:

```
CREATE OR REPLACE FUNCTION R_test_require(fname text)
RETURNS boolean AS
$BODY$
  return(require(fname,character.only=T))
$BODY$
LANGUAGE 'plr';
```

This SQL command checks if the R package arm can be loaded:

```
SELECT R_test_require('arm');
```

### Displaying R Library Information

You can use the R command line to display information about the installed libraries and functions on the Greenplum Database host. You can also add and remove libraries from the R installation. To start the R command line on the host, log into the host as the `gadmin` user and run the script R from the directory `$GPHOME/ext/R-3.3.3/bin`.

This R function lists the available R packages from the R command line:

```
> library()
```

Display the documentation for a particular R package

```
> library(help="package_name")
> help(package="package_name")
```

Display the help file for an R function:

```
> help("function_name")
> ?function_name
```

To see what packages are installed, use the R command `installed.packages()`. This will return a matrix with a row for each package that has been installed. Below, we look at the first 5 rows of this matrix.

```
> installed.packages()
```

Any package that does not appear in the installed packages matrix must be installed and loaded before its functions can be used.
An R package can be installed with `install.packages()`:

```r
> install.packages("package_name")
> install.packages("mypkg", dependencies = TRUE, type="source")
```

Load a package from the R command line.

```r
> library(" package_name ")
```

An R package can be removed with `remove.packages`

```r
> remove.packages("package_name")
```

You can use the R command `-e` option to run functions from the command line. For example, this command displays help on the R package MASS.

```bash
$ R -e 'help("MASS")'
```

**Aggregate Functions in R**

Greenplum Database PL/Python Language Extension

This section contains an overview of the Greenplum Database PL/Python Language.

- About Greenplum PL/Python
- Enabling and Removing PL/Python support
- Developing Functions with PL/Python
- Installing Python Modules
- Examples
- References

About Greenplum PL/Python

PL/Python is a loadable procedural language. With the Greenplum Database PL/Python extension, you can write a Greenplum Database user-defined functions in Python that take advantage of Python features and modules to quickly build robust database applications.

You can run PL/Python code blocks as anonymous code blocks. See the do command in the Greenplum Database Reference Guide.

The Greenplum Database PL/Python extension is installed by default with Greenplum Database. Greenplum Database installs a version of Python and PL/Python. This is location of the Python installation that Greenplum Database uses:

$GPHOME/ext/python/

Greenplum Database PL/Python Limitations

- Greenplum Database does not support PL/Python triggers.
- PL/Python is available only as a Greenplum Database untrusted language.
- Updatable cursors (UPDATE...WHERE CURRENT OF and DELETE...WHERE CURRENT OF) are not supported.

Enabling and Removing PL/Python support

The PL/Python language is installed with Greenplum Database. To create and run a PL/Python user-defined function (UDF) in a database, you must register the PL/Python language with the database.

Enabling PL/Python Support

For each database that requires its use, register the PL/Python language with the SQL command CREATE LANGUAGE or the Greenplum Database utility createlang. Because PL/Python is an untrusted language, only superusers can register PL/Python with a database. For example, running this command as the gpadmin system user registers PL/Python with the database named testdb:

$ createlang plpythonu -d testdb

PL/Python is registered as an untrusted language.

Removing PL/Python Support

For a database that no longer requires the PL/Python language, remove support for PL/Python with the SQL command DROP LANGUAGE or the Greenplum Database droplang utility. Because PL/Python is an untrusted language, only superusers can remove support for the PL/Python language from a database.
For example, running this command as the `gpadmin` system user removes support for PL/Python from the database named `testdb`:

```
$ droplang plpythonu -d testdb
```

When you remove support for PL/Python, the PL/Python user-defined functions that you created in the database will no longer work.

### Developing Functions with PL/Python

The body of a PL/Python user-defined function is a Python script. When the function is called, its arguments are passed as elements of the array `args[]`. Named arguments are also passed as ordinary variables to the Python script. The result is returned from the PL/Python function with `return` statement, or `yield` statement in case of a result-set statement.

PL/Python translates Python’s `None` into the SQL `null` value

### Data Type Mapping

The Greenplum to Python data type mapping follows.

<table>
<thead>
<tr>
<th>Greenplum Primitive Type</th>
<th>Python Data Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>boolean</td>
<td>bool</td>
</tr>
<tr>
<td>byte</td>
<td>bytes</td>
</tr>
<tr>
<td>smallint, bigint, oid</td>
<td>int</td>
</tr>
<tr>
<td>real, double</td>
<td>float</td>
</tr>
<tr>
<td>numeric</td>
<td>decimal</td>
</tr>
<tr>
<td>other primitive types</td>
<td>string</td>
</tr>
<tr>
<td>SQL null value</td>
<td>None</td>
</tr>
</tbody>
</table>

1 When the UDF return type is `boolean`, the Greenplum Database evaluates the return value for truth according to Python rules. That is, 0 and empty string are `false`, but notably 'f' is `true`.

Example:

```sql
CREATE OR REPLACE FUNCTION pybool_func(a int) RETURNS boolean AS $$
# container: plc_python3_shared
    if (a > 0):
        return True
    else:
        return False
$$ LANGUAGE plcontainer;

SELECT pybool_func(-1);
```

```
pybool_func
----------
f
(1 row)
```
Arrays and Lists

You pass SQL array values into PL/Python functions with a Python list. Similarly, PL/Python functions return SQL array values as a Python list. In the typical PL/Python usage pattern, you will specify an array with `[]`.

The following example creates a PL/Python function that returns an array of integers:

```sql
CREATE FUNCTION return_py_int_array()
    RETURNS int[]
AS $$
    return [1, 11, 21, 31]
$$ LANGUAGE plpythonu;

SELECT return_py_int_array();
```

```
return_py_int_array
---------------------
{1,11,21,31}
(1 row)
```

PL/Python treats multi-dimensional arrays as lists of lists. You pass a multi-dimensional array to a PL/Python function using nested Python lists. When a PL/Python function returns a multi-dimensional array, the inner lists at each level must all be of the same size.

The following example creates a PL/Python function that takes a multi-dimensional array of integers as input. The function displays the type of the provided argument, and returns the multi-dimensional array:

```sql
CREATE FUNCTION return_multidim_py_array(x int4[][])
    RETURNS int4[]
AS $$
    plpy.info(x, type(x))
    return x
$$ LANGUAGE plpythonu;

SELECT * FROM return_multidim_py_array(ARRAY[[1,2,3], [4,5,6]]);
```

```
INFO:  (Array: [(1, 2, 3), (4, 5, 6)], <type 'list'>)
CONTEXT:  PL/Python function "return_multidim_py_type"
return_multidim_py_array
--------------------------
{{1,2,3},{4,5,6}}
(1 row)
```

PL/Python also accepts other Python sequences, such as tuples, as function arguments for backwards compatibility with Greenplum versions where multi-dimensional arrays were not supported. In such cases, the Python sequences are always treated as one-dimensional arrays because they are ambiguous with composite types.

Composite Types

You pass composite-type arguments to a PL/Python function using Python mappings. The element names of the mapping are the attribute names of the composite types. If an attribute has the null value, its mapping value is None.

You can return a composite type result as a sequence type (tuple or list). You must specify a composite type as a tuple, rather than a list, when it is used in a multi-dimensional array. You cannot return an array of composite types as a list because it would be ambiguous to determine whether the list represents a composite type or another array dimension. In the typical usage pattern, you will specify composite type tuples with `()`.
In the following example, you create a composite type and a PL/Python function that returns an array of the composite type:

```
CREATE TYPE type_record AS (
    first text,
    second int4
);

CREATE FUNCTION composite_type_as_list()
    RETURNS type_record[]
AS $$
    return [([('first', 1), ('second', 1)], [('first', 2), ('second', 2)], [('first', 3), ('second', 3)])];
$$ LANGUAGE plpythonu;

SELECT * FROM composite_type_as_list();
```

Refer to the PostgreSQL Arrays, Lists documentation for additional information on PL/Python handling of arrays and composite types.

**Set-Returning Functions**

A Python function can return a set of scalar or composite types from any sequence type (for example: tuple, list, set).

In the following example, you create a composite type and a Python function that returns a `SETOF` of the composite type:

```
CREATE TYPE greeting AS (
    how text,
    who text
);

CREATE FUNCTION greet (how text)
    RETURNS SETOF greeting
AS $$
    # return tuple containing lists as composite types
    # all other combinations work also
    return ( ("how": how, "who": "World"), ("how": how, "who": "Greenplum") );
$$ LANGUAGE plpythonu;

select greet('hello');
```

**Executing and Preparing SQL Queries**

The PL/Python `plpy` module provides two Python functions to execute an SQL query and prepare an execution plan for a query, `plpy.execute` and `plpy.prepare`. Preparing the execution plan for a query is useful if you run the query from multiple Python functions.
PL/Python also supports the `plpy.subtransaction()` function to help manage `plpy.execute` calls in an explicit subtransaction. See *Explicit Subtransactions* in the PostgreSQL documentation for additional information about `plpy.subtransaction()`.

### plpy.execute

Calling `plpy.execute` with a query string and an optional limit argument causes the query to be run and the result to be returned in a Python result object. The result object emulates a list or dictionary object. The rows returned in the result object can be accessed by row number and column name. The result set row numbering starts with 0 (zero). The result object can be modified. The result object has these additional methods:

- `nrows` that returns the number of rows returned by the query.
- `status` which is the SPI_execute() return value.

For example, this Python statement in a PL/Python user-defined function executes a query.

```python
rv = plpy.execute("SELECT * FROM my_table", 5)
```

The `plpy.execute` function returns up to 5 rows from `my_table`. The result set is stored in the `rv` object. If `my_table` has a column `my_column`, it would be accessed as:

```python
my_col_data = rv[i]["my_column"]
```

Since the function returns a maximum of 5 rows, the index `i` can be an integer between 0 and 4.

### plpy.prepare

The function `plpy.prepare` prepares the execution plan for a query. It is called with a query string and a list of parameter types, if you have parameter references in the query. For example, this statement can be in a PL/Python user-defined function:

```python
plan = plpy.prepare("SELECT last_name FROM my_users WHERE first_name = $1", [ "text" ])
```

The string `text` is the data type of the variable that is passed for the variable `$1`. After preparing a statement, you use the function `plpy.execute` to run it:

```python
rv = plpy.execute(plan, [ "Fred" ], 5)
```

The third argument is the limit for the number of rows returned and is optional.

When you prepare an execution plan using the PL/Python module the plan is automatically saved. See the Postgres Server Programming Interface (SPI) documentation for information about the execution plans [https://www.postgresql.org/docs/8.3/static/spi.html](https://www.postgresql.org/docs/8.3/static/spi.html).

To make effective use of saved plans across function calls you use one of the Python persistent storage dictionaries SD or GD.

The global dictionary SD is available to store data between function calls. This variable is private static data. The global dictionary GD is public data, available to all Python functions within a session. Use GD with care.

Each function gets its own execution environment in the Python interpreter, so that global data and function arguments from `myfunc` are not available to `myfunc2`. The exception is the data in the GD dictionary, as mentioned previously.

This example uses the SD dictionary:

```python
CREATE FUNCTION usesavedplan() RETURNS trigger AS $$
  if SD.has_key("plan"): 
```
plan = SD["plan"]
else:
    plan = plpy.prepare("SELECT 1")
SD["plan"] = plan

# rest of function
$$ LANGUAGE plpythonu;

Handling Python Errors and Messages

The Python module `plpy` implements these functions to manage errors and messages:

- `plpy.debug`
- `plpy.log`
- `plpy.info`
- `plpy.notice`
- `plpy.warning`
- `plpy.error`
- `plpy.fatal`
- `plpy.debug`

The message functions `plpy.error` and `plpy.fatal` raise a Python exception which, if uncaught, propagates out to the calling query, causing the current transaction or subtransaction to be aborted. The functions `raise plpy.ERROR(msg)` and `raise plpy.FATAL(msg)` are equivalent to calling `plpy.error` and `plpy.fatal`, respectively. The other message functions only generate messages of different priority levels.

Whether messages of a particular priority are reported to the client, written to the server log, or both is controlled by the Greenplum Database server configuration parameters `log_min_messages` and `client_min_messages`. For information about the parameters see the Greenplum Database Reference Guide.

Using the dictionary GD To Improve PL/Python Performance

In terms of performance, importing a Python module is an expensive operation and can affect performance. If you are importing the same module frequently, you can use Python global variables to load the module on the first invocation and not require importing the module on subsequent calls. The following PL/Python function uses the GD persistent storage dictionary to avoid importing a module if it has already been imported and is in the GD.

```
psql=#
CREATE FUNCTION pytest() returns text as $$
    if 'mymodule' not in GD:
        import mymodule
        GD['mymodule'] = mymodule
    return GD['mymodule'].sumd([1,2,3])
$$;
```

Installing Python Modules

When you install a Python module on Greenplum Database, the Greenplum Database Python environment must have the module added to it across all segment hosts and mirror hosts in the cluster. When expanding Greenplum Database, you must add the Python modules to the new segment hosts. You can use the Greenplum Database utilities `gpssh` and `gpscp` run commands on Greenplum Database hosts and copy files to the hosts. For information about the utilities, see the Greenplum Database Utility Guide.
As part of the Greenplum Database installation, the `gpadmin` user environment is configured to use Python that is installed with Greenplum Database.

To check the Python environment, you can use the `which` command:

```
which python
```

The command returns the location of the Python installation. The Python installed with Greenplum Database is in the Greenplum Database `ext/python` directory.

```
/path_to_greenplum-db/ext/python/bin/python
```

When running shell commands on remote hosts with `gpssh`, you can specify the `-s` option. When the option is specified, `gpssh` sources the `greenplum_path.sh` file before running commands on the remote hosts. For example, this command should display the Python installed with Greenplum Database on each host.

```
gpssh -f gpdb_hosts which python
```

If it does not, you can add the `-s` to source `greenplum_path.sh` on the remote hosts before running the command.

```
gpssh -s -f gpdb_hosts which python
```

To display the list of currently installed Python modules, run this command.

```
python -c "help('modules')"
```

Run `gpssh` in interactive mode to display Python modules on remote hosts. This example starts `gpssh` in interactive mode and lists the Python modules on the Greenplum Database host `sdw1`.

```
$ gpssh -s -h sdw1
=> python -c "help('modules')"
  . . .
=> exit
$
```

Greenplum Database provides a collection of data science-related Python libraries that can be used with the Greenplum Database PL/Python language. You can download these libraries in `.gppkg` format from Pivotal Network. For information about the libraries, see Python Data Science Module Package.

These sections describe installing and testing Python modules:

- Installing Python pip
- Installing Python Packages with pip
- Building and Installing Python Modules Locally
- Testing Installed Python Modules

## Installing Python pip

The Python utility `pip` installs Python packages that contain Python modules and other resource files from versioned archive files.

Run this command to install `pip`.

```
python -m ensurepip --default-pip
```

The command runs the `ensurepip` module to bootstrap (install and configure) the `pip` utility from the local Python installation.
You can run this command to ensure the `pip`, `setuptools` and `wheel` projects are current. Current Python projects ensure that you can install Python packages from source distributions or pre-built distributions (wheels).

```bash
python -m pip install --upgrade pip setuptools wheel
```

You can use `gpssh` to run the commands on the Greenplum Database hosts. This example runs `gpssh` in interactive mode to install `pip` on the hosts listed in the file `gpdb_hosts`.

```bash
$ gpssh -s -f gpdb_hosts
=> python -m ensurepip --default-pip
[centos6-mdw1] Ignoring indexes: https://pypi.python.org/simple
[centos6-mdw1] Collecting setuptools
[centos6-mdw1] Collecting pip
[centos6-mdw1] Successfully installed pip-8.1.1 setuptools-20.10.1
[centos6-sdw1] Ignoring indexes: https://pypi.python.org/simple
[centos6-sdw1] Collecting setuptools
[centos6-sdw1] Collecting pip
[centos6-sdw1] Successfully installed pip-8.1.1 setuptools-20.10.1
=> exit
$
```

The `=>` is the inactive prompt for `gpssh`. The utility displays the output from each host. The `exit` command exits from `gpssh` interactive mode.

This `gpssh` command runs a single command on all hosts listed in the file `gpdb_hosts`.

```bash
gpssh -s -f gpdb_hosts python -m pip install --upgrade pip setuptools wheel
```

The utility displays the output from each host.

For more information about installing Python packages, see [https://packaging.python.org/tutorials/installing-packages/](https://packaging.python.org/tutorials/installing-packages/).

### Installing Python Packages with pip

After installing `pip`, you can install Python packages. This command installs the `numpy` and `scipy` packages.

```bash
python -m pip install --user numpy scipy
```

The `--user` option attempts to avoid conflicts when installing Python packages.

You can use `gpssh` to run the command on the Greenplum Database hosts.

For information about these and other Python packages, see *References*.

### Building and Installing Python Modules Locally

If you are building a Python module, you must ensure that the build creates the correct executable. For example on a Linux system, the build should create a 64-bit executable.

Before building a Python module to be installed, ensure that the appropriate software to build the module is installed and properly configured. The build environment is required only on the host where you build the module.

You can use the Greenplum Database utilities `gpssh` and `gpscp` to run commands on Greenplum Database hosts and to copy files to the hosts.
Testing Installed Python Modules

You can create a simple PL/Python user-defined function (UDF) to validate that Python a module is available in the Greenplum Database. This example tests the NumPy module.

This PL/Python UDF imports the NumPy module. The function returns SUCCESS if the module is imported, and FAILURE if an import error occurs.

```sql
CREATE OR REPLACE FUNCTION plpy_test(x int)
returns text
as $$
    try:
        from numpy import *
        return 'SUCCESS'
    except ImportError, e:
        return 'FAILURE'
$$
language plpythonu;
```

Create a table that contains data on each Greenplum Database segment instance. Depending on the size of your Greenplum Database installation, you might need to generate more data to ensure data is distributed to all segment instances.

```sql
CREATE TABLE DIST AS (SELECT x FROM generate_series(1,50) x ) DISTRIBUTED RANDOMLY ;
```

This SELECT command runs the UDF on the segment hosts where data is stored in the primary segment instances.

```sql
SELECT gp_segment_id, plpy_test(x) AS status
FROM dist
GROUP BY gp_segment_id, status
ORDER BY gp_segment_id, status;
```

The SELECT command returns SUCCESS if the UDF imported the Python module on the Greenplum Database segment instance. If the SELECT command returns FAILURE, you can find the segment host of the segment instance host. The Greenplum Database system table `gp_segment_configuration` contains information about mirroring and segment configuration. This command returns the host name for a segment ID.

```sql
SELECT hostname, content AS seg_ID FROM gp_segment_configuration
WHERE content = seg_id ;
```

If FAILURE is returned, these are some possible causes:

- A problem accessing required libraries. For the NumPy example, a Greenplum Database might have a problem accessing the OpenBLAS libraries or the Python libraries on a segment host.
  
  Make sure you get no errors when running command on the segment host as the `gpadmin` user. This `gpssh` command tests importing the numpy module on the segment host `mdw1`.

  ```bash
  gpssh -s -h mdw1 python -c "import numpy"
  ```

- If the Python import command does not return an error, environment variables might not be configured in the Greenplum Database environment. For example, the Greenplum Database might not have been restarted after installing the Python Package on the host system.
Examples

This PL/Python UDF returns the maximum of two integers:

```sql
CREATE FUNCTION pymax (a integer, b integer)
RETURNS integer
AS $$
  if (a is None) or (b is None):
    return None
  if a > b:
    return a
  return b
$$ LANGUAGE plpythonu;
```

You can use the `STRICT` property to perform the null handling instead of using the two conditional statements.

```sql
CREATE FUNCTION pymax (a integer, b integer)
RETURNS integer AS $$
  return max(a,b)
$$ LANGUAGE plpythonu STRICT;
```

You can run the user-defined function `pymax` with `SELECT` command. This example runs the UDF and shows the output.

```sql
SELECT ( pymax(123, 43));
column1
---------
   123
(1 row)
```

This example that returns data from an SQL query that is run against a table. These two commands create a simple table and add data to the table.

```sql
CREATE TABLE sales (id int, year int, qtr int, day int, region text)
DISTRIBUTED BY (id);
INSERT INTO sales VALUES
  (1, 2014, 1,1, 'usa'),
  (2, 2002, 2,2, 'europe'),
  (3, 2014, 3,3, 'asia'),
  (4, 2014, 4,4, 'usa'),
  (5, 2014, 1,5, 'europe'),
  (6, 2014, 2,6, 'asia'),
  (7, 2002, 3,7, 'usa');
```

This PL/Python UDF executes a `SELECT` command that returns 5 rows from the table. The Python function returns the `REGION` value from the row specified by the input value. In the Python function, the row numbering starts from 0. Valid input for the function is an integer between 0 and 4.

```sql
CREATE OR REPLACE FUNCTION mypytest(a integer)
RETURNS text
AS $$
  rv = plpy.execute("SELECT * FROM sales ORDER BY id", 5)
  region = rv[a]['region']
  return region
$$ language plpythonu;
Running this `SELECT` statement returns the `REGION` column value from the third row of the result set.

```sql
SELECT mypytest(2) ;
```

This command deletes the UDF from the database.

```sql
DROP FUNCTION mypytest(integer) ;
```

This example executes the PL/Python function in the previous example as an anonymous block with the `DO` command. In the example, the anonymous block retrieves the input value from a temporary table.

```sql
CREATE TEMP TABLE mytemp AS VALUES (2) DISTRIBUTED RANDOMLY;
DO $$
  temprow = plpy.execute("SELECT * FROM mytemp", 1)
  myval = temprow[0]["column1"]
  rv = plpy.execute("SELECT * FROM sales ORDER BY id", 5)
  region = rv[myval]["region"]
  plpy.notice("region is \%s \% region")
$$ language plpythonu;
```

**References**

**Technical References**

For information about the Python language, see [https://www.python.org/](https://www.python.org/).

For information about PL/Python see the PostgreSQL documentation at [https://www.postgresql.org/docs/8.3/static/plpython.html](https://www.postgresql.org/docs/8.3/static/plpython.html).

For information about Python Package Index (PyPI), see [https://pypi.python.org/pypi](https://pypi.python.org/pypi).

These are some Python modules that can be installed:

- SciPy library provides user-friendly and efficient numerical routines such as routines for numerical integration and optimization. The SciPy site includes other similar Python libraries [http://www.scipy.org/index.html](http://www.scipy.org/index.html).
PL/Container Language

PL/Container enables users to run Greenplum procedural language functions inside a Docker container, to avoid security risks associated with executing Python or R code on Greenplum segment hosts. This topic covers information about the architecture, installation, and setup of PL/Container:

• About the PL/Container Language Extension
• Install PL/Container
• Upgrade PL/Container
• Uninstall PL/Container
• Docker References

For detailed information about using PL/Container, refer to the sections:

• PL/Container Resource Management
• PL/Container Functions

For reference documentation, see:

• plcontainer utility reference page
• plcontainer configuration file reference page

The PL/Container language extension is available as an open source module. For information about the module, see the README file in the GitHub repository at https://github.com/greenplum-db/plcontainer

About the PL/Container Language Extension

The Greenplum Database PL/Container language extension allows users to create and run PL/Python or PL/R user-defined functions (UDFs) securely, inside a Docker container. Docker provides the ability to package and run an application in a loosely isolated environment called a container. For information about Docker, see the Docker web site.

Running UDFs inside the Docker container ensures that:

• The function execution process takes place in a separate environment and allows decoupling of the data processing. SQL operators such as "scan," "filter," and "project" are executed at the query executor (QE) side, and advanced data analysis is executed at the container side.
• User code cannot access the OS or the file system of the local host.
• User code cannot introduce any security risks.
• Functions cannot connect back to the Greenplum Database if the container is started with limited or no network access.
PL/Container Architecture

Example of the process flow:

Consider a query that selects table data using all available segments, and transforms the data using a PL/Container function. On the first call to a function in a segment container, the query executor on the master host starts the container on that segment host. It then contacts the running container to obtain the results. The container might respond with a Service Provider Interface (SPI) - a SQL query executed by the container to get some data back from the database - returning the result to the query executor.
A container running in standby mode waits on the socket and does not consume any CPU resources. PL/Container memory consumption depends on the amount of data cached in global dictionaries.

The container connection is closed by closing the Greenplum Database session that started the container, and the container shuts down.

**Install PL/Container**

*Warning:* PL/Container is compatible with Greenplum Database 5.2.0 and later. PL/Container has not been tested for compatibility with Greenplum Database 5.1.0 or 5.0.0.

This topic describes how to:

- Install Docker
- Install PL/Container
- Install the PL/Container Docker images
- Test the PL/Container installation

The following sections describe these tasks in detail.

**Prerequisites**

- PL/Container is supported on Pivotal Greenplum Database 5.2.x on Red Hat Enterprise Linux (RHEL) 7.x (or later) and CentOS 7.x (or later). PL/Container is not supported on RHEL/CentOS 6.x systems, because those platforms do not officially support Docker.

  *Note:* PL/Container 1.6.0 (introduced in Greenplum 5.26) and later versions support Docker images with Python 3 installed.

- The minimum Linux OS kernel version supported is 3.10. To verify your kernel release use:

  ```
  $ uname -r
  ```

**Install Docker**

To use PL/Container you need to install Docker on all Greenplum Database host systems. These are the minimum Docker versions that must be installed on Greenplum Database hosts (master, primary and all standby hosts):

- For PL/Container versions up to 1.5.0 - Docker 17.05
- For PL/Container 1.6.0 and later - Docker 19.03

These instructions show how to set up the Docker service on CentOS 7, but RHEL 7 is a similar process. These steps install the docker package and start the Docker service as a user with sudo privileges.

1. Ensure the user has sudo privileges or is root.
2. Install the dependencies required for Docker:

   ```
   sudo yum install -y yum-utils device-mapper-persistent-data lvm2
   ```

3. Add the Docker repo:

   ```
   sudo yum-config-manager --add-repo https://download.docker.com/linux/centos/docker-ce.repo
   ```

4. Update yum cache:

   ```
   sudo yum makecache fast
   ```

5. Install Docker:

   ```
   sudo yum -y install docker-ce
   ```
6. Start Docker daemon:

```
sudo systemctl start docker
```

7. On each Greenplum Database host, the `gpadmin` user should be part of the docker group for the user to be able to manage Docker images and containers. Assign the Greenplum Database administrator `gpadmin` to the group `docker`:

```
sudo usermod -aG docker gpadmin
```

8. Exit the session and login again to update the privileges.

9. Configure Docker to start when the host system starts:

```
sudo systemctl enable docker.service
```

```
sudo systemctl start docker.service
```

10. Run a Docker command to test the Docker installation. This command lists the currently running Docker containers.

```
docker ps
```

11. After you install Docker on all Greenplum Database hosts, restart the Greenplum Database system to give Greenplum Database access to Docker.

