**log_disconnections**
Log disconnections, with reasons.
Default: 1

**log_pooler_errors**
Log error messages that the pooler sends to clients.
Default: 1

**stats_period**
How often to write aggregated statistics to the log.
Default: 60

**Console Access Control**

**admin_users**
Comma-separated list of database users that are allowed to connect and run all commands on the PgBouncer Administration Console. Ignored when auth_type=any, in which case any username is allowed in as admin.
Default: empty

**stats_users**
Comma-separated list of database users that are allowed to connect and run read-only queries on the console. This includes all SHOW commands except SHOW FDS.
Default: empty

**Connection Sanity Checks, Timeouts**

**server_reset_query**
Query sent to server on connection release, before making it available to other clients. At that moment no transaction is in progress so it should not include ABORT or ROLLBACK.

The query should clean any changes made to a database session so that the next client gets a connection in a well-defined state. Default is DISCARD ALL which cleans everything, but that leaves the next client no pre-cached state.

When transaction pooling is used, the server_reset_query should be empty, as clients should not use any session features. If clients do use session features, they will be broken because transaction pooling does not guarantee that the next query will run on the same connection.

Default: DISCARD ALL;

**server_reset_query_always**
Whether server_reset_query should be run in all pooling modes. When this setting is off (default), the server_reset_query will be run only in pools that are in sessions pooling mode. Connections in transaction pooling mode should not have any need for reset query.
Default: 0
**server_check_delay**
How long to keep released connections available for re-use without running sanity-check queries on it. If 0, then the query is run always.
Default: 30.0

**server_check_query**
A simple do-nothing query to test the server connection.
If an empty string, then sanity checking is disabled.
Default: SELECT 1;

**server_lifetime**
The pooler tries to close server connections that have been connected longer than this number of seconds. Setting it to 0 means the connection is to be used only once, then closed.
Default: 3600.0

**server_idle_timeout**
If a server connection has been idle more than this many seconds it is dropped. If this parameter is set to 0, timeout is disabled. [seconds]
Default: 600.0

**server_connect_timeout**
If connection and login will not finish in this number of seconds, the connection will be closed.
Default: 15.0

**server_login_retry**
If a login fails due to failure from connect() or authentication, the pooler waits this many seconds before retrying to connect.
Default: 15.0

**client_login_timeout**
If a client connects but does not manage to login in this number of seconds, it is disconnected. This is needed to avoid dead connections stalling SUSPEND and thus online restart.
Default: 60.0

**autodb_idle_timeout**
If database pools created automatically (via *) have been unused this many seconds, they are freed. Their statistics are also forgotten.
Default: 3600.0

**dns_max_ttl**
How long to cache DNS lookups, in seconds. If a DNS lookup returns several answers, PgBouncer round-robins between them in the meantime. The actual DNS TTL is ignored.
Default: 15.0

**dns_nxdomain_ttl**
How long error and NXDOMAIN DNS lookups can be cached, in seconds.
Default: 15.0

**dns_zone_check_period**
Period to check if zone serial numbers have changed.
PgBouncer can collect DNS zones from hostnames (everything after first dot) and then periodically check if the zone serial numbers change. If changes are detected, all hostnames in that zone are looked up again. If any host IP changes, its connections are invalidated.

Works only with UDNS and c-ares backend (\(--\text{with-udns} \text{ or } --\text{with-cares} \text{ to configure}\).

Default: 0.0 (disabled)

**TLS settings**

**client_tls_sslmode**

TLS mode to use for connections from clients. TLS connections are disabled by default. When enabled, `client_tls_key_file` and `client_tls_cert_file` must be also configured to set up the key and certificate PgBouncer uses to accept client connections.

- **disable**: Plain TCP. If client requests TLS, it’s ignored. Default.
- **allow**: If client requests TLS, it is used. If not, plain TCP is used. If client uses client-certificate, it is not validated.
- **prefer**: Same as `allow`.
- **require**: Client must use TLS. If not, client connection is rejected. If client uses client-certificate, it is not validated.
- **verify-ca**: Client must use TLS with valid client certificate.
- **verify-full**: Same as `verify-ca`.

**client_tls_key_file**

Private key for PgBouncer to accept client connections.

Default: not set

**client_tls_cert_file**

Root certificate file to validate client certificates.

Default: unset

**client_tls_ca_file**

Root certificate to validate client certificates.

Default: unset

**client_tls_protocols**

Which TLS protocol versions are allowed.

Valid values: are `tlsv1.0`, `tlsv1.1`, `tlsv1.2`.

Shortcuts: `all` (`tlsv1.0`, `tlsv1.1`, `tlsv1.2`), `secure` (`tlsv1.2`), `legacy` (all).

Default: `all`

**client_tls_ciphers**

Default: `fast`

**client_tls_ecdhcurve**

Elliptic Curve name to use for ECDH key exchanges.

Allowed values: `none` (DH is disabled), `auto` (256-bit ECDH), `curve` name.

Default: `auto`

**client_tls_dheparams**

DHE key exchange type.

Allowed values: `none` (DH is disabled), `auto` (2048-bit DH), `legacy` (1024-bit DH).
Default: auto

**server_tls_sslmode**

TLS mode to use for connections to Greenplum Database and PostgreSQL servers. TLS connections are disabled by default.

- **disabled**: Plain TCP. TLS is not requested from the server. Default.
- **allow**: If server rejects plain, try TLS. (*PgBouncer Documentation is speculative on this.*)
- **prefer**: TLS connection is always requested first. When connection is refused, plain TCP is used. Server certificate is not validated.
- **require**: Connection must use TLS. If server rejects it, plain TCP is not attempted. Server certificate is not validated.
- **verify-ca**: Connection must use TLS and server certificate must be valid according to **server_tls_ca_file**. The server hostname is not verified against the certificate.
- **verify-full**: Connection must use TLS and the server certificate must be valid according to **server_tls_ca_file**. The server hostname must match the hostname in the certificate.

**server_tls_ca_file**

Path to the root certificate file used to validate Greenplum Database and PostgreSQL server certificates.

Default: unset

**server_tls_key_file**

The private key for PgBouncer to authenticate against Greenplum Database or PostgreSQL server.

Default: not set

**server_tls_cert_file**

Certificate for private key. Greenplum Database or PostgreSQL servers can validate it.

Default: not set

**server_tls_protocols**

Which TLS protocol versions are allowed.

Valid values are: `tlsv1.0`, `tlsv1.1`, `tlsv1.2`.

Shortcuts: `all` (tlsv1.0, tlsv1.1, tlsv1.2); `secure` (tlsv1.2); `legacy` (all).

Default: all

**server_tls_ciphers**

Default: fast

---

**Dangerous Timeouts**

Setting the following timeouts can cause unexpected errors.

**query_timeout**

Queries running longer than this (seconds) are canceled. This parameter should be used only with a slightly smaller server-side **statement_timeout**, to trap queries with network problems. [seconds]

Default: 0.0 (disabled)

**query_wait_timeout**
The maximum time, in seconds, queries are allowed to wait for execution. If the query is not assigned a connection during that time, the client is disconnected. This is used to prevent unresponsive servers from grabbing up connections.

Default: 120

client_idle_timeout
Client connections idling longer than this many seconds are closed. This should be larger than the client-side connection lifetime settings, and only used for network problems.

Default: 0.0 (disabled)

idle_transaction_timeout
If client has been in "idle in transaction" state longer than this (seconds), it is disconnected.

Default: 0.0 (disabled)

**Low-level Network Settings**

pkt_buf
Internal buffer size for packets. Affects the size of TCP packets sent and general memory usage. Actual libpq packets can be larger than this so there is no need to set it large.

Default: 4096

max_packet_size
Maximum size for packets that PgBouncer accepts. One packet is either one query or one result set row. A full result set can be larger.

Default: 2147483647

listen_backlog
Backlog argument for the listen(2) system call. It determines how many new unanswered connection attempts are kept in queue. When the queue is full, further new connection attempts are dropped.

Default: 128

sbuf_loopcnt
How many times to process data on one connection, before proceeding. Without this limit, one connection with a big result set can stall PgBouncer for a long time. One loop processes one pkt_buf amount of data. 0 means no limit.

Default: 5

suspend_timeout
How many seconds to wait for buffer flush during SUSPEND or restart (-R). Connection is dropped if flush does not succeed.

Default: 10

tcp_defer_accept
For details on this and other TCP options, please see the tcp(7) man page.

Default: 45 on Linux, otherwise 0

tcp_socket_buffer
Default: not set

tcp_keepalive
Turns on basic keepalive with OS defaults.

On Linux, the system defaults are tcp_keepidle=7200, tcp_keepintvl=75, tcp_keepcnt=9.
Default: 1

**tcp_keepcnt**
Default: not set

**tcp_keepidle**
Default: not set

**tcp_keepintvl**
Default: not set

### [users] Section

This section contains *key=value* pairs, where the *key* is a user name and the *value* is a *libpq* connect-string list of *key=value* pairs.

### Pool configuration

**pool_mode**

Set the pool mode for all connections from this user. If not set, the database or default *pool_mode* is used.

### Example Configuration Files

#### Minimal Configuration

```plaintext
[databases]
postgres = host=127.0.0.1 dbname=postgres auth_user=gpadmin

[pgbouncer]
pool_mode = session
listen_port = 6543
listen_addr = 127.0.0.1
auth_type = md5
auth_file = users.txt
logfile = pgbouncer.log
pidfile = pgbouncer.pid
admin_users = someuser
stats_users = stat_collector
```

Use connection parameters passed by the client:

```plaintext
[databases]
* =

[pgbouncer]
listen_port = 6543
listen_addr = 0.0.0.0
auth_type = trust
auth_file = bouncer/users.txt
logfile = pgbouncer.log
pidfile = pgbouncer.pid
ignore_startup_parameters=options
```

#### Database Defaults

```plaintext
[databases]
; foodb over unix socket
foodb =
```
See Also

*pgbouncer*, *pgbouncer-admin*, *PgBouncer Configuration Page*

**pgbouncer-admin**

PgBouncer Administration Console.

**Synopsis**

```
psql -p port pgbouncer
```

**Description**

The PgBouncer Administration Console is available via `psql`. Connect to the PgBouncer `port` and the virtual database named `pgbouncer` to log in to the console.

Users listed in the `pgbouncer.ini` configuration parameters `admin_users` and `stats_users` have privileges to log in to the PgBouncer Administration Console.

You can control connections between PgBouncer and Greenplum Database from the console. You can also set PgBouncer configuration parameters.

**Options**

```
-p port
```

The PgBouncer port number.

**Command Syntax**

```
pgbouncer=# SHOW help;
NOTICE:  Console usage
DETAIL:    SHOW HELP|CONFIG|DATABASES|POOLS|CLIENTS|SERVERS|VERSION
           SHOW FDS|SOCKETS|ACTIVE_SOCKETS|LISTS|MEM
           SHOW DNS_HOSTS|DNS_ZONES
           SHOW STATS|STATS_TOTALS|STATS_AVERAGES
           SET key = arg
           RELOAD
           PAUSE [<db>]
           RESUME [<db>]
           DISABLE <db>
           ENABLE <db>
           KILL <db>
           SUSPEND
           SHUTDOWN
```

**Administration Commands**

The following PgBouncer administration commands control the running `pgbouncer` process.
PAUSE [db]
If no database is specified, PgBouncer tries to disconnect from all servers, first waiting for all queries to complete. The command will not return before all queries are finished. This command is to be used to prepare to restart the database.

If a database name is specified, PgBouncer pauses only that database.

If you run a PAUSE db command, and then a PAUSE command to pause all databases, you must execute two RESUME commands, one for all databases, and one for the named database.

SUSPEND
All socket buffers are flushed and PgBouncer stops listening for data on them. The command will not return before all buffers are empty. To be used when rebooting PgBouncer online.

RESUME [ db ]
Resume work from a previous PAUSE or SUSPEND command.

If a database was specified for the PAUSE command, the database must also be specified with the RESUME command.

After pausing all databases with the PAUSE command, resuming a single database with RESUME db is not supported.

DISABLE db
Reject all new client connections on the database.

ENABLE db
Allow new client connections on the database.

KILL db
Immediately drop all client and server connections to the named database.

SHUTDOWN
Stop PgBouncer process. To exit from the psql command line session, enter \q.

RELOAD
The PgBouncer process reloads the current configuration file and updates the changeable settings.

SET key = value
Override specified configuration setting. See the SHOW CONFIG; command.

SHOW Command
The SHOW category command displays different types of PgBouncer information. You can specify one of the following categories:

• ACTIVE_SOCKETS
• CLIENTS
• CONFIG
• DATABASES
• DNS_HOSTS
• DNS_ZONES
• FDS
• POOLS
• SERVERS
• SOCKETS
• STATS
### ACTIVE_SOCKETS

**Table 67: Active Socket Information**

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>type</td>
<td>S, for server, C for client.</td>
</tr>
<tr>
<td>user</td>
<td>Username <code>pgbouncer</code> uses to connect to server.</td>
</tr>
<tr>
<td>database</td>
<td>Database name.</td>
</tr>
<tr>
<td>state</td>
<td>State of the server connection, one of <code>active</code>, <code>used</code> or <code>idle</code>.</td>
</tr>
<tr>
<td>addr</td>
<td>IP address of PostgreSQL server.</td>
</tr>
<tr>
<td>port</td>
<td>Port of PostgreSQL server.</td>
</tr>
<tr>
<td>local_addr</td>
<td>Connection start address on local machine.</td>
</tr>
<tr>
<td>local_port</td>
<td>Connection start port on local machine.</td>
</tr>
<tr>
<td>connect_time</td>
<td>When the connection was made.</td>
</tr>
<tr>
<td>request_time</td>
<td>When last request was issued.</td>
</tr>
<tr>
<td>wait</td>
<td>Time waiting.</td>
</tr>
<tr>
<td>wait_us</td>
<td>Time waiting (microseconds).</td>
</tr>
<tr>
<td>ptr</td>
<td>Address of internal object for this connection. Used as unique ID.</td>
</tr>
<tr>
<td>link</td>
<td>Address of client connection the server is paired with.</td>
</tr>
<tr>
<td>remote_pid</td>
<td>Process identifier of backend server process.</td>
</tr>
<tr>
<td>tls</td>
<td>TLS context.</td>
</tr>
<tr>
<td>recv_pos</td>
<td>Receive position in the I/O buffer.</td>
</tr>
<tr>
<td>pkt_pos</td>
<td>Parse position in the I/O buffer.</td>
</tr>
<tr>
<td>pkt_remain</td>
<td>Number of packets remaining on the socket.</td>
</tr>
<tr>
<td>send_pos</td>
<td>Send position in the packet.</td>
</tr>
<tr>
<td>send_remain</td>
<td>Total packet length remaining to send.</td>
</tr>
<tr>
<td>pkt_avail</td>
<td>Amount of I/O buffer left to parse.</td>
</tr>
<tr>
<td>send_avail</td>
<td>Amount of I/O buffer left to send.</td>
</tr>
</tbody>
</table>
### CLIENTS

**Table 68: Clients**

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>type</td>
<td>C, for client.</td>
</tr>
<tr>
<td>user</td>
<td>Client connected user.</td>
</tr>
<tr>
<td>database</td>
<td>Database name.</td>
</tr>
<tr>
<td>state</td>
<td>State of the client connection, one of active, used, waiting or idle.</td>
</tr>
<tr>
<td>addr</td>
<td>IP address of client, or unix for a socket connection.</td>
</tr>
<tr>
<td>port</td>
<td>Port client is connected to.</td>
</tr>
<tr>
<td>local_addr</td>
<td>Connection end address on local machine.</td>
</tr>
<tr>
<td>local_port</td>
<td>Connection end port on local machine.</td>
</tr>
<tr>
<td>connect_time</td>
<td>Timestamp of connect time.</td>
</tr>
<tr>
<td>request_time</td>
<td>Timestamp of latest client request.</td>
</tr>
<tr>
<td>wait</td>
<td>Time waiting.</td>
</tr>
<tr>
<td>wait_us</td>
<td>Time waiting (microseconds).</td>
</tr>
<tr>
<td>ptr</td>
<td>Address of internal object for this connection. Used as unique ID.</td>
</tr>
<tr>
<td>link</td>
<td>Address of server connection the client is paired with.</td>
</tr>
<tr>
<td>remote_pid</td>
<td>Process ID, if client connects with Unix socket and the OS supports getting it.</td>
</tr>
<tr>
<td>tls</td>
<td>Client TLS context.</td>
</tr>
</tbody>
</table>

### CONFIG

List of current PgBouncer parameter settings

**Table 69: Config**

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>key</td>
<td>Configuration variable name</td>
</tr>
<tr>
<td>value</td>
<td>Configuration value</td>
</tr>
<tr>
<td>changeable</td>
<td>Either yes or no. Shows whether the variable can be changed while running. If no, the variable can be changed only at boot time.</td>
</tr>
</tbody>
</table>

### DATABASES

**Table 70: Databases**

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>Name of configured database entry.</td>
</tr>
<tr>
<td>host</td>
<td>Host pgbouncer connects to.</td>
</tr>
<tr>
<td>Column</td>
<td>Description</td>
</tr>
<tr>
<td>-------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>port</td>
<td>Port pgbouncer connects to.</td>
</tr>
<tr>
<td>database</td>
<td>Actual database name pgbouncer connects to.</td>
</tr>
<tr>
<td>force_user</td>
<td>When user is part of the connection string, the connection between pgbouncer and the database server is forced to the given user, whatever the client user.</td>
</tr>
<tr>
<td>pool_size</td>
<td>Maximum number of server connections.</td>
</tr>
<tr>
<td>reserve_pool</td>
<td>The number of additional connections that can be created if the pool reaches pool_size.</td>
</tr>
<tr>
<td>pool_mode</td>
<td>The database's override pool_mode or NULL if the default will be used instead.</td>
</tr>
<tr>
<td>max_connections</td>
<td>Maximum number of connections for all pools for this database.</td>
</tr>
<tr>
<td>current_connections</td>
<td>The total count of connections for all pools for this database.</td>
</tr>
<tr>
<td>paused</td>
<td>Paused/unpaused state of the database.</td>
</tr>
<tr>
<td>disabled</td>
<td>Enabled/disabled state of the database.</td>
</tr>
</tbody>
</table>

**DNS_HOSTS**

Table 71: DNS Zones in Cache

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>hostname</td>
<td>Host name</td>
</tr>
<tr>
<td>ttl</td>
<td>How many seconds until next lookup.</td>
</tr>
<tr>
<td>addrs</td>
<td>Comma-separated list of addresses.</td>
</tr>
</tbody>
</table>

**DNS_ZONES**

Table 72: DNS Zones in Cache

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>zonename</td>
<td>Zone name</td>
</tr>
<tr>
<td>serial</td>
<td>Current DNS serial number</td>
</tr>
<tr>
<td>count</td>
<td>Hostnames belonging to this zone</td>
</tr>
</tbody>
</table>

**FDS**

*SHOW FDS* is an internal command used for an online restart, for example when upgrading to a new PgBouncer version. It displays a list of file descriptors in use with the internal state attached to them. This command blocks the internal event loop, so it should not be used while PgBouncer is in use.

When the connected user has username "pgbouncer", connects through a Unix socket, and has the same UID as the running process, the actual file descriptors are passed over the connection.
Table 73: FDS

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>fd</td>
<td>File descriptor numeric value.</td>
</tr>
<tr>
<td>task</td>
<td>One of pooler, client, or server.</td>
</tr>
<tr>
<td>user</td>
<td>User of the connection using the file descriptor.</td>
</tr>
<tr>
<td>database</td>
<td>Database of the connection using the file descriptor.</td>
</tr>
<tr>
<td>addr</td>
<td>IP address of the connection using the file descriptor, &quot;unix&quot; if a Unix socket is used.</td>
</tr>
<tr>
<td>port</td>
<td>Port used by the connection using the file descriptor.</td>
</tr>
<tr>
<td>cancel</td>
<td>Cancel key for this connection.</td>
</tr>
<tr>
<td>link</td>
<td>File descriptor for corresponding server/client. NULL if idle.</td>
</tr>
<tr>
<td>client_encoding</td>
<td>Character set used for the database.</td>
</tr>
<tr>
<td>std_strings</td>
<td>This controls whether ordinary string literals ('...') treat backslashes literally, as specified in the SQL standard.</td>
</tr>
<tr>
<td>datestyle</td>
<td>Display format for date and time values.</td>
</tr>
<tr>
<td>timezone</td>
<td>The timezone for interpreting and displaying time stamps.</td>
</tr>
<tr>
<td>password</td>
<td>auth_user's password.</td>
</tr>
</tbody>
</table>

LISTS

Shows the following PgBouncer statistics in two columns: the item label and value.

Table 74: Count of PgBouncer Items

<table>
<thead>
<tr>
<th>Item</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>databases</td>
<td>Count of databases.</td>
</tr>
<tr>
<td>users</td>
<td>Count of users.</td>
</tr>
<tr>
<td>pools</td>
<td>Count of pools.</td>
</tr>
<tr>
<td>free_clients</td>
<td>Count of free clients.</td>
</tr>
<tr>
<td>used_clients</td>
<td>Count of used clients.</td>
</tr>
<tr>
<td>login_clients</td>
<td>Count of clients in login state.</td>
</tr>
<tr>
<td>free_servers</td>
<td>Count of free servers.</td>
</tr>
<tr>
<td>used_servers</td>
<td>Count of used servers.</td>
</tr>
<tr>
<td>dns_names</td>
<td>Count of DNS names.</td>
</tr>
<tr>
<td>dns_zones</td>
<td>Count of DNS zones.</td>
</tr>
<tr>
<td>dns_queries</td>
<td>Count of DNS queries.</td>
</tr>
<tr>
<td>dns_pending</td>
<td>Count of in-flight DNS queries.</td>
</tr>
</tbody>
</table>
**MEM**

Shows cache memory information for these PgBouncer caches:

- user_cache
- db_cache
- pool_cache
- server_cache
- client_cache
- iobuf_cache

Table 75: In Memory Cache

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>Name of cache.</td>
</tr>
<tr>
<td>size</td>
<td>The size of a single slot in the cache.</td>
</tr>
<tr>
<td>used</td>
<td>Number of used slots in the cache.</td>
</tr>
<tr>
<td>free</td>
<td>The number of available slots in the cache.</td>
</tr>
<tr>
<td>memtotal</td>
<td>Total bytes used by the cache.</td>
</tr>
</tbody>
</table>

**POOLS**

A new pool entry is made for each pair of (database, user).