```
gpstop -ra
```

For a list of observations while using Docker and PL/Container, see the Notes section. For a list of Docker reference documentation, see Docker References.

## Docker Notes

- If a PL/Container Docker container exceeds the maximum allowed memory, it is terminated and an out of memory warning is displayed.
- PL/Container does not limit the Docker base device size, the size of the Docker container. In some cases, the Docker daemon controls the base device size. For example, if the Docker storage driver is devicemapper, the Docker daemon `--storage-opt` option flag `dm.basesize` controls the base device size. The default base device size for devicemapper is 10GB. The Docker command `docker info` displays Docker system information including the storage driver. The base device size is displayed in Docker 1.12 and later. For information about Docker storage drivers, see the Docker information `Daemon storage-driver`.

When setting the Docker base device size, the size must be set on all Greenplum Database hosts.

- **Known issue:**

  Occasionally, when PL/Container is running in a high concurrency environment, the Docker daemon hangs with log entries that indicate a memory shortage. This can happen even when the system seems to have adequate free memory.

  The issue seems to be triggered by the aggressive virtual memory requirement of the Go language (golang) runtime that is used by PL/Container, and the Greenplum Database Linux server kernel parameter setting for `overcommit_memory`. The parameter is set to 2 which does not allow memory overcommit.

  A workaround that might help is to increase the amount of swap space and increase the Linux server kernel parameter `overcommit_ratio`. If the issue still occurs after the changes, there might be memory shortage. You should check free memory on the system and add more RAM if needed. You can also decrease the cluster load.
Install PL/Container

Note: The PL/Container version 1.1 and later extension is installed by gppkg as a Greenplum Database extension, while the PL/Container version 1.0 extension is installed as a Greenplum Database language. Refer to the documentation associated with your Greenplum Database version to install PL/Container.

Install the PL/Container language extension using the gppkg utility.

1. Download the "PL/Container for RHEL 7" package that applies to your Greenplum Database version, from the VMware Tanzu Network. PL/Container is listed under Greenplum Procedural Languages.
2. As gpadmin, copy the PL/Container language extension package to the master host.
3. Run the package installation command:

   $ gppkg -i plcontainer-1.6.0-rhel7-x86_64.gppkg

4. Source the file $GPHOME/greenplum_path.sh:

   $ source $GPHOME/greenplum_path.sh

5. Make sure Greenplum Database is up and running:

   $ gpstate -s

   If it is not, start it:

   $ gpstart -a

6. Restart Greenplum Database:

   $ gpstop -ra

7. Login into one of the available databases, for example:

   $ psql postgres

8. Register the PL/Container extension, which installs the plcontainer utility:

   postgres=# CREATE EXTENSION plcontainer;

   You need to register the utility separately on each database that might need the PL/Container functionality.

Install PL/Container Docker Images

Install the Docker images that PL/Container uses to create language-specific containers to run the UDFs.

- Download the tar.gz file that contains the Docker images from Pivotal Network.
  - plcontainer-python3-images-<version>.tar.gz
  - plcontainer-python-images-<version>.tar.gz
  - plcontainer-r-images-<version>.tar.gz

Each image supports a different language or language version:

- PL/Container for Python 3 - Docker image with Python 3.7 and the Python Data Science Module package installed.

  Note: PL/Container 1.6.0 and later supports Docker images with Python 3 installed.

- PL/Container for Python 2 - Docker image with Python 2.7.12 and the Python Data Science Module package installed.
• PL/Container for R - A Docker image with container with R-3.3.3 and the R Data Science Library package installed.

The Data Science packages contain a set of Python modules or R functions and data sets related to data science. For information about the packages, see Python Data Science Module Package and R Data Science Library Package.

If you require different images from the ones provided by Pivotal Greenplum, you can create custom Docker images, install the image, and add the image to the PL/Container configuration.

• Use the `plcontainer` utility command `image-add` to install the images on all Greenplum Database hosts where `-f` indicates the location of the downloaded files:

```
# Install a Python 2 based Docker image
$ plcontainer image-add -f /home/gpadmin/plcontainer-python-image-1.6.0.tar.gz

# Install a Python 3 based Docker image
$ plcontainer image-add -f /home/gpadmin/plcontainer-python3-image-1.6.0.tar.gz

# Install an R based Docker image
$ plcontainer image-add -f /home/gpadmin/plcontainer-r-image-1.6.0.tar.gz
```

The utility displays progress information, similar to:

```
20200127:21:54:43:004607 plcontainer:mdw:gpadmin-[INFO]:-Checking whether docker is installed on all hosts...
20200127:21:54:43:004607 plcontainer:mdw:gpadmin-[INFO]:-Distributing image file /home/gpadmin/plcontainer-python-images-1.6.0.tar to all hosts...
20200127:21:54:55:004607 plcontainer:mdw:gpadmin-[INFO]:-Loading image on all hosts...
20200127:21:55:37:004607 plcontainer:mdw:gpadmin-[INFO]:-Removing temporary image files on all hosts...
```

For more information on `image-add` options, visit the `plcontainer` reference page.

• To display the installed Docker images on the local host use:

```
$ plcontainer image-list
```

<table>
<thead>
<tr>
<th>REPOSITORY</th>
<th>TAG</th>
<th>IMAGE ID</th>
</tr>
</thead>
<tbody>
<tr>
<td>pivotaldata/plcontainer_r_shared</td>
<td>devel</td>
<td>7427f920669d</td>
</tr>
<tr>
<td>pivotaldata/plcontainer_python_shared</td>
<td>devel</td>
<td>e36827eba53e</td>
</tr>
<tr>
<td>pivotaldata/plcontainer_python3_shared</td>
<td>devel</td>
<td>y32827ebe55b</td>
</tr>
</tbody>
</table>

• Add the image information to the PL/Container configuration file using `plcontainer runtime-add`, to allow PL/Container to associate containers with specified Docker images.

Use the `-r` option to specify your own user defined runtime ID name, use the `-i` option to specify the Docker image, and the `-l` option to specify the Docker image language. When there are multiple versions of the same docker image, for example 1.0.0 or 1.2.0, specify the TAG version using ":" after the image name.

```
# Add a Python 2 based runtime
```
The utility displays progress information as it updates the PL/Container configuration file on the Greenplum Database instances.

For details on other `runtime-add` options, see the `plcontainer` reference page.

- Optional: Use Greenplum Database resource groups to manage and limit the total CPU and memory resources of containers in PL/Container runtimes. In this example, the Python runtime will be used with a preconfigured resource group 16391:

  ```bash
  $ plcontainer runtime-add -r plc_python_shared -i pivotaldata/
  plcontainer_python_shared:devel -l python -s resource_group_id=16391
  ```

  For more information about enabling, configuring, and using Greenplum Database resource groups with PL/Container, see [PL/Container Resource Management](#).

You can now create a simple function to test your PL/Container installation.

### Test the PL/Container Installation

List the names of the runtimes your created and added to the PL/Container XML file:

```bash
$ plcontainer runtime-show
```

The command shows a list of all installed runtimes:

```
PL/Container Runtime Configuration:
-----------------------------------------------
Runtime ID: plc_python_shared
Linked Docker Image: pivotaldata/plcontainer_python_shared:devel
Runtime Setting(s):
  Shared Directory: ---- Shared Directory From HOST '/usr/local/greenplum-db/.bin/plcontainer_clients' to Container '/clientdir', access mode is 'ro'
-----------------------------------------------
```

You can also view the PL/Container configuration information with the `plcontainer runtime-show -r <runtime_id>` command. You can view the PL/Container configuration XML file with the `plcontainer runtime-edit` command.

Use the `psql` utility and select an existing database:

```bash
$ psql postgres;
```

If the PL/Container extension is not registered with the selected database, first enable it using:

```bash
postgres=# CREATE EXTENSION plcontainer;
```
Create a simple function to test your installation; in the example, the function will use the runtime `plc_python_shared`:

```sql
postgres=# CREATE FUNCTION dummyPython() RETURNS text AS $$
# container: plc_python_shared
return 'hello from Python'
$$ LANGUAGE plcontainer;
```

Test the function using:

```sql
postgres=# SELECT dummyPython();
  dummypython
-------------------
    hello from Python
(1 row)
```

Similarly, to test the R runtime:

```sql
postgres=# CREATE FUNCTION dummyR() RETURNS text AS $$
# container: plc_r_shared
return ('hello from R')
$$ LANGUAGE plcontainer;
```

```sql
postgres=# select dummyR();
  dummyr
------------
    hello from R
(1 row)
```

For further details and examples about using PL/Container functions, see [PL/Container Functions](#).

### Upgrade PL/Container

#### Upgrading from PL/Container 1.1 or Later

**Note:** To upgrade PL/Container 1.0, you must uninstall the old version and install the new version. See [Upgrading from PL/Container 1.0](#).

To upgrade from PL/Container 1.1 or higher, you save the current configuration, use `gppkg` to upgrade the PL/Container software, and then restore the configuration after upgrade. There is no need to update the Docker images when you upgrade PL/Container.

**Note:** Before you perform this upgrade procedure, ensure that you have migrated your existing PL/Container package from your previous Greenplum Database installation to your new Greenplum Database installation. Refer to the `gppkg` command for package installation and migration information.

Perform the following procedure to upgrade from PL/Container 1.1 or later:

1. Save the PL/Container configuration. For example, to save the configuration to a file named `plcontainer150-backup.xml` in the local directory:

   ```bash
   $ plcontainer runtime-backup -f plcontainer150-backup.xml
   ```

2. Use the Greenplum Database `gppkg` utility with the `-u` option to update the PL/Container language extension. For example, the following command updates the PL/Container language extension to version 1.6.0 on a Linux system:

   ```bash
   $ gppkg -u plcontainer-1.6.0-rhel7-x86_64.gppkg
   ```
3. Source the Greenplum Database environment file $GPHOME/greenplum_path.sh:

   $ source $GPHOME/greenplum_path.sh

4. Restore the PL/Container configuration. For example, this command restores the PL/Container configuration that you saved in a previous step:

   $ plcontainer runtime-restore -f plcontainer150-backup.xml

5. Restart Greenplum Database:

   $ gpstop -ra

6. You do not need to re-register the PL/Container extension in the databases in which you previously created the extension. However, you must register the PL/Container extension in each new database that will run PL/Container UDFs. For example, the following command registers PL/Container in a database named mytest:

   $ psql -d mytest -c 'CREATE EXTENSION plcontainer;'

   The command also creates PL/Container-specific functions and views.

   Note: PL/Container 1.2 and later utilizes the new resource group capabilities introduced in Greenplum Database 5.8.0. If you downgrade to a Greenplum Database system that uses PL/Container 1.1.0 or earlier, you must use plcontainer runtime-edit to remove any resource_group_id settings from your PL/Container runtime configuration.

## Upgrading from PL/Container 1.0

You cannot use the gppkg -u option to upgrade from PL/Container 1.0, because PL/Container 1.0 is installed as a Greenplum Database language rather than as an extension. To upgrade to from PL/Container 1.0, you must install uninstall version 1.0 and then install the new version. The Docker images and the PL/Container configuration do not change when upgrading PL/Container, only the PL/Container extension installation changes.

As part of the upgrade process, you must drop PL/Container from all databases that are configured with PL/Container.

Important: Dropping PL/Container from a database drops all PL/Container UDFs from the database, including user-created PL/Container UDFs. If the UDFs are required, ensure you can re-create the UDFs before dropping PL/Container. This SELECT command lists the names of and body of PL/Container UDFs in a database.

   SELECT proname, prosrc FROM pg_proc WHERE prolang = (SELECT oid FROM pg_language WHERE lanname = 'plcontainer');

   For information about the catalog tables, pg_proc and pg_language, see System Tables.

   These steps upgrade from PL/Container 1.0 to PL/Container 1.1 or later. The steps save the PL/Container 1.0 configuration and restore the configuration for use with PL/Container 1.1 or later.

1. Save the PL/Container configuration. This example saves the configuration to plcontainer10-backup.xml in the local directory.

   $ plcontainer runtime-backup -f plcontainer10-backup.xml

2. Remove any setting elements that contain the use_container_network attribute from the configuration file. For example, this setting element must be removed from the configuration file.

   <setting use_container_network="yes"/>
3. Run the `plcontainer_uninstall.sql` script as the `gpadmin` user for each database that is configured with PL/Container. For example, this command drops the `plcontainer` language in the `mytest` database.

```
$ psql -d mytest -f $GPHOME/share/postgresql/plcontainer/plcontainer_uninstall.sql
```

The script drops the `plcontainer` language with the `CASCADE` clause that drops PL/Container-specific functions and views in the database.

4. Use the Greenplum Database `gppkg` utility with the `-r` option to uninstall the PL/Container language extension. This example uninstalls the PL/Container language extension on a Linux system.

```
$ gppkg -r plcontainer-1.0.0
```

5. Run the package installation command. This example installs the PL/Container 1.6.0 language extension on a Linux system.

```
$ gppkg -i plcontainer-1.6.0-rhel7-x86_64.gppkg
```

6. Source the file `$GPHOME/greenplum_path.sh`.

```
$ source $GPHOME/greenplum_path.sh
```

7. Update the PL/Container configuration. This command restores the saved configuration.

```
$ plcontainer runtime-restore -f plcontainer10-backup.xml
```

8. Restart Greenplum Database.

```
$ gpstop -ra
```

9. Register the new PL/Container extension as an extension for each database that uses PL/Container UDFs. This `psql` command runs a `CREATE EXTENSION` command to register PL/Container in the database `mytest`.

```
$ psql -d mytest -c 'CREATE EXTENSION plcontainer;'
```

The command registers PL/Container as an extension and creates PL/Container-specific functions and views.

After upgrading PL/Container for a database, re-install any user-created PL/Container UDFs that are required.

### Uninstall PL/Container

To uninstall PL/Container, remove Docker containers and images, and then remove the PL/Container support from Greenplum Database.

When you remove support for PL/Container, the `plcontainer` user-defined functions that you created in the database will no longer work.

### Uninstall Docker Containers and Images

On the Greenplum Database hosts, uninstall the Docker containers and images that are no longer required.

The `plcontainer image-list` command lists the Docker images that are installed on the local Greenplum Database host.

The `plcontainer image-delete` command deletes a specified Docker image from all Greenplum Database hosts.
Some Docker containers might exist on a host if the containers were not managed by PL/Container. You might need to remove the containers with Docker commands. These docker commands manage Docker containers and images on a local host.

- The command `docker ps -a` lists all containers on a host. The command `docker stop` stops a container.
- The command `docker images` lists the images on a host.
- The command `docker rmi` removes images.
- The command `docker rm` removes containers.

## Remove PL/Container Support for a Database

To remove support for PL/Container, drop the extension from the database. Use the `psql` utility with `DROP EXTENSION` command (using `-c`) to remove PL/Container from `mytest` database.

```bash
psql -d mytest -c 'DROP EXTENSION plcontainer CASCADE;'
```

The `CASCADE` keyword drops PL/Container-specific functions and views.

## Uninstall the PL/Container Language Extension

If no databases have `plcontainer` as a registered language, uninstall the Greenplum Database PL/Container language extension with the `gppkg` utility.

1. Use the Greenplum Database `gppkg` utility with the `-r` option to uninstall the PL/Container language extension. This example uninstalls the PL/Container language extension on a Linux system:

   ```bash
   $ gppkg -r plcontainer-2.1.1
   ```

   You can run the `gppkg` utility with the options `-q --all` to list the installed extensions and their versions.

2. **Reload** `greenplum_path.sh`.

   ```bash
   $ source $GPHOME/greenplum_path.sh
   ```

3. **Restart** the database.

   ```bash
   $ gpstop -ra
   ```

## Using PL/Container

This topic covers further details on:

- **PL/Container Resource Management**
- **PL/Container Functions**

### PL/Container Resource Management

The Docker containers and the Greenplum Database servers share CPU and memory resources on the same hosts. In the default case, Greenplum Database is unaware of the resources consumed by running PL/Container instances. You can use Greenplum Database resource groups to control overall CPU and memory resource usage for running PL/Container instances.

PL/Container manages resource usage at two levels - the container level and the runtime level. You can control container-level CPU and memory resources with the `memory_mb` and `cpu_share` settings that you configure for the PL/Container runtime. `memory_mb` governs the memory resources available to each container instance. The `cpu_share` setting identifies the relative weighting of a container's CPU usage.
compared to other containers. See `../../utility_guide/admin_utilities/plcontainer-configuration.xml` for further details.

You cannot, by default, restrict the number of executing PL/Container container instances, nor can you restrict the total amount of memory or CPU resources that they consume.

### Using Resource Groups to Manage PL/Container Resources

With PL/Container 1.2.0 and later, you can use Greenplum Database resource groups to manage and limit the total CPU and memory resources of containers in PL/Container runtimes. For more information about enabling, configuring, and using Greenplum Database resource groups, refer to Using Resource Groups in the Greenplum Database Administrator Guide.

**Note:** If you do not explicitly configure resource groups for a PL/Container runtime, its container instances are limited only by system resources. The containers may consume resources at the expense of the Greenplum Database server.

Resource groups for external components such as PL/Container use Linux control groups (cgroups) to manage component-level use of memory and CPU resources. When you manage PL/Container resources with resource groups, you configure both a memory limit and a CPU limit that Greenplum Database applies to all container instances that share the same PL/Container runtime configuration.

When you create a resource group to manage the resources of a PL/Container runtime, you must specify `MEMORY_AUDITOR=cgroup` and `CONCURRENCY=0` in addition to the required CPU and memory limits. For example, the following command creates a resource group named `plpy_run1_rg` for a PL/Container runtime:

```sql
CREATE RESOURCE GROUP plpy_run1_rg WITH (MEMORY_AUDITOR=cgroup,
  CONCURRENCY=0,
  CPU_RATE_LIMIT=10, MEMORY_LIMIT=10);
```

PL/Container does not use the `MEMORY_SHARED_QUOTA` and `MEMORY_SPILL_RATIO` resource group memory limits. Refer to the `CREATE RESOURCE GROUP` reference page for detailed information about this SQL command.

You can create one or more resource groups to manage your running PL/Container instances. After you create a resource group for PL/Container, you assign the resource group to one or more PL/Container runtimes. You make this assignment using the `groupid` of the resource group. You can determine the `groupid` for a given resource group name from the `gp_resgroup_config gp_toolkit` view. For example, the following query displays the `groupid` of a resource group named `plpy_run1_rg`:

```sql
SELECT groupname, groupid FROM gp_toolkit.gp_resgroup_config
WHERE groupname='plpy_run1_rg';
```

| groupname   |  groupid |
|-------------+----------|
| plpy_run1_rg |   16391  |

(1 row)

You assign a resource group to a PL/Container runtime configuration by specifying the `resource_group_id=rg_groupid` option to the `plcontainer runtime-add (new runtime)` or `plcontainer runtime-replace (existing runtime)` commands. For example, to assign the `plpy_run1_rg` resource group to a new PL/Container runtime named `python_run1`:

```bash
plcontainer runtime-add -r python_run1 -i pivotaldata/plcontainer_python_shared:devel -l python -s resource_group_id=16391
```

You can also assign a resource group to a PL/Container runtime using the `plcontainer runtime-edit` command. For information about the `plcontainer` command, see `../../utility_guide/admin_utilities/plcontainer.xml` reference page.
After you assign a resource group to a PL/Container runtime, all container instances that share the same runtime configuration are subject to the memory limit and the CPU limit that you configured for the group. If you decrease the memory limit of a PL/Container resource group, queries executing in running containers in the group may fail with an out of memory error. If you drop a PL/Container resource group while there are running container instances, Greenplum Database kills the running containers.

**Configuring Resource Groups for PL/Container**

To use Greenplum Database resource groups to manage PL/Container resources, you must explicitly configure both resource groups and PL/Container.

Perform the following procedure to configure PL/Container to use Greenplum Database resource groups for CPU and memory resource management:

1. If you have not already configured and enabled resource groups in your Greenplum Database deployment, configure cgroups and enable Greenplum Database resource groups as described in Using Resource Groups in the *Greenplum Database Administrator Guide*.

   **Note:** If you have previously configured and enabled resource groups in your deployment, ensure that the Greenplum Database resource group `gpdb.conf` cgroups configuration file includes a `memory { }` block as described in the previous link.

2. Analyze the resource usage of your Greenplum Database deployment. Determine the percentage of resource group CPU and memory resources that you want to allocate to PL/Container Docker containers.

3. Determine how you want to distribute the total PL/Container CPU and memory resources that you identified in the step above among the PL/Container runtimes. Identify:
   - The number of PL/Container resource group(s) that you require.
   - The percentage of memory and CPU resources to allocate to each resource group.
   - The resource-group-to-PL/Container-runtime assignment(s).

4. Create the PL/Container resource groups that you identified in the step above. For example, suppose that you choose to allocate 25% of both memory and CPU Greenplum Database resources to PL/Container. If you further split these resources among 2 resource groups 60/40, the following SQL commands create the resource groups:

   ```sql
   CREATE RESOURCE GROUP plr_run1_rg WITH (MEMORY_AUDITOR=cgroup,
                                          CONCURRENCY=0,
                                          CPU_RATE_LIMIT=15, MEMORY_LIMIT=15);
   CREATE RESOURCE GROUP plpy_run1_rg WITH (MEMORY_AUDITOR=cgroup,
                                          CONCURRENCY=0,
                                          CPU_RATE_LIMIT=10, MEMORY_LIMIT=10);
   ```

5. Find and note the `groupid` associated with each resource group that you created. For example:

   ```sql
   SELECT groupname, groupid FROM gp_toolkit.gp_resgroup_config
   WHERE groupname IN ('plpy_run1_rg', 'plr_run1_rg');
   
<table>
<thead>
<tr>
<th>groupname</th>
<th>groupid</th>
</tr>
</thead>
<tbody>
<tr>
<td>plpy_run1_rg</td>
<td>16391</td>
</tr>
<tr>
<td>plr_run1_rg</td>
<td>16393</td>
</tr>
</tbody>
</table>
   (1 row)
   ```

6. Assign each resource group that you created to the desired PL/Container runtime configuration. If you have not yet created the runtime configuration, use the `plcontainer runtime-add` command. If the runtime already exists, use the `plcontainer runtime-replace` or `plcontainer runtime-edit` command to add the resource group assignment to the runtime configuration. For example:

   ```bash
   plcontainer runtime-add -r python_run1 -i pivotaldata/plcontainer_python_shared:devel -l python -s resource_group_id=16391
   ```
For information about the `plcontainer` command, see `../../utility_guide/admin_utilities/plcontainer.xml` reference page.

**Notes**

**PL/Container logging**

When PL/Container logging is enabled, you can set the log level with the Greenplum Database server configuration parameter `log_min_messages`. The default log level is `warning`. The parameter controls the PL/Container log level and also controls the Greenplum Database log level.

- PL/Container logging is enabled or disabled for each runtime ID with the `use_container_logging` attribute. The default is no logging.
- The PL/Container log information is the information from the UDF that is run in the Docker container. By default, the PL/Container log information is sent to a system service. On Red Hat 7 or CentOS 7 systems, the log information is sent to the `journald` service.
- The Greenplum Database log information is sent to log file on the Greenplum Database master.
- When testing or troubleshooting a PL/Container UDF, you can change the Greenplum Database log level with the `SET` command. You can set the parameter in the session before you run your PL/Container UDF. This example sets the log level to `debug1`.

```
SET log_min_messages='debug1' ;
```

**Note:** The parameter `log_min_messages` controls both the Greenplum Database and PL/Container logging, increasing the log level might affect Greenplum Database performance even if a PL/Container UDF is not running.

**PL/Container Functions**

When you enable PL/Container in a database of a Greenplum Database system, the language `plcontainer` is registered in that database. Specify `plcontainer` as a language in a UDF definition to create and run user-defined functions in the procedural languages supported by the PL/Container Docker images.

**Limitations**

Review the following limitations when creating and using PL/Container PL/Python and PL/R functions:

- Greenplum Database domains are not supported.
- Multi-dimensional arrays are not supported.
- Python and R call stack information is not displayed when debugging a UDF.
- The `plpy.execute()` methods `nrows()` and `status()` are not supported.
- The PL/Python function `plpy.SPIError()` is not supported.
- Executing the `SAVEPOINT` command with `plpy.execute()` is not supported.
- The `DO` command is not supported.
- Container flow control is not supported.
- Triggers are not supported.
- `OUT` parameters are not supported.
- The Python `dict` type cannot be returned from a PL/Python UDF. When returning the Python `dict` type from a UDF, you can convert the `dict` type to a Greenplum Database user-defined data type (UDT).
Using PL/Container functions

A UDF definition that uses PL/Container must have the these items.

- The first line of the UDF must be `# container: ID`
- The `LANGUAGE` attribute must be `plcontainer`

The `ID` is the name that PL/Container uses to identify a Docker image. When Greenplum Database executes a UDF on a host, the Docker image on the host is used to start a Docker container that runs the UDF. In the XML configuration file `plcontainer_configuration.xml`, there is a runtime XML element that contains a corresponding `id` XML element that specifies the Docker container startup information. See `../../utility_guide/admin_utilities/plcontainer-configuration.xml#topic_sk1_gdq_dw` for information about how PL/Container maps the `ID` to a Docker image. See `#function_examples` for example UDF definitions.

The PL/Container configuration file is read only on the first invocation of a PL/Container function in each Greenplum Database session that runs PL/Container functions. You can force the configuration file to be re-read by performing a `SELECT` command on the view `plcontainer_refresh_config` during the session. For example, this `SELECT` command forces the configuration file to be read.

```sql
SELECT * FROM plcontainer_refresh_config;
```

Running the command executes a PL/Container function that updates the configuration on the master and segment instances and returns the status of the refresh.

```
gp_segment_id | plcontainer_refresh_local_config
---------------+----------------------------------
     1  | ok
     0  | ok
    -1  | ok
     3  | ok
```

(3 rows)

Also, you can show all the configurations in the session by performing a `SELECT` command on the view `plcontainer_show_config`. For example, this `SELECT` command returns the PL/Container configurations.

```sql
SELECT * FROM plcontainer_show_config;
```

Running the command executes a PL/Container function that displays configuration information from the master and segment instances. This is an example of the start and end of the view output.

```
INFO: plcontainer: Container 'plc_py_test' configuration
INFO: plcontainer: image = 'pivotaldata/plcontainer_python_shared:devel'
INFO: plcontainer: memory_mb = '1024'
INFO: plcontainer: use container network = 'no'
INFO: plcontainer: use container logging = 'no'
INFO: plcontainer: shared directory from host '/usr/local/greenplum-db/bin/plcontainer_clients' to container '/clientdir'
INFO: plcontainer: access = readonly
...

INFO: plcontainer: Container 'plc_r_example' configuration (seg0 slice3 192.168.180.45:40000 pid=3304)
INFO: plcontainer: image = 'pivotaldata/plcontainer_r_without_clients:0.2' (seg0 slice3 192.168.180.45:40000 pid=3304)
INFO: plcontainer: memory_mb = '1024' (seg0 slice3 192.168.180.45:40000 pid=3304)
```
The PL/Container function `plcontainer_containers_summary()` displays information about the currently running Docker containers.

```
SELECT * FROM plcontainer_containers_summary();
```

If a normal (non-superuser) Greenplum Database user runs the function, the function displays information only for containers created by the user. If a Greenplum Database superuser runs the function, information for all containers created by Greenplum Database users is displayed. This is sample output when 2 containers are running.

<table>
<thead>
<tr>
<th>SEGMENT_ID</th>
<th>CONTAINER_ID</th>
<th>UP_TIME</th>
<th>OWNER</th>
<th>MEMORY_USAGE(KB)</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>693a6cb691fd2881ec0160a44daee2547a0d5b799875d4ec106c09c97da422ea</td>
<td>Up 8 seconds</td>
<td>gpadmin</td>
<td>12940</td>
</tr>
<tr>
<td>1</td>
<td>bc9a0c04019c266f6d8269ffe35769d118bfb96ec634549b2bd2401ea20158</td>
<td>Up 2 minutes</td>
<td>gpadmin</td>
<td>13628</td>
</tr>
</tbody>
</table>

When Greenplum Database executes a PL/Container UDF, Query Executer (QE) processes start Docker containers and reuse them as needed. After a certain amount of idle time, a QE process quits and destroys its Docker containers. You can control the amount of idle time with the Greenplum Database server configuration parameter `gp_vmem_idle_resource_timeout`. Controlling the idle time might help with Docker container reuse and avoid the overhead of creating and starting a Docker container.

**Warning:** Changing `gp_vmem_idle_resource_timeout` value, might affect performance due to resource issues. The parameter also controls the freeing of Greenplum Database resources other than Docker containers.

### Examples

The values in the `# container` lines of the examples, `plc_python_shared` and `plc_r_shared`, are the `id` XML elements defined in the `plcontainer_config.xml` file. The `id` element is mapped to the `image` element that specifies the Docker image to be started. If you configured PL/Container with a different ID, change the value of the `# container` line. For information about configuring PL/Container and viewing the configuration settings, see `../../utility_guide/admin_utilities/plcontainer-configuration.xml`.

This is an example of PL/Python function that runs using the `plc_python_shared` container that contains Python 2:

```
CREATE OR REPLACE FUNCTION pylog100() RETURNS double precision AS $$
# container: plc_python_shared
$$
```
import math
return math.log10(100)
$$ LANGUAGE plcontainer;
• Multi-dimensional arrays.

Also, the Python module has two global dictionary objects that retain the data between function calls. They are named GD and SD. GD is used to share the data between all the function running within the same container, while SD is used for sharing the data between multiple calls of each separate function. Be aware that accessing the data is possible only within the same session, when the container process lives on a segment or master. Be aware that for idle sessions Greenplum Database terminates segment processes, which means the related containers would be shut down and the data from GD and SD lost.

For information about PL/Python, see Greenplum PL/Python Language Extension.

About PL/Container Running PL/Python with Python 3

If you want to use PL/Container to run the same function body in both Python2 and Python3, you must create 2 different user-defined functions.

Keep in mind that UDFs that you created for Python 2 may not run in PL/Container with Python 3. The following Python references may be useful:

• Changes to Python - What's New in Python 3
• Porting from Python 2 to 3 - Porting Python 2 Code to Python 3

About PL/Container Running PL/R

In the R language container, the module pg.spi is implemented. The module contains these methods:

• pg.spi.exec(stmt) - Executes the query string stmt and returns query result in R data.frame. To be able to access the result fields make sure your query returns named fields.
• pg.spi.prepare(stmt[, argtypes]) - Prepares the execution plan for a query. It is called with a query string and a list of parameter types if you have parameter references in the query.
• pg.spi.execp(plan[, argtypes]) - Execute a prepared plan.
• pg.spi.debug(msg) - Sends a DEBUG2 message to the Greenplum Database log.
• pg.spi.log(msg) - Sends a LOG message to the Greenplum Database log.
• pg.spi.info(msg) - Sends an INFO message to the Greenplum Database log.
• pg.spi.notice(msg) - Sends a NOTICE message to the Greenplum Database log.
• pg.spi.warning(msg) - Sends a WARNING message to the Greenplum Database log.
• pg.spi.error(msg) - Sends an ERROR message to the Greenplum Database log. An ERROR message raised in Greenplum Database causes the query execution process to stop and the transaction to rollback.
• pg.spi.fatal(msg) - Sends a FATAL message to the Greenplum Database log. A FATAL message causes Greenplum Database session to be closed and transaction to be rolled back.

PL/Container does not support this PL/R feature:

• Multi-dimensional arrays.

For information about PL/R, see Greenplum PL/R Language Extension.

For information about the pg.spi methods, see http://www.joeconway.com/plr/doc/plr-spi-rsupport-funcs-normal.html

About PL/Java

With the Greenplum Database PL/Java extension, you can write Java methods using your favorite Java IDE and install the JAR files that contain those methods into Greenplum Database.

Greenplum Database PL/Java package is based on the open source PL/Java 1.5.0. Greenplum Database PL/Java provides the following features.

- Ability to execute PL/Java functions with Java 1.7 or higher.
- Ability to specify Java runtime.
- Standardized utilities (modeled after the SQL 2003 proposal) to install and maintain Java code in the database.
- Standardized mappings of parameters and result. Complex types as well as sets are supported.
- An embedded, high performance, JDBC driver utilizing the internal Greenplum Database SPI routines.
- Metadata support for the JDBC driver. Both DatabaseMetaData and ResultSetMetaData are included.
- The ability to return a ResultSet from a query as an alternative to building a ResultSet row by row.
- Full support for savepoints and exception handling.
- The ability to use IN, INOUT, and OUT parameters.
- Two separate Greenplum Database languages:
  - pljava, TRUSTED PL/Java language
  - pljavau, UNTRUSTED PL/Java language
- Transaction and Savepoint listeners enabling code execution when a transaction or savepoint is committed or rolled back.
- Integration with GNU GCJ on selected platforms.

A function in SQL will appoint a static method in a Java class. In order for the function to execute, the appointed class must available on the class path specified by the Greenplum Database server configuration parameter pljava_classpath. The PL/Java extension adds a set of functions that helps installing and maintaining the java classes. Classes are stored in normal Java archives, JAR files. A JAR file can optionally contain a deployment descriptor that in turn contains SQL commands to be executed when the JAR is deployed or undeployed. The functions are modeled after the standards proposed for SQL 2003.
PL/Java implements a standardized way of passing parameters and return values. Complex types and sets are passed using the standard JDBC ResultSet class.

A JDBC driver is included in PL/Java. This driver calls Greenplum Database internal SPI routines. The driver is essential since it is common for functions to make calls back to the database to fetch data. When PL/Java functions fetch data, they must use the same transactional boundaries that are used by the main function that entered PL/Java execution context.

PL/Java is optimized for performance. The Java virtual machine executes within the same process as the backend to minimize call overhead. PL/Java is designed with the objective to enable the power of Java to the database itself so that database intensive business logic can execute as close to the actual data as possible.

The standard Java Native Interface (JNI) is used when bridging calls between the backend and the Java VM.

About Greenplum Database PL/Java

There are a few key differences between the implementation of PL/Java in standard PostgreSQL and Greenplum Database.

Functions

The following functions are not supported in Greenplum Database. The classpath is handled differently in a distributed Greenplum Database environment than in the PostgreSQL environment.

- `sqlj.install_jar`
- `sqlj.replace_jar`
- `sqlj.remove_jar`
- `sqlj.get_classpath`
- `sqlj.set_classpath`

Greenplum Database uses the `pljava_classpath` server configuration parameter in place of the `sqlj.set_classpath` function.

Server Configuration Parameters

The following server configuration parameters are used by PL/Java in Greenplum Database. These parameters replace the `pljava.*` parameters that are used in the standard PostgreSQL PL/Java implementation:

- `pljava_classpath`

  A colon (:) separated list of the jar files containing the Java classes used in any PL/Java functions. The jar files must be installed in the same locations on all Greenplum Database hosts. With the trusted PL/Java language handler, jar file paths must be relative to the `$GPHOME/lib/postgresql/java/` directory. With the untrusted language handler (javaU language tag), paths may be relative to `$GPHOME/lib/postgresql/java/` or absolute.

  The server configuration parameter `pljava_classpath_insecure` controls whether the server configuration parameter `pljava_classpath` can be set by a user without Greenplum Database superuser privileges. When `pljava_classpath_insecure` is enabled, Greenplum Database developers who are working on PL/Java functions do not have to be database superusers to change `pljava_classpath`.

  **Warning:** Enabling `pljava_classpath_insecure` exposes a security risk by giving non-administrator database users the ability to run unauthorized Java methods.

- `pljava_statement_cache_size`

  Sets the size in KB of the Most Recently Used (MRU) cache for prepared statements.
• **pljava_release_linger_savepoints**
  
  If **TRUE**, lingering savepoints will be released on function exit. If **FALSE**, they will be rolled back.

• **pljava_vmoptions**
  
  Defines the start up options for the Greenplum Database Java VM.

See the *Greenplum Database Reference Guide* for information about the Greenplum Database server configuration parameters.

## Installing PL/Java

For Greenplum Database, the PL/Java extension is available as a package. Download the package from the Greenplum Database page on **Pivotal Network** and then install it with the Greenplum Package Manager (**gppkg**).

The **gppkg** utility installs Greenplum Database extensions, along with any dependencies, on all hosts across a cluster. It also automatically installs extensions on new hosts in the case of system expansion and segment recovery.

For information about **gppkg**, see the *Greenplum Database Utility Guide*.

**Important:** PL/Java requires a Java environment on each Greenplum Database host. Ensure that the same Java environment is at the same location on all hosts: masters and segments.

To install and use PL/Java:

1. Specify the Java version used by PL/Java. Set the environment variables **JAVA_HOME** and **LD_LIBRARY_PATH** in the **greenplum_path.sh**.

2. Install the Greenplum Database PL/Java extension.

3. Enable the language for each database where you intend to use PL/Java.

4. Install user-created JAR files containing Java methods into the same directory on all Greenplum Database hosts.

5. Add the name of the JAR file to the Greenplum Database server configuration parameter **pljava_classpath**. The parameter lists the installed JAR files. For information about the parameter, see the *Greenplum Database Reference Guide*.

### Installing the Greenplum PL/Java Extension

Before you install the PL/Java extension, make sure that your Greenplum database is running, you have sourced **greenplum_path.sh**, and that the **$MASTER_DATA_DIRECTORY** and **$GPHOME** variables are set.

1. Download the PL/Java extension package from the Greenplum Database page on **Pivotal Network** then copy it to the master host.

2. Install the software extension package by running the **gppkg** command. This example installs the PL/Java extension package on a Linux system:

   ```bash
   $ gppkg -i pljava-1.4.3-gp5-rhelosversion-x86_64.gppkg
   ```

3. Ensure that the environment variables **JAVA_HOME** and **LD_LIBRARY_PATH** are set properly in **$GPHOME/greenplum_path.sh** on all Greenplum Database hosts.

   • Set the **JAVA_HOME** variable to the directory where your Java Runtime is installed. For example, for Oracle JRE this directory would be /usr/java/latest. For OpenJDK, the directory is /usr/lib/jvm. This example changes the environment variable to use /usr/lib/jvm.

   ```bash
   JAVA_HOME=/usr/lib/jvm
   ```

   • Set the **LD_LIBRARY_PATH** to include the directory with the Java server runtime libraries. PL/Java depends on **libjvm.so** and the shared object should be in your **LD_LIBRARY_PATH**. By
default, libjvm.so is available in $JAVA_HOME/jre/lib/amd64/server. This example adds the directory to the environment variable.

```
LD_LIBRARY_PATH=$GPHOME/lib:$GPHOME/ext/python/lib:$JAVA_HOME/jre/lib/amd64/server:$LD_LIBRARY_PATH
```

This example gpscp command copies the file to all hosts specified in the file gphosts_file.

```
$ gpscp -f gphosts_file $GPHOME/greenplum_path.sh
```

4. Reload greenplum_path.sh.

```
$ source $GPHOME/greenplum_path.sh
```

5. Restart Greenplum Database.

```
$ gpstop -r
```

## Enabling PL/Java and Installing JAR Files

Perform the following steps as the Greenplum Database administrator gpadmin.

1. Enable PL/Java in a database by executing the `CREATE EXTENSION` command to register the language. For example, this command enables PL/Java in the testdb database:

```
$ psql -d testdb -c 'CREATE EXTENSION pljava;
```

   **Note:** The PL/Java install.sql script, used in previous releases to register the language, is deprecated.

2. Copy your Java archives (JAR files) to the same directory on all Greenplum Database hosts. This example uses the Greenplum Database gpscp utility to copy the file myclasses.jar to the directory $GPHOME/lib/postgresql/java/:

```
$ gpscp -f gphosts_file myclasses.jar
```

   The file gphosts_file contains a list of the Greenplum Database hosts.

3. Set the `pljava_classpath` server configuration parameter in the master postgresql.conf file. For this example, the parameter value is a colon (:) separated list of the JAR files. For example:

```
$ gpconfig -c pljava_classpath -v 'examples.jar:myclasses.jar'
```

   The file examples.jar is installed when you install the PL/Java extension package with the gppkg utility.

   **Note:** If you install JAR files in a directory other than $GPHOME/lib/postgresql/java/, you must specify the absolute path to the JAR file. Each JAR file must be in the same location on all Greenplum Database hosts. For more information about specifying the location of JAR files, see the information about the `pljava_classpath` server configuration parameter in the Greenplum Database Reference Guide.

4. Reload the postgresql.conf file.

```
$ gpstop -u
```
5. (optional) Greenplum provides an examples.sql file containing sample PL/Java functions that you can use for testing. Run the commands in this file to create the test functions (which use the Java classes in examples.jar).

   $ psql -f $GPHOME/share/postgresql/pljava/examples.sql

Uninstalling PL/Java

- Remove PL/Java Support for a Database
- Uninstall the Java JAR files and Software Package

Remove PL/Java Support for a Database

Use the DROP EXTENSION command to remove support for PL/Java from a database. For example, this command disables the PL/Java language in the testdb database:

   $ psql -d testdb -c 'DROP EXTENSION pljava;'

The default command fails if any existing objects (such as functions) depend on the language. Specify the CASCADE option to also drop all dependent objects, including functions that you created with PL/Java.

   Note: The PL/Java uninstall.sql script, used in previous releases to remove the language registration, is deprecated.

Uninstall the Java JAR files and Software Package

If no databases have PL/Java as a registered language, remove the Java JAR files and uninstall the Greenplum PL/Java extension with the gppkg utility.

1. Remove the pljava_classpath server configuration parameter from the postgresql.conf file on all Greenplum Database hosts. For example:

   $ gpconfig -r pljava_classpath

2. Remove the JAR files from the directories where they were installed on all Greenplum Database hosts. For information about JAR file installation directories, see Enabling PL/Java and Installing JAR Files.

3. Use the Greenplum gppkg utility with the -r option to uninstall the PL/Java extension. This example uninstalls the PL/Java extension on a Linux system:

   $ gppkg -r pljava-1.4.3

   You can run the gppkg utility with the options -q --all to list the installed extensions and their versions.

4. Reload greenplum_path.sh.

   $ source $GPHOME/greenplum_path.sh

5. Restart the database.

   $ gpstop -r

Writing PL/Java functions

Information about writing functions with PL/Java.

- SQL Declaration
- Type Mapping
SQL Declaration

A Java function is declared with the name of a class and a static method on that class. The class will be resolved using the classpath that has been defined for the schema where the function is declared. If no classpath has been defined for that schema, the public schema is used. If no classpath is found there either, the class is resolved using the system classloader.

The following function can be declared to access the static method `getProperty` on `java.lang.System` class:

```sql
CREATE FUNCTION getsysprop(VARCHAR)
RETURNS VARCHAR
AS 'java.lang.System.getProperty'
LANGUAGE java;
```

Run the following command to return the Java `user.home` property:

```sql
SELECT getsysprop('user.home');
```

Type Mapping

Scalar types are mapped in a straight forward way. This table lists the current mappings.

**Table 247: PL/Java data type mapping**

<table>
<thead>
<tr>
<th>PostgreSQL</th>
<th>Java</th>
</tr>
</thead>
<tbody>
<tr>
<td>bool</td>
<td>boolean</td>
</tr>
<tr>
<td>char</td>
<td>byte</td>
</tr>
<tr>
<td>int2</td>
<td>short</td>
</tr>
<tr>
<td>int4</td>
<td>int</td>
</tr>
<tr>
<td>int8</td>
<td>long</td>
</tr>
<tr>
<td>varchar</td>
<td>java.lang.String</td>
</tr>
<tr>
<td>text</td>
<td>java.lang.String</td>
</tr>
<tr>
<td>bytea</td>
<td>byte[ ]</td>
</tr>
<tr>
<td>date</td>
<td>java.sql.Date</td>
</tr>
<tr>
<td>time</td>
<td>java.sql.Time (stored value treated as local time)</td>
</tr>
<tr>
<td>timetz</td>
<td>java.sql.Time</td>
</tr>
<tr>
<td>timestamp</td>
<td>java.sql.Timestamp (stored value treated as local time)</td>
</tr>
<tr>
<td>timestamptz</td>
<td>java.sql.Timestamp</td>
</tr>
</tbody>
</table>
All other types are mapped to java.lang.String and will utilize the standard `textin/textout` routines registered for respective type.

### NULL Handling

The scalar types that map to Java primitives can not be passed as NULL values. To pass NULL values, those types can have an alternative mapping. You enable this mapping by explicitly denoting it in the method reference.

```sql
CREATE FUNCTION trueIfEvenOrNull(integer) RETURNS bool AS 'foo.fee.Fum.trueIfEvenOrNull(java.lang.Integer)' LANGUAGE java;
```

The Java code would be similar to this:

```java
package foo.fee;
public class Fum {
    static boolean trueIfEvenOrNull(Integer value) {
        return (value == null) ? true : (value.intValue() % 2) == 0;
    }
}
```

The following two statements both yield true:

```sql
SELECT trueIfEvenOrNull(NULL);
SELECT trueIfEvenOrNull(4);
```

In order to return NULL values from a Java method, you use the object type that corresponds to the primitive (for example, you return `java.lang.Integer` instead of `int`). The PL/Java resolve mechanism finds the method regardless. Since Java cannot have different return types for methods with the same name, this does not introduce any ambiguity.

### Complex Types

A complex type will always be passed as a read-only `java.sql.ResultSet` with exactly one row. The ResultSet is positioned on its row so a call to `next()` should not be made. The values of the complex type are retrieved using the standard getter methods of the ResultSet.

Example:

```sql
CREATE TYPE complexTest AS(base integer, incbase integer, ctime timestamptz);
CREATE FUNCTION useComplexTest(complexTest) RETURNS VARCHAR AS 'foo.fee.Fum.useComplexTest' IMmutable LANGUAGE java;
```
In the Java class `Fum`, we add the following static method:

```java
public static String useComplexTest(ResultSet complexTest) throws SQLException {
    int base = complexTest.getInt(1);
    int incbase = complexTest.getInt(2);
    Timestamp ctime = complexTest.getTimestamp(3);
    return "Base = \"" + base + ", incbase = \"" + incbase + ", ctime = \"" + ctime + \"";
}
```

### Returning Complex Types

Java does not stipulate any way to create a ResultSet. Hence, returning a ResultSet is not an option. The SQL-2003 draft suggests that a complex return value should be handled as an IN/OUT parameter. PL/Java implements a ResultSet that way. If you declare a function that returns a complex type, you will need to use a Java method with boolean return type with a last parameter of type `java.sql.ResultSet`. The parameter will be initialized to an empty updateable ResultSet that contains exactly one row.

Assume that the `complexTest` type in previous section has been created.

```sql
CREATE FUNCTION createComplexTest(int, int) RETURNS complexTest AS 'foo.fee.Fum.createComplexTest' IMMUTABLE LANGUAGE java;
```

The PL/Java method `resolve` will now find the following method in the `Fum` class:

```java
public static boolean complexReturn(int base, int increment, ResultSet receiver) throws SQLException {
    receiver.updateInt(1, base);
    receiver.updateInt(2, base + increment);
    receiver.updateTimestamp(3, new Timestamp(System.currentTimeMillis()));
    return true;
}
```

The return value denotes if the receiver should be considered as a valid tuple (true) or NULL (false).

### Functions That Return Sets

When returning result set, you should not build a result set before returning it, because building a large result set would consume a large amount of resources. It is better to produce one row at a time. Incidentally, that is what the Greenplum Database backend expects a function with SETOF return to do. You can return a SETOF a scalar type such as an `int`, `float` or `varchar`, or you can return a SETOF a complex type.

### Returning a SETOF <scalar type>

In order to return a set of a scalar type, you need create a Java method that returns something that implements the `java.util.Iterator` interface. Here is an example of a method that returns a SETOF `varchar`:

```sql
CREATE FUNCTION javatest.getSystemProperties() RETURNS SETOF varchar AS 'foo.fee.Bar.getNames'
```
This simple Java method returns an iterator:

```java
package foo.fee;
import java.util.Iterator;
public class Bar {
    public static Iterator getNames() {
        ArrayList names = new ArrayList();
        names.add("Lisa");
        names.add("Bob");
        names.add("Bill");
        names.add("Sally");
        return names.iterator();
    }
}
```

Returning a SETOF <complex type>

A method returning a SETOF <complex type> must use either the interface `org.postgresql.pljava.ResultSetProvider` or `org.postgresql.pljava.ResultSetHandle`. The reason for having two interfaces is that they cater for optimal handling of two distinct use cases. The former is for cases when you want to dynamically create each row that is to be returned from the SETOF function. The latter makes is in cases where you want to return the result of an executed query.

**Using the ResultSetProvider Interface**

This interface has two methods. The boolean `assignRowValues(java.sql.ResultSet tupleBuilder, int rowNumber)` and the void `close()` method. The Greenplum Database query evaluator will call the `assignRowValues` repeatedly until it returns false or until the evaluator decides that it does not need any more rows. Then it calls close.

You can use this interface the following way:

```java
CREATE FUNCTION javatest.listComplexTests(int, int)
RETURNS SETOF complexTest
AS 'foo.fee.Fum.listComplexTest'
IMMUTABLE LANGUAGE java;
```

The function maps to a static java method that returns an instance that implements the `ResultSetProvider` interface.

```java
public class Fum implements ResultSetProvider {
    private final int m_base;
    private final int m_increment;
    public Fum(int base, int increment) {
        m_base = base;
        m_increment = increment;
    }
    public boolean assignRowValues(ResultSet receiver, int currentRow)
            throws SQLException {
        // Stop when we reach 12 rows.
        if(currentRow >= 12)
return false;
receiver.updateInt(1, m_base);
receiver.updateInt(2, m_base + m_increment * currentRow);
receiver.updateTimestamp(3, new
Timestamp(System.currentTimeMillis()));
return true;
}
public void close()
{
    // Nothing needed in this example
}
public static ResultSetProvider listComplexTests(int base,
int increment)
throws SQLException
{
    return new Fum(base, increment);
}

The listComplexTests method is called once. It may return NULL if no results are available or an
instance of the ResultSetProvider. Here the Java class Fum implements this interface so it returns an
instance of itself. The method assignRowValues will then be called repeatedly until it returns false. At
that time, close will be called.

Using the ResultSetHandle Interface

This interface is similar to the ResultSetProvider interface in that it has a close() method that will
be called at the end. But instead of having the evaluator call a method that builds one row at a time, this
method has a method that returns a ResultSet. The query evaluator will iterate over this set and deliver the
ResultSet contents, one tuple at a time, to the caller until a call to next() returns false or the evaluator
decides that no more rows are needed.

Here is an example that executes a query using a statement that it obtained using the default connection.
The SQL suitable for the deployment descriptor looks like this:

CREATE FUNCTION javatest.listSupers()
RETURNS SETOF pg_user
AS 'org.postgresql.pljava.example.Users.listSupers'
LANGUAGE java;
CREATE FUNCTION javatest.listNonSupers()
RETURNS SETOF pg_user
AS 'org.postgresql.pljava.example.Users.listNonSupers'
LANGUAGE java;

And in the Java package org.postgresql.pljava.example a class Users is added:

public class Users implements ResultSetHandle
{
    private final String m_filter;
    private Statement m_statement;
    public Users(String filter)
    {
        m_filter = filter;
    }
    public ResultSet getResultSet()
    throws SQLException
    {
        m_statement =
        DriverManager.getConnection("jdbc:default:connection").cre
eateStatement();
        return m_statement.executeQuery("SELECT * FROM pg_user
WHERE " + m_filter);
Using JDBC

PL/Java contains a JDBC driver that maps to the PostgreSQL SPI functions. A connection that maps to the current transaction can be obtained using the following statement:

```java
Connection conn =
    DriverManager.getConnection("jdbc:default:connection");
```

After obtaining a connection, you can prepare and execute statements similar to other JDBC connections. These are limitations for the PL/Java JDBC driver:

- The transaction cannot be managed in any way. Thus, you cannot use methods on the connection such as:
  - `commit()`
  - `rollback()`
  - `setAutoCommit()`
  - `setTransactionIsolation()`
- Savepoints are available with some restrictions. A savepoint cannot outlive the function in which it was set and it must be rolled back or released by that same function.
- A `ResultSet` returned from `executeQuery()` are always `FETCH_FORWARD` and `CONCUR_READ_ONLY`.
- Meta-data is only available in PL/Java 1.1 or higher.
- `CallableStatement` (for stored procedures) is not implemented.
- The types `Clob` or `Blob` are not completely implemented, they need more work. The types `byte[]` and `String` can be used for `bytea` and `text` respectively.

Exception Handling

You can catch and handle an exception in the Greenplum Database backend just like any other exception. The backend `ErrorData` structure is exposed as a property in a class called `org.postgresql.pljava.ServerException` (derived from `java.sql.SQLException`) and the Java try/catch mechanism is synchronized with the backend mechanism.

**Important:** You will not be able to continue executing backend functions until your function has returned and the error has been propagated when the backend has generated an exception unless you have used a savepoint. When a savepoint is rolled back, the exceptional condition is reset and you can continue your execution.
Savepoints

Greenplum Database savepoints are exposed using the java.sql.Connection interface. Two restrictions apply.

- A savepoint must be rolled back or released in the function where it was set.
- A savepoint must not outlive the function where it was set.

Logging

PL/Java uses the standard Java Logger. Hence, you can write things like:

```java
Logger.getAnonymousLogger().info( "Time is " + new Date(System.currentTimeMillis()));
```

At present, the logger uses a handler that maps the current state of the Greenplum Database configuration setting `log_min_messages` to a valid Logger level and that outputs all messages using the Greenplum Database backend function `elog()`.

**Note:** The `log_min_messages` setting is read from the database the first time a PL/Java function in a session is executed. On the Java side, the setting does not change after the first PL/Java function execution in a specific session until the Greenplum Database session that is working with PL/Java is restarted.

The following mapping apply between the Logger levels and the Greenplum Database backend levels.

**Table 248: PL/Java Logging Levels**

<table>
<thead>
<tr>
<th>java.util.logging.Level</th>
<th>Greenplum Database Level</th>
</tr>
</thead>
<tbody>
<tr>

</tbody>
</table>

Security

- Installation
- Trusted Language

Installation

Only a database superuser can install PL/Java. The PL/Java utility functions are installed using SECURITY DEFINER so that they execute with the access permissions that where granted to the creator of the functions.
Trusted Language

PL/Java is a trusted language. The trusted PL/Java language has no access to the file system as stipulated by PostgreSQL definition of a trusted language. Any database user can create and access functions in a trusted language.

PL/Java also installs a language handler for the language `javau`. This version is not trusted and only a superuser can create new functions that use it. Any user can call the functions.

Some PL/Java Issues and Solutions

When writing the PL/Java, mapping the JVM into the same process-space as the Greenplum Database backend code, some concerns have been raised regarding multiple threads, exception handling, and memory management. Here are brief descriptions explaining how these issues were resolved.

- Multi-threading
- Exception Handling
- Java Garbage Collector Versus `palloc()` and Stack Allocation

Multi-threading

Java is inherently multi-threaded. The Greenplum Database backend is not. There is nothing stopping a developer from utilizing multiple Threads class in the Java code. Finalizers that call out to the backend might have been spawned from a background Garbage Collection thread. Several third party Java-packages that are likely to be used make use of multiple threads. How can this model coexist with the Greenplum Database backend in the same process?

Solution

The solution is simple. PL/Java defines a special object called the `Backend.THREADLOCK`. When PL/Java is initialized, the backend immediately grabs this objects monitor (i.e. it will synchronize on this object). When the backend calls a Java function, the monitor is released and then immediately regained when the call returns. All calls from Java out to backend code are synchronized on the same lock. This ensures that only one thread at a time can call the backend from Java, and only at a time when the backend is awaiting the return of a Java function call.

Exception Handling

Java makes frequent use of try/catch/finally blocks. Greenplum Database sometimes use an exception mechanism that calls `longjmp` to transfer control to a known state. Such a jump would normally effectively bypass the JVM.

Solution

The backend now allows errors to be caught using the macros `PG_TRY/PG_CATCH/PG_END_TRY` and in the catch block, the error can be examined using the `ErrorData` structure. PL/Java implements a `java.sql.SQLException` subclass called `org.postgresql.pljava.ServerException`. The `ErrorData` can be retrieved and examined from that exception. A catch handler is allowed to issue a rollback to a savepoint. After a successful rollback, execution can continue.

Java Garbage Collector Versus `palloc()` and Stack Allocation

Primitive types are always be passed by value. This includes the `String` type (this is a must since Java uses double byte characters). Complex types are often wrapped in Java objects and passed by reference. For example, a Java object can contain a pointer to a `palloc`ed or stack allocated memory and use native JNI calls to extract and manipulate data. Such data will become stale once a call has ended. Further
attempts to access such data will at best give very unpredictable results but more likely cause a memory fault and a crash.

**Solution**

The PL/Java contains code that ensures that stale pointers are cleared when the MemoryContext or stack where they were allocated goes out of scope. The Java wrapper objects might live on but any attempt to use them will result in a stale native handle exception.

**Example**

The following simple Java example creates a JAR file that contains a single method and runs the method.

**Note:** The example requires Java SDK to compile the Java file.

The following method returns a substring.

```java
{ 
    public static String substring(String text, int beginIndex, 
    int endIndex) 
    { 
        return text.substring(beginIndex, endIndex); 
    } 
}
```

Enter the java code in a text file `example.class`.