Table 76: Pools

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>database</td>
<td>Database name.</td>
</tr>
<tr>
<td>user</td>
<td>User name.</td>
</tr>
<tr>
<td>cl_active</td>
<td>Client connections that are linked to server connection and can process queries.</td>
</tr>
<tr>
<td>cl_waiting</td>
<td>Client connections have sent queries but have not yet got a server connection.</td>
</tr>
<tr>
<td>sv_active</td>
<td>Server connections that linked to client.</td>
</tr>
<tr>
<td>sv_idle</td>
<td>Server connections that are unused and immediately usable for client queries.</td>
</tr>
<tr>
<td>sv_used</td>
<td>Server connections that have been idle more than server_check_delay. The server_check_query query must be run on them before they can be used.</td>
</tr>
<tr>
<td>sv_tested</td>
<td>Server connections that are currently running either server_reset_query or server_check_query.</td>
</tr>
<tr>
<td>sv_login</td>
<td>Server connections currently in process of logging in.</td>
</tr>
<tr>
<td>maxwait</td>
<td>How long the first (oldest) client in the queue has waited, in seconds. If this begins to increase, the current pool of servers does not handle requests fast enough. The cause may be either an overloaded server or the pool_size setting is too small.</td>
</tr>
<tr>
<td>Column</td>
<td>Description</td>
</tr>
<tr>
<td>------------</td>
<td>--------------------------------------------------</td>
</tr>
<tr>
<td>maxwait_us</td>
<td>max_wait (microseconds).</td>
</tr>
<tr>
<td>pool_mode</td>
<td>The pooling mode in use.</td>
</tr>
</tbody>
</table>

**SERVERS**

Table 77: Servers

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>type</td>
<td>S, for server.</td>
</tr>
<tr>
<td>user</td>
<td>User ID that pgbouncer uses to connect to server.</td>
</tr>
<tr>
<td>database</td>
<td>Database name.</td>
</tr>
<tr>
<td>state</td>
<td>State of the pgbouncer server connection, one of active, used, or idle.</td>
</tr>
<tr>
<td>addr</td>
<td>IP address of the Greenplum or PostgreSQL server.</td>
</tr>
<tr>
<td>port</td>
<td>Port of the Greenplum or PostgreSQL server.</td>
</tr>
<tr>
<td>local_addr</td>
<td>Connection start address on local machine.</td>
</tr>
<tr>
<td>local_port</td>
<td>Connection start port on local machine.</td>
</tr>
<tr>
<td>connect_time</td>
<td>When the connection was made.</td>
</tr>
<tr>
<td>request_time</td>
<td>When the last request was issued.</td>
</tr>
<tr>
<td>wait</td>
<td>Time waiting.</td>
</tr>
<tr>
<td>wait_us</td>
<td>Time waiting (microseconds).</td>
</tr>
<tr>
<td>ptr</td>
<td>Address of the internal object for this connection. Used as unique ID.</td>
</tr>
<tr>
<td>link</td>
<td>Address of the client connection the server is paired with.</td>
</tr>
<tr>
<td>remote_pid</td>
<td>Pid of backend server process. If the connection is made over Unix socket and the OS supports getting process ID info, it is the OS pid. Otherwise it is extracted from the cancel packet the server sent, which should be PID in case server is PostgreSQL, but it is a random number in case server is another PgBouncer.</td>
</tr>
<tr>
<td>tls</td>
<td>TLS context.</td>
</tr>
</tbody>
</table>

**STATS**

Shows statistics.

Table 78: Stats

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>database</td>
<td>Statistics are presented per database.</td>
</tr>
<tr>
<td>total_xact_count</td>
<td>Total number of SQL transactions pooled by PgBouncer.</td>
</tr>
<tr>
<td>total_query_count</td>
<td>Total number of SQL queries pooled by PgBouncer.</td>
</tr>
<tr>
<td>total_received</td>
<td>Total volume in bytes of network traffic received by pgbouncer.</td>
</tr>
<tr>
<td>total_sent</td>
<td>Total volume in bytes of network traffic sent by pgbouncer.</td>
</tr>
<tr>
<td>Column</td>
<td>Description</td>
</tr>
<tr>
<td>--------------------</td>
<td>------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>total_xact_time</td>
<td>Total number of microseconds spent by PgBouncer when connected to Greenplum Database in a transaction, either idle in transaction or executing queries.</td>
</tr>
<tr>
<td>total_query_time</td>
<td>Total number of microseconds spent by pgbouncer when actively connected to the database server.</td>
</tr>
<tr>
<td>total_wait_time</td>
<td>Time spent (in microseconds) by clients waiting for a server.</td>
</tr>
<tr>
<td>avg_xact_count</td>
<td>Average number of SQL transactions pooled by PgBouncer.</td>
</tr>
<tr>
<td>avg_query_count</td>
<td>Average queries per second in last stats period.</td>

`psql`

Interactive command-line interface for Greenplum Database

**Synopsis**

`psql [option ...] [dbname [username]]`
Description

psql is a terminal-based front-end to Greenplum Database. It enables you to type in queries interactively, issue them to Greenplum Database, and see the query results. Alternatively, input can be from a file. In addition, it provides a number of meta-commands and various shell-like features to facilitate writing scripts and automating a wide variety of tasks.

Options

-a | --echo-all
  Print all nonempty input lines to standard output as they are read. (This does not apply to lines read interactively.) This is equivalent to setting the variable ECHO to all.

-A | --no-align
  Switches to unaligned output mode. (The default output mode is aligned.)

-c 'command' | --command='command'
  Specifies that psql is to execute the specified command string, and then exit. This is useful in shell scripts. command must be either a command string that is completely parseable by the server, or a single backslash command. Thus you cannot mix SQL and psql meta-commands with this option. To achieve that, you could pipe the string into psql, like this:

  ```
  echo '\x \ \ SELECT * FROM foo;' | psql
  ```

  (\x is the separator meta-command.)

  If the command string contains multiple SQL commands, they are processed in a single transaction, unless there are explicit BEGIN/COMMIT commands included in the string to divide it into multiple transactions. This is different from the behavior when the same string is fed to psql's standard input. Also, only the result of the last SQL command is returned.

-d dbname | --dbname=dbname
  Specifies the name of the database to connect to. This is equivalent to specifying dbname as the first non-option argument on the command line.

  If this parameter contains an = sign or starts with a valid URI prefix (postgresql:// or postgres://), it is treated as a conninfo string. See Connection Strings in the PostgreSQL documentation for more information.

-e | --echo-queries
  Copy all SQL commands sent to the server to standard output as well.

-E | --echo-hidden
  Echo the actual queries generated by \d and other backslash commands. You can use this to study psql's internal operations. This is equivalent to setting the variable ECHO_HIDDEN to on.

-f filename | --file=filename
  Use the file filename as the source of commands instead of reading commands interactively. After the file is processed, psql terminates. This is in many ways equivalent to the meta-command \i.

  If filename is – (hyphen), then standard input is read until an EOF indication or \q meta-command. Note however that Readline is not used in this case (much as if –n had been specified).

  Using this option is subtly different from writing psql < filename. In general, both will do what you expect, but using –f enables some nice features such as error messages with line numbers. There is also a slight chance that using this option will reduce the start-up overhead. On the other hand, the variant using the shell's input redirection is (in theory)
guaranteed to yield exactly the same output you would have received had you entered everything by hand.

-\textbf{F} separator | \textit{--field-separator=separator}

Use the specified separator as the field separator for unaligned output.

-\textbf{H} | \textit{--html}

Turn on HTML tabular output.

-\textbf{l} | \textit{--list}

List all available databases, then exit. Other non-connection options are ignored.

-\textbf{L} filename | \textit{--log-file=filename}

Write all query output into the specified log file, in addition to the normal output destination.

-\textbf{n} | \textit{--no-readline}

Do not use Readline for line editing and do not use the command history. This can be useful to turn off tab expansion when cutting and pasting.

-\textbf{o} filename | \textit{--output=filename}

Put all query output into the specified file.

-\textbf{P} assignment | \textit{--pset=assignment}

Allows you to specify printing options in the style of \texttt{\pset} on the command line. Note that here you have to separate name and value with an equal sign instead of a space. Thus to set the output format to LaTeX, you could write \texttt{-P format=latex}.

-\textbf{q} | \textit{--quiet}

Specifies that \texttt{psql} should do its work quietly. By default, it prints welcome messages and various informational output. If this option is used, none of this happens. This is useful with the \texttt{-c} option. This is equivalent to setting the variable \texttt{QUIET} to \texttt{on}.

-\textbf{R} separator | \textit{--record-separator=separator}

Use \texttt{separator} as the record separator for unaligned output.

-\textbf{s} | \textit{--single-step}

Run in single-step mode. That means the user is prompted before each command is sent to the server, with the option to cancel execution as well. Use this to debug scripts.

-\textbf{S} | \textit{--single-line}

Runs in single-line mode where a new line terminates an SQL command, as a semicolon does.

-\textbf{t} | \textit{--tuples-only}

Turn off printing of column names and result row count footers, etc. This command is equivalent to \texttt{\pset tuples_only} and is provided for convenience.

-\textbf{T} table_options | \textit{--table-attr= table_options}

Allows you to specify options to be placed within the HTML table tag. See \texttt{\pset} for details.

-\textbf{v} assignment | \textit{--set=assignment} | \textit{--variable= assignment}

Perform a variable assignment, like the \texttt{\set} meta command. Note that you must separate name and value, if any, by an equal sign on the command line. To unset a variable, leave off the equal sign. To set a variable with an empty value, use the equal sign but leave off the value. These assignments are done during a very early stage of start-up, so variables reserved for internal purposes might get overwritten later.

-\textbf{V} | \textit{--version}

Print the \texttt{psql} version and exit.

-\textbf{x} | \textit{--expanded}
Turn on the expanded table formatting mode.

-\x \ --no-psqlrc

Do not read the start-up file (neither the system-wide \texttt{psqlrc} file nor the user's \texttt{~/.psqlrc} file).

-\z \ --field-separator-zero

Set the field separator for unaligned output to a zero byte.

-\z \ --record-separator-zero

Set the record separator for unaligned output to a zero byte. This is useful for interfacing, for example, with \texttt{xargs -0}.

-\l \ --single-transaction

When \texttt{psql} executes a script, adding this option wraps \texttt{BEGIN/COMMIT} around the script to execute it as a single transaction. This ensures that either all the commands complete successfully, or no changes are applied.

If the script itself uses \texttt{BEGIN}, \texttt{COMMIT}, or \texttt{ROLLBACK}, this option will not have the desired effects. Also, if the script contains any command that cannot be executed inside a transaction block, specifying this option will cause that command (and hence the whole transaction) to fail.

-\? \ --help

Show help about \texttt{psql} command line arguments, and exit.

Connection Options

-\h \ --host=host

The host name of the machine on which the Greenplum master database server is running. If not specified, reads from the environment variable \texttt{PGHOST} or defaults to localhost.

When starting \texttt{psql} on the master host, if the \texttt{host} value begins with a slash, it is used as the directory for the UNIX-domain socket.

-\p \ --port=port

The TCP port on which the Greenplum master database server is listening for connections. If not specified, reads from the environment variable \texttt{PGPORT} or defaults to 5432.

-\U \ --username=username

The database role name to connect as. If not specified, reads from the environment variable \texttt{PGUSER} or defaults to the current system role name.

-\W \ --password

Force a password prompt. \texttt{psql} should automatically prompt for a password whenever the server requests password authentication. However, currently password request detection is not totally reliable, hence this option to force a prompt. If no password prompt is issued and the server requires password authentication, the connection attempt will fail.

-\W \ --no-password

Never issue a password prompt. If the server requires password authentication and a password is not available by other means such as a \texttt{.pgpass} file, the connection attempt will fail. This option can be useful in batch jobs and scripts where no user is present to enter a password.

\textbf{Note:} This option remains set for the entire session, and so it affects uses of the meta-command \texttt{\textbackslash connect} as well as the initial connection attempt.
Exit Status

`psql` returns 0 to the shell if it finished normally, 1 if a fatal error of its own (out of memory, file not found) occurs, 2 if the connection to the server went bad and the session was not interactive, and 3 if an error occurred in a script and the variable `ON_ERROR_STOP` was set.

Usage

Connecting to a Database

`psql` is a client application for Greenplum Database. In order to connect to a database you need to know the name of your target database, the host name and port number of the Greenplum master server and what database user name you want to connect as. `psql` can be told about those parameters via command line options, namely `-d`, `-h`, `-p`, and `-U` respectively. If an argument is found that does not belong to any option it will be interpreted as the database name (or the user name, if the database name is already given). Not all of these options are required; there are useful defaults. If you omit the host name, `psql` will connect via a UNIX-domain socket to a master server on the local host, or via TCP/IP to `localhost` on machines that do not have UNIX-domain sockets. The default master port number is 5432. If you use a different port for the master, you must specify the port. The default database user name is your operating-system user name, as is the default database name. Note that you cannot just connect to any database under any user name. Your database administrator should have informed you about your access rights.

When the defaults are not right, you can save yourself some typing by setting any or all of the environment variables `PGAPPNAME`, `PGDATABASE`, `PGHOST`, `PGPORT`, and `PGUSER` to appropriate values.

It is also convenient to have a `~/.pgpass` file to avoid regularly having to type in passwords. This file should reside in your home directory and contain lines of the following format:

```
hostname:port:database:username:password
```

The permissions on `~/.pgpass` must disallow any access to world or group (for example: `chmod 0600 ~/.pgpass`). If the permissions are less strict than this, the file will be ignored. (The file permissions are not currently checked on Microsoft Windows clients, however.)

An alternative way to specify connection parameters is in a `conninfo` string or a URI, which is used instead of a database name. This mechanism gives you very wide control over the connection. For example:

```
$ psql "service=myservice sslmode=require"
$ psql postgresql://gpmaster:5433/mydb?sslmode=require
```

This way you can also use LDAP for connection parameter lookup as described in `LDAP Lookup of Connection Parameters` in the PostgreSQL documentation. See `Parameter Keywords` in the PostgreSQL documentation for more information on all the available connection options.

If the connection could not be made for any reason (insufficient privileges, server is not running, etc.), `psql` will return an error and terminate.

If at least one of standard input or standard output are a terminal, then `psql` sets the client encoding to `auto`, which will detect the appropriate client encoding from the locale settings (`LC_CTYPE` environment variable on Unix systems). If this doesn't work out as expected, the client encoding can be overridden using the environment variable `PGCLIENTENCODING`.

Entering SQL Commands

In normal operation, `psql` provides a prompt with the name of the database to which `psql` is currently connected, followed by the string `=>` for a regular user or `=#` for a superuser. For example:

```
testdb=>
testdb=#
```
At the prompt, the user may type in SQL commands. Ordinarily, input lines are sent to the server when a command-terminating semicolon is reached. An end of line does not terminate a command. Thus commands can be spread over several lines for clarity. If the command was sent and executed without error, the results of the command are displayed on the screen.

If untrusted users have access to a database that has not adopted a secure schema usage pattern, begin your session by removing publicly-writable schemas from search_path. You can add `options=-c search_path=` to the connection string or issue `SELECT pg_catalog.set_config('search_path', ' ', false)` before other SQL commands. This consideration is not specific to `psql`; it applies to every interface for executing arbitrary SQL commands.

Meta-Commands

Anything you enter in `psql` that begins with an unquoted backslash is a `psql` meta-command that is processed by `psql` itself. These commands help make `psql` more useful for administration or scripting. Meta-commands are more commonly called slash or backslash commands.

The format of a `psql` command is the backslash, followed immediately by a command verb, then any arguments. The arguments are separated from the command verb and each other by any number of whitespace characters.

To include whitespace into an argument you may quote it with single quotes. To include a single quote into such an argument, write two single quotes within single-quoted text. Anything contained in single quotes is furthermore subject to C-like substitutions for \n (new line), \t (tab), \b (backspace), \r (carriage return), \f (form feed), \digits (octal), and \xdigits (hexadecimal). A backslash preceding any other character within single-quoted text quotes that single character, whatever it is.

Within an argument, text that is enclosed in backquotes (`) is taken as a command line that is passed to the shell. The output of the command (with any trailing newline removed) replaces the backquoted text.

If an unquoted colon (:) followed by a `psql` variable name appears within an argument, it is replaced by the variable's value, as described in SQL Interpolation.

Some commands take an SQL identifier (such as a table name) as argument. These arguments follow the syntax rules of SQL: Unquoted letters are forced to lowercase, while double quotes (") protect letters from case conversion and allow incorporation of whitespace into the identifier. Within double quotes, paired double quotes reduce to a single double quote in the resulting name. For example, FOO"BAR"BAZ is interpreted as fooBARbaz, and "A weird"" name" becomes A weird" name.

Parsing for arguments stops when another unquoted backslash occurs. This is taken as the beginning of a new meta-command. The special sequence \ \ (two backslashes) marks the end of arguments and continues parsing SQL commands, if any. That way SQL and `psql` commands can be freely mixed on a line. But in any case, the arguments of a meta-command cannot continue beyond the end of the line.

The following meta-commands are defined:

\a

If the current table output format is unaligned, it is switched to aligned. If it is not unaligned, it is set to unaligned. This command is kept for backwards compatibility. See \pset for a more general solution.

\c | \connect [dbname [username] [host] [port]] | conninfo

Establishes a new Greenplum Database connection. The connection parameters to use can be specified either using a positional syntax, or using conninfo connection strings as detailed in libpq Connection Strings.

Where the command omits database name, user, host, or port, the new connection can reuse values from the previous connection. By default, values from the previous connection are reused except when processing a conninfo string. Passing a first argument of -reuse-previous=on or -reuse-previous=off overrides that default. When the command neither specifies nor reuses a particular parameter, the libpq default
is used. Specifying any of `dbname`, `username`, `host` or `port` as -- is equivalent to omitting that parameter.

If the new connection is successfully made, the previous connection is closed. If the connection attempt failed, the previous connection will only be kept if `psql` is in interactive mode. When executing a non-interactive script, processing will immediately stop with an error. This distinction was chosen as a user convenience against typos, and a safety mechanism that scripts are not accidentally acting on the wrong database.

Examples:

```bash
=> \c mydb myuser host.dom 6432
=> \c service=foo
=> \c "host=localhost port=5432 dbname=mydb connect_timeout=10 sslmode=disable"
=> \c postgresql://tom@localhost/mydb?application_name=myapp
```

\C [title]

Sets the title of any tables being printed as the result of a query or unset any such title. This command is equivalent to \pset title.

\cd [directory]

Changes the current working directory. Without argument, changes to the current user's home directory. To print your current working directory, use \!pwd.

\conninfo

Displays information about the current connection including the database name, the user name, the type of connection (UNIX domain socket, TCP/IP, etc.), the host, and the port.

\copy {table [(column_list)] | (query)} {from | to} {'filename' | program 'command' | stdin | stdout | pstdin | pstdout} [with] (option [, ...])

Performs a frontend (client) copy. This is an operation that runs an SQL COPY command, but instead of the server reading or writing the specified file, `psql` reads or writes the file and routes the data between the server and the local file system. This means that file accessibility and privileges are those of the local user, not the server, and no SQL superuser privileges are required.

When `program` is specified, `command` is executed by `psql` and the data from or to `command` is routed between the server and the client. This means that the execution privileges are those of the local user, not the server, and no SQL superuser privileges are required.

\copy ... from stdin | to stdout reads/writes based on the command input and output respectively. All rows are read from the same source that issued the command, continuing until \. is read or the stream reaches EOF. Output is sent to the same place as command output. To read/write from `psql`'s standard input or output, use `pstdin` or `pstdout`. This option is useful for populating tables in-line within a SQL script file.

The syntax of the command is similar to that of the SQL COPY command, and `option` must indicate one of the options of the SQL COPY command. Note that, because of this, special parsing rules apply to the \copy command. In particular, the variable substitution rules and backslash escapes do not apply.

This operation is not as efficient as the SQL COPY command because all data must pass through the client/server connection.

\copyright

Shows the copyright and distribution terms of PostgreSQL on which Greenplum Database is based.

\d [relation_pattern] | \d+ [relation_pattern] | \dS [relation_pattern]
For each relation (table, external table, view, index, sequence, or foreign table) or composite type matching the relation pattern, show all columns, their types, the tablespace (if not the default) and any special attributes such as \texttt{NOT NULL} or defaults. Associated indexes, constraints, rules, and triggers are also shown. For foreign tables, the associated foreign server is shown as well.

- For some types of relation, \texttt{\textbackslash d} shows additional information for each column: column values for sequences, indexed expressions for indexes, and foreign data wrapper options for foreign tables.
- The command form \texttt{\textbackslash d+} is identical, except that more information is displayed: any comments associated with the columns of the table are shown, as is the presence of OIDs in the table, the view definition if the relation is a view.

For partitioned tables, the command \texttt{\textbackslash d} or \texttt{\textbackslash d+} specified with the root partition table or child partition table displays information about the table including partition keys on the current level of the partition table. The command \texttt{\textbackslash d+} also displays the immediate child partitions of the table and whether the child partition is an external table or regular table.

For append-optimized tables and column-oriented tables, \texttt{\textbackslash d+} displays the storage options for a table. For append-optimized tables, the options are displayed for the table. For column-oriented tables, storage options are displayed for each column.

- By default, only user-created objects are shown; supply a pattern or the \texttt{s} modifier to include system objects.

\textbf{Note:} If \texttt{\textbackslash d} is used without a pattern argument, it is equivalent to \texttt{\textbackslash dtvSE} which will show a list of all visible tables, views, sequences, and foreign tables.

\texttt{\textbackslash da[S]} \texttt{[aggregate_pattern]}

Lists aggregate functions, together with the data types they operate on. If a pattern is specified, only aggregates whose names match the pattern are shown. By default, only user-created objects are shown; supply a pattern or the \texttt{s} modifier to include system objects.

\texttt{\textbackslash db[+]} \texttt{[tablespace_pattern]}

Lists all available tablespaces and their corresponding paths. If pattern is specified, only tablespaces whose names match the pattern are shown. If + is appended to the command name, each object is listed with its associated permissions.

\texttt{\textbackslash dc[S+]} \texttt{[conversion_pattern]}

Lists conversions between character-set encodings. If a pattern is specified, only conversions whose names match the pattern are listed. By default, only user-created objects are shown; supply a pattern or the \texttt{s} modifier to include system objects. If + is appended to the command name, each object is listed with its associated description.

\texttt{\textbackslash dc[+]} \texttt{[pattern]}

Lists type casts. If a pattern is specified, only casts whose source or target types match the pattern are listed. If + is appended to the command name, each object is listed with its associated description.

\texttt{\textbackslash dd[S]} \texttt{[pattern]}

Shows the descriptions of objects of type \texttt{constraint}, \texttt{operator class}, \texttt{operator family}, \texttt{rule}, and \texttt{trigger}. All other comments may be viewed by the respective backslash commands for those object types.

\texttt{\textbackslash dd} displays descriptions for objects matching the pattern, or of visible objects of the appropriate type if no argument is given. But in either case, only objects that have a description are listed. By default, only user-created objects are shown; supply a pattern or the \texttt{s} modifier to include system objects.
Descriptions for objects can be created with the \texttt{COMMENT} SQL command.

\texttt{\textbackslash ddp [pattern]}
Lists default access privilege settings. An entry is shown for each role (and schema, if applicable) for which the default privilege settings have been changed from the built-in defaults. If \texttt{pattern} is specified, only entries whose role name or schema name matches the pattern are listed.

The \texttt{ALTER DEFAULT PRIVILEGES} command is used to set default access privileges. The meaning of the privilege display is explained under \texttt{GRANT}.

\texttt{\textbackslash dD[S+] [domain_pattern]}
Lists domains. If a pattern is specified, only domains whose names match the pattern are shown. By default, only user-created objects are shown; supply a pattern or the \texttt{S} modifier to include system objects. If + is appended to the command name, each object is listed with its associated permissions and description.

\texttt{\textbackslash dEistPv[S+] [external_table | index | sequence | table | parent_table | view]}
This is not the actual command name: the letters \texttt{E}, \texttt{i}, \texttt{s}, \texttt{t}, \texttt{P}, and \texttt{v} stand for external table, index, sequence, table, parent table, and view, respectively. You can specify any or all of these letters, in any order, to obtain a listing of objects of these types. For example, \texttt{\textbackslash dit} lists indexes and tables. If + is appended to the command name, each object is listed with its physical size on disk and its associated description, if any. If a pattern is specified, only objects whose names match the pattern are listed. By default, only user-created objects are shown; supply a pattern or the \texttt{S} modifier to include system objects.

\texttt{\textbackslash des[+] [foreign_server_pattern]}
Lists foreign servers. If a pattern is specified, only those servers whose name matches the pattern are listed. If the form \texttt{\textbackslash des+} is used, a full description of each server is shown, including the server's ACL, type, version, options, and description.

\texttt{\textbackslash det[+] [foreign_table_pattern]}
Lists all foreign tables. If a pattern is specified, only entries whose table name or schema name matches the pattern are listed. If the form \texttt{\textbackslash det+} is used, generic options and the foreign table description are also displayed.

\texttt{\textbackslash deu[+] [user_mapping_pattern]}
Lists user mappings. If a pattern is specified, only those mappings whose user names match the pattern are listed. If the form \texttt{\textbackslash deu+} is used, additional information about each mapping is shown.

\textbf{Warning:} \texttt{\textbackslash deu+} might also display the user name and password of the remote user, so care should be taken not to disclose them.

\texttt{\textbackslash dew[+] [foreign_data_wrapper_pattern]}
Lists foreign-data wrappers. If a pattern is specified, only those foreign-data wrappers whose name matches the pattern are listed. If the form \texttt{\textbackslash dew+} is used, the ACL, options, and description of the foreign-data wrapper are also shown.

\texttt{\textbackslash df[antwS+] [function_pattern]}
Lists functions, together with their arguments, return types, and function types, which are classified as "agg" (aggregate), "normal", "trigger", or "window". To display only functions of a specific type(s), add the corresponding letters \texttt{a}, \texttt{n}, \texttt{t}, or \texttt{w}, to the command. If a pattern is specified, only functions whose names match the pattern are shown. If the form \texttt{\textbackslash df+} is used, additional information about each function, including security, volatility, language, source code, and description, is shown. By default, only user-created objects are shown; supply a pattern or the \texttt{S} modifier to include system objects.

\texttt{\textbackslash dF[+] [pattern]}

815
Lists text search configurations. If a pattern is specified, only configurations whose names match the pattern are shown. If the form `\dF+` is used, a full description of each configuration is shown, including the underlying text search parser and the dictionary list for each parser token type.

```
\dFd[+] [pattern]
```

Lists text search dictionaries. If a pattern is specified, only dictionaries whose names match the pattern are shown. If the form `\dFd+` is used, additional information is shown about each selected dictionary, including the underlying text search template and the option values.

```
\dFp[+] [pattern]
```

Lists text search parsers. If a pattern is specified, only parsers whose names match the pattern are shown. If the form `\dFp+` is used, a full description of each parser is shown, including the underlying functions and the list of recognized token types.

```
\dFt[+] [pattern]
```

Lists text search templates. If a pattern is specified, only templates whose names match the pattern are shown. If the form `\dFt+` is used, additional information is shown about each template, including the underlying function names.

```
\dg[+] [role_pattern]
```

Lists database roles. (Since the concepts of "users" and "groups" have been unified into "roles", this command is now equivalent to `\du`.) If a pattern is specified, only those roles whose names match the pattern are listed. If the form `\dg+` is used, additional information is shown about each role; currently this adds the comment for each role.

```
\dl
```

This is an alias for `\lo_list`, which shows a list of large objects.

**Note:** Greenplum Database does not support the PostgreSQL large object facility for streaming user data that is stored in large-object structures.

```
\dL[S+] [pattern]
```

Lists procedural languages. If a pattern is specified, only languages whose names match the pattern are listed. By default, only user-created languages are shown; supply the `S` modifier to include system objects. If `+` is appended to the command name, each language is listed with its call handler, validator, access privileges, and whether it is a system object.

```
\dn[S+] [schema_pattern]
```

Lists all available schemas (namespaces). If a pattern is specified, only schemas whose names match the pattern are listed. By default, only user-create objects are show; supply a pattern or the `S` modifier to include system objects. If `+` is appended to the command name, each object is listed with its associated permissions and description, if any.

```
\do[S] [operator_pattern]
```

Lists available operators with their operand and return types. If a pattern is specified, only operators whose names match the pattern are listed. By default, only user-created objects are shown; supply a pattern or the `S` modifier to include system objects.

```
\dO[S+] [pattern]
```

Lists collations. If a pattern is specified, only collations whose names match the pattern are listed. By default, only user-created objects are shown; supply a pattern or the `S` modifier to include system objects. If `+` is appended to the command name, each collation is listed with its associated description, if any. Note that only collations usable with the current database's encoding are shown, so the results may vary in different databases of the same installation.

```
\dp [relation_pattern_to_show_privileges]
```
Lists tables, views, and sequences with their associated access privileges. If a pattern is specified, only tables, views, and sequences whose names match the pattern are listed. The `GRANT` and `REVOKE` commands are used to set access privileges. The meaning of the privilege display is explained under `GRANT`.

\drds \[role-pattern [database-pattern]]

Lists defined configuration settings. These settings can be role-specific, database-specific, or both. `role-pattern` and `database-pattern` are used to select specific roles and database to list, respectively. If omitted, or if * is specified, all settings are listed, including those not role-specific or database-specific, respectively.

The `ALTER ROLE` and `ALTER DATABASE` commands are used to define per-role and per-database role configuration settings.

\dT[S+] \[datatype_pattern\]

Lists data types. If a pattern is specified, only types whose names match the pattern are listed. If + is appended to the command name, each type is listed with its internal name and size, its allowed values if it is an enum type, and its associated permissions. By default, only user-created objects are shown; supply a pattern or the S modifier to include system objects.

\du[+] \[role_pattern\]

Lists database roles. (Since the concepts of "users" and "groups" have been unified into "roles", this command is now equivalent to \dg.) If a pattern is specified, only those roles whose names match the pattern are listed. If the form \du+ is used, additional information is shown about each role; currently this adds the comment for each role.

\dx[+] \[extension_pattern\]

Lists installed extensions. If a pattern is specified, only those extensions whose names match the pattern are listed. If the form \dx+ is used, all of the objects belonging to each matching extension are listed.

\dy[+] \[pattern\]

Lists event triggers. If a pattern is specified, only those triggers whose names match the pattern are listed. If + is appended to the command name, each object is listed with its associated description.

\dy[+] \[pattern\]

Lists event triggers. If a pattern is specified, only those triggers whose names match the pattern are listed. If + is appended to the command name, each object is listed with its associated description.

**Note:** Greenplum Database does not support user-defined triggers.

\e | \edit \[filename\] \[line_number\]

If `filename` is specified, the file is edited; after the editor exits, its content is copied back to the query buffer. If no `filename` is given, the current query buffer is copied to a temporary file which is then edited in the same fashion.

The new query buffer is then re-parsed according to the normal rules of `psql`, where the whole buffer is treated as a single line. (Thus you cannot make scripts this way. Use \i for that.) This means also that if the query ends with (or rather contains) a semicolon, it is immediately executed. In other cases it will merely wait in the query buffer; type semicolon or \g to send it, or \r to cancel.

If a line number is specified, `psql` will position the cursor on the specified line of the file or query buffer. Note that if a single all-digits argument is given, `psql` assumes it is a line number, not a file name.

See `Environment` for information about configuring and customizing your editor.

\echo text [ ... ]
Prints the arguments to the standard output, separated by one space and followed by a newline. This can be useful to intersperse information in the output of scripts. If the first argument is an unquoted \-n, the trailing newline is not written.

Note: If you use the \o command to redirect your query output you might wish to use \qecho instead of this command.

\ef [function_description [line_number]]
This command fetches and edits the definition of the named function, in the form of a CREATE OR REPLACE FUNCTION command. Editing is done in the same way as for \edit. After the editor exits, the updated command waits in the query buffer; type semicolon or \g to send it, or \r to cancel.

The target function can be specified by name alone, or by name and arguments, for example foo(integer, text). The argument types must be given if there is more than one function with the same name.

If no function is specified, a blank CREATE FUNCTION template is presented for editing.

If a line number is specified, psql will position the cursor on the specified line of the function body. (Note that the function body typically does not begin on the first line of the file.)

See Environment for information about configuring and customizing your editor.

\encoding [encoding]
Sets the client character set encoding. Without an argument, this command shows the current encoding.

\f [field_separator_string]
Sets the field separator for unaligned query output. The default is the vertical bar (|). See also \pset for a generic way of setting output options.

\g [filename]
\g [ command ]
Sends the current query input buffer to the server, and optionally stores the query's output in filename or pipes the output to the shell command command. The file or command is written to only if the query successfully returns zero or more tuples, not if the query fails or is a non-data-returning SQL command.

A bare \g is essentially equivalent to a semi-colon. A \g with argument is a one-shot alternative to the \o command.

\gset [prefix]
Sends the current query input buffer to the server and stores the query's output into psql variables. The query to be executed must return exactly one row. Each column of the row is stored into a separate variable, named the same as the column. For example:

```
=> SELECT 'hello' AS var1, 10 AS var2;
-> \gset
=> \echo :var1 :var2
hello 10
```

If you specify a prefix, that string is prepended to the query's column names to create the variable names to use:

```
=> SELECT 'hello' AS var1, 10 AS var2;
-> \gset result_
=> \echo :result_var1 :result_var2
hello 10
```

If a column result is NULL, the corresponding variable is unset rather than being set.
If the query fails or does not return one row, no variables are changed.

```
\h | \help [sql_command]
  Gives syntax help on the specified SQL command. If a command is not specified, then psql will list all the commands for which syntax help is available. If command is an asterisk (*) then syntax help on all SQL commands is shown. To simplify typing, commands that consist of several words do not have to be quoted.
```

```
\H | \html
  Turns on HTML query output format. If the HTML format is already on, it is switched back to the default aligned text format. This command is for compatibility and convenience, but see \pset about setting other output options.
```

```
\i | \include filename
  Reads input from the file filename and executes it as though it had been typed on the keyboard.

  If filename is – (hyphen), then standard input is read until an EOF indication or \q meta-command. This can be used to intersperse interactive input with input from files. Note that Readline behavior will be used only if it is active at the outermost level.

  If you want to see the lines on the screen as they are read you must set the variable ECHO to all.
```

```
\ir | \include_relative filename
  The \ir command is similar to \i, but resolves relative file names differently. When executing in interactive mode, the two commands behave identically. However, when invoked from a script, \ir interprets file names relative to the directory in which the script is located, rather than the current working directory.
```

```
\l[+] | \list[+] [pattern]
  List the databases in the server and show their names, owners, character set encodings, and access privileges. If a pattern is specified, only databases whose names match the pattern are listed. If + is appended to the command name, database sizes, default tablespaces, and descriptions are also displayed. (Size information is only available for databases that the current user can connect to.)
```

```
\lo_export loid filename
  Reads the large object with OID loid from the database and writes it to filename. Note that this is subtly different from the server function lo_export, which acts with the permissions of the user that the database server runs as and on the server’s file system. Use \lo_list to find out the large object's OID.
```

**Note:** Greenplum Database does not support the PostgreSQL large object facility for streaming user data that is stored in large-object structures.

```
\lo_import large_object_filename [comment]
  Stores the file into a large object. Optionally, it associates the given comment with the object. Example:
```

```bash
mydb=> \lo_import '/home/gpadmin/pictures/photo.xcf' 'a picture of me'
lo_import 152801
```

The response indicates that the large object received object ID 152801 which one ought to remember if one wants to access the object ever again. For that reason it is recommended to always associate a human-readable comment with every object. Those can then be seen with the \lo_list command. Note that this command is subtly different from the server-side \lo_import because it acts as the local user on the local file system, rather than the server’s user and file system.
**Note:** Greenplum Database does not support the PostgreSQL **large object facility** for streaming user data that is stored in large-object structures.

\lo_list

Shows a list of all large objects currently stored in the database, along with any comments provided for them.

**Note:** Greenplum Database does not support the PostgreSQL **large object facility** for streaming user data that is stored in large-object structures.

\lo_unlink  largeobject_oid

Deletes the large object of the specified OID from the database. Use \lo_list to find out the large object's OID.

**Note:** Greenplum Database does not support the PostgreSQL **large object facility** for streaming user data that is stored in large-object structures.

\o | \out [ filename ]
\o | \out [ | command ]

Saves future query results to the file *filename* or pipes future results to the shell command *command*. If no argument is specified, the query output is reset to the standard output. Query results include all tables, command responses, and notices obtained from the database server, as well as output of various backslash commands that query the database (such as \d), but not error messages. To intersperse text output in between query results, use \qecho.

\p

Print the current query buffer to the standard output.

\password [username]

Changes the password of the specified user (by default, the current user). This command prompts for the new password, encrypts it, and sends it to the server as an **ALTER ROLE** command. This makes sure that the new password does not appear in cleartext in the command history, the server log, or elsewhere.

\prompt [ text ] name

Prompts the user to supply text, which is assigned to the variable *name*. An optional prompt string, *text*, can be specified. (For multiword prompts, surround the text with single quotes.)

By default, \prompt uses the terminal for input and output. However, if the \-f command line switch was used, \prompt uses standard input and standard output.

\pset [print_option [value]]

This command sets options affecting the output of query result tables. *print_option* describes which option is to be set. The semantics of *value* vary depending on the selected option. For some options, omitting *value* causes the option to be toggled or unset, as described under the particular option. If no such behavior is mentioned, then omitting *value* just results in the current setting being displayed.

\pset without any arguments displays the current status of all printing options.

Adjustable printing options are:

- **border** – The *value* must be a number. In general, the higher the number the more borders and lines the tables will have, but this depends on the particular format. In HTML format, this will translate directly into the border=... attribute; in the other formats only values 0 (no border), 1 (internal dividing lines), and 2 (table frame) make sense. latex and latex-longtable also support a border value of 3 which adds a dividing line between each row.
- **columns** – Sets the target width for the `wrapped` format, and also the width limit for determining whether output is wide enough to require the pager or switch to the vertical display in expanded auto mode. The default is zero. Zero causes the target width to be controlled by the environment variable `COLUMNS`, or the detected screen width if `COLUMNS` is not set. In addition, if `columns` is zero then the wrapped format affects screen output only. If columns is nonzero then file and pipe output is wrapped to that width as well.

After setting the target width, use the command `\pset format wrapped` to enable the wrapped format.

- **expanded | x** – If `value` is specified it must be either `on` or `off`, which will enable or disable expanded mode, or `auto`. If `value` is omitted the command toggles between the `on` and `off` settings. When expanded mode is enabled, query results are displayed in two columns, with the column name on the left and the data on the right. This mode is useful if the data wouldn’t fit on the screen in the normal “horizontal” mode. In the `auto` setting, the expanded mode is used whenever the query output is wider than the screen, otherwise the regular mode is used. The `auto` setting is only effective in the aligned and wrapped formats. In other formats, it always behaves as if the expanded mode is `off`.

- **fieldsep** – Specifies the field separator to be used in unaligned output mode. That way one can create, for example, tab- or comma-separated output, which other programs might prefer. To set a tab as field separator, type `\pset fieldsep '\t'`. The default field separator is `'|'` (a vertical bar).

- **fieldsep_zero** - Sets the field separator to use in unaligned output format to a zero byte.

- **footer** – If `value` is specified it must be either `on` or `off` which will enable or disable display of the table footer (the `(n rows)` count). If `value` is omitted the command toggles footer display on or off.

- **format** – Sets the output format to one of `unaligned`, `aligned`, `html`, `latex` (uses `tabular`), `latex-longtable`, `troff-ms`, or `wrapped`. Unique abbreviations are allowed.

**unaligned** format writes all columns of a row on one line, separated by the currently active field separator. This is useful for creating output that might be intended to be read in by other programs (for example, tab-separated or comma-separated format).

**aligned** format is the standard, human-readable, nicely formatted text output; this is the default.

The `html`, `latex`, `latex-longtable`, and `troff-ms` formats put out tables that are intended to be included in documents using the respective mark-up language. They are not complete documents! (This might not be so dramatic in HTML, but in LaTeX you must have a complete document wrapper. `latex-longtable` also requires the LaTeX `longtable` and `booktabs` packages.)

The `wrapped` format is like `aligned`, but wraps wide data values across lines to make the output fit in the target column width. The target width is determined as described under the `columns` option. Note that `psql` does not attempt to wrap column header titles; the `wrapped` format behaves the same as `aligned` if the total width needed for column headers exceeds the target.

- **linestyle [unicode | ascii | old-ascii]** – Sets the border line drawing style to one of `unicode`, `ascii`, or `old-ascii`. Unique abbreviations, including one letter, are allowed for the three styles. The default setting is `ascii`. This option only affects the `aligned` and `wrapped` output formats.

**ascii** – uses plain ASCII characters. Newlines in data are shown using a `+` symbol in the right-hand margin. When the wrapped format wraps data from one line to the next
without a newline character, a dot (.) is shown in the right-hand margin of the first line, and again in the left-hand margin of the following line.

old-ascii – style uses plain ASCII characters, using the formatting style used in PostgreSQL 8.4 and earlier. Newlines in data are shown using a ; symbol in place of the left-hand column separator. When the data is wrapped from one line to the next without a newline character, a ; symbol is used in place of the left-hand column separator.

unicode – style uses Unicode box-drawing characters. Newlines in data are shown using a carriage return symbol in the right-hand margin. When the data is wrapped from one line to the next without a newline character, an ellipsis symbol is shown in the right-hand margin of the first line, and again in the left-hand margin of the following line.

When the border setting is greater than zero, this option also determines the characters with which the border lines are drawn. Plain ASCII characters work everywhere, but Unicode characters look nicer on displays that recognize them.

• null 'string' – The second argument is a string to print whenever a column is null. The default is to print nothing, which can easily be mistaken for an empty string. For example, one might prefer \pset null '(null)'.

• numericlocale – If value is specified it must be either on or off which will enable or disable display of a locale-specific character to separate groups of digits to the left of the decimal marker. If value is omitted the command toggles between regular and locale-specific numeric output.

• pager – Controls the use of a pager for query and psql help output. If the environment variable PAGER is set, the output is piped to the specified program. Otherwise a platform-dependent default (such as more) is used. When off, the pager program is not used. When on, the pager is used only when appropriate, i.e. when the output is to a terminal and will not fit on the screen. Pager can also be set to always, which causes the pager to be used for all terminal output regardless of whether it fits on the screen. \pset pager without a value toggles pager use on and off.

• recordsep – Specifies the record (line) separator to use in unaligned output mode. The default is a newline character.

• recordsep_zero - Sets the record separator to use in unaligned output format to a zero byte.

• tableattr | T [text] – In HTML format, this specifies attributes to be placed inside the HTML table tag. This could for example be cellpadding or bgcolor. Note that you probably don't want to specify border here, as that is already taken care of by \pset border. If no value is given, the table attributes are unset.

In latex-longtable format, this controls the proportional width of each column containing a left-aligned data type. It is specified as a whitespace-separated list of values, e.g. '0.2 0.2 0.6'. Unspecified output columns use the last specified value.

• title [text] – Sets the table title for any subsequently printed tables. This can be used to give your output descriptive tags. If no value is given, the title is unset.

• tuples_only | t [novalue | on | off] – If value is specified, it must be either on or off which will enable or disable tuples-only mode. If value is omitted the command toggles between regular and tuples-only output. Regular output includes extra information such as column headers, titles, and various footers. In tuples-only mode, only actual table data is shown. The \t command is equivalent to \psettuples_only and is provided for convenience.

Tip:

There are various shortcut commands for \pset. See \a, \c, \f, \H, \t, \T, and \x.

\q | \quit

Quits the psql program. In a script file, only execution of that script is terminated.
\qecho text [ ... ]
This command is identical to \echo except that the output will be written to the query output channel, as set by \o.

\r | \reset
Resets (clears) the query buffer.

\s [filename]
Print psql’s command line history to filename. If filename is omitted, the history is written to the standard output (using the pager if appropriate). This command is not available if psql was built without Readline support.

\set [name [value [ ... ]]]
Sets the psql variable name to value, or if more than one value is given, to the concatenation of all of them. If only one argument is given, the variable is just set with an empty value. To unset a variable, use the \unset command.
\set without any arguments displays the names and values of all currently-set psql variables.
Valid variable names can contain characters, digits, and underscores. See “Variables” in Advanced Features. Variable names are case-sensitive.
Although you are welcome to set any variable to anything you want, psql treats several variables as special. They are documented in the topic about variables.
This command is unrelated to the SQL command SET.

\setenv name [ value ]
Sets the environment variable name to value, or if the value is not supplied, unsets the environment variable. Example:

```
testdb=> \setenv PAGER less
testdb=> \setenv LESS -imx4F
```

\sf[+] function_description
This command fetches and shows the definition of the named function, in the form of a CREATE OR REPLACE FUNCTION command. The definition is printed to the current query output channel, as set by \o.

The target function can be specified by name alone, or by name and arguments, for example foo(integer, text). The argument types must be given if there is more than one function of the same name.

If + is appended to the command name, then the output lines are numbered, with the first line of the function body being line 1.

\t [novalue | on | off]
The \t command by itself toggles a display of output column name headings and row count footer. The values on and off set the tuples display, regardless of the current setting. This command is equivalent to \pset tuples_only and is provided for convenience.

\T table_options
Specifies attributes to be placed within the table tag in HTML output format. This command is equivalent to \pset tableattr table_options

\timing [novalue | on | off]
Without a parameter, toggles a display of how long each SQL statement takes, in milliseconds. The values on and off set the time display, regardless of the current setting.

\unset name
Unsets (deletes) the `psql` variable `name`.

\w | \write `filename`
\w | \write | `command`

Outputs the current query buffer to the file `filename` or pipes it to the shell command `command`.

\watch `[seconds]`
Repeatedly execute the current query buffer (like \g) until interrupted or the query fails. Wait the specified number of seconds (default 2) between executions.

\x [ on | off | auto ]
Sets or toggles expanded table formatting mode. As such it is equivalent to `\pset expanded`.

\z [pattern]
Lists tables, views, and sequences with their associated access privileges. If a pattern is specified, only tables, views and sequences whose names match the pattern are listed. This is an alias for `\dp`.

\! [command]
Escapes to a separate shell or executes the shell command `command`. The arguments are not further interpreted; the shell will see them as-is. In particular, the variable substitution rules and backslash escapes do not apply.

\?
Shows help information about the `psql` backslash commands.

**Patterns**

The various `\d` commands accept a pattern parameter to specify the object name(s) to be displayed. In the simplest case, a pattern is just the exact name of the object. The characters within a pattern are normally folded to lower case, just as in SQL names; for example, `\dt FOO` will display the table named `foo`. As in SQL names, placing double quotes around a pattern stops folding to lower case. Should you need to include an actual double quote character in a pattern, write it as a pair of double quotes within a double-quote sequence; again this is in accord with the rules for SQL quoted identifiers. For example, `\dt "FOO""BAR"` will display the table named `FOO"BAR` (not `foo"bar`). Unlike the normal rules for SQL names, you can put double quotes around just part of a pattern, for instance `\dt FOO"FOO"BAR` will display the table named `fooFOObar`.

Within a pattern, `*` matches any sequence of characters (including no characters) and `?` matches any single character. (This notation is comparable to UNIX shell file name patterns.) For example, `\dt int*` displays all tables whose names begin with `int`. But within double quotes, `*` and `?` lose these special meanings and are just matched literally.

A pattern that contains a dot (`.`) is interpreted as a schema name pattern followed by an object name pattern. For example, `\dt foo*.bar*` displays all tables whose table name starts with `bar` that are in schemas whose schema name starts with `foo`. When no dot appears, then the pattern matches only objects that are visible in the current schema search path. Again, a dot within double quotes loses its special meaning and is matched literally.