Contents of the file `manifest.txt`:

```plaintext
Manifest-Version: 1.0
Main-Class: Example
Specification-Title: "Example"
Specification-Version: "1.0"
Created-By: 1.6.0_35-b10-428-11M3811
Build-Date: 01/20/2013 10:09 AM
```

Compile the java code:

```bash
javac *.java
```

Create a JAR archive named `analytics.jar` that contains the class file and the manifest file MANIFEST file in the JAR.

```bash
jar cfm analytics.jar manifest.txt *.class
```

Upload the jar file to the Greenplum master host.

Run the `gpscp` utility to copy the jar file to the Greenplum Java directory. Use the `-f` option to specify the file that contains a list of the master and segment hosts.

```bash
gpscp -f gphosts_file analytics.jar 
=:/usr/local/greenplum-db/lib/postgresql/java/
```

Use the `gpconfig` utility to set the Greenplum `pljava_classpath` server configuration parameter. The parameter lists the installed jar files.

```bash
gpconfig -c pljava_classpath -v 'analytics.jar'
```
Run the `gpstop` utility with the `-u` option to reload the configuration files.

```
gpstop -u
```

From the `psql` command line, run the following command to show the installed jar files.

```
show pljava_classpath
```

The following SQL commands create a table and define a Java function to test the method in the jar file:

```sql
create table temp (a varchar) distributed randomly;
insert into temp values ('my string');
create or replace function java_substring(varchar, int, int)
returns varchar as 'Example.substring' language java;
select java_substring(a, 1, 5) from temp;
```

You can place the contents in a file, `mysample.sql` and run the command from a `psql` command line:

```
> \i mysample.sql
```

The output is similar to this:

```
java_substring
----------------
y st
(1 row)
```

Greenplum PL/Perl Language Extension

This chapter includes the following information:

• About Greenplum PL/Perl
• Greenplum Database PL/Perl Limitations
• Trusted/Untrusted Language
• Developing Functions with PL/Perl

About Greenplum PL/Perl

With the Greenplum Database PL/Perl extension, you can write user-defined functions in Perl that take advantage of its advanced string manipulation operators and functions. PL/Perl provides both trusted and untrusted variants of the language.

PL/Perl is embedded in your Greenplum Database distribution. Greenplum Database PL/Perl requires Perl to be installed on the system of each database host.

Refer to the PostgreSQL PL/Perl documentation for additional information.

Greenplum Database PL/Perl Limitations

Limitations of the Greenplum Database PL/Perl language include:

• Greenplum Database does not support PL/Perl triggers.
• PL/Perl functions cannot call each other directly.
• SPI is not yet fully implemented.
• If you fetch very large data sets using spi_exec_query(), you should be aware that these will all go into memory. You can avoid this problem by using spi_query()/spi_fetchrow(). A similar problem occurs if a set-returning function passes a large set of rows back to Greenplum Database via a return statement. Use return_next for each row returned to avoid this problem.
• When a session ends normally, not due to a fatal error, PL/Perl executes any END blocks that you have defined. No other actions are currently performed. (File handles are not automatically flushed and objects are not automatically destroyed.)

Trusted/Untrusted Language

PL/Perl includes trusted and untrusted language variants.

The PL/Perl trusted language is named plperl. The trusted PL/Perl language restricts file system operations, as well as require, use, and other statements that could potentially interact with the operating system or database server process. With these restrictions in place, any Greenplum Database user can create and execute functions in the trusted plperl language.

The PL/Perl untrusted language is named plperlu. You cannot restrict the operation of functions you create with the plperlu untrusted language. Only database superusers have privileges to create untrusted PL/Perl user-defined functions. And only database superusers and other database users that are explicitly granted the permissions can execute untrusted PL/Perl user-defined functions.

PL/Perl has limitations with respect to communication between interpreters and the number of interpreters running in a single process. Refer to the PostgreSQL Trusted and Untrusted PL/Perl documentation for additional information.
**Enabling and Removing PL/Perl Support**

You must register the PL/Perl language with a database before you can create and execute a PL/Perl user-defined function within that database. To remove PL/Perl support, you must explicitly remove the extension from each database in which it was registered. You must be a database superuser or owner to register or remove trusted languages in Greenplum databases.

**Note:** Only database superusers may register or remove support for the untrusted PL/Perl language plperlu.

Before you enable or remove PL/Perl support in a database, ensure that:

- Your Greenplum Database is running.
- You have sourced `greenplum_path.sh`.
- You have set the `$MASTER_DATA_DIRECTORY` and `$GPHOME` environment variables.

**Enabling PL/Perl Support**

For each database in which you want to enable PL/Perl, register the language using the SQL `CREATE EXTENSION` command. For example, run the following command as the `gpadmin` user to register the trusted PL/Perl language for the database named `testdb`:

```bash
$ psql -d testdb -c 'CREATE EXTENSION plperl;'
```

**Removing PL/Perl Support**

To remove support for PL/Perl from a database, run the SQL `DROP EXTENSION` command. For example, run the following command as the `gpadmin` user to remove support for the trusted PL/Perl language from the database named `testdb`:

```bash
$ psql -d testdb -c 'DROP EXTENSION plperl;'
```

The default command fails if any existing objects (such as functions) depend on the language. Specify the `CASCADE` option to also drop all dependent objects, including functions that you created with PL/Perl.

**Developing Functions with PL/Perl**

You define a PL/Perl function using the standard SQL `CREATE FUNCTION` syntax. The body of a PL/Perl user-defined function is ordinary Perl code. The PL/Perl interpreter wraps this code inside a Perl subroutine.

You can also create an anonymous code block with PL/Perl. An anonymous code block, called with the SQL `DO` command, receives no arguments, and whatever value it might return is discarded. Otherwise, a PL/Perl anonymous code block behaves just like a function. Only database superusers create an anonymous code block with the untrusted plperlu language.

The syntax of the `CREATE FUNCTION` command requires that you write the PL/Perl function body as a string constant. While it is more convenient to use dollar-quoting, you can choose to use escape string syntax (E'' ) provided that you double any single quote marks and backslashes used in the body of the function.

PL/Perl arguments and results are handled as they are in Perl. Arguments you pass in to a PL/Perl function are accessed via the @_ array. You return a result value with the `return` statement, or as the last expression evaluated in the function. A PL/Perl function cannot directly return a non-scalar type because you call it in a scalar context. You can return non-scalar types such as arrays, records, and sets in a PL/Perl function by returning a reference.
PL/Perl treats null argument values as "undefined". Adding the `STRICT` keyword to the `LANGUAGE` subclause instructs Greenplum Database to immediately return null when any of the input arguments are null. When created as `STRICT`, the function itself need not perform null checks.

The following PL/Perl function utilizes the `STRICT` keyword to return the greater of two integers, or null if any of the inputs are null:

```sql
CREATE FUNCTION perl_max (integer, integer) RETURNS integer AS $$
    if ($_[0] > $_[1]) { return $_[0]; }
    return $_[1];
$$ LANGUAGE plperl STRICT;

SELECT perl_max( 1, 3 );
perl_max
----------
    3
(1 row)

SELECT perl_max( 1, null );
perl_max
----------
       
(1 row)
```

PL/Perl considers anything in a function argument that is not a reference to be a string, the standard Greenplum Database external text representation. The argument values supplied to a PL/Perl function are simply the input arguments converted to text form (just as if they had been displayed by a `SELECT` statement). In cases where the function argument is not an ordinary numeric or text type, you must convert the Greenplum Database type to a form that is more usable by Perl. Conversely, the `return` and `return_next` statements accept any string that is an acceptable input format for the function's declared return type.

Refer to the PostgreSQL PL/Perl Functions and Arguments documentation for additional information, including composite type and result set manipulation.

**Built-in PL/Perl Functions**

PL/Perl includes built-in functions to access the database, including those to prepare and perform queries and manipulate query results. The language also includes utility functions for error logging and string manipulation.

The following example creates a simple table with an integer and a text column. It creates a PL/Perl user-defined function that takes an input string argument and invokes the `spi_exec_query()` built-in function to select all columns and rows of the table. The function returns all rows in the query results where the `v` column includes the function input string.

```sql
CREATE TABLE test (  
    i int,  
    v varchar
);
INSERT INTO test (i, v) VALUES (1, 'first line');
INSERT INTO test (i, v) VALUES (2, 'line2');
INSERT INTO test (i, v) VALUES (3, '3rd line');
INSERT INTO test (i, v) VALUES (4, 'different');

CREATE OR REPLACE FUNCTION return_match(varchar) RETURNS SETOF test AS $$
    # store the input argument
    $ss = $_[0];
```
# run the query
my $rv = spi_exec_query('select i, v from test;');

# retrieve the query status
my $status = $rv->{status};

# retrieve the number of rows returned in the query
my $nrows = $rv->{processed};

# loop through all rows, comparing column v value with input argument
foreach my $rn (0 .. $nrows - 1) {
    my $row = $rv->{rows}[$rn];
    my $textstr = $row->{v};
    if( index($textstr, $ss) != -1 ) {
        # match! return the row.
        return_next($row);
    }
}
return undef;

$$ LANGUAGE plperl;

SELECT return_match( 'iff' );

return_match
--------------
(4,different)
(1 row)

Refer to the PostgreSQL PL/Perl Built-in Functions documentation for a detailed discussion of available functions.

Global Values in PL/Perl

You can use the global hash map %_SHARED to share data, including code references, between PL/Perl function calls for the lifetime of the current session.

The following example uses %_SHARED to share data between the user-defined set_var() and get_var() PL/Perl functions:

CREATE OR REPLACE FUNCTION set_var(name text, val text) RETURNS text AS $$
if (%_SHARED{$_[0]} = $_[1]) {
    return 'ok';
} else {
    return "cannot set shared variable $_[0] to $_[1]";
}
$$ LANGUAGE plperl;

CREATE OR REPLACE FUNCTION get_var(name text) RETURNS text AS $$
return %_SHARED{$_[0]};
$$ LANGUAGE plperl;

SELECT set_var('key1', 'value1');
set_var
---------
ok
(1 row)

SELECT get_var('key1');
get_var
---------
value1
(1 row)
For security reasons, PL/Perl creates a separate Perl interpreter for each role. This prevents accidental or malicious interference by one user with the behavior of another user's PL/Perl functions. Each such interpreter retains its own value of the `%_SHARED` variable and other global state. Two PL/Perl functions share the same value of `%_SHARED` if and only if they are executed by the same SQL role.

There are situations where you must take explicit steps to ensure that PL/Perl functions can share data in `%_SHARED`. For example, if an application executes under multiple SQL roles (via `SECURITY DEFINER` functions, use of `SET ROLE`, etc.) in a single session, make sure that functions that need to communicate are owned by the same user, and mark these functions as `SECURITY DEFINER`.

**Notes**

Additional considerations when developing PL/Perl functions:

- PL/Perl internally utilizes the UTF-8 encoding. It converts any arguments provided in other encodings to UTF-8, and converts return values from UTF-8 back to the original encoding.
- Nesting named PL/Perl subroutines retains the same dangers as in Perl.
- Only the untrusted PL/Perl language variant supports module import. Use `plperlu` with care.
- Any module that you use in a `plperlu` function must be available from the same location on all Greenplum Database hosts.
Greenplum MADlib Extension for Analytics

This chapter includes the following information:

• About MADlib
• About Deep Learning
• Installing MADlib
• Upgrading MADlib
• Uninstalling MADlib
• Examples
• References

About MADlib

MADlib is an open-source library for scalable in-database analytics. With the Greenplum Database MADlib extension, you can use MADlib functionality in a Greenplum Database.

MADlib provides data-parallel implementations of mathematical, statistical and machine-learning methods for structured and unstructured data. It provides an suite of SQL-based algorithms for machine learning, data mining and statistics that run at scale within a database engine, with no need for transferring data between Greenplum Database and other tools.

MADlib requires the m4 macro processor version 1.4.13 or later.

MADlib can be used with PivotalR, an R package that enables users to interact with data resident in Greenplum Database using the R client. See About MADlib, R, and PivotalR.

About Deep Learning

Deep learning is a type of machine learning, originally inspired by biology of the brain, that uses a class of algorithms called artificial neural networks. Given the important use cases that can be effectively addressed with deep learning, it is starting to become a more important part of enterprise computing.

Deep learning support for Keras and TensorFlow was added to Apache MADlib starting with the 1.16 release. Refer to the following documents for more information about deep learning on Greenplum using Apache MADlib:

• MADlib user documentation
• Supported libraries and configuration instructions

Installing MADlib

To install MADlib on Greenplum Database, you first install a compatible Greenplum MADlib package and then install the MADlib function libraries on all databases that will use MADlib.

The gppkg utility installs Greenplum Database extensions, along with any dependencies, on all hosts across a cluster. It also automatically installs extensions on new hosts in the case of system expansion segment recovery.

Installing the Greenplum Database MADlib Package

Before you install the MADlib package, make sure that your Greenplum database is running, you have sourced greenplum_path.sh, and that the $MASTER_DATA_DIRECTORY and $GPHOME variables are set.

1. Download the MADlib extension package from Pivotal Network.
2. Copy the MADlib package to the Greenplum Database master host.
3. Unpack the MADlib distribution package. For example:

```
$ tar xzvf madlib-1.17.0-gp5-rhel7-x86_64.tar.gz
```

4. Install the software package by running the `gppkg` command. For example:

```
$ gppkg -i ./madlib-1.17.0-gp5-rhel7-x86_64/madlib-1.17.0-gp5-rhel7-x86_64.gppkg
```

### Adding MADlib Functions to a Database

After installing the MADlib package, run the `madpack` command to add MADlib functions to Greenplum Database. Madpack is in `$GPHOME/madlib/bin`.

```
$ madpack [-s schema_name] -p greenplum -c user@host:port/database install
```

For example, this command creates MADlib functions in the `testdb` database running on server `mdw` on port `5432`. The `madpack` command logs in as the user `gpadmin` and prompts for password. The target schema is `madlib`.

```
$ madpack -s madlib -p greenplum -c gpadmin@mdw:5432/testdb install
```

After installing the functions, the Greenplum Database `gpadmin` superuser role should grant all privileges on the target schema (in the example `madlib`) to users who will be accessing MADlib functions. Users without access to the functions will get the error `ERROR: permission denied for schema MADlib`.

The `madpack install-check` option runs test using Madlib modules to check the MADlib installation:

```
$ madpack -s madlib -p greenplum -c gpadmin@mdw:5432/testdb install-check
```

**Note:** The command `madpack -h` displays information for the utility.

### Upgrading MADlib

You upgrade an installed MADlib package with the Greenplum Database `gppkg` utility and the MADlib `madpack` command.

For information about the upgrade paths that MADlib supports, see the MADlib support and upgrade matrix in the [MADlib FAQ page](#).

### Upgrading a MADlib Package

To upgrade MADlib, run the `gppkg` utility with the `-u` option. This command upgrades an installed MADlib package to MADlib 1.17.

```
$ gppkg -u madlib-1.17.0-gp5-rhel7-x86_64.gppkg
```

**Note:** Upgrading from MADlib version 1.15 using `gppkg -U` does not work because of a change in the post-uninstall script that was introduced in version 1.15.1. If you are upgrading from MADlib version 1.15 to version 1.15.1 or newer, follow these steps:

1. Remove the existing MADlib version 1.15 rpm (this does not affect the Greenplum Database installation):

```
gppkg -r madlib-1.15.0
```
2. Manually remove the remaining MADlib files:
   ```bash
   rm -rf /usr/local/greenplum-db-5.13.0/madlib/Versions
   ```

3. Install the newer MADlib version. For example:
   ```bash
   $ gppkg -i ./madlib-1.17.0-gp5-rhel7-x86_64.gppkg
   ```

4. Upgrade the MADlib functions in each database. For example:
   ```bash
   madpack -p greenplum -c gpadmin@mdw:5432/testdb upgrade
   ```

### Upgrading MADlib Functions

After you upgrade the MADlib package, you run the `madpack upgrade` command to upgrade the MADlib functions in Greenplum Database.

**Note:** The upgrade to MADlib 1.13 has a minor issue with some leftover `knn` functions.

Before running the `madpack` command to upgrade to MADlib 1.13, run these `psql` commands as the `gpadmin` user to drop the leftover functions from the databases where MADlib is installed.

```bash
psql db_name -c "DROP FUNCTION IF EXISTS schema.knn(VARCHAR);"
psql db_name -c "DROP FUNCTION IF EXISTS schema.knn();"
```

`db_name` is the name of the database. `schema` is the name of the MADlib schema.

See the *MADlib Installation Guide*.

The `madpack upgrade` command upgrades the MADlib functions in the database schema. This example command upgrades the MADlib functions in the schema `madlib` of the Greenplum Database `test`.

```bash
madpack -s madlib -p greenplum -c gpadmin@mdw:5432/testdb upgrade
``` 

### Uninstalling MADlib

- **Remove MADlib objects from the database**
- **Uninstall the Greenplum Database MADlib Package**

When you remove MADlib support from a database, routines that you created in the database that use MADlib functionality will no longer work.

#### Remove MADlib objects from the database

Use the `madpack uninstall` command to remove MADlib objects from a database. For example, this command removes MADlib objects from the database `testdb`.

```bash
$ madpack -s madlib -p greenplum -c gpadmin@mdw:5432/testdb uninstall
```

#### Uninstall the Greenplum Database MADlib Package

If no databases use the MADlib functions, use the Greenplum `gppkg` utility with the `-r` option to uninstall the MADlib package. When removing the package you must specify the package and version. This example uninstalls MADlib package version 1.17.

```bash
$ gppkg -r madlib-1.17.0-gp5-rhel7-x86_64
```

You can run the `gppkg` utility with the options `-q --all` to list the installed extensions and their versions.
After you uninstall the package, restart the database.

$ gpstop -r

**Examples**

Following are examples using the Greenplum MADlib extension:

- *Linear Regression*
- *Association Rules*
- *Naive Bayes Classification*

See the MADlib documentation for additional examples.

**Linear Regression**

This example runs a linear regression on the table `regr_example`. The dependent variable data are in the `y` column and the independent variable data are in the `x1` and `x2` columns.

The following statements create the `regr_example` table and load some sample data:

```sql
DROP TABLE IF EXISTS regr_example;
CREATE TABLE regr_example (
    id int,
    y int,
    x1 int,
    x2 int
);
INSERT INTO regr_example VALUES
    (1, 5, 2, 3),
    (2, 10, 7, 2),
    (3, 6, 4, 1),
    (4, 8, 3, 4);
```

The MADlib `linregr_train()` function produces a regression model from an input table containing training data. The following `SELECT` statement runs a simple multivariate regression on the `regr_example` table and saves the model in the `regr_example_model` table.

```sql
SELECT madlib.linregr_train (  
    'regr_example', -- source table  
    'regr_example_model', -- output model table  
    'y', -- dependent variable  
    'ARRAY[1, x1, x2]' -- independent variables  
);  
```

The `madlib.linregr_train()` function can have additional arguments to set grouping columns and to calculate the heteroskedasticity of the model.

**Note:** The intercept is computed by setting one of the independent variables to a constant 1, as shown in the preceding example.

Running this query against the `regr_example` table creates the `regr_example_model` table with one row of data:

```sql
SELECT * FROM regr_example_model;
- [ RECORD 1 ]-----------------+------------------------
| coef                     |{0.1111111111111127,1.14814814814815,0.1851851851852}  
| r2                       |0.9686126804771118  
| std_err                  |
| (1.49587911309236,0.207043331249903,0.346449758034495)  
```
The model saved in the **regr_example_model** table can be used with the MADlib linear regression prediction function, `madlib.linregr_predict()`, to view the residuals:

```
SELECT regr_example.*,
    madlib.linregr_predict ( ARRAY[1, x1, x2], m.coef ) as predict,
    y - madlib.linregr_predict ( ARRAY[1, x1, x2], m.coef ) as residual
FROM regr_example, regr_example_model m;
```

```
id | y  | x1 | x2 | predict | residual
----+----+----+----+---------+----------
 1  |  5 |  2 |  3 | 5.46296296296297 | -0.462962962962971
 3  |  6 |  4 |  1 | 5.722222222222224 | 0.277777777777762
 2  | 10 |  7 |  2 | 10.1851851851852 | -0.185185185185201
 4  |  8 |  3 |  4 | 7.62962962962964 | 0.370370370370364
```

**Association Rules**

This example demonstrates the association rules data mining technique on a transactional data set. Association rule mining is a technique for discovering relationships between variables in a large data set. This example considers items in a store that are commonly purchased together. In addition to market basket analysis, association rules are also used in bioinformatics, web analytics, and other fields.

The example analyzes purchase information for seven transactions that are stored in a table with the MADlib function `MADlib.assoc_rules`. The function assumes that the data is stored in two columns with a single item and transaction ID per row. Transactions with multiple items consist of multiple rows with one row per item.

These commands create the table.

```
DROP TABLE IF EXISTS test_data;
CREATE TABLE test_data (  
    trans_id INT,
    product text
);
```

This **INSERT** command adds the data to the table.

```
INSERT INTO test_data VALUES
(1, 'beer'),
(1, 'diapers'),
(1, 'chips'),
(2, 'beer'),
(2, 'diapers'),
(3, 'beer'),
(3, 'diapers'),
(4, 'beer'),
(4, 'chips'),
```

The model saved in the **regr_example_model** table can be used with the MADlib linear regression prediction function, `madlib.linregr_predict()`, to view the residuals:
The MADlib function `madlib.assoc_rules()` analyzes the data and determines association rules with the following characteristics.

- A support value of at least .40. Support is the ratio of transactions that contain X to all transactions.
- A confidence value of at least .75. Confidence is the ratio of transactions that contain X to transactions that contain Y. One could view this metric as the conditional probability of X given Y.

This `SELECT` command determines association rules, creates the table `assoc_rules`, and adds the statistics to the table.

```sql
SELECT * FROM madlib.assoc_rules (.40, -- support .75, -- confidence 'trans_id', -- transaction column 'product', -- product purchased column 'test_data', -- table name 'public', -- schema name false); -- display processing details
```

This is the output of the `SELECT` command. There are two rules that fit the characteristics.

```
output_schema | output_table | total_rules | total_time
--------------+--------------+-------------+-----------------
public        | assoc_rules  | 2           | 00:00:01.153283
(1 row)
```

To view the association rules, you can run this `SELECT` command.

```sql
SELECT pre, post, support FROM assoc_rules
ORDER BY support DESC;
```

This is the output. The `pre` and `post` columns are the itemsets of left and right hand sides of the association rule respectively.

```
  pre    |  post  |      support
-----------+--------+-------------------
{diapers} | {beer} | 0.714285714285714
{chips}   | {beer} | 0.428571428571429
(2 rows)
```

Based on the data, beer and diapers are often purchased together. To increase sales, you might consider placing beer and diapers closer together on the shelves.

**Naive Bayes Classification**

Naive Bayes analysis predicts the likelihood of an outcome of a class variable, or category, based on one or more independent variables, or attributes. The class variable is a non-numeric categorial variable, a variable that can have one of a limited number of values or categories. The class variable is represented with integers, each integer representing a category. For example, if the category can be one of "true", "false", or "unknown," the values can be represented with the integers 1, 2, or 3.

The attributes can be of numeric types and non-numeric, categorical, types. The training function has two signatures – one for the case where all attributes are numeric and another for mixed numeric and
categorical types. Additional arguments for the latter identify the attributes that should be handled as numeric values. The attributes are submitted to the training function in an array.

The MADlib Naive Bayes training functions produce a features probabilities table and a class priors table, which can be used with the prediction function to provide the probability of a class for the set of attributes.

**Naive Bayes Example 1 - Simple All-numeric Attributes**

In the first example, the class variable is either 1 or 2 and there are three integer attributes.

1. The following commands create the input table and load sample data.

   ```sql
   DROP TABLE IF EXISTS class_example CASCADE;
   CREATE TABLE class_example (id int, class int, attributes int[]);
   INSERT INTO class_example VALUES
   (1, 1, '{1, 2, 3}'),
   (2, 1, '{1, 4, 3}'),
   (3, 2, '{0, 2, 2}'),
   (4, 1, '{1, 2, 1}'),
   (5, 2, '{1, 2, 2}'),
   (6, 2, '{0, 1, 3}');
   ```

   Actual data in production scenarios is more extensive than this example data and yields better results. Accuracy of classification improves significantly with larger training data sets.

2. Train the model with the `create_nb_prepared_data_tables()` function.

   ```sql
   SELECT * FROM madlib.create_nb_prepared_data_tables (
   'class_example', -- name of the training table
   'class',         -- name of the class (dependent) column
   'attributes',    -- name of the attributes column
   3,               -- the number of attributes
   'example_feature_probs', -- name for the feature probabilities output table
   'example_priors'  -- name for the class priors output table
   );
   ```

3. Create a table with data to classify using the model.

   ```sql
   DROP TABLE IF EXISTS class_example_topredict;
   CREATE TABLE class_example_topredict (id int, attributes int[]);
   INSERT INTO class_example_topredict VALUES
   (1, '{1, 3, 2}'),
   (2, '{4, 2, 2}'),
   (3, '{2, 1, 1}');
   ```

4. Create a classification view using the feature probabilities, class priors, and class_example_topredict tables.

   ```sql
   SELECT madlib.create_nb_probs_view (
   'example_feature_probs',  -- feature probabilities output table
   'example_priors',         -- class priors output table
   'class_example_topredict',-- table with data to classify
   'id',                     -- name of the key column
   'attributes',             -- name of the attributes column
   3,                        -- number of attributes
   'example_classified'      -- name of the view to create
   );
   ```

5. Display the classification results.

   ```sql
   SELECT * FROM example_classified;
   ```
Naive Bayes Example 2 – Weather and Outdoor Sports

This example calculates the probability that the user will play an outdoor sport, such as golf or tennis, based on weather conditions.

The table `weather_example` contains the example values.

The identification column for the table is `day`, an integer type.

The `play` column holds the dependent variable and has two classifications:

- 0 - No
- 1 - Yes

There are four attributes: outlook, temperature, humidity, and wind. These are categorical variables. The `MADlib create_nb_classify_view()` function expects the attributes to be provided as an array of `INTEGER`, `NUMERIC`, or `FLOAT8` values, so the attributes for this example are encoded with integers as follows:

- `outlook` may be sunny (1), overcast (2), or rain (3).
- `temperature` may be hot (1), mild (2), or cool (3).
- `humidity` may be high (1) or normal (2).
- `wind` may be strong (1) or weak (2).

The following table shows the training data, before encoding the variables.