Advanced users can use regular-expression notations. All regular expression special characters work as specified in the *PostgreSQL documentation on regular expressions*, except for `.`, which is taken as a separator as mentioned above, `*` which is translated to the regular-expression notation `.`, `*`, and `?` which is translated to `. `. You can emulate these pattern characters at need by writing `?` for `.`, `(R+|)` for `R*`, or `(R|)` for `R?`. Remember that the pattern must match the whole name, unlike the usual interpretation of regular expressions; write `*` at the beginning and/or end if you don't wish the pattern to be anchored. Note that within double quotes, all regular expression special characters lose their special meanings and are matched literally. Also, the regular expression special characters are matched literally in operator name patterns (such as the argument of `\do`).
Whenever the pattern parameter is omitted completely, the \d commands display all objects that are visible in the current schema search path – this is equivalent to using the pattern \*.*. To see all objects in the database, use the pattern \*.*

**Advanced Features**

**Variables**

`psql` provides variable substitution features similar to common UNIX command shells. Variables are simply name/value pairs, where the value can be any string of any length. The name must consist of letters (including non-Latin letters), digits, and underscores.

To set a variable, use the `psql` meta-command \set. For example,

```
testdb=> \set foo bar
```

sets the variable foo to the value bar. To retrieve the content of the variable, precede the name with a colon, for example:

```
  testdb=> \echo :foo
  bar
```

This works in both regular SQL commands and meta-commands; there is more detail in `SQL Interpolation`.

If you call \set without a second argument, the variable is set, with an empty string as value. To unset (i.e., delete) a variable, use the command \unset. To show the values of all variables, call \set without any argument.

**Note:** The arguments of \set are subject to the same substitution rules as with other commands. Thus you can construct interesting references such as \set :foo 'something' and get 'soft links' or 'variable variables' of Perl or PHP fame, respectively. Unfortunately, there is no way to do anything useful with these constructs. On the other hand, \set bar :foo is a perfectly valid way to copy a variable.

A number of these variables are treated specially by `psql`. They represent certain option settings that can be changed at run time by altering the value of the variable, or in some cases represent changeable state of `psql`. Although you can use these variables for other purposes, this is not recommended, as the program behavior might grow really strange really quickly. By convention, all specially treated variables' names consist of all upper-case ASCII letters (and possibly digits and underscores). To ensure maximum compatibility in the future, avoid using such variable names for your own purposes. A list of all specially treated variables follows.

**AUTOCOMMIT**

When on (the default), each SQL command is automatically committed upon successful completion. To postpone commit in this mode, you must enter a `BEGIN` or `START TRANSACTION` SQL command. When off or unset, SQL commands are not committed until you explicitly issue `COMMIT` or `END`. The autocommit-on mode works by issuing an implicit `BEGIN` for you, just before any command that is not already in a transaction block and is not itself a `BEGIN` or other transaction-control command, nor a command that cannot be executed inside a transaction block (such as `VACUUM`).

In autocommit-off mode, you must explicitly abandon any failed transaction by entering `ABORT` or `ROLLBACK`. Also keep in mind that if you exit the session without committing, your work will be lost.

The autocommit-on mode is PostgreSQL's traditional behavior, but autocommit-off is closer to the SQL spec. If you prefer autocommit-off, you may wish to set it in your ~/.psqlrc file.

**COMP_KEYWORD_CASE**
Determines which letter case to use when completing an SQL key word. If set to lower
or upper, the completed word will be in lower or upper case, respectively. If set to
preserve-lower or preserve-upper (the default), the completed word will be in the
case of the word already entered, but words being completed without anything entered will
be in lower or upper case, respectively.

**DBNAME**

The name of the database you are currently connected to. This is set every time you
connect to a database (including program start-up), but can be unset.

**ECHO**

If set to all, all nonempty input lines are printed to standard output as they are read. (This
does not apply to lines read interactively.) To select this behavior on program start-up, use
the switch -a. If set to queries, `psql` prints each query to standard output as it is sent to
the server. The switch for this is -e.

**ECHO_HIDDEN**

When this variable is set to on and a backslash command queries the database, the query
is first shown. This feature helps you to study Greenplum Database internals and provide
similar functionality in your own programs. (To select this behavior on program start-up,
use the switch -E.) If you set the variable to the value noexec, the queries are just shown
but are not actually sent to the server and executed.

**ENCODING**

The current client character set encoding.

**FETCH_COUNT**

If this variable is set to an integer value > 0, the results of SELECT queries are fetched
and displayed in groups of that many rows, rather than the default behavior of collecting
the entire result set before display. Therefore only a limited amount of memory is used,
regardless of the size of the result set. Settings of 100 to 1000 are commonly used when
enabling this feature. Keep in mind that when using this feature, a query may fail after
having already displayed some rows.

Although you can use any output format with this feature, the default aligned format tends
to look bad because each group of FETCH_COUNT rows will be formatted separately,
leading to varying column widths across the row groups. The other output formats work
better.

**HISTCONTROL**

If this variable is set to ignorespaces, lines which begin with a space are not entered
into the history list. If set to a value of ignoredups, lines matching the previous history
line are not entered. A value of ignoreboth combines the two options. If unset, or if set
to any other value than those above, all lines read in interactive mode are saved on the
history list.

**HISTFILE**

The file name that will be used to store the history list. The default value is
~/.psql_history. For example, putting

```
\set HISTFILE ~/.psql_history- :DBNAME
```

in ~/.psqlrc will cause `psql` to maintain a separate history for each database.

**HISTSIZE**

The number of commands to store in the command history. The default value is 500.

**HOST**

The database server host you are currently connected to. This is set every time you
connect to a database (including program start-up), but can be unset.
**IGNOREEOF**

If unset, sending an EOF character (usually CTRL+d) to an interactive session of psql will terminate the application. If set to a numeric value, that many EOF characters are ignored before the application terminates. If the variable is set but has no numeric value, the default is 10.

**LASTOID**

The value of the last affected OID, as returned from an INSERT or lo_import command. This variable is only guaranteed to be valid until after the result of the next SQL command has been displayed.

**ON_ERROR_ROLLBACK**

When set to on, if a statement in a transaction block generates an error, the error is ignored and the transaction continues. When set to interactive, such errors are only ignored in interactive sessions, and not when reading script files. When unset or set to off, a statement in a transaction block that generates an error aborts the entire transaction. The error rollback mode works by issuing an implicit SAVEPOINT for you, just before each command that is in a transaction block, and rolls back to the savepoint on error.

**ON_ERROR_STOP**

By default, command processing continues after an error. When this variable is set to on, processing will instead stop immediately. In interactive mode, psql will return to the command prompt; otherwise, psql will exit, returning error code 3 to distinguish this case from fatal error conditions, which are reported using error code 1. In either case, any currently running scripts (the top-level script, if any, and any other scripts which it may have in invoked) will be terminated immediately. If the top-level command string contained multiple SQL commands, processing will stop with the current command.

**PORT**

The database server port to which you are currently connected. This is set every time you connect to a database (including program start-up), but can be unset.

**PROMPT1**

**PROMPT2**

**PROMPT3**

These specify what the prompts psql issues should look like. See "Prompting".

**QUIET**

Setting this variable to on is equivalent to the command line option -q. It is not very useful in interactive mode.

**SINGLELINE**

This variable is equivalent to the command line option -s.

**SINGLESTEP**

Setting this variable to on is equivalent to the command line option -s.

**USER**

The database user you are currently connected as. This is set every time you connect to a database (including program start-up), but can be unset.

**VERBOSITY**

This variable can be set to the values default, verbose, or terse to control the verbosity of error reports.

**SQL Interpolation**

A key feature of psql variables is that you can substitute ("interpolate") them into regular SQL statements, as well as the arguments of meta-commands. Furthermore, psql provides facilities for ensuring that
variable values used as SQL literals and identifiers are properly quoted. The syntax for interpolating a value without any quoting is to prepend the variable name with a colon (:) for example,

```
  testdb=> \set foo 'my_table'
  testdb=> SELECT * FROM :foo;
```

would query the table `my_table`. Note that this may be unsafe: the value of the variable is copied literally, so it can contain unbalanced quotes, or even backslash commands. You must make sure that it makes sense where you put it.

When a value is to be used as an SQL literal or identifier, it is safest to arrange for it to be quoted. To quote the value of a variable as an SQL literal, write a colon followed by the variable name in single quotes. To quote the value as an SQL identifier, write a colon followed by the variable name in double quotes. These constructs deal correctly with quotes and other special characters embedded within the variable value. The previous example would be more safely written this way:

```
  testdb=> \set foo 'my_table'
  testdb=> SELECT * FROM :"foo";
```

Variable interpolation will not be performed within quoted SQL literals and identifiers. Therefore, a construction such as `:foo` doesn't work to produce a quoted literal from a variable's value (and it would be unsafe if it did work, since it wouldn't correctly handle quotes embedded in the value).

One example use of this mechanism is to copy the contents of a file into a table column. First load the file into a variable and then interpolate the variable's value as a quoted string:

```
  testdb=> \set content `cat my_file.txt`
  testdb=> INSERT INTO my_table VALUES (:content);
```

(Note that this still won't work if `my_file.txt` contains NUL bytes. `psql` does not support embedded NUL bytes in variable values.)

Since colons can legally appear in SQL commands, an apparent attempt at interpolation (that is, `:name`, `:'name'`, or `:"name"`) is not replaced unless the named variable is currently set. In any case, you can escape a colon with a backslash to protect it from substitution.

The colon syntax for variables is standard SQL for embedded query languages, such as ECPG. The colon syntaxes for array slices and type casts are Greenplum Database extensions, which can sometimes conflict with the standard usage. The colon-quote syntax for escaping a variable's value as an SQL literal or identifier is a `psql` extension.

**Prompting**

The prompts `psql` issues can be customized to your preference. The three variables `PROMPT1`, `PROMPT2`, and `PROMPT3` contain strings and special escape sequences that describe the appearance of the prompt. Prompt 1 is the normal prompt that is issued when `psql` requests a new command. Prompt 2 is issued when more input is expected during command entry, for example because the command was not terminated with a semicolon or a quote was not closed. Prompt 3 is issued when you are running an SQL `COPY FROM STDIN` command and you need to type in a row value on the terminal.

The value of the selected prompt variable is printed literally, except where a percent sign (%) is encountered. Depending on the next character, certain other text is substituted instead. Defined substitutions are:

- **%M**
  - The full host name (with domain name) of the database server, or `[local]` if the connection is over a UNIX domain socket, or `[local:/dir/name]`, if the UNIX domain socket is not at the compiled in default location.

- **%m**
The host name of the database server, truncated at the first dot, or [local] if the connection is over a UNIX domain socket.

%>

The port number at which the database server is listening.

%n

The database session user name. (The expansion of this value might change during a database session as the result of the command SET SESSION AUTHORIZATION.)

%/n

The name of the current database.

%~/

Like %/, but the output is ~ (tilde) if the database is your default database.

%#

If the session user is a database superuser, then a #, otherwise a >. (The expansion of this value might change during a database session as the result of the command SET SESSION AUTHORIZATION.)

%R

In prompt 1 normally =, but ^ if in single-line mode, or ! if the session is disconnected from the database (which can happen if \connect fails). In prompt 2 %R is replaced by a character that depends on why psql expects more input: – if the command simply wasn’t terminated yet, but * if there is an unfinished /* ... */ comment, a single quote if there is an unfinished quoted string, a double quote if there is an unfinished quoted identifier, a dollar sign if there is an unfinished dollar-quoted string, or ( if there is an unmatched left parenthesis. In prompt 3 %R doesn’t produce anything.

%x

Transaction status: an empty string when not in a transaction block, or * when in a transaction block, or ! when in a failed transaction block, or ? when the transaction state is indeterminate (for example, because there is no connection).

%digits

The character with the indicated octal code is substituted.

%:name:

The value of the psql variable name. See "Variables" in Advanced Features for details.

`command`

The output of command, similar to ordinary back-tick substitution.

%[ ... %]

Prompts may contain terminal control characters which, for example, change the color, background, or style of the prompt text, or change the title of the terminal window. In order for line editing to work properly, these non-printing control characters must be designated as invisible by surrounding them with %[ and %]. Multiple pairs of these may occur within the prompt. For example,

```
testdb=> \set PROMPT1 '%[033[1;33;40m]%n@%/R[%033[0m]%#'
```

results in a boldfaced (1;) yellow-on-black (33;40) prompt on VT100-compatible, color-capable terminals. To insert a percent sign into your prompt, write %%. The default prompts are '%/%R## ' for prompts 1 and 2, and '>> ' for prompt 3.

**Command-Line Editing**

psql uses the readline library for convenient line editing and retrieval. The command history is automatically saved when psql exits and is reloaded when psql starts up. Tab-completion is also
supported, although the completion logic makes no claim to be an SQL parser. The queries generated by tab-completion can also interfere with other SQL commands, e.g. `SET TRANSACTION ISOLATION LEVEL`. If for some reason you do not like the tab completion, you can turn it off by putting this in a file named `.inputrc` in your home directory:

```
$if psql
 set disable-completion on
$endif
```

### Environment

**COLUMNS**

If `\pset columns` is zero, controls the width for the wrapped format and width for determining if wide output requires the pager or should be switched to the vertical format in expanded auto mode.

**PAGER**

If the query results do not fit on the screen, they are piped through this command. Typical values are `more` or `less`. The default is platform-dependent. The use of the pager can be disabled by setting `PAGER` to empty, or by using pager-related options of the `\pset` command.

**PGDATABASE**

**PGHOST**

**PGPORT**

**PGUSER**

Default connection parameters.

**PSQL_EDITOR**

**EDITOR**

**VISUAL**

Editor used by the `\e` and `\ef` commands. The variables are examined in the order listed; the first that is set is used.

The built-in default editors are `vi` on Unix systems and `notepad.exe` on Windows systems.

**PSQL_EDITOR_LINENUMBER_ARG**

When `\e` or `\ef` is used with a line number argument, this variable specifies the command-line argument used to pass the starting line number to the user's editor. For editors such as Emacs or `vi`, this is a plus sign. Include a trailing space in the value of the variable if there needs to be space between the option name and the line number.

Examples:

```
PSQL_EDITOR_LINENUMBER_ARG='+'
PSQL_EDITOR_LINENUMBER_ARG='--line '
```

The default is `+` on Unix systems (corresponding to the default editor `vi`, and useful for many other common editors); but there is no default on Windows systems.

**PSQL_HISTORY**

Alternative location for the command history file. Tilde (~) expansion is performed.

**PSQLRC**

Alternative location of the user's `.psqlrc` file. Tilde (~) expansion is performed.

**SHELL**

Command executed by the `\!` command.

**TMPDIR**
Directory for storing temporary files. The default is /tmp.

Files

psqlrc and ~/.psqlrc

Unless it is passed an -X or -c option, psql attempts to read and execute commands from the system-wide startup file (psqlrc) and then the user's personal startup file (~/.psqlrc), after connecting to the database but before accepting normal commands. These files can be used to set up the client and/or the server to taste, typically with \set and SET commands.

The system-wide startup file is named psqlrc and is sought in the installation's "system configuration" directory, which is most reliably identified by running pg_config --sysconfdir. By default this directory will be ../etc/ relative to the directory containing the Greenplum Database executables. The name of this directory can be set explicitly via the PGSYSCONFDIR environment variable.

The user's personal startup file is named .psqlrc and is sought in the invoking user's home directory. On Windows, which lacks such a concept, the personal startup file is named %APPDATA%\postgresql\psqlrc.conf. The location of the user's startup file can be set explicitly via the PSQLRC environment variable.

Both the system-wide startup file and the user's personal startup file can be made psql-version-specific by appending a dash and the underlying PostgreSQL major or minor release number to the file name, for example ~/.psqlrc-9.4. The most specific version-matching file will be read in preference to a non-version-specific file.

.psql_history

The command-line history is stored in the file ~/.psql_history, or %APPDATA%\postgresql\psql_history on Windows.

The location of the history file can be set explicitly via the PSQL_HISTORY environment variable.

Notes

psql works best with servers of the same or an older major version. Backslash commands are particularly likely to fail if the server is of a newer version than psql itself. However, backslash commands of the \d family should work with older server versions, though not necessarily with servers newer than psql itself. The general functionality of running SQL commands and displaying query results should also work with servers of a newer major version, but this cannot be guaranteed in all cases.

If you want to use psql to connect to several servers of different major versions, it is recommended that you use the newest version of psql. Alternatively, you can keep a copy of psql from each major version around and be sure to use the version that matches the respective server. But in practice, this additional complication should not be necessary.

Notes for Windows Users

psql is built as a console application. Since the Windows console windows use a different encoding than the rest of the system, you must take special care when using 8-bit characters within psql. If psql detects a problematic console code page, it will warn you at startup. To change the console code page, two things are necessary:

Set the code page by entering:

```
cmd.exe /c chcp 1252
```

1252 is a character encoding of the Latin alphabet, used by Microsoft Windows for English and some other Western languages. If you are using Cygwin, you can put this command in /etc/profile.
Set the console font to Lucida Console, because the raster font does not work with the ANSI code page.

Examples

Start `psql` in interactive mode:

```
psql -p 54321 -U sally mydatabase
```

In `psql` interactive mode, spread a command over several lines of input. Notice the changing prompt:

```
testdb=> CREATE TABLE my_table ( 
    testdb(>  first integer not null default 0, 
    testdb(>  second text) 
    testdb-> ;
CREATE TABLE
```

Look at the table definition:

```
testdb=> \d my_table
Table "my_table"
| Attribute | Type       | Modifier     |
-------------|------------|--------------|
| first       | integer    | not null default 0 |
| second      | text       |              |
```

Run `psql` in non-interactive mode by passing in a file containing SQL commands:

```
psql -f /home/gpadmin/test/myscript.sql
```

**reindexdb**

Rebuilds indexes in a database.

**Synopsis**

```
reindexdb [connection-option ...] [--table | -t table] 
    [--index | -i index ] [dbname]
reindexdb [connection-option ...] --all | -a
reindexdb [connection-option ...] --system | -s [dbname]
reindexdb -? | --help
reindexdb -V | --version
```

**Description**

`reindexdb` is a utility for rebuilding indexes in Greenplum Database. `reindexdb` is a wrapper around the SQL command `REINDEX`. There is no effective difference between reindexing databases via this utility and via other methods for accessing the server.

**Options**

```
-a | --all
    Reindex all databases.

[-d] dbname | [--dbname=] dbname
```
Specifies the name of the database to be reindexed. If this is not specified and `-all` is not used, the database name is read from the environment variable `PGDATABASE`. If that is not set, the user name specified for the connection is used.

```
-e | --echo
   Echo the commands that reindexdb generates and sends to the server.

-i index | --index=index
   Recreate index only.

-q | --quiet
   Do not display a response.

-s | --system
   Reindex system catalogs.

-t table | --table=table
   Reindex table only. Multiple tables can be reindexed by writing multiple `-t` switches.

-V | --version
   Print the reindexdb version and exit.

-? | --help
   Show help about reindexdb command line arguments, and exit.
```

**Connection Options**

```
-h host | --host=host
   Specifies the host name of the machine on which the Greenplum master database server is running. If not specified, reads from the environment variable `PGHOST` or defaults to `localhost`.

-p port | --port=port
   Specifies the TCP port on which the Greenplum master database server is listening for connections. If not specified, reads from the environment variable `PGPORT` or defaults to 5432.

-U username | --username=username
   The database role name to connect as. If not specified, reads from the environment variable `PGUSER` or defaults to the current system user name.

-w | --no-password
   Never issue a password prompt. If the server requires password authentication and a password is not available by other means such as a `.pgpass` file, the connection attempt will fail. This option can be useful in batch jobs and scripts where no user is present to enter a password.

-W | --password
   Force a password prompt.

--maintenance-db=dbname
   Specifies the name of the database to connect to discover what other databases should be reindexed. If not specified, the `postgres` database will be used, and if that does not exist, `template1` will be used.
```

**Notes**

`reindexdb` might need to connect several times to the master server, asking for a password each time. It is convenient to have a `~/.pgpass` file in such cases.
Examples

To reindex the database mydb:

```
reindexdb mydb
```

To reindex the table foo and the index bar in a database named abcd:

```
reindexdb --table foo --index bar abcd
```

REINDEX in the Greenplum Database Reference Guide

vacuumdb

Garbage-collects and analyzes a database.

Synopsis

```
vacuumdb [connection-option...] [--full | -f] [--freeze | -F] [--verbose | -v]
    [--analyze | -a] [--analyze-only | -z] [--table | -t table [( column
    [, ...] )]] [dbname]
```

```
vacuumdb [connection-option...] [--all | -a] [--full | -f] [-F]
    [--analyze | -a] [--analyze-only | -z] [--table | -t table [( column
    [, ...] )]] [dbname]
```

```
vacuumdb -? | --help
```

```
vacuumdb -V | --version
```

Description

vacuumdb is a utility for cleaning a Greenplum Database database. vacuumdb will also generate internal statistics used by the Greenplum Database query optimizer.

vacuumdb is a wrapper around the SQL command VACUUM. There is no effective difference between vacuuming databases via this utility and via other methods for accessing the server.

Options

-a | --all

Vacuums all databases.

[-d] dbname | [--dbname=] dbname

The name of the database to vacuum. If this is not specified and -a (or --all) is not used, the database name is read from the environment variable PGDATABASE. If that is not set, the user name specified for the connection is used.

-e | --echo

Echo the commands that reindexdb generates and sends to the server.

-f | --full

Selects a full vacuum, which may reclaim more space, but takes much longer and exclusively locks the table.

**Warning:** A VACUUM FULL is not recommended in Greenplum Database.
-F | --freeze
Freeze row transaction information.

-q | --quiet
Do not display a response.

-t table [(column)] | --table= table [(column)]
Clean or analyze this table only. Column names may be specified only in conjunction with
the --analyze or --analyze-all options. Multiple tables can be vacuumed by writing
multiple -t switches. If you specify columns, you probably have to escape the parentheses
from the shell.

-v | --verbose
Print detailed information during processing.

-z | --analyze
Collect statistics for use by the query planner.

-Z | --analyze-only
Only calculate statistics for use by the query planner (no vacuum).

-V | --version
Print the vacuumdb version and exit.

-? | --help
Show help about vacuumdb command line arguments, and exit.

Connection Options

-h host | --host=host
Specifies the host name of the machine on which the Greenplum master database server
is running. If not specified, reads from the environment variable PGHOST or defaults to
localhost.

-p port | --port=port
Specifies the TCP port on which the Greenplum master database server is listening for
connections. If not specified, reads from the environment variable PGPORT or defaults to
5432.

-U username | --username=username
The database role name to connect as. If not specified, reads from the environment
variable PGUSER or defaults to the current system user name.

-w | --no-password
Never issue a password prompt. If the server requires password authentication and a
password is not available by other means such as a .pgpass file, the connection attempt
will fail. This option can be useful in batch jobs and scripts where no user is present to
enter a password.

-W | --password
Force a password prompt.

--maintenance-db=dbname
Specifies the name of the database to connect to discover what other databases should be
vacuumed. If not specified, the postgres database will be used, and if that does not exist,
template1 will be used.

Notes

vacuumdb might need to connect several times to the master server, asking for a password each time. It is
convenient to have a ~/.pgpass file in such cases.
Examples

To clean the database `test`:

```
vacuumdb test
```

To clean and analyze a database named `bigdb`:

```
vacuumdb --analyze bigdb
```

To clean a single table `foo` in a database named `mydb`, and analyze a single column `bar` of the table. Note the quotes around the table and column names to escape the parentheses from the shell:

```
vacuumdb --analyze --verbose --table 'foo(bar)' mydb
```

See Also

`VACUUM` and `ANALYZE` in the *Greenplum Database Reference Guide*
Additional Supplied Programs

Additional programs available in the Greenplum Database installation.

The following PostgreSQL contrib server utility programs are installed:

• \texttt{pg\_upgrade} - Server program to upgrade a Greenplum Database server instance.

  \textbf{Note:} \texttt{pg\_upgrade} is not intended for direct use with Greenplum 6, but will be used by Greenplum upgrade utilities in a future release.

• \texttt{pg\_upgrade\_support} - supporting library for \texttt{pg\_upgrade}.

• \texttt{pg\_xlogdump} - Server utility program to display a human-readable rendering of the write-ahead log of a Greenplum Database cluster.
Chapter 14

Greenplum Database Reference Guide

Reference information for Greenplum Database systems including SQL commands, system catalogs, environment variables, server configuration parameters, character set support, datatypes, and Greenplum Database extensions.
SQL Commands

The following SQL commands are available in Greenplum Database:

- ABORT
- ALTER AGGREGATE
- ALTER COLLATION
- ALTER CONVERSION
- ALTER DATABASE
- ALTER DEFAULT PRIVILEGES
- ALTER DOMAIN
- ALTER EXTERNAL TABLE
- ALTER FOREIGN DATA WRAPPER
- ALTER FOREIGN TABLE
- ALTER FUNCTION
- ALTER GROUP
- ALTER INDEX
- ALTER LANGUAGE
- ALTER OPERATOR
- ALTER OPERATOR CLASS
- ALTER OPERATOR FAMILY
- ALTER PROTOCOL
- ALTER RESOURCE GROUP
- ALTER RESOURCE QUEUE
- ALTER ROLE
- ALTER RULE
- ALTER SCHEMA
- ALTER SEQUENCE
- ALTER SERVER
- ALTER TABLE
- ALTER TABLESPACE
- ALTER TEXT SEARCH CONFIGURATION
- ALTER TEXT SEARCH DICTIONARY
- ALTER TEXT SEARCH PARSER
- ALTER TEXT SEARCH TEMPLATE
- ALTER TYPE
- ALTER USER
- ALTER USER MAPPING
- ALTER VIEW
- ANALYZE
- BEGIN
- CHECKPOINT
- CLOSE
- CLUSTER
- COMMENT
- COMMIT
- COPY
- CREATE AGGREGATE
- CREATE CAST
- CREATE COLLATION
- CREATE CONVERSION
- CREATE DATABASE
- CREATE DOMAIN
- CREATE EXTERNAL TABLE
- CREATE FOREIGN DATA WRAPPER
- CREATE FOREIGN TABLE
- CREATE FUNCTION
- CREATE GROUP
- CREATE INDEX
- CREATE LANGUAGE
- CREATE OPERATOR
- CREATE OPERATOR CLASS
- CREATE OPERATOR FAMILY
- CREATE PROTOCOL
- CREATE RESOURCE GROUP
- CREATE RESOURCE QUEUE
- CREATE ROLE
- CREATE RULE
- CREATE SCHEMA
- CREATE SEQUENCE
- CREATE SERVER
- CREATE TABLE
- CREATE TABLE AS
- CREATE TABLESPACE
- CREATE TEXT SEARCH CONFIGURATION
- CREATE TEXT SEARCH DICTIONARY
- CREATE TEXT SEARCH PARSER
- CREATE TEXT SEARCH TEMPLATE
- CREATE TYPE
- CREATE USER
- CREATE USER MAPPING
- CREATE VIEW
- DEALLOCATE
- DECLARE
- DELETE
- DISCARD
- DO
- DROP AGGREGATE
- DROP CAST
- DROP COLLATION
- DROP CONVERSION
- DROP DATABASE
- DROP DOMAIN
- DROP EXTERNAL TABLE
- DROP FOREIGN DATA WRAPPER
- DROP FOREIGN TABLE
- DROP FUNCTION
- DROP GROUP
- DROP INDEX
• DROP LANGUAGE
• DROP OPERATOR
• DROP OPERATOR CLASS
• DROP OPERATOR FAMILY
• DROP OWNED
• DROP PROTOCOL
• DROP RESOURCE GROUP
• DROP RESOURCE QUEUE
• DROP ROLE
• DROP RULE
• DROP SCHEMA
• DROP SEQUENCE
• DROP SERVER
• DROP TABLE
• DROP TABLESPACE
• DROP TEXT SEARCH CONFIGURATION
• DROP TEXT SEARCH DICTIONARY
• DROP TEXT SEARCH PARSER
• DROP TEXT SEARCH TEMPLATE
• DROP TYPE
• DROP USER
• DROP USER MAPPING
• DROP VIEW
• END
• EXECUTE
• EXPLAIN
• FETCH
• GRANT
• INSERT
• LOAD
• LOCK
• MOVE
• PREPARE
• REASSIGN OWNED
• REINDEX
• RELEASE SAVEPOINT
• RESET
• REVOKE
• ROLLBACK
• ROLLBACK TO SAVEPOINT
• SAVEPOINT
• SELECT
• SELECT INTO
• SET
• SET CONSTRAINTS
• SET ROLE
• SET SESSION AUTHORIZATION
• SET TRANSACTION
• SHOW
• START TRANSACTION
• TRUNCATE
• UPDATE
• VACUUM
• VALUES

* Not implemented in 5.0

**SQL Syntax Summary**

**ABORT**
Aborts the current transaction.

```
ABORT [WORK | TRANSACTION]
```

See **ABORT** for more information.

**ALTER AGGREGATE**
Changes the definition of an aggregate function.

```
ALTER AGGREGATE name ( aggregate_signature ) RENAME TO new_name
ALTER AGGREGATE name ( aggregate_signature ) OWNER TO new_owner
ALTER AGGREGATE name ( aggregate_signature ) SET SCHEMA new_schema
```

See **ALTER AGGREGATE** for more information.

**ALTER COLLATION**
Changes the definition of a collation.

```
ALTER COLLATION name RENAME TO new_name
ALTER COLLATION name OWNER TO new_owner
ALTER COLLATION name SET SCHEMA new_schema
```

See **ALTER COLLATION** for more information.

**ALTER CONVERSION**
Changes the definition of a conversion.

```
ALTER CONVERSION name RENAME TO newname
ALTER CONVERSION name OWNER TO newowner
ALTER CONVERSION name SET SCHEMA new_schema
```

See **ALTER CONVERSION** for more information.

**ALTER DATABASE**
Changes the attributes of a database.

```
ALTER DATABASE name [ WITH CONNECTION LIMIT connlimit ]
```
ALTER DATABASE name RENAME TO newname
ALTER DATABASE name OWNER TO new_owner
ALTER DATABASE name SET TABLESPACE new_tablespace
ALTER DATABASE name SET parameter { TO | = } { value | DEFAULT }
ALTER DATABASE name SET parameter FROM CURRENT
ALTER DATABASE name RESET parameter
ALTER DATABASE name RESET ALL

See ALTER DATABASE for more information.

**ALTER DEFAULT PRIVILEGES**

Changes default access privileges.

```
ALTER DEFAULT PRIVILEGES
  [ FOR { ROLE | USER } target_role [, ...] ]
  [ IN SCHEMA schema_name [, ...] ]
  abbreviated_grant_or_revoke

where abbreviated_grant_or_revoke is one of:

GRANT { { SELECT | INSERT | UPDATE | DELETE | TRUNCATE | REFERENCES |
  TRIGGER } [, ...] | ALL [ PRIVILEGES ] }
ON TABLES
TO { [ GROUP ] role_name | PUBLIC } [, ...] [ WITH GRANT OPTION ]

GRANT { { USAGE | SELECT | UPDATE } [, ...] | ALL [ PRIVILEGES ] }
ON SEQUENCES
TO { [ GROUP ] role_name | PUBLIC } [, ...] [ WITH GRANT OPTION ]

GRANT { EXECUTE | ALL [ PRIVILEGES ] }
ON FUNCTIONS
TO { [ GROUP ] role_name | PUBLIC } [, ...] [ WITH GRANT OPTION ]

GRANT { USAGE | ALL [ PRIVILEGES ] }
ON TYPES
TO { [ GROUP ] role_name | PUBLIC } [, ...] [ WITH GRANT OPTION ]

REVOKE [ GRANT OPTION FOR ]
  { { SELECT | INSERT | UPDATE | DELETE | TRUNCATE | REFERENCES |
  TRIGGER } [, ...] | ALL [ PRIVILEGES ] }
ON TABLES
FROM { [ GROUP ] role_name | PUBLIC } [, ...]
  [ CASCADE | RESTRICT ]

REVOKE [ GRANT OPTION FOR ]
  { { USAGE | SELECT | UPDATE } [, ...] | ALL [ PRIVILEGES ] }
ON SEQUENCES
FROM { [ GROUP ] role_name | PUBLIC } [, ...]
  [ CASCADE | RESTRICT ]

REVOKE [ GRANT OPTION FOR ]
  { EXECUTE | ALL [ PRIVILEGES ] }
ON FUNCTIONS
FROM { [ GROUP ] role_name | PUBLIC } [, ...]
```
ALTER DOMAIN

Changes the definition of a domain.

ALTER DOMAIN name { SET DEFAULT expression | DROP DEFAULT }
ALTER DOMAIN name { SET | DROP } NOT NULL
ALTER DOMAIN name ADD domain_constraint [ NOT VALID ]
ALTER DOMAIN name DROP CONSTRAINT [ IF EXISTS ] constraint_name [ RESTRICT | CASCADE ]
ALTER DOMAIN name RENAME CONSTRAINT constraint_name TO new_constraint_name
ALTER DOMAIN name VALIDATE CONSTRAINT constraint_name
ALTER DOMAIN name OWNER TO new_owner
ALTER DOMAIN name RENAME TO new_name
ALTER DOMAIN name SET SCHEMA new_schema

See ALTER DOMAIN for more information.

ALTER EXTENSION

Change the definition of an extension that is registered in a Greenplum database.

ALTER EXTENSION name UPDATE [ TO new_version ]
ALTER EXTENSION name SET SCHEMA new_schema
ALTER EXTENSION name ADD member_object
ALTER EXTENSION name DROP member_object

where member_object is:

ACCESS METHOD object_name |
AGGREGATE aggregate_name ( aggregate_signature ) |
CAST (source_type AS target_type) |
COLLATION object_name |
CONVERSION object_name |
DOMAIN object_name |
EVENT TRIGGER object_name |
FOREIGN DATA WRAPPER object_name |
FOREIGN TABLE object_name |
FUNCTION function_name ( [ [ argmode ] [ argname ] argtype [, ...] ] ) |
MATERIALIZED VIEW object_name |
OPERATOR operator_name (left_type, right_type) |
OPERATOR CLASS object_name USING index_method |
OPERATOR FAMILY object_name USING index_method |
[ PROCEDURAL ] LANGUAGE object_name |
SCHEMA object_name |
SEQUENCE `object_name` | 
SERVER `object_name` | 
TABLE `object_name` | 
TEXT SEARCH CONFIGURATION `object_name` | 
TEXT SEARCH DICTIONARY `object_name` | 
TEXT SEARCH PARSER `object_name` | 
TEXT SEARCH TEMPLATE `object_name` | 
TRANSFORM FOR `type_name` LANGUAGE `lang_name` | 
TYPE `object_name` | 
VIEW `object_name` | 

and aggregate_signature is:

```
* | 
[ argmode ] [ argname ] argtype [ , ... ] | 
[ [ argmode ] [ argname ] argtype [ , ... ] ] ORDER BY [ argmode ] [ argname ] argtype [ , ... ]
```

See ALTER EXTENSION for more information.

### ALTER EXTERNAL TABLE

Changes the definition of an external table.

```
ALTER EXTERNAL TABLE `name` action [, ... ]
```

where action is one of:

- ADD [COLUMN] `new_column` `type`
- DROP [COLUMN] `column` [RESTRICT|CASCADE]
- ALTER [COLUMN] `column` `TYPE` `type`
- OWNER TO `new_owner`

See ALTER EXTERNAL TABLE for more information.

### ALTER FOREIGN DATA WRAPPER

Changes the definition of a foreign-data wrapper.

```
ALTER FOREIGN DATA WRAPPER `name`
[ HANDLER `handler_function` | NO HANDLER ]
[ VALIDATOR `validator_function` | NO VALIDATOR ]
[ OPTIONS ( [ ADD | SET | DROP ] option ['value'] [, ... ] ) ]
```

```
ALTER FOREIGN DATA WRAPPER `name` OWNER TO `new_owner`
ALTER FOREIGN DATA WRAPPER `name` RENAME TO `new_name`
```

See ALTER FOREIGN DATA WRAPPER for more information.

### ALTER FOREIGN TABLE

Changes the definition of a foreign table.

```
ALTER FOREIGN TABLE [ IF EXISTS ] `name` action [, ... ]
ALTER FOREIGN TABLE [ IF EXISTS ] `name`
RENAME [ COLUMN ] `column_name` TO `new_column_name`
ALTER FOREIGN TABLE [ IF EXISTS ] `name`
RENAME TO `new_name`
ALTER FOREIGN TABLE [ IF EXISTS ] `name`
SET SCHEMA `new_schema`
```
See \textit{ALTER FOREIGN TABLE} for more information.

**ALTER FUNCTION**

Changes the definition of a function.

\texttt{ALTER FUNCTION name ( [ [argmode] [argname] argtype [, ...] ] )}
\texttt{action [, ...] [RESTRICT]}

\texttt{ALTER FUNCTION name ( [ [argmode] [argname] argtype [, ...] ] )}
\texttt{RENAME TO new_name}

\texttt{ALTER FUNCTION name ( [ [argmode] [argname] argtype [, ...] ] )}
\texttt{OWNER TO new_owner}

\texttt{ALTER FUNCTION name ( [ [argmode] [argname] argtype [, ...] ] )}
\texttt{SET SCHEMA new_schema}

See \textit{ALTER FUNCTION} for more information.

**ALTER GROUP**

Changes a role name or membership.

\texttt{ALTER GROUP groupname ADD USER username [, ... ]}

\texttt{ALTER GROUP groupname DROP USER username [, ... ]}

\texttt{ALTER GROUP groupname RENAME TO newname}

See \textit{ALTER GROUP} for more information.

**ALTER INDEX**

Changes the definition of an index.

\texttt{ALTER INDEX \{ IF EXISTS \} name RENAME TO new_name}

\texttt{ALTER INDEX \{ IF EXISTS \} name SET TABLESPACE tablespace_name}

\texttt{ALTER INDEX \{ IF EXISTS \} name SET ( storage_parameter = value [, ...] )}

\texttt{ALTER INDEX \{ IF EXISTS \} name RESET ( storage_parameter [, ...] )}

\texttt{ALTER INDEX ALL IN TABLESPACE name \{ OWNED BY role_name [, ... ] \}}
\texttt{SET TABLESPACE new_tablespace \{ NOWAIT \}}

See \textit{ALTER INDEX} for more information.

**ALTER LANGUAGE**

Changes the name of a procedural language.

\texttt{ALTER LANGUAGE name RENAME TO newname}

\texttt{ALTER LANGUAGE name OWNER TO new_owner}

See \textit{ALTER LANGUAGE} for more information.
**ALTER OPERATOR**
Changes the definition of an operator.

```
ALTER OPERATOR name ( { left_type | NONE } , { right_type | NONE } )
OWNER TO new_owner
```
```
ALTER OPERATOR name ( { left_type | NONE } , { right_type | NONE } )
SET SCHEMA new_schema
```

See **ALTER OPERATOR** for more information.

**ALTER OPERATOR CLASS**
Changes the definition of an operator class.

```
ALTER OPERATOR CLASS name USING index_method RENAME TO new_name
```
```
ALTER OPERATOR CLASS name USING index_method OWNER TO new_owner
```
```
ALTER OPERATOR CLASS name USING index_method SET SCHEMA new_schema
```

See **ALTER OPERATOR CLASS** for more information.

**ALTER OPERATOR FAMILY**
Changes the definition of an operator family.

```
ALTER OPERATOR FAMILY name USING index_method ADD
{ OPERATOR strategy_number operator_name ( op_type, op_type ) [ FOR
  SEARCH | FOR ORDER BY sort_family_name ]
  | FUNCTION support_number [ ( op_type [ , op_type ] ) ] funcname
  ( argument_type [, ... ] )
} [, ... ]
```
```
ALTER OPERATOR FAMILY name USING index_method DROP
{ OPERATOR strategy_number ( op_type, op_type )
  | FUNCTION support_number [ ( op_type [ , op_type ] )
} [, ... ]
```
```
ALTER OPERATOR FAMILY name USING index_method RENAME TO new_name
```
```
ALTER OPERATOR FAMILY name USING index_method OWNER TO new_owner
```
```
ALTER OPERATOR FAMILY name USING index_method SET SCHEMA new_schema
```

See **ALTER OPERATOR FAMILY** for more information.

**ALTER PROTOCOL**
Changes the definition of a protocol.

```
ALTER PROTOCOL name RENAME TO newname
```
```
ALTER PROTOCOL name OWNER TO newowner
```

See **ALTER PROTOCOL** for more information.
**ALTER RESOURCE GROUP**
Changes the limits of a resource group.

```
ALTER RESOURCE GROUP name SET group_attribute = value
```

See *ALTER RESOURCE GROUP* for more information.

**ALTER RESOURCE QUEUE**
Changes the limits of a resource queue.

```
ALTER RESOURCE QUEUE name WITH ( queue_attribute = value [, ... ] )
```

See *ALTER RESOURCE QUEUE* for more information.

**ALTER ROLE**
Changes a database role (user or group).

```
ALTER ROLE name [ [ WITH ] option [ ... ] ]
```

where option can be:

- SUPERUSER | NOSUPERUSER
- CREATEDB | NOCREATEDB
- CREATEROLE | NOCREATEROLE
- CREATEEXTABLE | NOCREATEEXTABLE [ ( attribute = 'value' [, ... ] ) ]

where attributes and values are:

- type = 'readable' | 'writable'
- protocol = 'gpfdist' | 'http'
- INHERIT | NOINHERIT
- LOGIN | NOLOGIN
- REPLICATION | NOREPLICATION
- CONNECTION LIMIT connlimit
- [ ENCRYPTED | UNENCRYPTED ] PASSWORD 'password'
- VALID UNTIL 'timestamp'

```
ALTER ROLE name RENAME TO new_name
```

```
ALTER ROLE { name | ALL } [ IN DATABASE database_name ]
SET configuration_parameter = { TO | = } { value | DEFAULT }
```

```
ALTER ROLE { name | ALL } [ IN DATABASE database_name ]
SET configuration_parameter FROM CURRENT
```

```
ALTER ROLE { name | ALL } [ IN DATABASE database_name ]
RESET configuration_parameter
```

```
ALTER ROLE { name | ALL } [ IN DATABASE database_name ] RESET ALL
```

```
ALTER ROLE name RESOURCE QUEUE (queue_name | NONE)
```

```
ALTER ROLE name RESOURCE GROUP (group_name | NONE)
```

See *ALTER ROLE* for more information.

**ALTER RULE**
Changes the definition of a rule.

```
ALTER RULE name ON table_name RENAME TO new_name
```

See *ALTER RULE* for more information.
### ALTER SCHEMA
Changes the definition of a schema.

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ALTER SCHEMA name RENAME TO newname</td>
<td></td>
</tr>
<tr>
<td>ALTER SCHEMA name OWNER TO newowner</td>
<td></td>
</tr>
</tbody>
</table>

See `ALTER SCHEMA` for more information.

### ALTER SEQUENCE
Changes the definition of a sequence generator.

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ALTER SEQUENCE [ IF EXISTS ] name [INCREMENT [ BY ] increment] [MINVALUE minvalue</td>
<td>NO MINVALUE] [MAXVALUE maxvalue</td>
</tr>
<tr>
<td>ALTER SEQUENCE [ IF EXISTS ] name OWNER TO new_owner</td>
<td></td>
</tr>
<tr>
<td>ALTER SEQUENCE [ IF EXISTS ] name RENAME TO new_name</td>
<td></td>
</tr>
<tr>
<td>ALTER SEQUENCE [ IF EXISTS ] name SET SCHEMA new_schema</td>
<td></td>
</tr>
</tbody>
</table>

See `ALTER SEQUENCE` for more information.

### ALTER SERVER
Changes the definition of a foreign server.

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ALTER SERVER server_name [ VERSION 'new_version' ] [ OPTIONS ( [ ADD</td>
<td>SET</td>
</tr>
<tr>
<td>ALTER SERVER server_name OWNER TO new_owner</td>
<td></td>
</tr>
<tr>
<td>ALTER SERVER server_name RENAME TO new_name</td>
<td></td>
</tr>
</tbody>
</table>

See `ALTER SERVER` for more information.

### ALTER TABLE
Changes the definition of a table.

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ALTER TABLE [IF EXISTS] [ONLY] name action [, ... ]</td>
<td></td>
</tr>
<tr>
<td>ALTER TABLE [IF EXISTS] [ONLY] name RENAME [COLUMN] column_name TO new_column_name</td>
<td></td>
</tr>
<tr>
<td>ALTER TABLE [ IF EXISTS ] [ ONLY ] name RENAME CONSTRAINT constraint_name TO new_constraint_name</td>
<td></td>
</tr>
<tr>
<td>ALTER TABLE [IF EXISTS] name RENAME TO new_name</td>
<td></td>
</tr>
<tr>
<td>ALTER TABLE [IF EXISTS] name SET SCHEMA new_schema</td>
<td></td>
</tr>
</tbody>
</table>

ALTER TABLE ALL IN TABLESPACE name [ OWNED BY role_name [, ... ] ]
    SET TABLESPACE new_tablespace [ NOWAIT ]

ALTER TABLE [IF EXISTS] [ONLY] name SET
    WITH (REORGANIZE=true|false)
    DISTRIBUTED BY ({{column_name [opclass]} [, ... ] })
    DISTRIBUTED RANDOMLY
    DISTRIBUTED REPLICATED

ALTER TABLE name
    [ ALTER PARTITION { partition_name | FOR (RANK(number))
        [ FOR (value) ] [...] ] partition_action

where action is one of:

    ADD [COLUMN] column_name data_type [ DEFAULT default_expr ]
        [column_constraint [ ... ]] [ COLLATE collation ]
        [ ENCODING ( storage_directive [, ... ] ) ]
    DROP [COLUMN] [IF EXISTS] column_name [RESTRICT | CASCADE]
    ALTER [COLUMN] column_name [ SET DATA ] TYPE type [COLLATE collation]
    [USING expression]
    ALTER [COLUMN] column_name SET DEFAULT expression
    ALTER [COLUMN] column_name DROP DEFAULT
    ALTER [COLUMN] column_name { SET | DROP } NOT NULL
    ALTER [COLUMN] column_name SET STATISTICS integer
    ALTER [COLUMN] column SET ( attribute_option = value [, ... ] )
    ALTER [COLUMN] column RESET ( attribute_option [, ... ] )
    ADD table_constraint [NOT VALID]
    ADD table_constraint_using_index
    VALIDATE CONSTRAINT constraint_name
    DROP CONSTRAINT [IF EXISTS] constraint_name [RESTRICT | CASCADE]
    DISABLE TRIGGER [trigger_name | ALL | USER]
    ENABLE TRIGGER [trigger_name | ALL | USER]
    CLUSTER ON index_name
    SET WITHOUT CLUSTER
    SET WITHOUT OIDS
    SET (storage_parameter = value)
    RESET (storage_parameter [, ... ])
    INHERIT parent_table
    NO INHERIT parent_table
    OF type_name
    NOT OF
    OWNER TO new_owner
    SET TABLESPACE new_tablespace

See ALTER TABLE for more information.

ALTER TABLESPACE
Changes the definition of a tablespace.