<table>
<thead>
<tr>
<th>day</th>
<th>play</th>
<th>outlook</th>
<th>temperature</th>
<th>humidity</th>
<th>wind</th>
</tr>
</thead>
<tbody>
<tr>
<td>2</td>
<td>No</td>
<td>Sunny</td>
<td>Hot</td>
<td>High</td>
<td>Strong</td>
</tr>
<tr>
<td>4</td>
<td>Yes</td>
<td>Rain</td>
<td>Mild</td>
<td>High</td>
<td>Weak</td>
</tr>
<tr>
<td>6</td>
<td>No</td>
<td>Rain</td>
<td>Cool</td>
<td>Normal</td>
<td>Strong</td>
</tr>
<tr>
<td>8</td>
<td>No</td>
<td>Sunny</td>
<td>Mild</td>
<td>High</td>
<td>Weak</td>
</tr>
<tr>
<td>10</td>
<td>Yes</td>
<td>Rain</td>
<td>Mild</td>
<td>Normal</td>
<td>Weak</td>
</tr>
<tr>
<td>12</td>
<td>Yes</td>
<td>Overcast</td>
<td>Mild</td>
<td>High</td>
<td>Strong</td>
</tr>
<tr>
<td>14</td>
<td>No</td>
<td>Rain</td>
<td>Mild</td>
<td>High</td>
<td>Strong</td>
</tr>
<tr>
<td>1</td>
<td>No</td>
<td>Sunny</td>
<td>Hot</td>
<td>High</td>
<td>Weak</td>
</tr>
<tr>
<td>3</td>
<td>Yes</td>
<td>Overcast</td>
<td>Hot</td>
<td>High</td>
<td>Weak</td>
</tr>
<tr>
<td>5</td>
<td>Yes</td>
<td>Rain</td>
<td>Cool</td>
<td>Normal</td>
<td>Weak</td>
</tr>
<tr>
<td>7</td>
<td>Yes</td>
<td>Overcast</td>
<td>Cool</td>
<td>Normal</td>
<td>Strong</td>
</tr>
<tr>
<td>9</td>
<td>Yes</td>
<td>Sunny</td>
<td>Cool</td>
<td>Normal</td>
<td>Weak</td>
</tr>
<tr>
<td>11</td>
<td>Yes</td>
<td>Sunny</td>
<td>Mild</td>
<td>Normal</td>
<td>Strong</td>
</tr>
<tr>
<td>13</td>
<td>Yes</td>
<td>Overcast</td>
<td>Hot</td>
<td>Normal</td>
<td>Weak</td>
</tr>
</tbody>
</table>

(14 rows)

1. Create the training table.

```sql
DROP TABLE IF EXISTS weather_example;
CREATE TABLE weather_example (  
day int,
play int,
attrs int[]);
INSERT INTO weather_example VALUES  
( 2, 0, '{1,1,1,1}'), -- sunny, hot, high, strong
(4, 1, '(3,2,1,2)'), -- rain, mild, high, weak
(6, 0, '(3,3,2,1)'), -- rain, cool, normal, strong
(8, 0, '(1,2,1,2)'), -- sunny, mild, high, weak
(10, 1, '(3,2,2,2)'), -- rain, mild, normal, weak
(12, 1, '(2,2,1,1)'), -- etc.
(14, 0, '(3,2,1,1)'),
(1, 0, '(1,1,1,2)'),
(3, 1, '(2,1,2,1)'),
(5, 1, '(3,3,2,2)'),
(7, 1, '(2,3,2,1)'),
(9, 1, '(1,3,2,2)'),
(11, 1, '(1,2,1,1)'),
(13, 1, '(2,1,2,2');

2. Create the model from the training table.

```
SELECT madlib.create_nb_prepared_data_tables (  
  'weather_example',  -- training source table
  'play',             -- dependent class column
  'attrs',            -- attributes column
  4,                  -- number of attributes
  'weather_probs',    -- feature probabilities output table
  'weather_priors'    -- class priors
);
```

3. View the feature probabilities:

```
SELECT * FROM weather_probs;
```

```
class | attr | value | cnt | attr_cnt  
-------+------|-------+-----+----------  
0 | 1 | 2 | 6 | 2  
1 | 1 | 2 | 4 | 3  
0 | 1 | 1 | 3 | 3  
0 | 1 | 3 | 2 | 3  
0 | 3 | 1 | 4 | 2  
1 | 4 | 1 | 3 | 2  
1 | 2 | 3 | 3 | 3  
1 | 2 | 1 | 2 | 3  
0 | 2 | 2 | 2 | 3  
0 | 4 | 2 | 2 | 2  
0 | 3 | 2 | 1 | 2  
0 | 1 | 2 | 0 | 3  
1 | 1 | 1 | 2 | 3  
1 | 1 | 3 | 3 | 3  
1 | 3 | 1 | 3 | 2  
0 | 4 | 1 | 3 | 2  
0 | 2 | 3 | 1 | 3  
0 | 2 | 1 | 2 | 3  
1 | 2 | 2 | 4 | 3  
1 | 4 | 2 | 6 | 2  
```

(20 rows)

4. To classify a group of records with a model, first load the data into a table. In this example, the table `t1` has four rows to classify.

```
DROP TABLE IF EXISTS t1;
CREATE TABLE t1 (  
  id integer,
  attributes integer[]);
insert into t1 values  
(1, '{1, 2, 1, 1}'),
(2, '{3, 3, 2, 1}'),
(3, '{2, 1, 2, 2}');
```
5. Use the MADlib `create_nb_classify_view()` function to classify the rows in the table.

```sql
SELECT madlib.create_nb_classify_view (
    'weather_probs',      -- feature probabilities table
    'weather_priors',     -- classPriorsName
    't1',                 -- table containing values to classify
    'id',                 -- key column
    'attributes',         -- attributes column
    4,                    -- number of attributes
    't1_out'              -- output table name
);
```

The result is four rows, one for each record in the `t1` table.

```sql
SELECT * FROM t1_out ORDER BY key;

<table>
<thead>
<tr>
<th>key</th>
<th>nb_classification</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>{0}</td>
</tr>
<tr>
<td>2</td>
<td>{1}</td>
</tr>
<tr>
<td>3</td>
<td>{1}</td>
</tr>
<tr>
<td>4</td>
<td>{0}</td>
</tr>
</tbody>
</table>
```

References

MADlib documentation is at [http://madlib.apache.org/documentation.html](http://madlib.apache.org/documentation.html).

PivotalR is a first class R package that enables users to interact with data resident in Greenplum Database and MADLib using an R client.

About MADlib, R, and PivotalR

The R language is an open-source language that is used for statistical computing. PivotalR is an R package that enables users to interact with data resident in Greenplum Database using the R client. Using PivotalR requires that MADlib is installed on the Greenplum Database.

PivotalR allows R users to leverage the scalability and performance of in-database analytics without leaving the R command line. The computational work is executed in-database, while the end user benefits from the familiar R interface. Compared with respective native R functions, there is an increase in scalability and a decrease in running time. Furthermore, data movement, which can take hours for very large data sets, is eliminated with PivotalR.

Key features of the PivotalR package:

- Explore and manipulate data in the database with R syntax. SQL translation is performed by PivotalR.
- Use the familiar R syntax for predictive analytics algorithms, for example linear and logistic regression. PivotalR accesses the MADlib in-database analytics function calls.
- Comprehensive documentation package with examples in standard R format accessible from an R client.
- The PivotalR package also supports access to the MADlib functionality.

For information about PivotalR, including supported MADlib functionality, see [https://cwiki.apache.org/confluence/display/MADLIB/PivotalR](https://cwiki.apache.org/confluence/display/MADLIB/PivotalR).

The R package for PivotalR can be found at [https://cran.r-project.org/web/packages/PivotalR/index.html](https://cran.r-project.org/web/packages/PivotalR/index.html).
Greenplum Partner Connector API

With the Greenplum Partner Connector API (GPPC API), you can write portable Greenplum Database user-defined functions (UDFs) in the C and C++ programming languages. Functions that you develop with the GPPC API require no recompilation or modification to work with older or newer Greenplum Database versions.

Functions that you write to the GPPC API can be invoked using SQL in Greenplum Database. The API provides a set of functions and macros that you can use to issue SQL commands through the Server Programming Interface (SPI), manipulate simple and composite data type function arguments and return values, manage memory, and handle data.

You compile the C/C++ functions that you develop with the GPPC API into a shared library. The GPPC functions are available to Greenplum Database users after the shared library is installed in the Greenplum Database cluster and the GPPC functions are registered as SQL UDFs.

**Note:** The Greenplum Partner Connector is supported for Greenplum Database versions 4.3.5.0 and later.

This topic contains the following information:

- Using the GPPC API
  - Requirements
  - Header and Library Files
  - Data Types
  - Function Declaration, Arguments, and Results
  - Memory Handling
  - Working With Variable-Length Text Types
  - Error Reporting and Logging
  - SPI Functions
  - About Tuple Descriptors and Tuples
  - Set-Returning Functions
  - Table Functions
  - Limitations
  - Sample Code
  - Building a GPPC Shared Library with PGXS
  - Registering a GPPC Function with Greenplum Database
  - Packaging and Deployment Considerations
  - GPPC Text Function Example
  - GPPC Set-Returning Function Example

**Using the GPPC API**

The GPPC API shares some concepts with C language functions as defined by PostgreSQL. Refer to C-Language Functions in the PostgreSQL documentation for detailed information about developing C language functions.

The GPPC API is a wrapper that makes a C/C++ function SQL-invokable in Greenplum Database. This wrapper shields GPPC functions that you write from Greenplum Database library changes by normalizing table and data manipulation and SPI operations through functions and macros defined by the API.

The GPPC API includes functions and macros to:

- Operate on base and composite data types.
- Process function arguments and return values.
• Allocate and free memory.
• Log and report errors to the client.
• Issue SPI queries.
• Return a table or set of rows.
• Process tables as function input arguments.

Requirements
When you develop with the GPPC API:

• You must develop your code on a system with the same hardware and software architecture as that of your Greenplum Database hosts.
• You must write the GPPC function(s) in the C or C++ programming languages.
• The function code must use the GPPC API, data types, and macros.
• The function code must not use the PostgreSQL C-Language Function API, header files, functions, or macros.
• The function code must not #include the postgres.h header file or use PG_MODULE_MAGIC.
• You must use only the GPPC-wrapped memory functions to allocate and free memory. See Memory Handling.
• Symbol names in your object files must not conflict with each other nor with symbols defined in the Greenplum Database server. You must rename your functions or variables if you get error messages to this effect.

Header and Library Files
The GPPC header files and libraries are installed in $GPHOME:

• $GPHOME/include/gppc.h - the main GPPC header file
• $GPHOME/include/gppc_config.h - header file defining the GPPC version
• $GPHOME/lib/libgppc.[a, so, so.1, so.1.2] - GPPC archive and shared libraries

Data Types
The GPPC functions that you create will operate on data residing in Greenplum Database. The GPPC API includes data type definitions for equivalent Greenplum Database SQL data types. You must use these types in your GPPC functions.

The GPPC API defines a generic data type that you can use to represent any GPPC type. This data type is named GppcDatum, and is defined as follows:

```
typedef int64_t GppcDatum;
```

The following table identifies each GPPC data type and the SQL type to which it maps.

<table>
<thead>
<tr>
<th>SQL Type</th>
<th>GPPC Type</th>
<th>GPPC Oid for Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>boolean</td>
<td>GppcBool</td>
<td>GppcOidBool</td>
</tr>
<tr>
<td>char (single byte)</td>
<td>GppcChar</td>
<td>GppcOidChar</td>
</tr>
<tr>
<td>int2/smallint</td>
<td>GppcInt2</td>
<td>GppcOidInt2</td>
</tr>
<tr>
<td>int4/integer</td>
<td>GppcInt4</td>
<td>GppcOidInt4</td>
</tr>
<tr>
<td>int8/bigint</td>
<td>GppcInt8</td>
<td>GppcOidInt8</td>
</tr>
<tr>
<td>float4/real</td>
<td>GppcFloat4</td>
<td>GppcOidFloat4</td>
</tr>
<tr>
<td>float8/double</td>
<td>GppcFloat8</td>
<td>GppcOidFloat8</td>
</tr>
</tbody>
</table>
The GPPC API treats text, numeric, and timestamp data types specially, providing functions to operate on these types.

Example GPPC base data type declarations:

```c
GppcText       message;
GppcInt4       arg1;
GppcNumeric    total_sales;
```

The GPPC API defines functions to convert between the generic `GppcDatum` type and the GPPC specific types. For example, to convert from an integer to a datum:

```c
GppcInt4 num = 13;
GppcDatum num_dat = GppcInt4GetDatum(num);
```

**Composite Types**

A composite data type represents the structure of a row or record, and is comprised of a list of field names and their data types. This structure information is typically referred to as a tuple descriptor. An instance of a composite type is typically referred to as a tuple or row. A tuple does not have a fixed layout and can contain null fields.

The GPPC API provides an interface that you can use to define the structure of, to access, and to set tuples. You will use this interface when your GPPC function takes a table as an input argument or returns table or set of record types. Using tuples in table and set returning functions is covered later in this topic.

**Function Declaration, Arguments, and Results**

The GPPC API relies on macros to declare functions and to simplify the passing of function arguments and results. These macros include:

<table>
<thead>
<tr>
<th>Task</th>
<th>Macro Signature</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Task</td>
<td>Macro Signature</td>
<td>Description</td>
</tr>
<tr>
<td>-------------------------------------</td>
<td>------------------------------------------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Declare a function</td>
<td>GppcDatum function_name(GPPC_FUNCTION_ARGS)</td>
<td>Declare a GPPC function named function_name; every function must have this same signature.</td>
</tr>
<tr>
<td>Return the number of arguments</td>
<td>GPPC_NARGS()</td>
<td>Return the number of arguments passed to the function.</td>
</tr>
<tr>
<td>Fetch an argument</td>
<td>GPPC_GETARG_&lt;ARGTYPE&gt;(arg_num)</td>
<td>Fetch the value of argument number arg_num (starts at 0), where &lt;ARGTYPE&gt; identifies the data type of the argument. For example, GPPC_GETARG_FLOAT8(0).</td>
</tr>
<tr>
<td>Fetch and make a copy of a text-type argument</td>
<td>GPPC_GETARG_&lt;ARGTYPE&gt;_COPY(arg_num)</td>
<td>Fetch and make a copy of the value of argument number arg_num (starts at 0). &lt;ARGTYPE&gt; identifies the text type (text, varchar, bpchar, bytea). For example, GPPC_GETARG_BYTEA_COPY(1).</td>
</tr>
<tr>
<td>Determine if an argument is NULL</td>
<td>GPPC_ARGISNULL(arg_num)</td>
<td>Return whether or not argument number arg_num is NULL.</td>
</tr>
<tr>
<td>Return a result</td>
<td>GPPC_RETURN_&lt;ARGTYPE&gt;(return_num)</td>
<td>Return the value return_val, where &lt;ARGTYPE&gt; identifies the data type of the return value. For example, GPPC_RETURN_INT4(131).</td>
</tr>
</tbody>
</table>

When you define and implement your GPPC function, you must declare it with the GPPC API using the two declarations identified above. For example, to declare a GPPC function named `add_int4s()`:

```c
GPPC_FUNCTION_INFO(add_int4s);
GppcDatum add_int4s(GPPC_FUNCTION_ARGS);
GppcDatum add_int4s(GPPC_FUNCTION_ARGS)
{
    // code here
}
```

If the `add_int4s()` function takes two input arguments of type `int4`, you use the GPPC_GETARG_INT4(arg_num) macro to access the argument values. The argument index starts at 0. For example:

```c
GppcInt4 first_int = GPPC_GETARG_INT4(0);
GppcInt4 second_int = GPPC_GETARG_INT4(1);
```

If `add_int4s()` returns the sum of the two input arguments, you use the GPPC_RETURN_INT8(return_val) macro to return this sum. For example:

```c
GppcInt8 sum = first_int + second_int;
GPPC_RETURN_INT8(sum);
```

The complete GPPC function:

```c
GPPC_FUNCTION_INFO(add_int4s);
GppcDatum add_int4s(GPPC_FUNCTION_ARGS);
GppcDatum add_int4s(GPPC_FUNCTION_ARGS)
```
```
// get input arguments
GppcInt4    first_int = GPPC_GETARG_INT4(0);
GppcInt4    second_int = GPPC_GETARG_INT4(1);

// add the arguments
GppcInt8    sum = first_int + second_int;

// return the sum
GPPC_RETURN_INT8(sum);
```
Greenplum Database typically calls a SQL-invoked function in a per-tuple context that it creates and deletes every time the server backend processes a table row. Do not assume that memory allocated in the current memory context is available across multiple function calls.

**Working With Variable-Length Text Types**

The GPPC API supports the variable length text, varchar, blank padded, and byte array types. You must use the GPPC API-provided functions when you operate on these data types. Variable text manipulation functions provided in the GPPC API include those to allocate memory for, determine string length of, get string pointers for, and access these types:

<table>
<thead>
<tr>
<th>Function Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>GppcText GppcAllocText( size_t len )</td>
<td>Allocate len bytes of memory for the varying length type.</td>
</tr>
<tr>
<td>GppcVarChar GppcAllocVarChar( size_t len )</td>
<td></td>
</tr>
<tr>
<td>GppcBpChar GppcAllocBpChar( size_t len )</td>
<td></td>
</tr>
<tr>
<td>GppcBytea GppcAllocBytea( size_t len )</td>
<td></td>
</tr>
<tr>
<td>size_t GppcGetTextLength( GppcText s )</td>
<td>Return the number of bytes in the memory chunk.</td>
</tr>
<tr>
<td>size_t GppcGetVarCharLength( GppcVarChar s )</td>
<td></td>
</tr>
<tr>
<td>size_t GppcGetBpCharLength( GppcBpChar s )</td>
<td></td>
</tr>
<tr>
<td>size_t GppcGetByteaLength( GppcBytea b )</td>
<td></td>
</tr>
<tr>
<td>char *GppcGetTextPointer( GppcText s )</td>
<td>Return a string pointer to the head of the memory chunk. The string is not null-terminated.</td>
</tr>
<tr>
<td>char *GppcGetVarCharPointer( GppcVarChar s )</td>
<td></td>
</tr>
<tr>
<td>char *GppcGetBpCharPointer( GppcBpChar s )</td>
<td></td>
</tr>
<tr>
<td>char *GppcGetByteaPointer( GppcBytea b )</td>
<td></td>
</tr>
<tr>
<td>char *GppcTextGetCString( GppcText s )</td>
<td>Return a string pointer to the head of the memory chunk. The string is null-terminated.</td>
</tr>
<tr>
<td>char *GppcVarCharGetCString( GppcVarChar s )</td>
<td></td>
</tr>
<tr>
<td>char *GppcBpCharGetCString( GppcBpChar s )</td>
<td></td>
</tr>
<tr>
<td>GppcText *GppcCStringGetText( const char *s )</td>
<td>Build a varying-length type from a character string.</td>
</tr>
<tr>
<td>GppcVarChar *GppcCStringGetVarChar( const char *s )</td>
<td></td>
</tr>
<tr>
<td>GppcBpChar *GppcCStringGetBpChar( const char *s )</td>
<td></td>
</tr>
</tbody>
</table>

Memory returned by the GppcGet<VLEN_ARGTYPE>Pointer() functions may point to actual database content. Do not modify the memory content. The GPPC API provides functions to allocate memory for these types should you require it. After you allocate memory, you can use system functions such as memcpy() to set the data.

The following example manipulates text input arguments and allocates and sets result memory for a text string concatenation operation:

```c
GppcText first_textstr = GPPC_GETARG_TEXT(0);
GppcText second_textstr = GPPC_GETARG_TEXT(1);

// determine the size of the concatenated string and allocate
// text memory of this size
size_t arg0_len = GppcGetTextLength(first_textstr);
size_t arg1_len = GppcGetTextLength(second_textstr);
GppcText retstring = GppcAllocText(arg0_len + arg1_len);
```
Error Reporting and Logging

The GPPC API provides error reporting and logging functions. The API defines reporting levels equivalent to those in Greenplum Database:

```c
typedef enum GppcReportLevel
{
    GPPC_DEBUG1     = 10,
    GPPC_DEBUG2     = 11,
    GPPC_DEBUG3     = 12,
    GPPC_DEBUG4     = 13,
    GPPC_DEBUG      = 14,
    GPPC_LOG        = 15,
    GPPC_INFO       = 17,
    GPPC_NOTICE     = 18,
    GPPC_WARNING    = 19,
    GPPC_ERROR      = 20,
} GppcReportLevel;
```

(The Greenplum Database `client_min_messages` server configuration parameter governs the current client logging level. The `log_min_messages` configuration parameter governs the current log-to-logfile level.)

A GPPC report includes the report level, a report message, and an optional report callback function.

Reporting and handling functions provide by the GPPC API include:

<table>
<thead>
<tr>
<th>Function Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>GppcReport()</td>
<td>Format and print/log a string of the specified report level.</td>
</tr>
<tr>
<td>GppcInstallReportCallback()</td>
<td>Register/install a report callback function.</td>
</tr>
<tr>
<td>GppcUninstallReportCallback()</td>
<td>Uninstall a report callback function.</td>
</tr>
<tr>
<td>GppcGetReportLevel()</td>
<td>Retrieve the level from an error report.</td>
</tr>
<tr>
<td>GppcGetReportMessage()</td>
<td>Retrieve the message from an error report.</td>
</tr>
<tr>
<td>GppcCheckForInterrupts()</td>
<td>Error out if an interrupt is pending.</td>
</tr>
</tbody>
</table>

The `GppcReport()` function signature is:

```c
void GppcReport(GppcReportLevel elevel, const char *fmt, ...);
```

`GppcReport()` takes a format string input argument similar to `printf()`. The following example generates an error level report message that formats a GPPC text argument:

```c
GppcText  uname = GPPC_GETARG_TEXT(1);
GppcReport(GPPC_ERROR, "Unknown user name: %s", GppcTextGetCString(uname));
```

Refer to the GPPC example code for example report callback handlers.
SPI Functions

The Greenplum Database Server Programming Interface (SPI) provides writers of C/C++ functions the ability to run SQL commands within a GPPC function. For additional information on SPI functions, refer to Server Programming Interface in the PostgreSQL documentation.

The GPPC API exposes a subset of PostgreSQL SPI functions. This subset enables you to issue SPI queries and retrieve SPI result values in your GPPC function. The GPPC SPI wrapper functions are:

<table>
<thead>
<tr>
<th>SPI Function Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SPI_connect()</td>
<td>Connect to the Greenplum Database server programming interface.</td>
</tr>
<tr>
<td>SPI_finish()</td>
<td>Disconnect from the Greenplum Database server programming interface.</td>
</tr>
<tr>
<td>SPI_exec()</td>
<td>Execute a SQL statement, returning the number of rows.</td>
</tr>
<tr>
<td>SPI_getvalue()</td>
<td>Retrieve the value of a specific attribute by number from a SQL result as a character string.</td>
</tr>
<tr>
<td>SPI_getvalueByName()</td>
<td>Retrieve the value of a specific attribute by name from a SQL result as a character string.</td>
</tr>
</tbody>
</table>

When you create a GPPC function that accesses the server programming interface, your function should comply with the following flow:

```c
GppcSPIConnect();
GppcSPIExec(...)
// process the results - GppcSPIGetValue(...), GppcSPIGetDatum(...)  
GppcSPIFinish()
```

You use `GppcSPIExec()` to execute SQL statements in your GPPC function. When you call this function, you also identify the maximum number of rows to return. The function signature of `GppcSPIExec()` is:

```c
GppcSPIResult GppcSPIExec(const char *sql_statement, long rcount);
```

`GppcSPIExec()` returns a `GppcSPIResult` structure. This structure represents SPI result data. It includes a pointer to the data, information about the number of rows processed, a counter, and a result code. The GPPC API defines this structure as follows:

```c
typedef struct GppcSPIResultData
{
    struct GppcSPITupleTableData   *tuptable;
    uint32_t                       processed;
    uint32_t                       current;
    int                            rescode;
} GppcSPIResultData;
typedef GppcSPIResultData *GppcSPIResult;
```

You can set and use the `current` field in the `GppcSPIResult` structure to examine each row of the `tuptable` result data.
The following code excerpt uses the GPPC API to connect to SPI, execute a simple query, loop through query results, and finish processing:

```c
GppcSPIResult   result;
char            *attname = "id";
char            *query = "SELECT i, 'foo' || i AS val FROM generate_series(1, 10)i ORDER BY 1";
bool            isnull = true;

// connect to SPI
if( GppcSPIConnect() < 0 ) {
    GppcReport(GPPC_ERROR, "cannot connect to SPI");
}

// execute the query, returning all rows
result = GppcSPIExec(query, 0);

// process result
while( result->current < result->processed ) {
    // get the value of attname column as a datum, making a copy
    datum = GppcSPIGetDatumByName(result, attname, &isnull, true);

    // do something with value

    // move on to next row
    result->current++;
}

// complete processing
GppcSPIFinish();
```

About Tuple Descriptors and Tuples

A table or a set of records contains one or more tuples (rows). The structure of each attribute of a tuple is defined by a tuple descriptor. A tuple descriptor defines the following for each attribute in the tuple:

- attribute name
- object identifier of the attribute data type
- byte length of the attribute data type
- object identifier of the attribute modifier

The GPPC API defines an abstract type, `GppcTupleDesc`, to represent a tuple/row descriptor. The API also provides functions that you can use to create, access, and set tuple descriptors:

<table>
<thead>
<tr>
<th>Function Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>GppcCreateTemplateTupleDesc()</td>
<td>Create an empty tuple descriptor with a specified number of attributes.</td>
</tr>
<tr>
<td>GppcTupleDescInitEntry()</td>
<td>Add an attribute to the tuple descriptor at a specified position.</td>
</tr>
<tr>
<td>GppcTupleDescNattrs()</td>
<td>Fetch the number of attributes in the tuple descriptor.</td>
</tr>
<tr>
<td>GppcTupleDescAttrName()</td>
<td>Fetch the name of the attribute in a specific position (starts at 0) in the tuple descriptor.</td>
</tr>
<tr>
<td>GppcTupleDescAttrType()</td>
<td>Fetch the type object identifier of the attribute in a specific position (starts at 0) in the tuple descriptor.</td>
</tr>
<tr>
<td>GppcTupleDescAttrLen()</td>
<td>Fetch the type length of an attribute in a specific position (starts at 0) in the tuple descriptor.</td>
</tr>
</tbody>
</table>
Function Name | Description
---|---
GppcTupleDescAttrTypmod() | Fetch the type modifier object identifier of an attribute in a specific position (starts at 0) in the tuple descriptor.

To construct a tuple descriptor, you first create a template, and then fill in the descriptor fields for each attribute. The signatures for these functions are:

```c
GppcTupleDesc GppcCreateTemplateTupleDesc(int natts);
void GppcTupleDescInitEntry(GppcTupleDesc desc, uint16_t attno,
const char *attname, GppcOid typid, int32_t typmod);
```

In some cases, you may want to initialize a tuple descriptor entry from an attribute definition in an existing tuple. The following functions fetch the number of attributes in a tuple descriptor, as well as the definition of a specific attribute (by number) in the descriptor:

```c
int GppcTupleDescNattrs(GppcTupleDesc tupdesc);
const char *GppcTupleDescAttrName(GppcTupleDesc tupdesc, int16_t attno);
GppcOid GppcTupleDescAttrType(GppcTupleDesc tupdesc, int16_t attno);
int16_t GppcTupleDescAttrLen(GppcTupleDesc tupdesc, int16_t attno);
int32_t GppcTupleDescAttrTypmod(GppcTupleDesc tupdesc, int16_t attno);
```

The following example initializes a two attribute tuple descriptor. The first attribute is initialized with the definition of an attribute from a different descriptor, and the second attribute is initialized to a boolean type attribute:

```c
GppcTupleDesc       tdesc;
GppcTupleDesc       indesc = some_input_descriptor;

// initialize the tuple descriptor with 2 attributes
tdesc = GppcCreateTemplateTupleDesc(2);

// use third attribute from the input descriptor
GppcTupleDescInitEntry(tdesc, 1,
    GppcTupleDescAttrName(indesc, 2),
    GppcTupleDescAttrType(indesc, 2),
    GppcTupleDescAttrTypmod(indesc, 2));

// create the boolean attribute
GppcTupleDescInitEntry(tdesc, 2, "is_active", GppcOidBool, 0);
```

The GPPC API defines an abstract type, `GppcHeapTuple`, to represent a tuple/record/row. A tuple is defined by its tuple descriptor, the value for each tuple attribute, and an indicator of whether or not each value is NULL.

The GPPC API provides functions that you can use to set and access a tuple and its attributes:

<table>
<thead>
<tr>
<th>Function Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>GppcHeapFormTuple()</td>
<td>Form a tuple from an array of <code>GppcDatum</code>s.</td>
</tr>
<tr>
<td>GppcBuildHeapTupleDatum()</td>
<td>Form a <code>GppcDatum</code> tuple from an array of <code>GppcDatum</code>s.</td>
</tr>
<tr>
<td>GppcGetAttributeByName()</td>
<td>Fetch an attribute from the tuple by name.</td>
</tr>
<tr>
<td>GppcGetAttributeByNum()</td>
<td>Fetch an attribute from the tuple by number (starts at 1).</td>
</tr>
</tbody>
</table>
The signatures for the tuple-building GPPC functions are:

```c
GppcHeapTuple GppcHeapFormTuple(GppcTupleDesc tupdesc, GppcDatum *values, bool *nulls);
GppcDatum    GppcBuildHeapTupleDatum(GppcTupleDesc tupdesc, GppcDatum *values, bool *nulls);
```

The following code excerpt constructs a `GppcDatum` tuple from the tuple descriptor in the above code example, and from integer and boolean input arguments to a function:

```c
GppcDatum intarg = GPPC_GETARG_INT4(0);
GppcDatum boolarg = GPPC_GETARG_BOOL(1);
GppcDatum result, values[2];
bool nulls[2] = { false, false };

// construct the values array
values[0] = intarg;
values[1] = boolarg;
result = GppcBuildHeapTupleDatum( tdesc, values, nulls );
```

### Set-Returning Functions

Greenplum Database UDFs whose signatures include `RETURNS SETOF RECORD` or `RETURNS TABLE(...)` are set-returning functions.

The GPPC API provides support for returning sets (for example, multiple rows/tuples) from a GPPC function. Greenplum Database calls a set-returning function (SRF) once for each row or item. The function must save enough state to remember what it was doing and to return the next row on each call. Memory that you allocate in the SRF context must survive across multiple function calls.

The GPPC API provides macros and functions to help keep track of and set this context, and to allocate SRF memory. They include:

<table>
<thead>
<tr>
<th>Function/Macro Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>GPPC_SRF_RESULT_DESC()</td>
<td>Get the output row tuple descriptor for this SRF. The result tuple descriptor is determined by an output table definition or a DESCRIBE function.</td>
</tr>
<tr>
<td>GPPC_SRF_IS_FIRSTCALL()</td>
<td>Determine if this is the first call to the SRF.</td>
</tr>
<tr>
<td>GPPC_SRF_FIRSTCALL_INIT()</td>
<td>Initialize the SRF context.</td>
</tr>
<tr>
<td>GPPC_SRF_PERCALL_SETUP()</td>
<td>Restore the context on each call to the SRF.</td>
</tr>
<tr>
<td>GPPC_SRF_RETURN_NEXT()</td>
<td>Return a value from the SRF and continue processing.</td>
</tr>
<tr>
<td>GPPC_SRF_RETURN_DONE()</td>
<td>Signal that SRF processing is complete.</td>
</tr>
<tr>
<td>GppSRFAlloc()</td>
<td>Allocate memory in this SRF context.</td>
</tr>
<tr>
<td>GppSRFAlloc0()</td>
<td>Allocate memory in this SRF context and initialize it to zero.</td>
</tr>
<tr>
<td>GppSRFSave()</td>
<td>Save user state in this SRF context.</td>
</tr>
<tr>
<td>GppSRFRestore()</td>
<td>Restore user state in this SRF context.</td>
</tr>
</tbody>
</table>

The `GppcFuncCallContext` structure provides the context for an SRF. You create this context on the first call to your SRF. Your set-returning GPPC function must retrieve the function context on each invocation. For example:

```c
// set function context
```
The GPPC function must provide the context when it returns a tuple result or to indicate that processing is complete. For example:

GPPC_SRF_RETURN_NEXT(fctx, result_tuple);
// or
GPPC_SRF_RETURN_DONE(fctx);

Use a `DESCRIBE` function to define the output tuple descriptor of a function that uses the `RETURNS SETOF RECORD` clause. Use the `GPPC_SRF_RESULT_DESC()` macro to get the output tuple descriptor of a function that uses the `RETURNS TABLE( ... )` clause.

Refer to the [GPPC Set-Returning Function Example](#) for a set-returning function code and deployment example.

## Table Functions

The GPPC API provides the `GppcAnyTable` type to pass a table to a function as an input argument, or to return a table as a function result.

Table-related functions and macros provided in the GPPC API include:

<table>
<thead>
<tr>
<th>Function/Macro Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>GPPC_GETARG_ANYTABLE()</td>
<td>Fetch an anytable function argument.</td>
</tr>
<tr>
<td>GPPC_RETURN_ANYTABLE()</td>
<td>Return the table.</td>
</tr>
<tr>
<td>GppcAnyTableGetTupleDesc()</td>
<td>Fetch the tuple descriptor for the table.</td>
</tr>
<tr>
<td>GppcAnyTableGetNextTuple()</td>
<td>Fetch the next row in the table.</td>
</tr>
</tbody>
</table>

You can use the `GPPC_GETARG_ANYTABLE()` macro to retrieve a table input argument. When you have access to the table, you can examine the tuple descriptor for the table using the `GppcAnyTableGetTupleDesc()` function. The signature of this function is:

GppcTupleDesc GppcAnyTableGetTupleDesc(GppcAnyTable t);

For example, to retrieve the tuple descriptor of a table that is the first input argument to a function:

GppcAnyTable     intbl;
GppcTupleDesc    in_desc;

intbl = GPPC_GETARG_ANYTABLE(0);
in_desc = GppcAnyTableGetTupleDesc(intbl);

The `GppcAnyTableGetNextTuple()` function fetches the next row from the table. Similarly, to retrieve the next tuple from the table above:

GppcHeapTuple    ntuple;

ntuple = GppcAnyTableGetNextTuple(intbl);
Limitations

The GPPC API does not support the following operators with Greenplum Database version 5.0.x:

- integer || integer
- integer = text
- text < integer

Sample Code

The gppc test directory in the Greenplum Database github repository includes sample GPPC code:

- gppc_demo/ - sample code exercising GPPC SPI functions, error reporting, data type argument and return macros, set-returning functions, and encoding functions
- tabfunc_gppc_demo/ - sample code exercising GPPC table and set-returning functions

Building a GPPC Shared Library with PGXS

You compile functions that you write with the GPPC API into one or more shared libraries that the Greenplum Database server loads on demand.

You can use the PostgreSQL build extension infrastructure (PGXS) to build the source code for your GPPC functions against a Greenplum Database installation. This framework automates common build rules for simple modules. If you have a more complicated use case, you will need to write your own build system.

To use the PGXS infrastructure to generate a shared library for functions that you create with the GPPC API, create a simple Makefile that sets PGXS-specific variables.

Note: Refer to Extension Building Infrastructure in the PostgreSQL documentation for information about the Makefile variables supported by PGXS.

For example, the following Makefile generates a shared library named sharedlib_name.so from two C source files named src1.c and src2.c:

```makefile
MODULE_big = sharedlib_name
OBJS = src1.o src2.o
PG_CPPFLAGS = -I$(shell $(PG_CONFIG) --includedir)
SHLIB_LINK = -L$(shell $(PG_CONFIG) --libdir) -lgppc

PG_CONFIG = pg_config
PGXS := $(shell $(PG_CONFIG) --pgxs)
include $(PGXS)
```

The MODULE_big identifies the base name of the shared library generated by the Makefile.

PG_CPPFLAGS adds the Greenplum Database installation include directory to the compiler header file search path.

SHLIB_LINK adds the Greenplum Database installation library directory to the linker search path. This variable also adds the GPPC library (-lgppc) to the link command.

The PG_CONFIG and PGXS variable settings and the include statement are required and typically reside in the last three lines of the Makefile.

Registering a GPPC Function with Greenplum Database

Before users can invoke a GPPC function from SQL, you must register the function with Greenplum Database.
Registering a GPPC function involves mapping the GPPC function signature to a SQL user-defined function. You define this mapping with the `CREATE FUNCTION ... AS` command specifying the GPPC shared library name. You may choose to use the same name or differing names for the GPPC and SQL functions.

Sample `CREATE FUNCTION ... AS` syntax follows:

```
CREATE FUNCTION sql_function_name(arg[, ...]) RETURNS return_type
AS 'shared_library_path'[, 'gppc_function_name']
LANGUAGE C STRICT [WITH (DESCRIBE=describe_function)];
```

You may omit the shared library `.so` extension when you specify `shared_library_path`.

The following command registers the example `add_int4s()` function referenced earlier in this topic to a SQL UDF named `add_two_int4s_gppc()` if the GPPC function was compiled and linked in a shared library named `gppc_try.so`:

```
CREATE FUNCTION add_two_int4s_gppc(int4, int4) RETURNS int8
AS 'gppc_try.so', 'add_int4s'
LANGUAGE C STRICT;
```

### About Dynamic Loading

You specify the name of the GPPC shared library in the SQL `CREATE FUNCTION ... AS` command to register a GPPC function in the shared library with Greenplum Database. The Greenplum Database dynamic loader loads a GPPC shared library file into memory the first time that a user invokes a user-defined function linked in that shared library. If you do not provide an absolute path to the shared library in the `CREATE FUNCTION ... AS` command, Greenplum Database attempts to locate the library using these ordered steps:

1. If the shared library file path begins with the string `$libdir`, Greenplum Database looks for the file in the PostgreSQL package library directory. Run the `pg_config --pkglibdir` command to determine the location of this directory.
2. If the shared library file name is specified without a directory prefix, Greenplum Database searches for the file in the directory identified by the `dynamic_library_path` server configuration parameter value.
3. The current working directory.

### Packaging and Deployment Considerations

You must package the GPPC shared library and SQL function registration script in a form suitable for deployment by the Greenplum Database administrator in the Greenplum cluster. Provide specific deployment instructions for your GPPC package.

When you construct the package and deployment instructions, take into account the following:

- Consider providing a shell script or program that the Greenplum Database administrator runs to both install the shared library to the desired file system location and register the GPPC functions.
- The GPPC shared library must be installed to the same file system location on the master host and on every segment host in the Greenplum Database cluster.
- The `gpadmin` user must have permission to traverse the complete file system path to the GPPC shared library file.
- The file system location of your GPPC shared library after it is installed in the Greenplum Database deployment determines how you reference the shared library when you register a function in the library with the `CREATE FUNCTION ... AS` command.
- Create a `.sql` script file that registers a SQL UDF for each GPPC function in your GPPC shared library. The functions that you create in the `.sql` registration script must reference the deployment location of the GPPC shared library. Include this script in your GPPC deployment package.
• Document the instructions for running your GPPC package deployment script, if you provide one.
• Document the instructions for installing the GPPC shared library if you do not include this task in a package deployment script.
• Document the instructions for installing and running the function registration script if you do not include this task in a package deployment script.

**GPPC Text Function Example**

In this example, you develop, build, and deploy a GPPC shared library and register and run a GPPC function named `concat_two_strings`. This function uses the GPPC API to concatenate two string arguments and return the result.

You will develop the GPPC function on your Greenplum Database master host. Deploying the GPPC shared library that you create in this example requires administrative access to your Greenplum Database cluster.

Perform the following procedure to run the example:

1. Log in to the Greenplum Database master host and set up your environment. For example:

   ```
   $ ssh gpadmin@<gpmaster>
   gpadmin@gpmaster$ . /usr/local/greenplum-db/greenplum_path.sh
   ```

2. Create a work directory and navigate to the new directory. For example:

   ```
   gpadmin@gpmaster$ mkdir gppc_work
   gpadmin@gpmaster$ cd gppc_work
   ```

3. Prepare a file for GPPC source code by opening the file in the editor of your choice. For example, to open a file named `gppc_concat.c` using `vi`:

   ```
   gpadmin@gpmaster$ vi gppc_concat.c
   ```

4. Copy/paste the following code into the file:

   ```c
   #include <stdio.h>
   #include <string.h>
   #include "gppc.h"

   // make the function SQL-invokable
   GPPC_FUNCTION_INFO(concat_two_strings);

   // declare the function
   GppcDatum concat_two_strings(GPPC_FUNCTION_ARGS);

   GppcDatum concat_two_strings(GPPC_FUNCTION_ARGS)
   {
     // retrieve the text input arguments
     GppcText arg0 = GPPC_GETARG_TEXT(0);
     GppcText arg1 = GPPC_GETARG_TEXT(1);

     // determine the size of the concatenated string and allocate
     // text memory of this size
     size_t arg0_len = GppcGetTextLength(arg0);
     size_t arg1_len = GppcGetTextLength(arg1);
     GppcText retstring = GppcAllocText(arg0_len + arg1_len);

     // construct the concatenated return string
     memcpy(GppcGetTextPointer(retstring), GppcGetTextPointer(arg0),
     arg0_len);
   }
   ```
memcpy(GppcGetTextPointer(retstring) + arg0_len,
         GppcGetTextPointer(arg1), arg1_len);

GPPC_RETURN_TEXT( retstring );
}

The code declares and implements the `concat_two_strings()` function. It uses GPPC data types, macros, and functions to get the function arguments, allocate memory for the concatenated string, copy the arguments into the new string, and return the result.

5. Save the file and exit the editor.

6. Open a file named `Makefile` in the editor of your choice. Copy/paste the following text into the file:

```plaintext
MODULE_big = gppc_concat
OBJS = gppc_concat.o

PG_CONFIG = pg_config
PGXS := $(shell $(PG_CONFIG) --pgxs)

PG_CPPFLAGS = -I$(shell $(PG_CONFIG) --includedir)
SHLIB_LINK = -L$(shell $(PG_CONFIG) --libdir) -lgppc
include $(PGXS)
```

7. Save the file and exit the editor.

8. Build a GPPC shared library for the `concat_two_strings()` function. For example:

```
gpadmin@gpmaster$ make all
```

The `make` command generates a shared library file named `gppc_concat.so` in the current working directory.

9. Copy the shared library to your Greenplum Database installation. You must have Greenplum Database administrative privileges to copy the file. For example:

```
gpadmin@gpmaster$ cp gppc_concat.so /usr/local/greenplum-db/lib/postgresql/
```

10. Copy the shared library to every host in your Greenplum Database installation. For example, if `seghostfile` contains a list, one-host-per-line, of the segment hosts in your Greenplum Database cluster:

```
gpadmin@gpmaster$ gpscp -v -f seghostfile /usr/local/greenplum-db/lib/postgresql/gppc_concat.so =:/usr/local/greenplum-db/lib/postgresql/gppc_concat.so
```

11. Open a `psql` session. For example:

```
gpadmin@gpmaster$ psql -d testdb
```

12. Register the GPPC function named `concat_two_strings()` with Greenplum Database. For example, to map the Greenplum Database function `concat_with_gppc()` to the GPPC `concat_two_strings()` function:

```
testdb=# CREATE FUNCTION concat_with_gppc(text, text) RETURNS text
       AS 'gppc_concat', 'concat_two_strings'
       LANGUAGE C STRICT;
```

13. Run the `concat_with_gppc()` function. For example:

```
testdb=# SELECT concat_with_gppc( 'happy', 'monday' );
concat_with_gppc
------------------
happymonday
```
**GPPC Set-Returning Function Example**

In this example, you develop, build, and deploy a GPPC shared library. You also create and run a .sql registration script for a GPPC function named `return_tbl()`. This function uses the GPPC API to take an input table with an integer and a text column, determine if the integer column is greater than 13, and returns a result table with the input integer column and a boolean column identifying whether or not the integer is greater than 13. `return_tbl()` utilizes GPPC API reporting and SRF functions and macros.

You will develop the GPPC function on your Greenplum Database master host. Deploying the GPPC shared library that you create in this example requires administrative access to your Greenplum Database cluster.

Perform the following procedure to run the example:

1. Log in to the Greenplum Database master host and set up your environment. For example:

   ```
   $ ssh gpadmin@gpmaster
   gpadmin@gpmaster$ . /usr/local/greenplum-db/greenplum_path.sh
   ```

2. Create a work directory and navigate to the new directory. For example:

   ```
   gpadmin@gpmaster$ mkdir gppc_work
   gpadmin@gpmaster$ cd gppc_work
   ```

3. Prepare a source file for GPPC code by opening the file in the editor of your choice. For example, to open a file named `gppc_concat.c` using `vi`:

   ```
   gpadmin@gpmaster$ vi gppc_rettbl.c
   ```

4. Copy/paste the following code into the file:

   ```
   #include <stdio.h>
   #include <string.h>
   #include "gppc.h"

   // initialize the logging level
   GppcReportLevel level = GPPC_INFO;

   // make the function SQL-invokable and declare the function
   GPPC_FUNCTION_INFO(return_tbl);
   GppcDatum return_tbl(GPPC_FUNCTION_ARGS);

   GppcDatum return_tbl(GPPC_FUNCTION_ARGS)
   {
      GppcFuncCallContext fctx;
      GppcAnyTable intbl;
      GppcHeapTuple intuple;
      GppcTupleDesc intupdesc, out_tupdesc;
      GppcBool resbool = false;
      GppcDatum result, boolres, values[2];
      bool nulls[2] = {false, false};

      // single input argument - the table
      intbl = GPPC_GETARG_ANYTABLE(0);

      // set the function context
      if (GPPC_SRF_IS_FIRSTCALL()) {
         fctx = GPPC_SRF_FIRSTCALL_INIT();
      }
   }
   ```
The code declares and implements the `return_tbl()` function. It uses GPPC data types, macros, and functions to fetch the function arguments, examine tuple descriptors, build the return tuple, and return the result. The function also uses the SRF macros to keep track of the tuple context across function calls.

5. Save the file and exit the editor.
6. Open a file named Makefile in the editor of your choice. Copy/paste the following text into the file:

```plaintext
MODULE_big = gppc_rettbl
OBJS = gppc_rettbl.o

PG_CONFIG = pg_config
PGXS := $(shell $(PG_CONFIG) --pgxs)
PG_CPPFLAGS = -I$(shell $(PG_CONFIG) --includedir)
SHLIB_LINK = -L$(shell $(PG_CONFIG) --libdir) -lgppc
include $(PGXS)
```

7. Save the file and exit the editor.

8. Build a GPPC shared library for the return_tbl() function. For example:

```plaintext
gpadmin@gpmaster$ make all
```

The `make` command generates a shared library file named `gppc_rettbl.so` in the current working directory.

9. Copy the shared library to your Greenplum Database installation. You must have Greenplum Database administrative privileges to copy the file. For example:

```plaintext
gpadmin@gpmaster$ cp gppc_rettbl.so /usr/local/greenplum-db/lib/postgresql/
```

10. Copy the shared library to every host in your Greenplum Database installation. For example, if `seghostfile` contains a list, one-host-per-line, of the segment hosts in your Greenplum Database cluster:

```plaintext
gpadmin@gpmaster$ gpscp -v -f seghostfile /usr/local/greenplum-db/lib/postgresql/gppc_rettbl.so =:/usr/local/greenplum-db/lib/postgresql/gppc_rettbl.so
```

11. Create a `.sql` file to register the GPPC return_tbl() function. Open a file named `gppc_rettbl_reg.sql` in the editor of your choice.

12. Copy/paste the following text into the file:

```sql
CREATE FUNCTION rettbl_gppc(anytable) RETURNS TABLE(id int4, thirteen bool)
    AS 'gppc_rettbl', 'return_tbl'
    LANGUAGE C STRICT;
```

13. Register the GPPC function by running the script you just created. For example, to register the function in a database named `testdb`:

```plaintext
gpadmin@gpmaster$ psql -d testdb -f gppc_rettbl_reg.sql
```

14. Open a `psql` session. For example:

```plaintext
gpadmin@gpmaster$ psql -d testdb
```

15. Create a table with some test data. For example:

```sql
CREATE TABLE gppc_testtbl( id int, msg text );
INSERT INTO gppc_testtbl VALUES (1, 'f1');
INSERT INTO gppc_testtbl VALUES (7, 'f7');
INSERT INTO gppc_testtbl VALUES (10, 'f10');
INSERT INTO gppc_testtbl VALUES (13, 'f13');
INSERT INTO gppc_testtbl VALUES (15, 'f15');
```
INSERT INTO gppc_testtbl VALUES (17, 'f17');

16. Run the `rettbl_gppc()` function. For example:

```
testdb=# SELECT * FROM rettbl_gppc(TABLE(SELECT * FROM gppc_testtbl));
     id | thirteen
--------
     1  | f
     7  | f
    13  | f
    15  | t
    17  | t
    10  | f
(6 rows)
```
Greenplum Fuzzy String Match Extension

The Greenplum Database Fuzzy String Match extension provides functions to determine similarities and distance between strings based on various algorithms.

- **Soundex Functions**
- **Levenshtein Functions**
- **Metaphone Functions**
- **Double Metaphone Functions**

### Installing and Uninstalling the Fuzzy String Match Functions

The Greenplum Database installation contains the files required for the functions in this extension module and SQL scripts to define the extension functions in a database and remove the functions from a database.

**Warning:** The functions `soundex`, `metaphone`, `dmetaphone`, and `dmetaphone_alt` do not work well with multibyte encodings (such as UTF-8).

The Greenplum Database Fuzzy String Match extension is based on the PostgreSQL fuzzystormatch module.

## Soundex Functions

The Soundex system is a method of matching similar-sounding (similar phonemes) names by converting them to the same code.

**Note:** Soundex is most useful for English names.

These functions work with Soundex codes:

```sql
soundex(text string1) returns text
difference(text string1, text string2) returns int
```

The `soundex` function converts a string to its Soundex code. Soundex codes consist of four characters. The `difference` function converts two strings to their Soundex codes and then reports the number of matching code positions. The result ranges from zero to four, zero being no match and four being an exact match. These are some examples:

```sql
SELECT soundex('hello world!');
SELECT soundex('Anne'), soundex('Ann'), difference('Anne', 'Ann');
SELECT soundex('Anne'), soundex('Andrew'), difference('Anne', 'Andrew');
SELECT soundex('Anne'), soundex('Margaret'), difference('Anne', 'Margaret');
```

CREATE TABLE s (nm text);

```sql
INSERT INTO s VALUES ('john');
INSERT INTO s VALUES ('joan');
INSERT INTO s VALUES ('wobbly');
INSERT INTO s VALUES ('jack');
```

```sql
SELECT * FROM s WHERE soundex(nm) = soundex('john');
SELECT * FROM s WHERE difference(s.nm, 'john') > 2;
```

For information about the Soundex indexing system see [https://www.archives.gov/research/census/soundex.html](https://www.archives.gov/research/census/soundex.html).
Levenshtein Functions

These functions calculate the Levenshtein distance between two strings:

- levenshtein(text source, text target, int ins_cost, int del_cost, int sub_cost) returns int
- levenshtein(text source, text target) returns int
- levenshtein_less_equal(text source, text target, int ins_cost, int del_cost, int sub_cost, int max_d) returns int
- levenshtein_less_equal(text source, text target, int max_d) returns int

Both the source and target parameters can be any non-null string, with a maximum of 255 bytes. The cost parameters ins_cost, del_cost, and sub_cost specify cost of a character insertion, deletion, or substitution, respectively. You can omit the cost parameters, as in the second version of the function; in that case the cost parameters default to 1.

levenshtein_less_equal is accelerated version of levenshtein function for low values of distance. If actual distance is less or equal then max_d, then levenshtein_less_equal returns an accurate value of the distance. Otherwise, this function returns value which is greater than max_d. Examples:

```
test=# SELECT levenshtein('GUMBO', 'GAMBOL');
levenshtein
-------------
     2
(1 row)
test=# SELECT levenshtein('GUMBO', 'GAMBOL', 2,1,1);
levenshtein
-------------
     3
(1 row)
test=# SELECT levenshtein_less_equal('extensive', 'exhaustive',2);
levenshtein_less_equal
------------------------
     3
(1 row)
test=# SELECT levenshtein_less_equal('extensive', 'exhaustive',4);
levenshtein_less_equal
------------------------
     4
(1 row)
```

For information about the Levenshtein algorithm, see [http://www.levenshtein.net/](http://www.levenshtein.net/).

Metaphone Functions

Metaphone, like Soundex, is based on the idea of constructing a representative code for an input string. Two strings are then deemed similar if they have the same codes. This function calculates the metaphone code of an input string:

- metaphone(text source, int max_output_length) returns text

The source parameter must be a non-null string with a maximum of 255 characters. The max_output_length parameter sets the maximum length of the output metaphone code; if longer, the output is truncated to this length. Example:

```
test=# SELECT metaphone('GUMBO', 4);
```

For information about the Metaphone algorithm, see [https://en.wikipedia.org/wiki/Metaphone](https://en.wikipedia.org/wiki/Metaphone).

**Double Metaphone Functions**

The Double Metaphone system computes two "sounds like" strings for a given input string - a "primary" and an "alternate". In most cases they are the same, but for non-English names especially they can be a bit different, depending on pronunciation. These functions compute the primary and alternate codes:

```sql
dmetaphone(text source) returns text
dmetaphone_alt(text source) returns text
```

There is no length limit on the input strings. Example:

```sql
test=# select dmetaphone('gumbo');
dmetaphone
------------
KMP
(1 row)
```

**Installing and Uninstalling the Fuzzy String Match Functions**

Greenplum Database supplies SQL scripts to install and uninstall the Fuzzy String Match extension functions.

To install the functions in a database, run the following SQL script:

```sql
psql -f $GPHOME/share/postgresql/contrib/fuzzystrmatch.sql
```

To uninstall the functions, run the following SQL script:

```sql
psql -f $GPHOME/share/postgresql/contrib/uninstall_fuzzystrmatch.sql
```

**Note:** When you uninstall the Fuzzy String Match functions from a database, routines that you created in the database that use the functions will no longer work.
Summary of Greenplum Features

This section provides a high-level overview of the system requirements and feature set of Greenplum Database. It contains the following topics:

- Greenplum SQL Standard Conformance
- Greenplum and PostgreSQL Compatibility

Greenplum SQL Standard Conformance

The SQL language was first formally standardized in 1986 by the American National Standards Institute (ANSI) as SQL 1986. Subsequent versions of the SQL standard have been released by ANSI and as International Organization for Standardization (ISO) standards: SQL 1989, SQL 1992, SQL 1999, SQL 2003, SQL 2006, and finally SQL 2008, which is the current SQL standard. The official name of the standard is ISO/IEC 9075-14:2008. In general, each new version adds more features, although occasionally features are deprecated or removed.

It is important to note that there are no commercial database systems that are fully compliant with the SQL standard. Greenplum Database is almost fully compliant with the SQL 1992 standard, with most of the features from SQL 1999. Several features from SQL 2003 have also been implemented (most notably the SQL OLAP features).

This section addresses the important conformance issues of Greenplum Database as they relate to the SQL standards. For a feature-by-feature list of Greenplum’s support of the latest SQL standard, see SQL 2008 Optional Feature Compliance.

Core SQL Conformance

In the process of building a parallel, shared-nothing database system and query optimizer, certain common SQL constructs are not currently implemented in Greenplum Database. The following SQL constructs are not supported:

1. Some set returning subqueries in EXISTS or NOT EXISTS clauses that Greenplum's parallel optimizer cannot rewrite into joins.
2. Backwards scrolling cursors, including the use of FETCH PRIOR, FETCH FIRST, FETCH ABOLUTE, and FETCH RELATIVE.
3. In CREATE TABLE statements (on hash-distributed tables): a UNIQUE or PRIMARY KEY clause must include all of (or a superset of) the distribution key columns. Because of this restriction, only one UNIQUE clause or PRIMARY KEY clause is allowed in a CREATE TABLE statement. UNIQUE or PRIMARY KEY clauses are not allowed on randomly-distributed tables.
4. CREATE UNIQUE INDEX statements that do not contain all of (or a superset of) the distribution key columns. CREATE UNIQUE INDEX is not allowed on randomly-distributed tables.

Note that UNIQUE INDEXES (but not UNIQUE CONSTRAINTS) are enforced on a part basis within a partitioned table. They guarantee the uniqueness of the key within each part or sub-part.

5. VOLATILE or STABLE functions cannot execute on the segments, and so are generally limited to being passed literal values as the arguments to their parameters.
6. Triggers are not supported since they typically rely on the use of VOLATILE functions.
7. Referential integrity constraints (foreign keys) are not enforced in Greenplum Database. Users can declare foreign keys and this information is kept in the system catalog, however.
8. Sequence manipulation functions CURRVAL and LASTVAL.

SQL 1992 Conformance

The following features of SQL 1992 are not supported in Greenplum Database:
1. NATIONAL CHARACTER (NCHAR) and NATIONAL CHARACTER VARYING (NVARCHAR). Users can declare the NCHAR and NVARCHAR types, however they are just synonyms for CHAR and VARCHAR in Greenplum Database.

2. CREATE ASSERTION statement.

3. INTERVAL literals are supported in Greenplum Database, but do not conform to the standard.

4. GET DIAGNOSTICS statement.

5. GRANT INSERT or UPDATE privileges on columns. Privileges can only be granted on tables in Greenplum Database.

6. GLOBAL TEMPORARY TABLES and LOCAL TEMPORARY TABLES. Greenplum temporary tables do not conform to the SQL standard, but many commercial database systems have implemented temporary tables in the same way. Greenplum temporary tables are the same as VOLATILE TABLES in Teradata.

7. UNIQUE predicate.

8. MATCH PARTIAL for referential integrity checks (most likely will not be implemented in Greenplum Database).

SQL 1999 Conformance

The following features of SQL 1999 are not supported in Greenplum Database:

1. Large Object data types: BLOB, CLOB, NCLOB. However, the BYTEA and TEXT columns can store very large amounts of data in Greenplum Database (hundreds of megabytes).

2. MODULE (SQL client modules).

3. CREATE PROCEDURE (SQL/PSM). This can be worked around in Greenplum Database by creating a function that returns void, and invoking the function as follows:

   ```sql
   SELECT myfunc(args);
   ```

4. The PostgreSQL/Greenplum function definition language (PL/PGSQL) is a subset of Oracle's PL/SQL, rather than being compatible with the SQL/PSM function definition language. Greenplum Database also supports function definitions written in Python, Perl, Java, and R.

5. BIT and BIT VARYING data types (intentionally omitted). These were deprecated in SQL 2003, and replaced in SQL 2008.

6. Greenplum supports identifiers up to 63 characters long. The SQL standard requires support for identifiers up to 128 characters long.

7. Prepared transactions (PREPARE TRANSACTION, COMMIT PREPARED, ROLLBACK PREPARED). This also means Greenplum does not support XA Transactions (2 phase commit coordination of database transactions with external transactions).

8. CHARACTER SET option on the definition of CHAR() or VARCHAR() columns.

9. Specification of CHARACTERS or OCTETS (BYTES) on the length of a CHAR() or VARCHAR() column. For example, VARCHAR(15 CHARACTERS) or VARCHAR(15 OCTETS) or VARCHAR(15 BYTES).

10. CURRENT_SCHEMA function.

11. CREATE DISTINCT TYPE statement. CREATE DOMAIN can be used as a work-around in Greenplum.

12. The explicit table construct.

SQL 2003 Conformance

The following features of SQL 2003 are not supported in Greenplum Database:

1. MERGE statements.

2. IDENTITY columns and the associated GENERATED ALWAYS/GENERATED BY DEFAULT clause. The SERIAL or BIGSERIAL data types are very similar to INT or BIGINT GENERATED BY DEFAULT AS IDENTITY.

3. MULTISET modifiers on data types.

4. ROW data type.
5. Greenplum Database syntax for using sequences is non-standard. For example, `nextval('seq')` is used in Greenplum instead of the standard `NEXT VALUE FOR seq`.

6. `GENERATED ALWAYS AS` columns. Views can be used as a work-around.

7. The sample clause (TABLESAMPLE) on `SELECT` statements. The `random()` function can be used as a work-around to get random samples from tables.

8. The `partitioned join tables` construct (PARTITION BY in a join).

9. GRANT SELECT privileges on columns. Privileges can only be granted on tables in Greenplum Database. Views can be used as a work-around.

10. For `CREATE TABLE x (LIKE(y))` statements, Greenplum does not support the [INCLUDING|EXCLUDING] [DEFAULTS|CONSTRAINTS|INDEXES] clauses.

11. Greenplum array data types are almost SQL standard compliant with some exceptions. Generally customers should not encounter any problems using them.

### SQL 2008 Conformance

The following features of SQL 2008 are not supported in Greenplum Database:

1. `BINARY` and `VARBINARY` data types. `BYTEA` can be used in place of `VARBINARY` in Greenplum Database.

2. FETCH FIRST or FETCH NEXT clause for `SELECT`, for example:

   ```
   SELECT id, name FROM tab1 ORDER BY id OFFSET 20 ROWS FETCH NEXT 10 ROWS ONLY;
   ```

   Greenplum has `LIMIT` and `LIMIT OFFSET` clauses instead.

3. The `ORDER BY` clause is ignored in views and subqueries unless a `LIMIT` clause is also used. This is intentional, as the Greenplum optimizer cannot determine when it is safe to avoid the sort, causing an unexpected performance impact for such `ORDER BY` clauses. To work around, you can specify a really large `LIMIT`. For example: `SELECT * FROM mytable ORDER BY 1 LIMIT 9999999999

4. The `row subquery` construct is not supported.

5. `TRUNCATE TABLE` does not accept the `CONTINUE IDENTITY` and `RESTART IDENTITY` clauses.

### Greenplum and PostgreSQL Compatibility

Greenplum Database is based on PostgreSQL 8.3 with additional features from newer PostgreSQL releases. To support the distributed nature and typical workload of a Greenplum Database system, some SQL commands have been added or modified, and there are a few PostgreSQL features that are not supported. Greenplum has also added features not found in PostgreSQL, such as physical data distribution, parallel query optimization, external tables, resource queues, and enhanced table partitioning.

For full SQL syntax and references, see the [SQL Command Reference](#).

Chapter 9

Greenplum Database UNIX Client Documentation

Information and instructions for installing and using client and load tools on UNIX systems.
Greenplum Database Client Tools for UNIX

Utility programs that connect to Greenplum Database from UNIX systems.

Installing the Greenplum Client Tools

This section contains information for installing the client programs on your client machine and for enabling Greenplum Database to accept remote client connections:

• Running the Client Tools Installer
• Configuring the Command-Line Tools
• Enabling Greenplum Database for Remote Client Connections
• Configuring a Client System for Kerberos Authentication
• Next Steps

See the Greenplum Database Release Notes for the list of currently supported platforms for the Client Tools.

Running the Client Tools Installer

The Greenplum Database client tools installer installs the following client tools:

• PostgreSQL Interactive Terminal (psql)
• PostgreSQL Database Dump Utilities (pg_dump and pg_dumpall)

To install the Greenplum Database client tools

1. Download the appropriate Greenplum Clients installer package for your platform from Pivotal Network.
2. Unzip the installer:

   ```
   unzip greenplum-clients-<version>-PLATFORM.zip
   ```
3. Run the installer:

   ```
   /bin/bash greenplum-clients-<version>-PLATFORM.bin
   ```
4. The installer will prompt you to accept the license agreement and to provide an installation path. For the installation path, be sure to enter an absolute path if you choose not to accept the default location (for example, /mydir/gp-client-tools). The default install location for the client tools is /usr/local/greenplum-clients-<version>

About Your Installation

Your Greenplum Database client tools installation contains the following files and directories:

• bin — client command-line tools
• ext — python dependencies
• include — header files
• lib — client tools library files
• greenplum_clients_path.sh — environment variables

Configuring the Command-Line Tools

As a convenience, a greenplum_clients_path.sh file is provided in your client tools installation directory following installation. It has the following environment variable settings:

GPHOME_CLIENTS — The installation directory of the Greenplum Database client tools.
**PATH** — Adds the path to the command-line utilities.

**LD_LIBRARY_PATH** — The path to the library files.

You can source this file in your user's startup shell profile (such as `.bashrc` or `.bash_profile`).

For example, you could add a line similar to the following to your chosen profile files (making sure the right install path is used):

```
source greenplum-clients-<version>/greenplum_clients_path.sh
```

After editing the chosen profile file, source it as the correct user to make the changes active. For example:

```
source ~/.bashrc
```

### Additional Connection Environment Variables

The PostgreSQL command-line tools require several connection parameters in order to be able to connect to a Greenplum Database database. In order to save some typing on the command-line, you can create the following environment variables in your preferred profile file (such as `.bashrc`).

- **PGDATABASE** — The name of the default Greenplum database to connect to.
- **PGHOST** — The Greenplum master host name or IP address.
- **PGPORT** — The port number that the Greenplum master instance (postmaster process) is running on.
- **PGUSER** — The default database role name to use for login.

### Enabling Greenplum Database for Remote Client Connections

In order for Greenplum Database to be able to accept remote client connections, you must configure your Greenplum Database master so that connections are allowed from the client hosts and database users that will be connecting to Greenplum Database.

#### To enable remote client connections

1. Make sure that the `pg_hba.conf` file of the Greenplum Database master is correctly configured to allow connections from the users to the database(s) using the authentication method you want. For details, see "Editing the pg_hba.conf File" in the [Greenplum Database Administration Guide](#), and also see the [Greenplum Database Security Configuration Guide](#).

   Make sure the authentication method you choose is supported by the client tool you are using.

2. If you edited `pg_hba.conf` file, the change requires a server reload (using the `gpstop -u` command) to take effect.

3. Make sure that the databases and roles you are using to connect exist in the system and that the roles have the correct privileges to the database objects.

### Configuring a Client System for Kerberos Authentication

If you use Kerberos authentication to connect to a Greenplum Database with the `psql` utility, your client system must be configured to use Kerberos authentication. If you are not using Kerberos authentication to connect to a Greenplum Database, Kerberos is not needed on your client system.

- **Requirements**
- **Setting Up a Client System with Kerberos Authentication**
- **Accessing Greenplum Database with psql**

For information about enabling Kerberos authentication with Greenplum Database, see the "Kerberos Authentication" chapter in the [Greenplum Database Administrator Guide](#).
**Requirements**

The following are requirements to connect to a Greenplum Database that is enabled with Kerberos authentication from a client system with Greenplum Database client software.

- **Prerequisites**
- **Required Software on the Client Machine**

**Prerequisites**

- Kerberos must be installed and configured on the Greenplum Database master host. See [Enabling Greenplum Database for Remote Client Connections](#).
- The client systems require the Kerberos configuration file `krb5.conf` from the Greenplum Database master.
- The client systems require a Kerberos keytab file that contains the authentication credentials for the Greenplum Database user that is used to log into the database.
- The client machines must be able to connect to Greenplum Database master host.

  If necessary, add the Greenplum Database master host name and IP address to the system `hosts` file. On Linux systems, the `hosts` file is located in `/etc`.

**Required Software on the Client Machine**

The Kerberos `kinit` utility is required on the client machine. The `kinit` utility is available when you install the Kerberos packages:

- `krb5-libs`
- `krb5-workstation`

  **Note:** When you install the Kerberos packages, you can use other Kerberos utilities such as `klist` to display Kerberos ticket information.

**Setting Up a Client System with Kerberos Authentication**

To connect to Greenplum Database with Kerberos authentication requires a Kerberos ticket. On client systems, tickets are generated from Kerberos keytab files with the `kinit` utility and are stored in a cache file.

1. Install a copy of the Kerberos configuration file `krb5.conf` from the Greenplum Database master. The file is used by the Greenplum Database client software and the Kerberos utilities.

   Install `krb5.conf` in the `/etc` directory.

   If needed, add the parameter `default_ccache_name` to the `[libdefaults]` section of the `krb5.ini` file and specify the location of the Kerberos ticket cache file on the client system.

2. Obtain a Kerberos keytab file that contains the authentication credentials for the Greenplum Database user.

3. Run `kinit` specifying the keytab file to create a ticket on the client machine. For this example, the keytab file `gpdb-kerberos.keytab` is in the current directory. The ticket cache file is in the `gpadmin` user home directory. For example:

   ```
   $ kinit -k -t gpdb-kerberos.keytab
   -c /home/gpadmin/cache.txt
gadmin/kerberos-gpdb@KRB.EXAMPLE.COM
   ```

**Accessing Greenplum Database with psql**

From a remote system, you can access a Greenplum Database that has Kerberos authentication enabled.
To connect to Greenplum Database with psql

1. As the gpadmin user, open a command window.
2. Start `psql` from the command window and specify a connection to the Greenplum Database specifying the user that is configured with Kerberos authentication.

   The following example logs into the Greenplum Database on the machine `kerberos-gpdb` as the `gpadmin` user with the Kerberos credentials `gpadmin/kerberos-gpdb`:

   ```bash
   $ psql -U "gpadmin/kerberos-gpdb" -h kerberos-gpdb postgres
   ```

Next Steps

Refer to the client tool reference documentation for further instructions:

- Greenplum Database SQL Syntax — See SQL Syntax Summary.

## Client Tools Reference

This chapter references the client tools provided with this release. They all require certain connection information such as the Greenplum Database master host name, port, database name, and role name. These can be configured using environment variables. See Configuring the Command-Line Tools.

The following tools are provided:

- `pg_dump`
- `pg_dumpall`
- `psql`

See also the SQL Syntax Summary for a quick reference to available SQL commands.
Greenplum Database Load Tools for UNIX

Programs that load data into Greenplum Database from UNIX systems.

Installing the Greenplum Load Tools

This section contains information for installing the Greenplum data loading programs on your client machine and for enabling Greenplum Database to accept remote client connections:

- Running the Load Tools Installer
- Configuring the Command-Line Load Tools
- Enabling Greenplum Database for Remote Client Connections
- Next Steps

See the Greenplum Database Release Notes for the list of currently supported platforms for the Load Tools.

Running the Load Tools Installer

The Greenplum Database load tools installer installs the following data loading tools:

- Greenplum parallel file distribution program (gpfdist)
- Greenplum data loading utility (gpload)

To install the Greenplum Database load tools

1. Download the appropriate Greenplum Loaders installer package for your platform from Pivotal Network.
2. Unzip the installer:
   ```
   unzip greenplum-loaders-<version>-PLATFORM.zip
   ```
3. Run the installer:
   ```
   /bin/bash greenplum-loaders-<version>-PLATFORM.bin
   ```
4. The installer will prompt you to accept the license agreement and to provide an installation path. For the installation path, be sure to enter an absolute path if you choose not to accept the default location (for example, /mydir/gp-loader-tools). The default install location for the load tools is /usr/local/greenplum-loaders-<version>.

About Your Installation

Your Greenplum Database load tools installation contains the following files and directories:

- **bin** — data loading command-line tools
- **ext** — python dependencies
- **lib** — load tools library files
- **greenplum_loaders_path.sh** — environment variables

Configuring the Command-Line Load Tools

As a convenience, a greenplum_loaders_path.sh file is provided in your load tools installation directory following installation. It has the following environment variable settings:

- **GPHOME_LOADERS** — The installation directory of the Greenplum Database load tools.
- **PATH** — Adds the path to the data loading command-line utilities.
- **LD_LIBRARY_PATH** — The path to additional Python library files needed for gpload.
You can source this file in your user's startup shell profile (such as .bashrc or .bash_profile).
For example, you could add a line similar to the following to your chosen profile files (making sure the right install path is used):

```
source greenplum-loaders-<version>/greenplum_loaders_path.sh
```

After editing the chosen profile file, source it as the correct user to make the changes active. For example:

```
source ~/.bashrc
```

### Additional Connection Environment Variables

The Greenplum load tools require several connection parameters in order to be able to connect to a Greenplum Database instance. In order to save some typing on the command-line, you can create the following environment variables in your preferred profile file (such as .bashrc).

- **PGDATABASE** — The name of the default Greenplum database to connect to.
- **PGHOST** — The Greenplum master host name or IP address.
- **PGPORT** — The port number that the Greenplum master instance is running on.
- **PGUSER** — The default database role name to use for login.

### Enabling Greenplum Database for Remote Client Connections

In order for Greenplum Database to be able to accept remote client connections, you must configure your Greenplum Database master so that connections are allowed from the client hosts and database users that will be connecting to Greenplum Database.

#### To enable remote client connections

1. Make sure that the `pg_hba.conf` file of the Greenplum Database master is correctly configured to allow connections from the users to the database(s) using the authentication method you want. For details, see "Editing the pg_hba.conf File" in the [Greenplum Database Administration Guide](https://greenplum-db.org/docs/pdmu/), and also see the [Greenplum Database Security Configuration Guide](https://greenplum-db.org/docs/pdmu/).
   
   Make sure the authentication method you choose is supported by the client tool you are using.

2. If you edited `pg_hba.conf` file, the change requires a server reload (using the `gpstop -u` command) to take effect.

3. Make sure that the databases and roles you are using to connect exist in the system and that the roles have the correct privileges to the database objects.

### Next Steps

Refer to the load tool reference documentation for further instructions:

- **Greenplum Load Tools** — See [Load Tools Reference](#).
- **Greenplum Database SQL Syntax** — See [SQL Syntax Summary](#).

### Load Tools Reference

This chapter describes the data loading tools provided with this release. They all require certain connection information such as the Greenplum Database master host name, port, database name, and role name. These can be configured using environment variables. For more information, see [Configuring the Command-Line Load Tools](#).

The following tools are provided:

- Greenplum parallel file distribution program (`gpfdist`)
- Greenplum data loading utility (`gpload`)
See also the *SQL Syntax Summary* for a quick reference to available SQL commands.
Chapter 10

Greenplum Database Windows Client Documentation

Information and instructions for installing and using client and load tools on Microsoft Windows systems.
Greenplum Database Client Tools for Windows

Utility programs that connect to Greenplum Database from Microsoft Windows systems.

**Installing the Greenplum Client Tools**

This section contains information for installing the various client programs on your Windows machine and for enabling Greenplum Database to accept remote client connections:

- Running the Client Tools Installer
- Configuring the Client Tools
- Enabling Greenplum Database for Remote Client Connections
- Configuring a Client System for Kerberos Authentication

See the *Greenplum Database Release Notes* for the list of currently supported platforms for the Client Tools.

**Running the Client Tools Installer**

The Greenplum Database client tools installer installs `psql.exe`, the interactive command-line client interface to Greenplum Database.

**To install the Greenplum Database client tools**

1. Download the `greenplum-clients-<version>-WinXP-x86_32.msi` package from Pivotal Network.
2. Double-click on the `greenplum-clients-<version>-WinXP-x86_32.msi` package to launch the installer.
3. Click **Next** on the Welcome screen.
4. Click **I Agree** on the License Agreement screen.
5. By default, the Greenplum Database client tools will be installed into `greenplum-db-<version>`. Click **Browse** if you want to choose another location.
6. Click **Next** when you have chosen the install path you want.
7. Click **Install** to begin the installation.
8. Click **Finish** to exit the installer.

**About Your Installation**

Your Greenplum Database client tools installation contains the following files and directories:

- **bin** — client tools programs
- **greenplum_clients_path.bat** — sets environment variables
- **lib** — client tools library files

**Configuring the Client Tools**

Greenplum provides a batch program (`greenplum_clients_path.bat`) to set the required environment settings for Greenplum loader (located in `greenplum-db-<version>` by default).

**To set the required environment settings**

1. Open a Windows command prompt (**Start > Run** and type **cmd**).
2. At the command prompt, go to the directory where you installed Greenplum loader. For example:

   ```
   cd "Program Files"\Greenplum\greenplum-clients-<version>
   ```
3. Execute the `greenplum_loaders_path.bat` program:

```
greenplum_clients_path.bat
```

The PostgreSQL command-line tools also require several connection parameters in order to be able to connect to a Greenplum database. In order to save some typing on the command-line, you can optionally create the following environment variables in your Windows Control Panel.

- **PGDATABASE** — The name of the default Greenplum database to connect to.
- **PGHOST** — The Greenplum Database master host name or IP address.
- **PGPORT** — The port number that the Greenplum master instance (postmaster process) is running on.
- **PGUSER** — The default database role name to use for login.

### To add a new user environment variable on Windows XP

1. In Windows Explorer, go to `C:\\Control Panel`.
2. Double-click the **System** icon.
3. On the **Advanced** tab, click **Environment Variables** (bottom).
4. Click **New**.
5. Define the new environment variable. For example:

```
PGDATABASE = MyDefaultDatabase
```

6. Click OK.

### Enabling Greenplum Database for Remote Client Connections

In order for Greenplum Database to be able to accept remote client connections, you must configure your Greenplum Database master so that connections are allowed from the client hosts and database users that will be connecting to Greenplum Database.

### To enable remote client connections

1. Make sure that the `pg_hba.conf` file of the Greenplum Database master is correctly configured to allow connections from the users to the database(s) using the authentication method you want. For details, see "Editing the pg_hba.conf File" in the *Greenplum Database Administration Guide*, and also see the *Greenplum Database Security Configuration Guide*.

   Make sure the authentication method you choose is supported by the client tool you are using.

2. If you edited `pg_hba.conf` file, the change requires a server reload (using the `gpstop -u` command) to take effect.

3. Make sure that the databases and roles you are using to connect exist in the system and that the roles have the correct privileges to the database objects.

### Configuring a Client System for Kerberos Authentication

If you use Kerberos authentication to connect to your Greenplum Database with the `psql` utility, your client system must be configured to use Kerberos authentication. If you are not using Kerberos authentication to connect to a Greenplum Database, Kerberos is not needed on your client system.

- **Requirements**
- **Setting Up a Client System with Kerberos Authentication**
- **Accessing Greenplum Database with psql**

For information about enabling Kerberos authentication with Greenplum Database, see the chapter "Kerberos Authentication" in the *Greenplum Database Administrator Guide*. 
**Requirements**

The following are requirements to connect to a Greenplum Database that is enabled with Kerberos authentication from a client system with Greenplum Database client software.

- **Prerequisites**
- **Required Software on the Client Machine**

**Prerequisites**

- Kerberos must be installed and configured on the Greenplum Database master host. See "Enabling Greenplum Database for Remote Client Connections."
- The client systems require the Kerberos configuration file `krb5.conf` from the Greenplum Database master.
- The client systems require a Kerberos keytab file that contains the authentication credentials for the Greenplum Database user that is used to log into the database.
- The client machines must be able to connect to Greenplum Database master host.

If necessary, add the Greenplum Database master host name and IP address to the system `hosts` file. On Windows 7 systems, the `hosts` file is located in `C:\Windows\System32\drivers\etc\`.

**Required Software on the Client Machine**

  **Note:** When you install the Kerberos software, you can use other Kerberos utilities such as `klist` to display Kerberos ticket information.

**Setting Up a Client System with Kerberos Authentication**

To connect to Greenplum Database with Kerberos authentication requires a Kerberos ticket. On client systems, tickets are generated from Kerberos keytab files with the `kinit` utility and are stored in a cache file.

1. Install a copy of the Kerberos configuration file `krb5.conf` from the Greenplum Database master. The file is used by the Greenplum Database client software and the Kerberos utilities.
   
   Rename `krb5.conf` to `krb5.ini` and move it to the Windows directory. On Windows 7, the Windows directory is `C:\Windows`.
   
   `klist` to display Kerberos ticket information.

2. Obtain a Kerberos keytab file that contains the authentication credentials for the Greenplum Database user.

3. Run `kinit` specifying the keytab file to create a ticket on the client machine. For the following example, the keytab file `gpdb-kerberos.keytab` is in the current directory. The ticket cache file is in the `gpadmin` user home directory.

```
> kinit -k -t gpdb-kerberos.keytab
-c C:\Users\gpadmin\cache.txt
 gpadmin/kerberos-gpdb@KRB.EXAMPLE.COM
```

**Accessing Greenplum Database with psql**

From a remote system, you can access a Greenplum Database that has Kerberos authentication enabled.

1. As the `gpadmin` user, open a command window.
2. Run the client tool batch file from command window `greenplum_clients_path.bat`

Change the current directory to the `bin` directory of the Kerberos for Windows installation. For example:

```
> cd C:\test\MIT\Kerberos\bin
```

3. Start `psql` from the command window and specify a connection to the Greenplum Database specifying the user that is configured with Kerberos authentication.

The following example logs into the Greenplum Database on the machine `keberos-gpdb` as the `gpadmin` user with the Kerberos credentials `gpadmin/kerberos-gpdb`:

```
> psql -U "gpadmin/kerberos-gpdb" -h kerberos-gpdb template1
```

For information about running `psql`, see "Running the Greenplum Client Tools."

### Running the Greenplum Client Tools

This section contains information for connecting to Greenplum Database using the `psql.exe` command-line client tool.

### Connecting to Greenplum Database

Users and administrators always connect to Greenplum Database through the master host. In order to establish a connection to the Greenplum Database master, you will need to know the following connection information and configure your client program accordingly. See Configuring the Client Tools for more information.

#### Table 250: Connection Parameters

<table>
<thead>
<tr>
<th>Connection Parameter</th>
<th>Description</th>
<th>Environment Variable</th>
</tr>
</thead>
<tbody>
<tr>
<td>Database name</td>
<td>The name of the database to which you want to connect. For a newly initialized system, use the <code>postgres</code> database to connect for the first time.</td>
<td>$PGDATABASE</td>
</tr>
<tr>
<td>Host name</td>
<td>The host name of the Greenplum Database master. The default host is the local host.</td>
<td>$PGHOST</td>
</tr>
<tr>
<td>Port</td>
<td>The port number that the Greenplum Database master instance is running on. The default is 5432.</td>
<td>$PGPORT</td>
</tr>
<tr>
<td>Connection Parameter</td>
<td>Description</td>
<td>Environment Variable</td>
</tr>
<tr>
<td>----------------------</td>
<td>-------------</td>
<td>----------------------</td>
</tr>
<tr>
<td>User name</td>
<td>The database user (role) name to connect as. This is not necessarily the same as your OS user name. Check with your Greenplum administrator if you are not sure what you database user name is. Note that every Greenplum Database system has one superuser account that is created automatically at initialization time. This account has the same name as the OS name of the user who initialized the Greenplum system (typically gpadmin).</td>
<td>$PGUSER</td>
</tr>
</tbody>
</table>

**Running psql.exe**

The `psql.exe` program is invoked from a Windows command-line session. For complete command syntax and options for `psql.exe`, see `psql.exe`.

Depending on the default values used or the environment variables you have set, the following examples show how to access a database in Greenplum Database via `psql`:

```
$ psql.exe -d gpdatabase -h master_host -p 5432 -U gpadmin
$ psql.exe gpdatabase
$ psql.exe
```

If a user-defined database has not yet been created, you can access the system by connecting to the `postgres` database. For example:

```
$ psql.exe postgres
```

After connecting to a database, `psql` provides a prompt with the name of the database to which `psql` is currently connected, followed by the string `=>` (or `=#` if you are the database superuser). For example:

```
gpdatabase=>
```

At the prompt, you may type in SQL commands. A SQL command must end with a `;` (semicolon) in order to be sent to the server and executed. For example:

```
=> SELECT count(*) FROM mytable;
```

For more information on using the `psql.exe` client application, see `psql.exe`. For more information on SQL commands and syntax, see `SQL Syntax Summary`.

**Client Tools Reference**

This is a reference of the command-line client tools provided with this release. All of these tools can be run from a Windows console session (`cmd`) or a command-line utility such as Cygwin. They all require certain connection information such as the Greenplum master host name, port, database name, and role name. These can be configured using environment variables. For more information, see `Configuring the Client Tools`.
The following tools are provided:

- `psql.exe` (PostgreSQL interactive terminal)

See also the *SQL Syntax Summary* for a quick reference to available SQL commands.
Greenplum Database Load Tools for Windows

Programs that load data into Greenplum Database from Microsoft Windows systems.

Installing Greenplum Loader

This section contains information for installing the Greenplum data loading programs on your Windows machine and for enabling Greenplum Database to accept remote client connections:

- Installing Python
- Running the Loader Installer
- Configuring Greenplum Loader
- Enabling Greenplum Database for Remote Client Connections

See the Greenplum Database Release Notes for the list of currently supported platforms for the Load Tools.

Installing Python

The Greenplum loader program (gpload.py) for Windows requires Python 2.5.4 (32-bit version) to also be installed on your machine. If you do not have an installation of Python, you can get one from https://www.python.org.

**Note:** The 64-bit version of Python is not compatible with the Greenplum loader program for Windows.

To install Python

1. Download the Python 2.5.4 installer for Windows from https://www.python.org/downloads/.
2. Locate, then double-click on the python Load Tools for Windows-2.5.4.x.msi package to launch the installer.
3. Select Install for all users and click Next.
4. By default, Python will be installed into C:\Pythonxx. Click Up or New if you want to choose another location. Click Next.
5. Click Next to install the selected Python components.
6. Click Finish to complete your installation.

Running the Loader Installer

The Greenplum loader installer installs the following loader programs:

- gpload.py (loader program)
- gpfdist.exe (parallel file distribution program used by gpload.py)

To install Greenplum loader

1. Download the greenplum-clients-<version>-WinXP-x86_32.msi package from Pivotal Network.
2. Double-click on the greenplum-clients-<version>-WinXP-x86_32.msi package to launch the installer.
3. Click Next on the Welcome screen.
4. Click I Agree on the License Agreement screen.
5. By default, Greenplum loader will be installed into greenplum-db-<version>. Click Browse to choose another location.
6. Click Next.
7. Click **Install** to begin the installation.
8. Click **Finish** to exit the installer.

**About Your Installation**

Your Greenplum loader installation contains the following files and directories:

- **bin** — loader command-line utilities (gpload.py and gpfdist.exe)
- **bin/lib** — additional Python libraries needed by gpload.py
- **greenplum_loaders_path.bat** — sets the required environment variables

**Configuring Greenplum Loader**

Greenplum provides a batch program (greenplum_loaders_path.bat) to set the required environment settings for Greenplum loader (located in greenplum-db-<version> by default).

**To set the required environment settings**

1. Open a Windows command prompt (Start > Run and type cmd).
2. At the command prompt, go to the directory where you installed Greenplum loader. For example:

   ```bash
   cd "Program Files"\Greenplum\greenplum-loaders-<version>
dir
   ```
3. Execute the greenplum_loaders_path.bat program:

   ```bash
   greenplum_loaders_path.bat
   ```
4. Verify that you can execute the gpload.py program:

   ```bash
   gpload.py -?
   ```

The loader command-line tools also require several connection parameters in order to be able to connect to a Greenplum database. In order to save some typing on the command-line, you can optionally create the following environment variables in your Windows Control Panel.

- **PGDATABASE** — The name of the default Greenplum database to connect to.
- **PGHOST** — The Greenplum Database master host name or IP address.
- **PGPORT** — The port number that the Greenplum master instance (postmaster process) is running on.
- **PGUSER** — The default database role name to use for login.

**To add a new user environment variable on Windows XP**

1. In Windows Explorer, go to C:\Control Panel.
2. Double-click the System icon.
3. On the Advanced tab, click Environment Variables (bottom).
4. Click New.
5. Define the new environment variable. For example:

6. Click OK.

**Enabling Greenplum Database for Remote Client Connections**

In order for Greenplum Database to be able to accept remote client connections, you must configure your Greenplum Database master so that connections are allowed from the client hosts and database users that will be connecting to Greenplum Database.
To enable remote client connections

1. Make sure that the pg_hba.conf file of the Greenplum Database master is correctly configured to allow connections from the users to the database(s) using the authentication method you want. For details, see "Editing the pg_hba.conf File" in the Greenplum Database Administration Guide, and also see the Greenplum Database Security Configuration Guide.

Make sure the authentication method you choose is supported by the client tool you are using.

2. If you edited pg_hba.conf file, the change requires a server reload (using the gpstop -u command) to take effect.

3. Make sure that the databases and roles you are using to connect exist in the system and that the roles have the correct privileges to the database objects.

Running Greenplum Loader

This section contains information for defining a load job and running the Greenplum loader program (gpload.py).

• Before You Begin
• Creating the Load Control File
• Formatting the Input Data
• Running Greenplum Loader
• Greenplum Loader Log Files
• Updating Database Statistics After Data Loads
• Vacuuming the Database After Load Errors

Before You Begin

Before you can run Greenplum loader:

1. Make sure you have installed and configured Python and the Greenplum loader programs. See Installing Greenplum Loader.

2. Make sure that you have network access to and from all hosts in your Greenplum Database array (master and segments), and to and from the hosts where the data to be loaded resides (if not on the local machine).

3. Make sure that the ports you declare in your load control file are unblocked by your Windows firewall.

4. Make sure your Greenplum Database system is up and running and that you know all of the connection information (host name, port, role name, database name, etc.).

5. Create your database, schema, and table structures in Greenplum Database prior to loading data.

6. Prepare your data so that it is in a format acceptable by Greenplum loader. See Formatting the Input Data.

7. Write your control file. The control file specifies the source data, load rules, and target table for loading the data. See Creating the Load Control File.

Creating the Load Control File

Before you can run Greenplum loader (gpload.py), you must create a text file that contains the load specification information. This file must be in valid YAML 1.1 document format and use the Greenplum schema for defining the various steps of a load operation. See gpload.py for details on the correct control file format and schema.

Here is an example of a load control file:

```yaml
---
VERSION: 1.0.0.1
DATABASE: ops
USER: gpadmin
```
Formatting the Input Data

When you use Greenplum loader, you need to specify how your data is formatted. Data can be in either delimited text (TEXT) or comma separated values (CSV) format. External data must be formatted correctly in order to be read by Greenplum Database. This section explains the format of data files expected by Greenplum Database.

- Formatting Rows
- Formatting Columns
- Representing NULL Values
- Escaping
- Character Encoding

Formatting Rows

Greenplum Database expects rows of data to be separated by the LF character (Line feed, 0x0A), CR (Carriage return, 0x0D), or CR followed by LF (CR+LF, 0x0D 0x0A). LF is the standard newline representation on UNIX or UNIX-like operating systems. Other operating systems (such as Windows or Mac OS 9) may use CR individually, or CR+LF. All of these representations of a newline are supported by Greenplum Database as a row delimiter.

Formatting Columns

The default column or field delimiter is the horizontal TAB character (0x09) for text files and the comma character (0x2C) for CSV files. However, it is possible to declare another single character delimiter using the DELIMITER attribute in the load configuration file. The delimiter character must only appear between
any two data value fields. Do not place a delimiter at the beginning or end of a row. For example, if using the pipe character (|) as your delimiter:

```
data value 1 | data value 2 | data value 3
```

**Representing NULL Values**

NULL is the value used to represent an unknown piece of data in a column or field. Within your data files you can designate a string to represent null values. The default string is `\N` (backslash-N) in TEXT mode, or an empty value with no quotations in CSV mode. You can also declare a different string using the NULL attribute in the load configuration file. For example, you might prefer an empty string for cases where you do not want to distinguish nulls from empty strings. When using the Greenplum Database loading tools, any data item that matches the designated null string will be considered a null value.

**Escaping**

The data file has two reserved characters that have special meaning to Greenplum Database:

- The designated delimiter character, which is used to separate columns or fields in the data file.
- The newline character used to designate a new row in the data file.

If your data contains either of these characters, you must escape the character so Greenplum treats it as data and not as a field separator or new row. By default, the escape character is a backslash (\) for text-formatted files and a double quote (") for csv-formatted files.

**Escaping in Text Formatted Files**

By default, the escape character is a backslash (\) for text-formatted files. If you want to use a different escape character, use the ESCAPE attribute in the load configuration file. In cases where your selected escape character is present in your data, you can use it to escape itself.

For example, suppose you have a table with three columns and you want to load the following three fields:

- `\` = `\`
- `|` = `|`
- `!` = `!`

Your designated delimiter character is pipe (|), and your designated escape character is backslash (\). The formatted row in your data file would look like this:

```
backslash = \ | vertical bar = | | exclamation point = !
```

Notice how the backslash character that is part of the data is escaped with another backslash character, and the pipe character that is part of the data is escaped with a backslash character.

The escape character can also be used to escape octal and hexadecimal sequences. When used in this way, the escaped value will get converted to the equivalent character when loaded into Greenplum Database. For example, to load the ampersand character (&), you could use the escape character to escape its equivalent hexadecimal (\0x26) or octal (\046) representation.

If there is no need to escape the data in text-formatted files, you can disable escaping using the ESCAPE clause of the COPY and CREATE EXTERNAL TABLE commands or the ESCAPE attribute of the load control file for `gpload.py` as follows:

```
ESCAPE 'OFF'
```

This is useful for input data that contains a lot of backslash characters within the data itself (such as web log data).
**Escaping in CSV Formatted Files**

By default, the escape character is a double quote (") for CSV-formatted files. If you want to use a different escape character, use the `ESCAPE` clause of `COPY` and `CREATE EXTERNAL TABLE` commands or the `ESCAPE` attribute of the load control file for `gpload.py` to declare a different escape character. In cases where your selected escape character is present in your data, you can use it to escape itself.

For example, suppose you have a table with three columns and you want to load the following three fields:

- Free trip to A,B
- 5.89
- Special rate "1.79"

Your designated delimiter character is comma (,), and your designated escape character is double quote ("). The formatted row in your data file would look like this:

```
"Free trip to A,B","5.89","Special rate "1.79"
```

Notice how that for the comma character that is part of the data, the entire data value is enclosed in double quotes. Also notice how the double quotes that are part of the data are also escaped with a double quote even though the field value is enclosed in double quotes.

Embedding the entire field inside a set of double quotes also guarantees preservation of leading and trailing whitespace characters:

```
"Free trip to A,B " ,"5.89 " ,"Special rate ""1.79" "
```

**Character Encoding**

A character encoding system consists of a code that pairs each character from a given repertoire with something else, such as a sequence of numbers or octets, in order to facilitate the transmission and storage of data. The character set support in Greenplum Database allows you to store text in a variety of character sets, including single-byte character sets such as the ISO 8859 series and multiple-byte character sets such as EUC (Extended UNIX Code), UTF-8, and Mule internal code. All supported character sets can be used transparently by clients, but a few are not supported for use within the server (that is, as a server-side encoding).

Data files must be in a character encoding recognized by Greenplum Database. See the *Greenplum Database Reference Guide* for the supported character sets. Data files that contain invalid or unsupported encoding sequences will encounter errors when loading into Greenplum Database.

**Note:** On data files generated on a Microsoft Windows operating system, try running the `dos2unix` system command to remove any Windows-only characters prior to loading into Greenplum Database.

**Running Greenplum Loader**

Greenplum loader is invoked by running the `gpload.py` program from a Windows command-line session. For complete command syntax and options, see `gpload.py`.

**Greenplum Loader Log Files**

By default, `gpload.py` creates a directory called `gpAdminLogs` in the same location from where you execute the program and writes its log files there. Alternatively, you can use the `-l` option when executing `gpload.py` to direct the log output to a different location. See `gpload.py` for the format of these log files.
Updating Database Statistics After Data Loads

After loading data, always run the `ANALYZE` SQL command to update the database statistics used by the query planner. `ANALYZE` collects statistics about the contents of tables in the database, and stores the results in the system table `pg_statistic`. The query planner uses these statistics to help determine the most efficient execution plans for queries. For example, to collect statistics on a newly loaded table, run the following on the Greenplum master host:

```
psql dbname -c 'ANALYZE mytable;
'
```

Vacuuming the Database After Load Errors

The Greenplum loader will stop a load operation if it encounters an error. When this happens, the target table may already have received earlier rows in the load operation. Although these rows will not be visible or accessible, they still occupy disk space. This may amount to a considerable amount of wasted disk space if the failure happened well into a large load operation. You may wish to invoke the `VACUUM` command to recover the wasted space. For example, run the following command on the master host after a load error:

```
vacuumdb dbname [table_name]
```

`VACUUM` reclaims storage occupied by deleted tuples. In normal operation, tuples that are deleted or obsoleted by an update are not physically removed from their table; they remain present until a `VACUUM` is done. Therefore it's recommended to do `VACUUM` periodically, especially on frequently-updated tables.

Running gpfdist as a Windows Service

Greenplum Database Loaders allow `gpfdist` to run as a Windows Service.

Follow the instructions below to download, register and activate `gpfdist` as a service:

1. Update your Greenplum Database Loader package to the latest version. This package is available from Pivotal Network.
2. Register `gpfdist` as a Windows service:
   a. Open a Windows command window
   b. Run the following command:
      ```
      sc create gpfdist binpath= "path_to_gpfdist.exe -p 8081 -d External\load \files\path -l Log\file\path"
      ```
      You can create multiple instances of `gpfdist` by running the same command again, with a unique name and port number for each instance:
      ```
      sc create gpfdistN binpath= "path_to_gpfdist.exe -p 8082 -d External \load\files\path -l Log\file\path"
      ```
3. Activate the `gpfdist` service:
   a. Open the Windows Control Panel and select **Administrative Tools > Services**.
   b. Highlight then right-click on the `gpfdist` service in the list of services.
   c. Select **Properties** from the right-click menu, the Service Properties window opens.
      Note that you can also stop this service from the Service Properties window.
   d. Optional: Change the **Startup Type** to **Automatic** (after a system restart, this service will be running), then under **Service status**, click **Start**.
   e. Click **OK**.
Repeat the above steps for each instance of gpfdist that you created.

Loader Program Reference

This is a reference of the command-line loader programs. These programs can be run from a Windows console session (cmd) or a command-line utility such as Cygwin. They all require certain connection information such as the Greenplum master host name, port, database name, and role name. These can be configured using environment variables. For more information, see Configuring Greenplum Loader.

The following loader programs are provided:

- gpload.py (loader program)
- gpfdist.exe (parallel file distribution program used by gpload.py)

See also the SQL Syntax Summary for a quick reference to available SQL commands.
Chapter 11

DataDirect ODBC Drivers for Pivotal Greenplum

ODBC drivers enable third party applications to connect via a common interface to the Pivotal Greenplum Database system. This document describes how to install DataDirect Connect XE for ODBC drivers for Pivotal Greenplum on either a Linux or Windows system. Unless specified otherwise, references to DataDirect Connect XE for ODBC refer to DataDirect Connect XE for ODBC and DataDirect Connect64 XE for ODBC.

The DataDirect ODBC Drivers for Pivotal Greenplum are available for download from Pivotal Network.
Prerequisites

- Install KornShell (ksh) on your system if it is not available.
- Note the appropriate serial number and license key (use the same number for both the serial number and license key during the installation):

<table>
<thead>
<tr>
<th>Driver</th>
<th>Serial Number / License Key</th>
</tr>
</thead>
<tbody>
<tr>
<td>DataDirect Connect XE for ODBC 7.1 drivers (32-bit drivers)</td>
<td>1076681728</td>
</tr>
<tr>
<td>DataDirect Connect64 XE for ODBC 7.1 drivers (64-bit drivers)</td>
<td>1076681984</td>
</tr>
</tbody>
</table>
Supported Client Platforms

DataDirect Connect64 XE for ODBC drivers for Greenplum support the following 64-bit client platforms:

- AIX 64: 7.1, 6.1, 5.3 Fixpack 5 or higher
- HP-UX IPF: 11i v3.0 (B.11.3X), 11i v2.0 (B.11.23)
- Linux Itanium: Red Hat Enterprise Linux (RHEL) 7.x, 6.x, RHEL 5.x, RHEL 4.x
- Linux x64: RHEL 7.x RHEL 6.x, RHEL 5.x, RHEL 4.x, SUSE Linux Enterprise Server (SLES) 12, SLES 11, SLES 10, Ubuntu 16.04
- Solaris on SPARC: 11 and 11 Express (Solaris 5.11), 10 (Solaris 5.10), 9 (Solaris 5.9), 8 (Solaris 5.8)
- Solaris x64: 11 (Solaris 5.11), 10 (Solaris 5.10)
- Windows x64: Windows 8, Windows 10, Windows Server 20016

DataDirect Connect XE for ODBC drivers for Greenplum support the following 32-bit client platforms:

- AIX 32: 7.1, 6.1, 5.3 Fixpack 5 or higher
- HP-UX IPF: 11i v3.0 (B.11.3X), 11i v2.0 (B.11.23)
- HP-UX PA-RISC: 11i v3 (B.11.3X), 11i v2 (B.11.23) 11i v1 (B.11.11), 11
- Linux x86: Red Hat Enterprise Linux (RHEL) 6.x, RHEL 5.x, RHEL 4.x, SUSE Linux Enterprise Server (SLES) 11, SLES 10, Ubuntu 16.04, Ubuntu 14.04
- Solaris on SPARC: 11 and 11 Express (Solaris 5.11), 10 (Solaris 5.10), 9 (Solaris 5.9), 8 (Solaris 5.8)
- Windows: Windows 8, Windows 10, Windows Server 20016
Installing on Linux Systems

To install ODBC drivers on your client:

1. Log into Pivotal Network and download the correct ODBC driver for your operating system. The following Linux and UNIX files are available:
   - PROGRESS_DATADIRECT_CONNECT64_ODBC_7.1.6.HOTFIX_LINUX_64.tar.Z
   - PROGRESS_DATADIRECT_CONNECT_ODBC_7.1.6.HOTFIX_LINUX_32.tar.Z
   - PROGRESS_DATADIRECT_CONNECT64_ODBC_7.1.6.HOTFIX_AIX_64.tar.Z
   - PROGRESS_DATADIRECT_CONNECT_ODBC_7.1.6.HOTFIX_AIX_32.tar.Z

2. Unpack the files. For example:

   $ tar -zxvf PROGRESS_DATADIRECT_CONNECT64_ODBC_7.1.6.HOTFIX_LINUX_64.tar.Z

   The files are extracted to the current directory.

3. Execute the installer:

   $ ksh unixmi.ksh
   Progress DataDirect Connect for ODBC Setup is preparing....
   English has been set as the installation language.
   Log file : /tmp/logfile.492.1
   Progress DataDirect Connect (R) and Connect XE for ODBC 7.1 SP5
   for UNIX operating systems
   The following operating system has been detected:
   LinuxX64
   Is this the current operating system on your machine (Y/N) ?

4. Press Y to confirm your operating system. The installer displays the license agreement.

5. Enter YES to accept the End User License Agreement. The installer prompts you for registration information:

   Enter YES to accept the above agreement : YES
   Please enter the following information for proper registration.
   In the Key field, enter either EVAL or the Key provided.
   Name          :

6. Enter the required registration information at each prompt:

<table>
<thead>
<tr>
<th>Prompt</th>
<th>Enter</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name:</td>
<td>Name to associate with the registration.</td>
</tr>
<tr>
<td>Company:</td>
<td>Your company name.</td>
</tr>
<tr>
<td>Serial Number:</td>
<td>• 1076681984 for 64-bit driver, or</td>
</tr>
<tr>
<td></td>
<td>• 1076681728 for 32-bit driver.</td>
</tr>
<tr>
<td>Key:</td>
<td>• 1076681984 for 64-bit driver, or</td>
</tr>
<tr>
<td></td>
<td>• 1076681728 for 32-bit driver.</td>
</tr>
</tbody>
</table>
The installation program displays the registered driver information. For example:

You have chosen the Greenplum Wire Protocol driver.
Server Unlimited
Unlimited Connections
To change this information, enter C. Otherwise, press Enter to continue.

7. Press Enter to continue with the installation. The installer prompts you for a temporary directory:

DataDirect Connect for ODBC Setup is preparing the installation.
Choose a temporary directory.
Enter the full path to the temporary install directory. [/tmp]:

8. Press Enter to accept the default /tmp directory or enter a custom directory to store temporary files. The installer extracts temporary files and prompts you for an installation directory:

Checking for available space...
There is enough space.
Extracting files...
Choose a destination directory.
Enter the full path to the install directory. [/opt/Progress/DataDirect/Connect64_for_ODBC_71]:

9. Press Enter to accept the default directory or enter a custom destination directory. The installer checks for available space and installs the software:

Checking for available space...
There is enough space.
Extracting files...
Creating license file......

DataDirect Connect for ODBC Setup successfully removed all of the temporary files.

Thank you for using Progress DataDirect products under OEM license to Greenplum Inc.

Would you like to install another product (Y/N) ? [Y]

10. Enter N to exit the installer.

**Configuring the Driver on Linux**

After you install the driver software, perform these steps to configure the driver.

1. Change to the installation directory for your driver. For example:

   $ cd /opt/Progress/DataDirect/Connect64_for_ODBC_71/

2. Set the LD_LIBRARY_PATH, ODBCINI and ODBCINST environment variables with the command:

   $ source odbc.sh
3. Open the odbc.ini file and create a new DSN entry. You can use the existing “Greenplum Wire Protocol” entry as a template.

```
$ vi $ODBCINI
```

You must edit the following entries to add values that match your system:

<table>
<thead>
<tr>
<th>Entry</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Database</td>
<td>Pivotal Greenplum database name.</td>
</tr>
<tr>
<td>HostName</td>
<td>Master host name.</td>
</tr>
<tr>
<td>PortNumber</td>
<td>Master host port number.</td>
</tr>
<tr>
<td>LogonID</td>
<td>Greenplum Database user.</td>
</tr>
<tr>
<td>Password</td>
<td>Password.</td>
</tr>
</tbody>
</table>

4. Verify the driver version:

```
$ cd /opt/Progress/DataDirect/Connect64_for_ODBC_71/bin
$ ./ddtestlib ddgplm27.so
Load of ddgplm27.so successful, qehandle is 0x19B4C60
File version: 07.16.0270 (B00357, U0237)
```

**Testing the Driver Connection on Linux**

To test the DSN connection:

1. Execute the example utility to test the DSN connection, entering the Greenplum Wire Protocol data source name and the credentials of a Pivotal Greenplum user. For example:

```
$ cd /opt/Progress/DataDirect/Connect64_for_ODBC_71/samples/example
$ ./example
./example DataDirect Technologies, Inc. ODBC Example Application.
Enter the data source name : Greenplum Wire Protocol
Enter the user name      : gpadmin
Enter the password       : gpadmin

Enter SQL statements (Press ENTER to QUIT)
SQL>
```

2. Enter the following select statement to confirm database connectivity:

```
Enter SQL statements (Press ENTER to QUIT)
SQL> select version();
```

```
version
PostgreSQL 8.3.23 (Greenplum Database 5.0.0 build
commit:8c709516061cff5476c03d6e2da99aae42722ae1) on x86_64-pc-linux-gnu,
compiled by GCC gcc (GCC) 6.2.0 compiled on Sep 1 2017 22:39:53

Enter SQL statements (Press ENTER to QUIT)
SQL>
```

3. Press the ENTER key to exit the example application.
Installing on Windows Systems

To install ODBC drivers on your client:

1. Log into *Pivotal Network* and download the correct ODBC driver for your operating system (32-bit or 64-bit). The following Windows files are available:
   - PROGRESS_DATADIRECT_CONNECT64_ODBC_7.1.6.HOTFIX_WIN_64.zip
   - PROGRESS_DATADIRECT_CONNECT_ODBC_7.1.6.HOTFIX_WIN_32.zip
2. Uncompress the installer.
3. Double-click setup.exe to launch the install wizard.
4. If necessary, permit the InstallAnywhere installer to run.
5. Click Next at the Introduction screen to begin the installation.
6. Accept the End User License Agreement and click Next.
7. Select OEM or Licensed Installation as the installation type and click Next.
8. Enter your licensing information: Division name, Company Name, and serial number/license key found in Prerequisites.
9. Select Add. You should see this driver in the License dialog box: ODBC Greenplum Wire Protocol Third Party All Platform Server Unlimited Cores
10. Select Next.
11. Choose options appropriate for your installation. For example, select to replace the existing drivers and/or to create the default data sources. Click Next.
12. Accept the default installation directory or choose a custom directory. Click Next.
13. Verify the selected installation options, and click Install to begin installation. The installation process may take several minutes.
14. Select Done to complete installing the driver package.

Verifying the Version on Windows

To verify your driver version:

1. Select *Start > All Programs > DataDirect > ODBC Administrator* to open the Windows ODBC Administrator.
2. Click the Drivers tab, and scroll down to DataDirect <version> Greenplum Wire Protocol. Ensure that you see the expected version number.

Configuring and Testing the Driver on Windows

To configure and test a DSN connection to a Greenplum Database:

1. Open the ODBC Administrator.
2. Select the System DSN tab.
3. Select Add.
5. Enter the details for your chosen Greenplum Database instance. For example:

   Recommended: Set the Max Long Varchar size.
   Select the Advanced tab.
   In Max Long Varchar Size, enter 8192 then select Apply.
6. Select **Test Connect**.
7. Enter your user name and password, then select **OK**.
8. You should see the confirmation message **Connection Established!**

If your connection fails, check the following for accuracy:

- Host Name
- Port Number
- Database Name
- User Name
- Password
- Greenplum instance is active
DataDirect Driver Documentation

For more information on working with Data Direct, see documentation that is installed with the driver. By default, you can access the installed documentation by using a Web browser to open the file `/opt/Progress/DataDirect/Connect64_for_ODBC_71/help/index.html.

Documentation is also available online at https://www.progress.com/documentation/datadirect-connectors. Titles include:

- UNIX/Linux Readme
Chapter 12

DataDirect JDBC Driver for Pivotal Greenplum

DataDirect JDBC drivers are compliant with the Type 4 architecture, but provide advanced features that define them as Type 5 drivers. Additionally, the drivers consistently support the latest database features and are fully compliant with Java™ SE 8 and JDBC 4.0 functionality.

The DataDirect JDBC Driver for Pivotal Greenplum is available for download from Pivotal Network.
Prerequisites

• The DataDirect JDBC Driver requires Java SE 5 or higher. See System and Product Requirements in the DataDirect documentation for information and requirements associated with specific features of the JDBC driver.

• The license key is embedded in the greenplum.jar file itself. You do not need to apply a specific license key to the driver to activate it.
Downloading the DataDirect JDBC Driver

To install the JDBC driver on your client:

1. Log into Pivotal Network and download the DataDirect JDBC driver file: greenplum.jar
2. Add the full path to the greenplum.jar to your Java CLASSPATH environment variable, or add it to your classpath with the -classpath option when executing a Java application.
Obtaining Version Details for the Driver

To view the JDBC driver version information:

1. Change to the directory that contains the downloaded `greenplum.jar` driver file. For example:

   ```bash
   $ cd /opt/Progress/DataDirect/Connect_for_JDBC_51/lib
   ```

2. Execute the data source class to display the version information.

   For Linux/Unix systems:
   ```bash
   $ java -classpath greenplum.jar com.pivotal.jdbc.GreenplumDriver
   [Pivotal][Greenplum JDBC Driver]Driver Version: 5.1.4.000212
   (F000427.U000206)
   ```

   For Windows systems:
   ```bash
   java -classpath .;\greenplum.jar com.pivotal.jdbc.GreenplumDriver
   [Pivotal][Greenplum JDBC Driver]Driver Version: 5.1.4.000212
   (F000427.0000206)
   ```
Usage Information

The JDBC driver is provided in the greenplum.jar file. Use the following data source class and connection URL information with the driver.

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Driver File Name</td>
<td>greenplum.jar</td>
</tr>
<tr>
<td>Data Source Class</td>
<td>com.pivotal.jdbc.GreenplumDriver</td>
</tr>
<tr>
<td>Connection URL</td>
<td>jdbc:pivotal:greenplum://host:port;DatabaseName=&lt;name&gt;</td>
</tr>
<tr>
<td>Driver Defaults</td>
<td>FetchTWFSasTime=true, MaxLongVarcharSize=8190, MaxNumericPrecision=28,</td>
</tr>
<tr>
<td></td>
<td>MaxNumericScale=6, PrepareThreshold=0, ResultSetMetadataOptions=1,</td>
</tr>
<tr>
<td></td>
<td>SupportsCatalogs=true</td>
</tr>
</tbody>
</table>
Configuring Prepared Statement Execution

The DataDirect JDBC driver version 5.1.4.000270 (F000450.U000214) introduced support for the `PrepareThreshold` connection property. This property specifies the number of prepared statement executions to be performed before the driver switches to using server-side prepared statements.

The `PrepareThreshold` default value is 0, always use server-side prepare for prepared statements. This setting preserves the behavior of previous versions of the JDBC driver.

When the `PrepareThreshold` value is greater than 1, it specifies on which execution of a prepared statement the driver starts using server-side prepared statements.

Note: `statement.executeBatch()` always uses server-side prepare for prepared statements. This matches the behavior of the PostgreSQL open source JDBC driver.

Refer to `PrepareThreshold` in the DataDirect documentation for additional information about this connection property.

Limitation

When the `PrepareThreshold` value is greater than one and the prepared statement includes parameterized operations, the driver does not send any SQL prepare calls during `connection.prepareStatement()`. The driver instead sends the query all at once, at execution time. This requires that the driver determine the data types of every column before it sends the query to the server. While the driver can make this determination for many data types, it cannot for the JDBC types that can be mapped to multiple Greenplum data types:

- BIT VARYING
- BOOLEAN
- JSON
- TIME WITH TIME ZONE
- UUIDCOL

To work around this limitation, set `PrepareThreshold` to 0 when a prepared statement uses parameterized values with any of the above data types. And use `ResultSet.getMetaData()` to determine if any of the above types are used in a query in advance of submitting the prepared statement.

Note: GPORCA does not support prepared statements that have parameterized values, and will fall back to using the Postgres Planner.