ALTER TABLESPACE name RENAME TO new_name
ALTER TABLESPACE name OWNER TO new_owner
ALTER TABLESPACE name SET ( tablespace_option = value [, ... ] )
ALTER TABLESPACE name RESET ( tablespace_option [, ... ] )

See ALTER TABLESPACE for more information.
ALTER TEXT SEARCH CONFIGURATION
Changes the definition of a text search configuration.

```
ALTER TEXT SEARCH CONFIGURATION name
    ALTER MAPPING FOR token_type [, ... ] WITH dictionary_name [, ... ]
ALTER TEXT SEARCH CONFIGURATION name
    ALTER MAPPING REPLACE old_dictionary WITH new_dictionary
ALTER TEXT SEARCH CONFIGURATION name
    ALTER MAPPING FOR token_type [, ... ] REPLACE old_dictionary
    WITH new_dictionary
ALTER TEXT SEARCH CONFIGURATION name
    DROP MAPPING [ IF EXISTS ] FOR token_type [, ... ]
ALTER TEXT SEARCH CONFIGURATION name RENAME TO new_name
ALTER TEXT SEARCH CONFIGURATION name OWNER TO new_owner
ALTER TEXT SEARCH CONFIGURATION name SET SCHEMA new_schema
```

See `ALTER TEXT SEARCH CONFIGURATION` for more information.

ALTER TEXT SEARCH DICTIONARY
Changes the definition of a text search dictionary.

```
ALTER TEXT SEARCH DICTIONARY name {
    option [ = value ] [, ... ]
}
ALTER TEXT SEARCH DICTIONARY name RENAME TO new_name
ALTER TEXT SEARCH DICTIONARY name OWNER TO new_owner
ALTER TEXT SEARCH DICTIONARY name SET SCHEMA new_schema
```

See `ALTER TEXT SEARCH DICTIONARY` for more information.

ALTER TEXT SEARCH PARSER
Changes the definition of a text search parser.

```
ALTER TEXT SEARCH PARSER name RENAME TO new_name
ALTER TEXT SEARCH PARSER name SET SCHEMA new_schema
```

See `ALTER TEXT SEARCH PARSER` for more information.

ALTER TEXT SEARCH TEMPLATE
Changes the definition of a text search template.

```
ALTER TEXT SEARCH TEMPLATE name RENAME TO new_name
ALTER TEXT SEARCH TEMPLATE name SET SCHEMA new_schema
```

See `ALTER TEXT SEARCH TEMPLATE` for more information.

ALTER TYPE
Changes the definition of a data type.

```
ALTER TYPE name action [, ... ]
ALTER TYPE name OWNER TO new_owner
ALTER TYPE name RENAME ATTRIBUTE attribute_name TO new_attribute_name
    [ CASCADE | RESTRICT ]
ALTER TYPE name RENAME TO new_name
ALTER TYPE name SET SCHEMA new_schema
```
ALTER TYPE name ADD VALUE [ IF NOT EXISTS ] new_enum_value [ { BEFORE | AFTER } existing_enum_value ]
ALTER TYPE name SET DEFAULT ENCODING ( storage_directive )

where action is one of:

- ADD ATTRIBUTE attribute_name data_type [ COLLATE collation ] [ CASCADE | RESTRICT ]
- DROP ATTRIBUTE [ IF EXISTS ] attribute_name [ CASCADE | RESTRICT ]
- ALTER ATTRIBUTE attribute_name [ SET DATA ] TYPE data_type [ COLLATE collation ] [ CASCADE | RESTRICT ]

See ALTER TYPE for more information.

ALTER USER
Changes the definition of a database role (user).

ALTER USER name RENAME TO newname
ALTER USER name SET config_parameter {TO | =} {value | DEFAULT}
ALTER USER name RESET config_parameter
ALTER USER name RESOURCE QUEUE {queue_name | NONE}
ALTER USER name RESOURCE GROUP {group_name | NONE}
ALTER USER name [ [WITH] option [ ... ] ]

See ALTER USER for more information.

ALTER USER MAPPING
Changes the definition of a user mapping for a foreign server.

ALTER USER MAPPING FOR { username | USER | CURRENT_USER | PUBLIC } SERVER servername OPTIONS ( [ ADD | SET | DROP ] option ['value'] [, ... ] )

See ALTER USER MAPPING for more information.

ALTER VIEW
Changes properties of a view.

ALTER VIEW [ IF EXISTS ] name ALTER [ COLUMN ] column_name SET DEFAULT expression
ALTER VIEW [ IF EXISTS ] name ALTER [ COLUMN ] column_name DROP DEFAULT
ALTER VIEW [ IF EXISTS ] name OWNER TO new_owner
ALTER VIEW [ IF EXISTS ] name RENAME TO new_name
ALTER VIEW [ IF EXISTS ] name SET SCHEMA new_schema
ALTER VIEW [ IF EXISTS ] name SET ( view_option_name [= view_option_value] [, ... ] )
ALTER VIEW [ IF EXISTS ] name RESET ( view_option_name [, ... ] )
See ALTER VIEW for more information.

**ANALYZE**
Collects statistics about a database.

ANALYZE [VERBOSE] [table [ (column [, ...]) ]]  
ANALYZE [VERBOSE] {root_partition|leaf_partition} [ (column [, ...]) ]  
ANALYZE [VERBOSE] ROOTPARTITION {ALL | root_partition [ (column [, ...]) ]}

See ANALYZE for more information.

**BEGIN**
Starts a transaction block.

BEGIN [WORK | TRANSACTION] [transaction_mode]

See BEGIN for more information.

**CHECKPOINT**
Forces a transaction log checkpoint.

CHECKPOINT

See CHECKPOINT for more information.

**CLOSE**
Closes a cursor.

CLOSE cursor_name

See CLOSE for more information.

**CLUSTER**
Physically reorders a heap storage table on disk according to an index. Not a recommended operation in Greenplum Database.

CLUSTER indexname ON tablename  
CLUSTER [VERBOSE] tablename  
CLUSTER [VERBOSE]

See CLUSTER for more information.

**COMMENT**
Defines or changes the comment of an object.

COMMENT ON  
{ TABLE object_name  |  
  COLUMN relation_name.column_name  |  
  AGGREGATE agg_name (agg_signature)  |  
  CAST (source_type AS target_type)  |}
The document contains several SQL commands and their descriptions. Here is a summary:

**COLLATION**

`object_name`

**CONSTRAINT**

`constraint_name ON table_name`

**DATABASE**

`object_name`

**DOMAIN**

`object_name`

**EXTENSION**

`object_name`

**FOREIGN DATA WRAPPER**

`object_name`

**FOREIGN TABLE**

`object_name`

**FUNCTION**

`func_name (argmode argname argtype [, ...])`

**INDEX**

`object_name`

**LARGE OBJECT**

`large_object_oid`

**OPERATOR**

`operator_name (left_type, right_type)`

**OPERATOR CLASS**

`object_name USING index_method`

**PROCEDURAL LANGUAGE**

`object_name`

**RESOURCE GROUP**

`object_name`

**RESOURCE QUEUE**

`object_name`

**ROLE**

`object_name`

**RULE**

`rule_name ON table_name`

**SCHEMA**

`object_name`

**SEQUENCE**

`object_name`

**SERVER**

`object_name`

**TABLESPACE**

`object_name`

**TRIGGER**

`trigger_name ON table_name`

**TYPE**

`object_name`

**VIEW**

`object_name`

**IS 'text'**

See **COMMENT** for more information.

**COMMIT**

Commits the current transaction.

`COMMIT [WORK | TRANSACTION]`

See **COMMIT** for more information.

**COPY**

Copies data between a file and a table.

`COPY table_name [(column_name [, ...])]`

`FROM {'filename' | PROGRAM 'command' | STDIN}`

`[ [ WITH ] (option [, ...]) ]`

`[ ON SEGMENT ]`

`COPY { table_name [(column_name [, ...])] | (query)} TO {'filename' | PROGRAM 'command' | STDOUT}`

`[ [ WITH ] (option [, ...]) ]`

`[ ON SEGMENT ]`

See **COPY** for more information.

**CREATE AGGREGATE**

Defines a new aggregate function.

`CREATE AGGREGATE name ( [ argmode ] [ argname ] arg_data_type [, ... ] )`

`SFUNC = statefunc,`

`STYPE = state_data_type`

`[ , SSPACE = state_data_size ]`

`[ , FINALFUNC = ffunc ]`
CREATE AGGREGATE name ( [ [ argmode ] [ argname ] arg_data_type [ , ... ] ] ) ( ORDER BY [ argmode ] [ argname ] arg_data_type [ , ... ] ) ( SFUNC = statefunc, STYPE = state_data_type [ , SSPACE = state_data_size ] [ , FINALFUNC = ffunc ] [ , FINALFUNC_EXTRA ] [ , COMBINEFUNC = combinefunc ] [ , SERIALFUNC = serialfunc ] [ , DESERIALFUNC = deserialfunc ] [ , INITCOND = initial_condition ] [ , HYPOTHETICAL ] )

or the old syntax

CREATE AGGREGATE name ( BASETYPE = base_type, SFUNC = statefunc, STYPE = state_data_type [ , SSPACE = state_data_size ] [ , FINALFUNC = ffunc ] [ , FINALFUNC_EXTRA ] [ , COMBINEFUNC = combinefunc ] [ , SERIALFUNC = serialfunc ] [ , DESERIALFUNC = deserialfunc ] [ , INITCOND = initial_condition ] [ , MSFUNC = msfunc ] [ , MINVFUNC = minvfunc ] [ , MSTYPE = mstate_data_type ] [ , MSSPACE = mstate_data_size ] [ , MFINALFUNC = mffunc ] [ , MFINALFUNC_EXTRA ] [ , MINITCOND = minitial_condition ] [ , SORTOP = sort_operator ] )

See CREATE AGGREGATE for more information.

CREATE CAST

Defines a new cast.

CREATE CAST (sourcetype AS targettype)
    WITH FUNCTION funcname (argtype [, ...])
    [AS ASSIGNMENT | AS IMPLICIT]
CREATE CAST (sourcetype AS targettype)
WITHOUT FUNCTION
[AS ASSIGNMENT | AS IMPLICIT]

CREATE CAST (sourcetype AS targettype)
WITH INOUT
[AS ASSIGNMENT | AS IMPLICIT]

See CREATE CAST for more information.

CREATE COLLATION
Defines a new collation using the specified operating system locale settings, or by copying an existing collation.

CREATE COLLATION name (  
[ LOCALE = locale, ]  
[ LC_COLLATE = lc_collate, ]  
[ LC_CTYPE = lc_ctype ]

CREATE COLLATION name FROM existing_collation

See CREATE COLLATION for more information.

CREATE CONVERSION
Defines a new encoding conversion.

CREATE [DEFAULT] CONVERSION name FOR source_encoding TO dest_encoding FROM funcname

See CREATE CONVERSION for more information.

CREATE DATABASE
Creates a new database.

CREATE DATABASE name [ [WITH] [OWNER [=] user_name]  
[TEMPLATE [=] template]  
[ENCODING [=] encoding]  
[LC_COLLATE [=] lc_collate]  
[LC_CTYPE [=] lc_ctype]  
[TABLESPACE [=] tablespace]  
[CONNECTION LIMIT [=] connlimit ] ]

See CREATE DATABASE for more information.

CREATE DOMAIN
Defines a new domain.

CREATE DOMAIN name [AS] data_type [DEFAULT expression]  
[ COLLATE collation ]  
[ CONSTRAINT constraint_name  
| NOT NULL | NULL  
| CHECK (expression) [...]]

See CREATE DOMAIN for more information.
**CREATE EXTENSION**
Registers an extension in a Greenplum database.

```sql
CREATE EXTENSION [ IF NOT EXISTS ] extension_name
[ WITH ] [ SCHEMA schema_name ]
[ VERSION version ]
[ FROM old_version ]
[ CASCADE ]
```

See `CREATE EXTENSION` for more information.

**CREATE EXTERNAL TABLE**
Defines a new external table.

```sql
CREATE [READABLE] EXTERNAL [TEMPORARY | TEMP] TABLE table_name
( column_name data_type [, ...] | LIKE other_table )
LOCATION ('file://seghost[:port]/path/file' [, ...])
| ('gpfdist://filehost[:port]/file_pattern[#transform=trans_name]' [, ...])
| ('pxf://path-to-data?PROFILE=profile_name[&SERVER=server_name]
[&custom-option=value[...]]')
| ('s3://S3_endpoint[:port]/bucket_name/[S3_prefix] [region=S3-region] [config=config_file]')
[ON MASTER]
FORMAT 'TEXT'
[ ([HEADER]
  [DELIMITER [AS] 'delimiter' | 'OFF']
  [NULL [AS] 'null string']
  [ESCAPE [AS] 'escape' | 'OFF']
  [NEWLINE [ AS ] 'LF' | 'CR' | 'CRLF']
  [FILL MISSING FIELDS] )]
| 'CSV'
[ ([HEADER]
  [QUOTE [AS] 'quote']
  [DELIMITER [AS] 'delimiter']
  [NULL [AS] 'null string']
  [FORCE NOT NULL column [, ...]]
  [ESCAPE [AS] 'escape']
  [NEWLINE [ AS ] 'LF' | 'CR' | 'CRLF']
  [FILL MISSING FIELDS] )]
| 'CUSTOM' (Formatter=<formatter_specifications>)
[ ENCODING 'encoding' ]
[ [ LOG ERRORS ] SEGMENT REJECT LIMIT count
  [ROWS | PERCENT] ]
```

```sql
CREATE [READABLE] EXTERNAL WEB [TEMPORARY | TEMP] TABLE table_name
( column_name data_type [, ...] | LIKE other_table )
LOCATION ('http://webhost[:port]/path/file' [, ...])
| EXECUTE 'command' [ ON ALL
  MASTER number_of_segments
  HOST ['segment_hostname']
  SEGMENT segment_id ]
```

```sql
FORMAT 'TEXT'
[ ([HEADER]
  [DELIMITER [AS] 'delimiter' | 'OFF']
  [NULL [AS] 'null string']
  [ESCAPE [AS] 'escape' | 'OFF']
  [NEWLINE [ AS ] 'LF' | 'CR' | 'CRLF']
```
CREATE WRITABLE EXTERNAL [TEMPORARY | TEMP] TABLE table_name
( column_name data_type [, ...] | LIKE other_table )

  | 'CUSTOM' (Formatter=<formatter specifications>)
  [ ENCODING 'encoding' ]
  [ DISTRIBUTED BY ((column [opclass]), [ ... ] ) | DISTRIBUTED RANDOMLY ]
CREATE FOREIGN DATA WRAPPER

Defines a new foreign-data wrapper.

```
CREATE FOREIGN DATA WRAPPER name
    [ HANDLER handler_function | NO HANDLER ]
    [ VALIDATOR validator_function | NO VALIDATOR ]
    [ OPTIONS ( [ mpp_execute { 'master' | 'any' | 'all segments' } ]
          [, [ ] option 'value' [, ... ] ] ) ]
```

See `CREATE FOREIGN DATA WRAPPER` for more information.

CREATE FOREIGN TABLE

Defines a new foreign table.

```
CREATE FOREIGN TABLE [ IF NOT EXISTS ] table_name ( [ column_name data_type [ OPTIONS ( option 'value' [, ... ] ) ] ]
    [ COLLATE collation ] [ column_constraint [ ... ] ]
    [, ... ]
)
```

SERVER server_name
    [ OPTIONS ( [ mpp_execute { 'master' | 'any' | 'all segments' } ]
          [, [ ] option 'value' [, ... ] ] ) ]

See `CREATE FOREIGN TABLE` for more information.

CREATE FUNCTION

Defines a new function.

```
CREATE [OR REPLACE] FUNCTION name
    ( [ [ argmode ] [ argname ] argtype [ { DEFAULT | = } default_expr ] ]
    [, ... ]
    )
    [ RETURNS rettype ]
    RETURN TABLE ( column_name column_type [, ... ] )

{ LANGUAGE langname
    WINDOW
    IMMUTABLE | STABLE | VOLATILE | [NOT] LEAKPROOF
    CALLED ON NULL INPUT | RETURNS NULL ON NULL INPUT | STRICT
    [EXTERNAL] SECURITY INVOKER | [EXTERNAL] SECURITY DEFINER
    EXECUTE ON { ANY | MASTER | ALL SEGMENTS }
    COST execution_cost
    SET configuration_parameter ( TO value | = value | FROM CURRENT )
    AS 'definition'
    AS 'obj_file', 'link_symbol' ) ...
    [ WITH ({ { DESCRIBE = describe_function
              } [, ... ] ) ]
```

See `CREATE FUNCTION` for more information.
CREATE GROUP
Defines a new database role.

```
CREATE GROUP name [[WITH] option [ ... ]]
```
See CREATE GROUP for more information.

CREATE INDEX
Defines a new index.

```
CREATE [UNIQUE] INDEX [name] ON table_name [USING method]
    ( {column_name | (expression)) [COLLATE parameter] [opclass] [ ASC |
    DESC ] [ NULLS { FIRST | LAST } ] [, ... ] )
    [ WITH ( storage_parameter = value [, ... ] ) ]
    [ TABLESPACE tablespace ]
    [ WHERE predicate ]
```
See CREATE INDEX for more information.

CREATE LANGUAGE
Defines a new procedural language.

```
CREATE [ OR REPLACE ] [ PROCEDURAL ] LANGUAGE name
CREATE [ OR REPLACE ] [ TRUSTED ] [ PROCEDURAL ] LANGUAGE name
    HANDLER call_handler [ INLINE inline_handler ]
    [ VALIDATOR valfunction ]
```
See CREATE LANGUAGE for more information.

CREATE OPERATOR
Defines a new operator.

```
CREATE OPERATOR name ( 
    PROCEDURE = funcname
    [, LEFTARG = lefttype] [, RIGHTARG = righttype]
    [, COMMUTATOR = com_op] [, NEGATOR = neg_op]
    [, RESTRICT = res_proc] [, JOIN = join_proc]
    [, HASHES] [, MERGES] )
```
See CREATE OPERATOR for more information.

CREATE OPERATOR CLASS
Defines a new operator class.

```
CREATE OPERATOR CLASS name [DEFAULT] FOR TYPE data_type
    USING index_method [ FAMILY family_name ] AS
    { OPERATOR strategy_number operator_name [ ( op_type, op_type ) ] [ FOR
    SEARCH | FOR ORDER BY sort_family_name ]
    | FUNCTION support_number funcname (argument_type [, ...] )
    | STORAGE storage_type
    } [, ... ]
```
See CREATE OPERATOR CLASS for more information.
CREATE OPERATOR FAMILY
Defines a new operator family.

CREATE OPERATOR FAMILY name USING index_method

See CREATE OPERATOR FAMILY for more information.

CREATE PROTOCOL
Registers a custom data access protocol that can be specified when defining a Greenplum Database external table.

CREATE [TRUSTED] PROTOCOL name ( [readfunc='read_call_handler'] [, writefunc='write_call_handler'] [, validatorfunc='validate_handler'] )

See CREATE PROTOCOL for more information.

CREATE RESOURCE GROUP
Defines a new resource group.

CREATE RESOURCE GROUP name WITH (group_attribute=value [, ... ])

See CREATE RESOURCE GROUP for more information.

CREATE RESOURCE QUEUE
Defines a new resource queue.

CREATE RESOURCE QUEUE name WITH (queue_attribute=value [, ... ])

See CREATE RESOURCE QUEUE for more information.

CREATE ROLE
Defines a new database role (user or group).

CREATE ROLE name [[WITH] option [ ... ]]

See CREATE ROLE for more information.

CREATE RULE
Defines a new rewrite rule.

CREATE [OR REPLACE] RULE name AS ON event TO table_name [WHERE condition] DO [ALSO | INSTEAD] ( NOTHING | command | (command; command ... ) )

See CREATE RULE for more information.

CREATE SCHEMA
Defines a new schema.

CREATE SCHEMA schema_name [AUTHORIZATION username] [schema_element [ ... ]]
CREATE SCHEMA AUTHORIZATION rolename [schema_element [ ... ]]  
CREATE SCHEMA IF NOT EXISTS schema_name [ AUTHORIZATION user_name ]  
CREATE SCHEMA IF NOT EXISTS AUTHORIZATION user_name  

See CREATE SCHEMA for more information.

CREATE SEQUENCE  
Defines a new sequence generator.  

CREATE [TEMPORARY | TEMP] SEQUENCE name 
[INCREMENT [BY] value]  
[MINVALUE minvalue | NO MINVALUE]  
[MAXVALUE maxvalue | NO MAXVALUE]  
[START [ WITH ] start]  
[CACHE cache]  
[[NO] CYCLE]  
[OWNED BY { table.column | NONE }]  

See CREATE SEQUENCE for more information.

CREATE SERVER  
Defines a new foreign server.  

CREATE SERVER server_name [ TYPE 'server_type' ] [ VERSION 'server_version' ] 
FOREIGN DATA WRAPPER fdw_name 
[ OPTIONS ( [ mpp_execute { 'master' | 'any' | 'all segments' } [, ... ] ) ] 

See CREATE SERVER for more information.

CREATE TABLE  
Defines a new table.  

CREATE [ [GLOBAL | LOCAL] {TEMPORARY | TEMP } | UNLOGGED] TABLE [IF NOT EXISTS] 
  table_name (  
  [ { column_name data_type [ COLLATE collation ] [column_constraint 
  [ ... ] ] ]  
  [ ENCODING ( storage_directive [, ... ] ) ]  
  table_constraint  
  LIKE source_table [ like_option ... ] )  
  [ column_reference_storage_directive [, ... ] ]  
  [, ... ] )  
)  
[ INHERITS ( parent_table [, ... ] ) ]  
[ WITH ( storage_parameter [=value] [, ... ] ) ]  
[ ON COMMIT { PRESERVE ROWS | DELETE ROWS | DROP } ]  
[ TABLESPACE tablespace_name ]  
[ DISTRIBUTED BY (column [opclass], [ ... ]) ]  
   DISTRIBUTED RANDOMLY | DISTRIBUTED REPLICATED ]  
[ PARTITION BY partition_type (column) ]  
   [ SUBPARTITION BY partition_type (column) ]  
   [ SUBPARTITION TEMPLATE ( template_spec ) ]  
[ ... ]
CREATE TABLE [ [GLOBAL | LOCAL] {TEMPORARY | TEMP} | UNLOGGED ] TABLE [IF NOT EXISTS] table_name
OF type_name [ ( column_name WITH OPTIONS [ column_constraint [ ... ] ]
| table_constraint ) [, ... ] ]
[ WITH ( storage_parameter [=value] [, ... ] ) ]
[ ON COMMIT { PRESERVE ROWS | DELETE ROWS | DROP } ]
[ TABLESPACE tablespace_name ]

See CREATE TABLE for more information.

CREATE TABLE AS
Defines a new table from the results of a query.

CREATE TABLE [ [GLOBAL | LOCAL] {TEMPORARY | TEMP} | UNLOGGED ]
TABLE table_name
[ (column_name [, ...] ) ]
[ WITH ( storage_parameter [=value] [, ... ] ) | WITHOUT OIDS ]
[ ON COMMIT { PRESERVE ROWS | DELETE ROWS | DROP } ]
[ TABLESPACE tablespace_name ]
AS query
[ WITH [ NO ] DATA ]
[ DISTRIBUTED BY (column [, ...] ) ] | DISTRIBUTED RANDOMLY |
DISTRIBUTED REPLICATED ]

See CREATE TABLE AS for more information.

CREATE TABLESPACE
Defines a new tablespace.

CREATE TABLESPACE tablespace_name [OWNER username]  LOCATION '/path/to/dir'
[WITH (contentID_1='/path/to/dir1'[, contentID_2='/path/to/dir2' ... ])]

See CREATE TABLESPACE for more information.

CREATE TEXT SEARCH CONFIGURATION
Defines a new text search configuration.

CREATE TEXT SEARCH CONFIGURATION name ( PARSER = parser_name |
COPY = source_config )

See CREATE TEXT SEARCH CONFIGURATION for more information.
CREATE TEXT SEARCH DICTIONARY

Defines a new text search dictionary.

CREATE TEXT SEARCH DICTIONARY name (  
    TEMPLATE = template  
    [, option = value [, ... ]]  
)

See CREATE TEXT SEARCH DICTIONARY for more information.

CREATE TEXT SEARCH PARSER

Defines a new text search parser.

CREATE TEXT SEARCH PARSER name (  
    START = start_function ,  
    GETTOKEN = gettoken_function ,  
    END = end_function ,  
    LEXTYPES = lextypes_function  
    [, HEADLINE = headline_function ]  
)

See CREATE TEXT SEARCH PARSER for more information.

CREATE TEXT SEARCH TEMPLATE

Defines a new text search template.

CREATE TEXT SEARCH TEMPLATE name (  
    [ INIT = init_function , ]  
    LEXIZE = lexize_function  
)

See CREATE TEXT SEARCH TEMPLATE for more information.

CREATE TYPE

Defines a new data type.

CREATE TYPE name AS  
    ( attribute_name data_type [ COLLATE collation ] [, ... ] )

CREATE TYPE name AS ENUM  
    ( [ 'label' [, ... ] ] )

CREATE TYPE name AS RANGE (  
    SUBTYPE = subtype  
    [, SUBTYPE_OPCCLASS = subtype_operator_class ]  
    [, COLLATION = collation ]  
    [, CANONICAL = canonical_function ]  
    [, SUBTYPE_DIFF = subtype_diff_function ]  
)

CREATE TYPE name (  
    INPUT = input_function,  
    OUTPUT = output_function  
    [, RECEIVE = receive_function]  
    [, SEND = send_function]  
    [, TYPMOD_IN = type_modifier_input_function ]  
    [, TYPMOD_OUT = type_modifier_output_function ]  
    [, INTERNALLENGTH = {internallength | VARIABLE}]  
)
CREATE TYPE name

See `CREATE TYPE` for more information.

**CREATE USER**

Defines a new database role with the `LOGIN` privilege by default.

```sql
CREATE USER name [[WITH] option [ ... ]]
```

See `CREATE USER` for more information.

**CREATE USER MAPPING**

Defines a new mapping of a user to a foreign server.

```sql
CREATE USER MAPPING FOR { username | USER | CURRENT_USER | PUBLIC }
SERVER servername
[ OPTIONS ( option 'value' [, ... ] ) ]
```

See `CREATE USER MAPPING` for more information.

**CREATE VIEW**

Defines a new view.

```sql
CREATE [OR REPLACE] [TEMP | TEMPORARY] [RECURSIVE] VIEW name [ ( column_name [, ... ] ) ]
[ WITH ( view_option_name = view_option_value [, ... ] ) ]
AS query
[ WITH [ CASCADED | LOCAL ] CHECK OPTION ]
```

See `CREATE VIEW` for more information.

**DEALLOCATE**

Deallocates a prepared statement.

```sql
DEALLOCATE [PREPARE] name
```

See `DEALLOCATE` for more information.
DECLARE
Defines a cursor.

DECLARE name [BINARY] [INSENSITIVE] [NO SCROLL] CURSOR
[[WITH | WITHOUT] HOLD]
FOR query [FOR READ ONLY]

See DECLARE for more information.

DELETE
Delete rows from a table.

[ WITH [ RECURSIVE ] with_query [, ...] ]
DELETE FROM [ONLY] table [[AS] alias]
[USING usinglist]
WHERE condition | WHERE CURRENT OF cursor_name
[RETURNING * | output_expression [[AS] output_name] [, ...]]

See DELETE for more information.

DISCARD
Discards the session state.

DISCARD { ALL | PLANS | TEMPORARY | TEMP }

See DISCARD for more information.

DROP AGGREGATE
Removes an aggregate function.

DROP AGGREGATE [IF EXISTS] name ( aggregate_signature ) [CASCADE | RESTRICT]

See DROP AGGREGATE for more information.

DO
Executes an anonymous code block as a transient anonymous function.

DO [ LANGUAGE lang_name ] code

See DO for more information.

DROP CAST
Removes a cast.

DROP CAST [IF EXISTS] (sourcetype AS targettype) [CASCADE | RESTRICT]

See DROP CAST for more information.

DROP COLLATION
Removes a previously defined collation.

DROP COLLATION [ IF EXISTS ] name [ CASCADE | RESTRICT ]
See `DROP COLLATION` for more information.

**DROP CONVERSION**
Removes a conversion.

```
DROP CONVERSION [IF EXISTS] name [CASCADE | RESTRICT]
```

See `DROP CONVERSION` for more information.

**DROP DATABASE**
Removes a database.

```
DROP DATABASE [IF EXISTS] name
```

See `DROP DATABASE` for more information.

**DROP DOMAIN**
Removes a domain.

```
DROP DOMAIN [IF EXISTS] name [, ...] [CASCADE | RESTRICT]
```

See `DROP DOMAIN` for more information.

**DROP EXTENSION**
Removes an extension from a Greenplum database.

```
DROP EXTENSION [ IF EXISTS ] name [, ...] [ CASCADE | RESTRICT ]
```

See `DROP EXTENSION` for more information.

**DROP EXTERNAL TABLE**
Removes an external table definition.

```
DROP EXTERNAL [WEB] TABLE [IF EXISTS] name [CASCADE | RESTRICT]
```

See `DROP EXTERNAL TABLE` for more information.

**DROP FOREIGN DATA WRAPPER**
Removes a foreign-data wrapper.

```
DROP FOREIGN DATA WRAPPER [ IF EXISTS ] name [ CASCADE | RESTRICT ]
```

See `DROP FOREIGN DATA WRAPPER` for more information.

**DROP FOREIGN TABLE**
Removes a foreign table.

```
DROP FOREIGN TABLE [ IF EXISTS ] name [, ...] [ CASCADE | RESTRICT ]
```

See `DROP FOREIGN TABLE` for more information.
**DROP FUNCTION**
Removes a function.

```
DROP FUNCTION [IF EXISTS] name ( [ [argmode] [argname] argtype [, ...] ] ) [CASCADE | RESTRICT]
```

See *DROP FUNCTION* for more information.

**DROP GROUP**
Removes a database role.

```
DROP GROUP [IF EXISTS] name [, ...]
```

See *DROP GROUP* for more information.

**DROP INDEX**
Removes an index.

```
DROP INDEX [ CONCURRENTLY ] [ IF EXISTS ] name [, ...] [ CASCADE | RESTRICT ]
```

See *DROP INDEX* for more information.

**DROP LANGUAGE**
Removes a procedural language.

```
DROP [PROCEDURAL] LANGUAGE [IF EXISTS] name [CASCADE | RESTRICT]
```

See *DROP LANGUAGE* for more information.

**DROP OPERATOR**
Removes an operator.

```
DROP OPERATOR [IF EXISTS] name ( {lefttype | NONE} , {righttype | NONE} ) [CASCADE | RESTRICT]
```

See *DROP OPERATOR* for more information.

**DROP OPERATOR CLASS**
Removes an operator class.

```
DROP OPERATOR CLASS [IF EXISTS] name USING index_method [CASCADE | RESTRICT]
```

See *DROP OPERATOR CLASS* for more information.

**DROP OPERATOR FAMILY**
Removes an operator family.

```
DROP OPERATOR FAMILY [IF EXISTS] name USING index_method [CASCADE | RESTRICT]
```

See *DROP OPERATOR FAMILY* for more information.
### DROP OWNED
Removes database objects owned by a database role.

```
DROP OWNED BY name [, ...] [CASCADE | RESTRICT]
```

See **DROP OWNED** for more information.

### DROP PROTOCOL
Removes a external table data access protocol from a database.

```
DROP PROTOCOL [IF EXISTS] name
```

See **DROP PROTOCOL** for more information.

### DROP RESOURCE GROUP
Removes a resource group.

```
DROP RESOURCE GROUP group_name
```

See **DROP RESOURCE GROUP** for more information.

### DROP RESOURCE QUEUE
Removes a resource queue.

```
DROP RESOURCE QUEUE queue_name
```

See **DROP RESOURCE QUEUE** for more information.

### DROP ROLE
Removes a database role.

```
DROP ROLE [IF EXISTS] name [, ...]
```

See **DROP ROLE** for more information.

### DROP RULE
Removes a rewrite rule.

```
DROP RULE [IF EXISTS] name ON table_name [CASCADE | RESTRICT]
```

See **DROP RULE** for more information.

### DROP SCHEMA
Removes a schema.

```
DROP SCHEMA [IF EXISTS] name [, ...] [CASCADE | RESTRICT]
```

See **DROP SCHEMA** for more information.
DROP SEQUENCE
Removes a sequence.

```
DROP SEQUENCE [IF EXISTS] name [, ...] [CASCADE | RESTRICT]
```

See `DROP SEQUENCE` for more information.

DROP SERVER
Removes a foreign server descriptor.

```
DROP SERVER [ IF EXISTS ] servername [ CASCADE | RESTRICT ]
```

See `DROP SERVER` for more information.

DROP TABLE
Removes a table.

```
DROP TABLE [IF EXISTS] name [, ...] [CASCADE | RESTRICT]
```

See `DROP TABLE` for more information.

DROP TABLESPACE
Removes a tablespace.

```
DROP TABLESPACE [IF EXISTS] tablesapcename
```

See `DROP TABLESPACE` for more information.

DROP TEXT SEARCH CONFIGURATION
Removes a text search configuration.

```
DROP TEXT SEARCH CONFIGURATION [IF EXISTS] name [CASCADE | RESTRICT]
```

See `DROP TEXT SEARCH CONFIGURATION` for more information.

DROP TEXT SEARCH DICTIONARY
Removes a text search dictionary.

```
DROP TEXT SEARCH DICTIONARY [IF EXISTS] name [CASCADE | RESTRICT]
```

See `DROP TEXT SEARCH DICTIONARY` for more information.

DROP TEXT SEARCH PARSER
Remove a text search parser.

```
DROP TEXT SEARCH PARSER [IF EXISTS] name [CASCADE | RESTRICT]
```

See `DROP TEXT SEARCH PARSER` for more information.
**DROP TEXT SEARCH TEMPLATE**
Removes a text search template.

```
DROP TEXT SEARCH TEMPLATE [ IF EXISTS ] name [ CASCADE | RESTRICT ]
```

See *DROP TEXT SEARCH TEMPLATE* for more information.

**DROP TYPE**
Removes a data type.

```
DROP TYPE [IF EXISTS] name [, ...] [CASCADE | RESTRICT]
```

See *DROP TYPE* for more information.

**DROP USER**
Removes a database role.

```
DROP USER [IF EXISTS] name [, ...]
```

See *DROP USER* for more information.

**DROP USER MAPPING**
Removes a user mapping for a foreign server.

```
DROP USER MAPPING [ IF EXISTS ] { username | USER | CURRENT_USER | PUBLIC }
SERVER servername
```

See *DROP USER MAPPING* for more information.

**DROP VIEW**
Removes a view.

```
DROP VIEW [IF EXISTS] name [, ...] [CASCADE | RESTRICT]
```

See *DROP VIEW* for more information.

**END**
Commits the current transaction.

```
END [WORK | TRANSACTION]
```

See *END* for more information.

**EXECUTE**
Executes a prepared SQL statement.

```
EXECUTE name [ (parameter [, ...] ) ]
```

See *EXECUTE* for more information.
**EXPLAIN**

Shows the query plan of a statement.

```
EXPLAIN [ ( option [, ...] ) ] statement
EXPLAIN [ANALYZE] [VERBOSE] statement
```

See *EXPLAIN* for more information.

**FETCH**

Retrieves rows from a query using a cursor.

```
FETCH [ forward_direction { FROM | IN } ] cursor_name
```

See *FETCH* for more information.

**GRANT**

Defines access privileges.

```
GRANT { {SELECT | INSERT | UPDATE | DELETE | REFERENCES | TRIGGER | TRUNCATE } [, ...] | ALL [PRIVILEGES] }
ON { [TABLE] table_name [, ...]
    | ALL TABLES IN SCHEMA schema_name [, ...] }
TO { [ GROUP ] role_name | PUBLIC } [, ...] [ WITH GRANT OPTION ]

GRANT { { SELECT | INSERT | UPDATE | REFERENCES } ( column_name [, ...] ) [, ...] | ALL [ PRIVILEGES ] ( column_name [, ...] ) }
ON [ TABLE ] table_name [, ...]
TO { role_name | PUBLIC } [, ...] [ WITH GRANT OPTION ]

GRANT { { USAGE | SELECT | UPDATE } [, ...] | ALL [ PRIVILEGES ] }
ON SEQUENCE sequence_name [, ...]
TO { [ GROUP ] role_name | PUBLIC } [, ...] [ WITH GRANT OPTION ]

GRANT { {CREATE | CONNECT | TEMPORARY | TEMP} [, ...] | ALL [ PRIVILEGES ] }
ON DATABASE database_name [, ...]
TO { [ GROUP ] role_name | PUBLIC } [, ...] [ WITH GRANT OPTION ]

GRANT { USAGE | ALL [ PRIVILEGES ] }
ON DOMAIN domain_name [, ...]
TO { [ GROUP ] role_name | PUBLIC } [, ...] [ WITH GRANT OPTION ]

GRANT { USAGE | ALL [ PRIVILEGES ] }
ON FOREIGN DATA WRAPPER fdw_name [, ...]
TO { [ GROUP ] role_name | PUBLIC } [, ...] [ WITH GRANT OPTION ]

GRANT { USAGE | ALL [ PRIVILEGES ] }
ON FOREIGN SERVER server_name [, ...]
TO { [ GROUP ] role_name | PUBLIC } [, ...] [ WITH GRANT OPTION ]

GRANT { EXECUTE | ALL [PRIVILEGES] }
ON { FUNCTION function_name ( [ [ argmode ] [ argname ] argtype [, ...] ] ) [, ...]
    | ALL FUNCTIONS IN SCHEMA schema_name [, ...] }
TO { [ GROUP ] role_name | PUBLIC } [, ...] [ WITH GRANT OPTION ]

GRANT { USAGE | ALL [PRIVILEGES] }
ON LANGUAGE lang_name [, ...]
```
TO { [ GROUP ] role_name | PUBLIC } [, ...] [ WITH GRANT OPTION ]

GRANT { { CREATE | USAGE } [, ...] | ALL [ PRIVILEGES ] }
ON SCHEMA schema_name [, ...]
TO { [ GROUP ] role_name | PUBLIC } [, ...] [ WITH GRANT OPTION ]

GRANT { CREATE | ALL [ PRIVILEGES ] }
ON TABLESPACE tablespace_name [, ...]
TO { [ GROUP ] role_name | PUBLIC } [, ...] [ WITH GRANT OPTION ]

GRANT { USAGE | ALL [ PRIVILEGES ] }
ON TYPE type_name [, ...]
TO { [ GROUP ] role_name | PUBLIC } [, ...] [ WITH GRANT OPTION ]

GRANT parent_role [, ...]
TO member_role [, ...] [WITH ADMIN OPTION]

GRANT { SELECT | INSERT | ALL [ PRIVILEGES ] }
ON PROTOCOL protocolname
TO username

See **GRANT** for more information.

**INSERT**

Creates new rows in a table.

[ WITH [ RECURSIVE ] with_query [, ...] ]
INSERT INTO table [( column [, ...] )]
{DEFAULT VALUES | VALUES ( {expression | DEFAULT} [, ...] ) [, ...]
| query}
[RETURNING * | output_expression [(AS output_name) [, ...]]

See **INSERT** for more information.

**LOAD**

Loads or reloads a shared library file.

LOAD 'filename'

See **LOAD** for more information.

**LOCK**

Locks a table.

LOCK [TABLE] [ONLY] name [ * ] [, ...] [IN lockmode MODE] [NOWAIT]

See **LOCK** for more information.

**MOVE**

Positions a cursor.

MOVE [ forward_direction [ FROM | IN ] ] cursor_name

See **MOVE** for more information.
**PREPARE**
Prepare a statement for execution.

```
PREPARE name [ (datatype [, ...] ) ] AS statement
```

See *PREPARE* for more information.

**REASSIGN OWNED**
Changes the ownership of database objects owned by a database role.

```
REASSIGN OWNED BY old_role [, ...] TO new_role
```

See *REASSIGN OWNED* for more information.

**REINDEX**
Rebuilds indexes.

```
REINDEX {INDEX | TABLE | DATABASE | SYSTEM} name
```

See *REINDEX* for more information.

**RELEASE SAVEPOINT**
Destroys a previously defined savepoint.

```
RELEASE [SAVEPOINT] savepoint_name
```

See *RELEASE SAVEPOINT* for more information.

**RESET**
Restores the value of a system configuration parameter to the default value.

```
RESET configuration_parameter
RESET ALL
```

See *RESET* for more information.

**REVOKE**
Removes access privileges.

```
REVOKE [GRANT OPTION FOR] { {SELECT | INSERT | UPDATE | DELETE |
| REFERENCES | TRIGGER | TRUNCATE } [, ...] | ALL [PRIVILEGES] } 
| [TABLE] table_name [, ...] 
| { ALL TABLES IN SCHEMA schema_name [, ...] }
FROM { { GROUP } role_name | PUBLIC } [, ...] 
| [CASCADE | RESTRICT]
REVOKE [ GRANT OPTION FOR ] { { SELECT | INSERT | UPDATE 
| REFERENCES } ( column_name [, ...] ) 
| [, ...] | ALL [ PRIVILEGES ] ( column_name [, ...] ) } 
ON [ TABLE ] table_name [, ...]
FROM { { GROUP } role_name | PUBLIC } [, ...] 
| [ CASCADE | RESTRICT ]
```
REVOKE [GRANT OPTION FOR] { {USAGE | SELECT | UPDATE} [, ...] 
| ALL [PRIVILEGES] } 
ON { SEQUENCE sequence_name [, ...] 
| ALL SEQUENCES IN SCHEMA schema_name [, ...] } 
FROM { [ GROUP ] role_name | PUBLIC } [, ...] 
[CASCADE | RESTRICT]

REVOKE [GRANT OPTION FOR] { {CREATE | CONNECT 
| TEMPORARY | TEMP} [, ...] | ALL [PRIVILEGES] } 
ON DATABASE database_name [, ...] 
FROM { [ GROUP ] role_name | PUBLIC } [, ...] 
[CASCADE | RESTRICT]

REVOKE [ GRANT OPTION FOR ] 
{ USAGE | ALL [ PRIVILEGES ] } 
ON DOMAIN domain_name [, ...] 
FROM { [ GROUP ] role_name | PUBLIC } [, ...] 
[ CASCADE | RESTRICT ]

REVOKE [ GRANT OPTION FOR ] 
{ USAGE | ALL [ PRIVILEGES ] } 
ON FOREIGN DATA WRAPPER fdw_name [, ...] 
FROM { [ GROUP ] role_name | PUBLIC } [, ...] 
[ CASCADE | RESTRICT ]

REVOKE [ GRANT OPTION FOR ] 
{ USAGE | ALL [ PRIVILEGES ] } 
ON FOREIGN SERVER server_name [, ...] 
FROM { [ GROUP ] role_name | PUBLIC } [, ...] 
[ CASCADE | RESTRICT ]

REVOKE [GRANT OPTION FOR] {EXECUTE | ALL [PRIVILEGES]} 
ON { FUNCTION funcname ([argmode] [argname] argtype 
[, ...]) [, ...] | ALL FUNCTIONS IN SCHEMA schema_name [, ...] } 
FROM { [ GROUP ] role_name | PUBLIC } [, ...] 
[CASCADE | RESTRICT]

REVOKE [GRANT OPTION FOR] {USAGE | ALL [PRIVILEGES]} 
ON LANGUAGE langname [, ...] 
FROM { [ GROUP ] role_name | PUBLIC } [, ...] 
[ CASCADE | RESTRICT ]

REVOKE [GRANT OPTION FOR] { {CREATE | USAGE} [, ...]

[CASCADE | RESTRICT]

REVOKE [ GRANT OPTION FOR ] 
{ USAGE | ALL [ PRIVILEGES ] } 
ON TYPE type_name [, ...] 
FROM { [ GROUP ] role_name | PUBLIC } [, ...] 
[ CASCADE | RESTRICT ]

REVOKE [ ADMIN OPTION FOR] parent_role [, ...] 
FROM [ GROUP ] member_role [, ...]
**ROLLBACK**
Aborts the current transaction.

**ROLLBACK [WORK | TRANSACTION]**
See **ROLLBACK** for more information.

**ROLLBACK TO SAVEPOINT**
Rolls back the current transaction to a savepoint.

**ROLLBACK [WORK | TRANSACTION] TO [SAVEPOINT] savepoint_name**
See **ROLLBACK TO SAVEPOINT** for more information.

**SAVEPOINT**
Defines a new savepoint within the current transaction.

**SAVEPOINT savepoint_name**
See **SAVEPOINT** for more information.

**SELECT**
Retrieves rows from a table or view.

```
[ WITH [ RECURSIVE ] with_query [, ...] ]
SELECT [ALL | DISTINCT [ON (expression [, ...])]]
  * | expression [[AS] output_name] [, ...]
  [FROM from_item [, ...]]
  [WHERE condition]
  [GROUP BY grouping_element [, ...]]
  [HAVING condition [, ...]]
  [WINDOW window_name AS (window_definition) [, ...]]
  [(UNION | INTERSECT | EXCEPT) [ALL | DISTINCT] select]
  [ORDER BY expression [ASC | DESC | USING operator] [NULLS {FIRST | LAST}] [, ...]]
  [LIMIT {count | ALL}]
  [OFFSET start [ ROW | ROWS ]]
  [FETCH { FIRST | NEXT } [ count ] { ROW | ROWS } ONLY]
  [FOR {UPDATE | NO KEY UPDATE | SHARE | KEY SHARE} [OF table_name [, ...]]
  [NOWAIT] [...]]
TABLE { [ ONLY ] table_name [ * ] | with_query_name }
```

See **SELECT** for more information.

**SELECT INTO**
Defines a new table from the results of a query.

```
[ WITH [ RECURSIVE ] with_query [, ...] ]
SELECT [ALL | DISTINCT [ON ( expression [, ...] )]]
  * | expression [AS output_name] [, ...]
```
INTO [TEMPORARY | TEMP | UNLOGGED] [TABLE] new_table
[FROM from_item [, ...]]
[WHERE condition]
[GROUP BY expression [, ...]]
[HAVING condition [, ...]]
[(UNION | INTERSECT | EXCEPT) [ALL | DISTINCT ] select]
[ORDER BY expression [ASC | DESC | USING operator] [NULLS {FIRST | LAST}] [, ...]]
[LIMIT {count | ALL}]}
[OFFSET start [ ROW | ROWS ]]
[FETCH { FIRST | NEXT } [ count ] [ ROW | ROWS ] ONLY ]
[FOR {UPDATE | SHARE} [OF table_name [, ...]] [NOWAIT]]
[...]

See SELECT INTO for more information.

SET
Changes the value of a Greenplum Database configuration parameter.

SET [SESSION | LOCAL] configuration_parameter {TO | =} value |
'value' | DEFAULT}

SET [SESSION | LOCAL] TIME ZONE {timezone | LOCAL | DEFAULT}

See SET for more information.

SET CONSTRAINTS
Sets constraint check timing for the current transaction.

SET CONSTRAINTS { ALL | name [, ...] } { DEFERRED | IMMEDIATE }

See SET CONSTRAINTS for more information.

SET ROLE
Sets the current role identifier of the current session.

SET [SESSION | LOCAL] ROLE rolename
SET [SESSION | LOCAL] ROLE NONE
RESET ROLE

See SET ROLE for more information.

SET SESSION AUTHORIZATION
Sets the session role identifier and the current role identifier of the current session.

SET [SESSION | LOCAL] SESSION AUTHORIZATION rolename
SET [SESSION | LOCAL] SESSION AUTHORIZATION DEFAULT
RESET SESSION AUTHORIZATION

See SET SESSION AUTHORIZATION for more information.
**SET TRANSACTION**
Sets the characteristics of the current transaction.

```
SET TRANSACTION [transaction_mode] [READ ONLY | READ WRITE]
SET TRANSACTION SNAPSHOT snapshot_id
SET SESSION CHARACTERISTICS AS TRANSACTION transaction_mode
   [READ ONLY | READ WRITE]
   [NOT] DEFERRABLE
```

See **SET TRANSACTION** for more information.

**SHOW**
Shows the value of a system configuration parameter.

```
SHOW configuration_parameter
SHOW ALL
```

See **SHOW** for more information.

**START TRANSACTION**
Starts a transaction block.

```
START TRANSACTION [transaction_mode] [READ WRITE | READ ONLY]
```

See **START TRANSACTION** for more information.

**TRUNCATE**
Empties a table of all rows.

```
TRUNCATE [TABLE] [ONLY] name [ * ] [, ...]
   [ RESTART IDENTITY | CONTINUE IDENTITY ] [CASCADE | RESTRICT]
```

See **TRUNCATE** for more information.

**UPDATE**
Updates rows of a table.

```
[ WITH [ RECURSIVE ] with_query [, ...] ]
UPDATE [ONLY] table [[AS] alias]
   SET {column = {expression | DEFAULT} |
   (column [, ...]) = ({expression | DEFAULT} [, ...])} [, ...]
   [FROM fromlist]
   [WHERE condition | WHERE CURRENT OF cursor_name ]
```

See **UPDATE** for more information.

**VACUUM**
Garbage-collects and optionally analyzes a database.

```
VACUUM [(( FULL | FREEZE | VERBOSE | ANALYZE ) [, ...])] [table [(column [, ...)]]]
```
VACUUM [FULL] [FREEZE] [VERBOSE] [table]
VACUUM [FULL] [FREEZE] [VERBOSE] ANALYZE
    [table [((column [, , ... ] ))]]

See VACUUM for more information.

VALUES
Computes a set of rows.
VALUES ( expression [, ...] ) [, ...]
    [ORDER BY sort_expression [ ASC | DESC | USING operator ] [, ... ] ]
    [LIMIT { count | ALL } ]
    [OFFSET start [ ROW | ROWS ] ]
    [FETCH { FIRST | NEXT } [count ] { ROW | ROWS } ONLY ]

See VALUES for more information.

ABORT
Aborts the current transaction.

Synopsis
ABORT [WORK | TRANSACTION]

Description
ABORT rolls back the current transaction and causes all the updates made by the transaction to be discarded. This command is identical in behavior to the standard SQL command ROLLBACK, and is present only for historical reasons.

Parameters
WORK
TRANSACTION
Optional key words. They have no effect.

Notes
Use COMMIT to successfully terminate a transaction.
Issuing ABORT when not inside a transaction does no harm, but it will provoke a warning message.

Compatibility
This command is a Greenplum Database extension present for historical reasons. ROLLBACK is the equivalent standard SQL command.

See Also
BEGIN, COMMIT, ROLLBACK

ALTER AGGREGATE
Changes the definition of an aggregate function
Synopsis

ALTER AGGREGATE name ( aggregate_signature )  RENAME TO new_name
ALTER AGGREGATE name ( aggregate_signature ) OWNER TO new_owner
ALTER AGGREGATE name ( aggregate_signature ) SET SCHEMA new_schema

where aggregate_signature is:

* | [ argmode ] [ argname ] argtype [ , ... ] |
[ [ argmode ] [ argname ] argtype [ , ... ] ] ORDER BY [ argmode ] [ argname ] argtype [ , ... ]

Description

ALTER AGGREGATE changes the definition of an aggregate function.

You must own the aggregate function to use ALTER AGGREGATE. To change the schema of an aggregate function, you must also have CREATE privilege on the new schema. To alter the owner, you must also be a direct or indirect member of the new owning role, and that role must have CREATE privilege on the aggregate function's schema. (These restrictions enforce that altering the owner does not do anything you could not do by dropping and recreating the aggregate function. However, a superuser can alter ownership of any aggregate function anyway.)

Parameters

name
The name (optionally schema-qualified) of an existing aggregate function.

argmode
The mode of an argument: IN or VARIADIC. If omitted, the default is IN.

argname
The name of an argument. Note that ALTER AGGREGATE does not actually pay any attention to argument names, since only the argument data types are needed to determine the aggregate function's identity.

argtype
An input data type on which the aggregate function operates. To reference a zero-argument aggregate function, write * in place of the list of input data types. To reference an ordered-set aggregate function, write ORDER BY between the direct and aggregated argument specifications.

new_name
The new name of the aggregate function.

new_owner
The new owner of the aggregate function.

new_schema
The new schema for the aggregate function.

Notes

The recommended syntax for referencing an ordered-set aggregate is to write ORDER BY between the direct and aggregated argument specifications, in the same style as in CREATE AGGREGATE. However, it will also work to omit ORDER BY and just run the direct and aggregated argument specifications into
a single list. In this abbreviated form, if VARIADIC "any" was used in both the direct and aggregated argument lists, write VARIADIC "any" only once.

Examples
To rename the aggregate function myavg for type integer to my_average:

```
ALTER AGGREGATE myavg(integer) RENAME TO my_average;
```

To change the owner of the aggregate function myavg for type integer to joe:

```
ALTER AGGREGATE myavg(integer) OWNER TO joe;
```

To move the aggregate function myavg for type integer into schema myschema:

```
ALTER AGGREGATE myavg(integer) SET SCHEMA myschema;
```

Compatibility
There is no ALTER AGGREGATE statement in the SQL standard.

See Also
CREATE AGGREGATE, DROP AGGREGATE

**ALTER COLLATION**
Changes the definition of a collation.

Synopsis
```
ALTER COLLATION name RENAME TO new_name
ALTER COLLATION name OWNER TO new_owner
ALTER COLLATION name SET SCHEMA new_schema
```

Parameters

- **name**
  The name (optionally schema-qualified) of an existing collation.

- **new_name**
  The new name of the collation.

- **new_owner**
  The new owner of the collation.

- **new_schema**
  The new schema for the collation.

Description
You must own the collation to use ALTER COLLATION. To alter the owner, you must also be a direct or indirect member of the new owning role, and that role must have CREATE privilege on the collation's schema. (These restrictions enforce that altering the owner doesn't do anything you couldn't do by dropping and recreating the collation. However, a superuser can alter ownership of any collation anyway.)
Examples
To rename the collation \textit{de\_DE} to \textit{german}:

\begin{verbatim}
ALTER COLLATION "de\_DE" RENAME TO german;
\end{verbatim}

To change the owner of the collation \textit{en\_US} to \textit{joe}:

\begin{verbatim}
ALTER COLLATION "en\_US" OWNER TO joe;
\end{verbatim}

Compatibility
There is no \texttt{ALTER COLLATION} statement in the SQL standard.

See Also
\texttt{CREATE COLLATION}, \texttt{DROP COLLATION}

\textbf{ALTER CONVERSION}
Changes the definition of a conversion.

Synopsis
\begin{verbatim}
ALTER CONVERSION name RENAME TO newname
ALTER CONVERSION name OWNER TO newowner
ALTER CONVERSION name SET SCHEMA new_schema
\end{verbatim}

Description
\texttt{ALTER CONVERSION} changes the definition of a conversion.

You must own the conversion to use \texttt{ALTER CONVERSION}. To alter the owner, you must also be a direct or indirect member of the new owning role, and that role must have \texttt{CREATE} privilege on the conversion's schema. (These restrictions enforce that altering the owner does not do anything you could not do by dropping and recreating the conversion. However, a superuser can alter ownership of any conversion anyway.)

Parameters
- \textit{name} \\
  The name (optionally schema-qualified) of an existing conversion.

- \textit{newname} \\
  The new name of the conversion.

- \textit{newowner} \\
  The new owner of the conversion.

- \textit{new\_schema} \\
  The new schema for the conversion.

Examples
To rename the conversion \texttt{iso\_8859\_1_to_utf8} to \texttt{latin1_to_unicode}:

\begin{verbatim}
ALTER CONVERSION iso\_8859\_1_to_utf8 RENAME TO
\end{verbatim}
ALTER DATABASE
Changes the attributes of a database.

Synopsis

```
ALTER DATABASE name [ WITH CONNECTION LIMIT connlimit ]
ALTER DATABASE name RENAME TO newname
ALTER DATABASE name OWNER TO new_owner
ALTER DATABASE name SET TABLESPACE new_tablespace
ALTER DATABASE name SET parameter { TO | = } { value | DEFAULT }
ALTER DATABASE name SET parameter FROM CURRENT
ALTER DATABASE name RESET parameter
ALTER DATABASE name RESET ALL
```

Description

```
ALTER DATABASE changes the attributes of a database.

The first form changes the allowed connection limit for a database. Only the database owner or a superuser can change this setting.

The second form changes the name of the database. Only the database owner or a superuser can rename a database; non-superuser owners must also have the CREATEDB privilege. You cannot rename the current database. Connect to a different database first.

The third form changes the owner of the database. To alter the owner, you must own the database and also be a direct or indirect member of the new owning role, and you must have the CREATEDB privilege. (Note that superusers have all these privileges automatically.)

The fourth form changes the default tablespace of the database. Only the database owner or a superuser can do this; you must also have create privilege for the new tablespace. This command physically moves any tables or indexes in the database’s old default tablespace to the new tablespace. Note that tables and indexes in non-default tablespaces are not affected.

The remaining forms change the session default for a configuration parameter for a Greenplum database. Whenever a new session is subsequently started in that database, the specified value becomes the session default value. The database-specific default overrides whatever setting is present in the server configuration file (postgresql.conf). Only the database owner or a superuser can change the session defaults for a database. Certain parameters cannot be set this way, or can only be set by a superuser.
```
Parameters

**name**

The name of the database whose attributes are to be altered.

**connlimit**

The maximum number of concurrent connections possible. The default of -1 means there is no limitation.

**parameter value**

Set this database's session default for the specified configuration parameter to the given value. If value is **DEFAULT** or, equivalently, **RESET** is used, the database-specific setting is removed, so the system-wide default setting will be inherited in new sessions. Use **RESET ALL** to clear all database-specific settings. See *Server Configuration Parameters* for information about all user-settable configuration parameters.

**newname**

The new name of the database.

**new_owner**

The new owner of the database.

**new_tablespace**

The new default tablespace of the database.

Notes

It is also possible to set a configuration parameter session default for a specific role (user) rather than to a database. Role-specific settings override database-specific ones if there is a conflict. See **ALTER ROLE**.

Examples

To set the default schema search path for the **mydatabase** database:

```
ALTER DATABASE mydatabase SET search_path TO myschema, public, pg_catalog;
```

Compatibility

The **ALTER DATABASE** statement is a Greenplum Database extension.

See Also

*CREATE DATABASE*, *DROP DATABASE*, *SET*, *CREATE TABLESPACE*

---

**ALTER DEFAULT PRIVILEGES**

Changes default access privileges.

Synopsis

```
ALTER DEFAULT PRIVILEGES
  [ FOR { ROLE | USER } target_role [, ...] ]
  [ IN SCHEMA schema_name [, ...] ]
  abbreviated_grant_or_revoke

where abbreviated_grant_or_revoke is one of:
```

GRANT { { SELECT | INSERT | UPDATE | DELETE | TRUNCATE | REFERENCES | TRIGGER } [, ...] | ALL [ PRIVILEGES ] } ON TABLES TO { [ GROUP ] role_name | PUBLIC } [, ...] [ WITH GRANT OPTION ]

GRANT { { USAGE | SELECT | UPDATE } [, ...] | ALL [ PRIVILEGES ] } ON SEQUENCES TO { [ GROUP ] role_name | PUBLIC } [, ...] [ WITH GRANT OPTION ]

GRANT { EXECUTE | ALL [ PRIVILEGES ] } ON FUNCTIONS TO { [ GROUP ] role_name | PUBLIC } [, ...] [ WITH GRANT OPTION ]

GRANT { USAGE | ALL [ PRIVILEGES ] } ON TYPES TO { [ GROUP ] role_name | PUBLIC } [, ...] [ WITH GRANT OPTION ]

REVOKE [ GRANT OPTION FOR ] { { SELECT | INSERT | UPDATE | DELETE | TRUNCATE | REFERENCES | TRIGGER } [, ...] | ALL [ PRIVILEGES ] } ON TABLES FROM { [ GROUP ] role_name | PUBLIC } [, ...] [ CASCADE | RESTRICT ]

REVOKE [ GRANT OPTION FOR ] { { USAGE | SELECT | UPDATE } [, ...] | ALL [ PRIVILEGES ] } ON SEQUENCES FROM { [ GROUP ] role_name | PUBLIC } [, ...] [ CASCADE | RESTRICT ]

REVOKE [ GRANT OPTION FOR ] { EXECUTE | ALL [ PRIVILEGES ] } ON FUNCTIONS FROM { [ GROUP ] role_name | PUBLIC } [, ...] [ CASCADE | RESTRICT ]

REVOKE [ GRANT OPTION FOR ] { USAGE | ALL [ PRIVILEGES ] } ON TYPES FROM { [ GROUP ] role_name | PUBLIC } [, ...] [ CASCADE | RESTRICT ]

**Description**

ALTER DEFAULT PRIVILEGES allows you to set the privileges that will be applied to objects created in the future. (It does not affect privileges assigned to already-existing objects.) Currently, only the privileges for tables (including views and foreign tables), sequences, functions, and types (including domains) can be altered.

You can change default privileges only for objects that will be created by yourself or by roles that you are a member of. The privileges can be set globally (i.e., for all objects created in the current database), or just for objects created in specified schemas. Default privileges that are specified per-schema are added to whatever the global default privileges are for the particular object type.

As explained under GRANT, the default privileges for any object type normally grant all grantable permissions to the object owner, and may grant some privileges to PUBLIC as well. However, this behavior can be changed by altering the global default privileges with ALTER DEFAULT PRIVILEGES.
Parameters

**target_role**

The name of an existing role of which the current role is a member. If `FOR ROLE` is omitted, the current role is assumed.

**schema_name**

The name of an existing schema. If specified, the default privileges are altered for objects later created in that schema. If `IN SCHEMA` is omitted, the global default privileges are altered.

**role_name**

The name of an existing role to grant or revoke privileges for. This parameter, and all the other parameters in `abbreviated_grant_or_revoke`, act as described under `GRANT` or `REVOKE`, except that one is setting permissions for a whole class of objects rather than specific named objects.

Notes

Use `psql`'s `\ddp` command to obtain information about existing assignments of default privileges. The meaning of the privilege values is the same as explained for `\dp` under `GRANT`.

If you wish to drop a role for which the default privileges have been altered, it is necessary to reverse the changes in its default privileges or use `DROP OWNED BY` to get rid of the default privileges entry for the role.

Examples

Grant SELECT privilege to everyone for all tables (and views) you subsequently create in schema `myschema`, and allow role `webuser` to INSERT into them too:

```
ALTER DEFAULT PRIVILEGES IN SCHEMA myschema GRANT SELECT ON TABLES TO PUBLIC;
ALTER DEFAULT PRIVILEGES IN SCHEMA myschema GRANT INSERT ON TABLES TO webuser;
```

Undo the above, so that subsequently-created tables won't have any more permissions than normal:

```
ALTER DEFAULT PRIVILEGES IN SCHEMA myschema REVOKE SELECT ON TABLES FROM PUBLIC;
ALTER DEFAULT PRIVILEGES IN SCHEMA myschema REVOKE INSERT ON TABLES FROM webuser;
```

Remove the public EXECUTE permission that is normally granted on functions, for all functions subsequently created by role `admin`:

```
ALTER DEFAULT PRIVILEGES FOR ROLE admin REVOKE EXECUTE ON FUNCTIONS FROM PUBLIC;
```

Compatibility

There is no `ALTER DEFAULT PRIVILEGES` statement in the SQL standard.

See Also

`GRANT, REVOKE`
**ALTER DOMAIN**

Changes the definition of a domain.

### Synopsis

```sql
ALTER DOMAIN name { SET DEFAULT expression | DROP DEFAULT }
ALTER DOMAIN name { SET | DROP } NOT NULL
ALTER DOMAIN name ADD domain_constraint [ NOT VALID ]
ALTER DOMAIN name DROP CONSTRAINT [ IF EXISTS ] constraint_name [RESTRICT | CASCADE]
ALTER DOMAIN name RENAME CONSTRAINT constraint_name TO new_constraint_name
ALTER DOMAIN name VALIDATE CONSTRAINT constraint_name
ALTER DOMAIN name OWNER TO new_owner
ALTER DOMAIN name RENAME TO new_name
ALTER DOMAIN name SET SCHEMA new_schema
```

### Description

**ALTER DOMAIN** changes the definition of an existing domain. There are several sub-forms:

- **SET/DROP DEFAULT** — These forms set or remove the default value for a domain. Note that defaults only apply to subsequent `INSERT` commands. They do not affect rows already in a table using the domain.
- **SET/DROP NOT NULL** — These forms change whether a domain is marked to allow `NULL` values or to reject `NULL` values. You may only `SET NOT NULL` when the columns using the domain contain no null values.
- **ADD domain_constraint [ NOT VALID ]** — This form adds a new constraint to a domain using the same syntax as `CREATE DOMAIN`. When a new constraint is added to a domain, all columns using that domain will be checked against the newly added constraint. These checks can be suppressed by adding the new constraint using the `NOT VALID` option; the constraint can later be made valid using `ALTER DOMAIN ... VALIDATE CONSTRAINT`. Newly inserted or updated rows are always checked against all constraints, even those marked `NOT VALID`. `NOT VALID` is only accepted for `CHECK` constraints.
- **DROP CONSTRAINT [ IF EXISTS ]** — This form drops constraints on a domain. If `IF EXISTS` is specified and the constraint does not exist, no error is thrown. In this case a notice is issued instead.
- **RENAME CONSTRAINT** — This form changes the name of a constraint on a domain.
- **VALIDATE CONSTRAINT** — This form validates a constraint previously added as `NOT VALID`, that is, verify that all data in columns using the domain satisfy the specified constraint.
- **OWNER** — This form changes the owner of the domain to the specified user.
- **RENAME** — This form changes the name of the domain.
- **SET SCHEMA** — This form changes the schema of the domain. Any constraints associated with the domain are moved into the new schema as well.

You must own the domain to use **ALTER DOMAIN**. To change the schema of a domain, you must also have `CREATE` privilege on the new schema. To alter the owner, you must also be a direct or indirect member of the new owning role, and that role must have `CREATE` privilege on the domain's schema.

(These restrictions enforce that altering the owner does not do anything you could not do by dropping and recreating the domain. However, a superuser can alter ownership of any domain anyway.)
Parameters

*name*

The name (optionally schema-qualified) of an existing domain to alter.

*domain_constraint*

New domain constraint for the domain.

*constraint_name*

Name of an existing constraint to drop or rename.

*NOT VALID*

Do not verify existing column data for constraint validity.

*CASCADE*

Automatically drop objects that depend on the constraint.

*RESTRICT*

Refuse to drop the constraint if there are any dependent objects. This is the default behavior.

*new_name*

The new name for the domain.

*new_constraint_name*

The new name for the constraint.

*new_owner*

The user name of the new owner of the domain.

*new_schema*

The new schema for the domain.

Examples

To add a *NOT NULL* constraint to a domain:

```
ALTER DOMAIN zipcode SET NOT NULL;
```

To remove a *NOT NULL* constraint from a domain:

```
ALTER DOMAIN zipcode DROP NOT NULL;
```

To add a check constraint to a domain:

```
ALTER DOMAIN zipcode ADD CONSTRAINT zipchk CHECK (char_length(VALUE) = 5);
```

To remove a check constraint from a domain:

```
ALTER DOMAIN zipcode DROP CONSTRAINT zipchk;
```

To rename a check constraint on a domain:

```
ALTER DOMAIN zipcode RENAME CONSTRAINT zipchk TO zip_check;
```

To move the domain into a different schema:

```
ALTER DOMAIN zipcode SET SCHEMA customers;
```
Compatibility

ALTER DOMAIN conforms to the SQL standard, except for the OWNER, RENAME, SET SCHEMA, and VALIDATE CONSTRAINT variants, which are Greenplum Database extensions. The NOT VALID clause of the ADD CONSTRAINT variant is also a Greenplum Database extension.

See Also

CREATE DOMAIN, DROP DOMAIN

ALTER EXTENSION

Change the definition of an extension that is registered in a Greenplum database.

Synopsis

```
ALTER EXTENSION name UPDATE [ TO new_version ]
ALTER EXTENSION name SET SCHEMA new_schema
ALTER EXTENSION name ADD member_object
ALTER EXTENSION name DROP member_object

where member_object is:

ACCESS METHOD object_name |
AGGREGATE aggregate_name ( aggregate_signature ) |
CAST (source_type AS target_type) |
COLLATION object_name |
CONVERSION object_name |
DOMAIN object_name |
EVENT TRIGGER object_name |
FOREIGN DATA WRAPPER object_name |
FOREIGN TABLE object_name |
FUNCTION function_name ( [ [ argmode ] [ argname ] argtype [, ...] ] ) |
MATERIALIZED VIEW object_name |
OPERATOR operator_name (left_type, right_type) |
OPERATOR CLASS object_name USING index_method |
OPERATOR FAMILY object_name USING index_method |
[ PROCEDURAL ] LANGUAGE object_name |
SCHEMA object_name |
SEQUENCE object_name |
SERVER object_name |
TABLE object_name |
TEXT SEARCH CONFIGURATION object_name |
TEXT SEARCH DICTIONARY object_name |
TEXT SEARCH PARSER object_name |
TEXT SEARCH TEMPLATE object_name |
TRANSFORM FOR type_name LANGUAGE lang_name |
TYPE object_name |
VIEW object_name
```

and aggregate_signature is:

```
* |
[ argmode ] [ argname ] argtype [ , ... ] |
[ [ argmode ] [ argname ] argtype [ , ... ] ] ORDER BY [ argmode ] [ argname ] argtype [ , ... ]
```

Description

ALTER EXTENSION changes the definition of an installed extension. These are the subforms:
UPDATE

This form updates the extension to a newer version. The extension must supply a suitable update script (or series of scripts) that can modify the currently-installed version into the requested version.

SET SCHEMA

This form moves the extension member objects into another schema. The extension must be relocatable.

ADD member_object

This form adds an existing object to the extension. This is useful in extension update scripts. The added object is treated as a member of the extension. The object can only be dropped by dropping the extension.

DROP member_object

This form removes a member object from the extension. This is mainly useful in extension update scripts. The object is not dropped, only disassociated from the extension.

See Packaging Related Objects into an Extension for more information about these operations.

You must own the extension to use ALTER EXTENSION. The ADD and DROP forms also require ownership of the object that is being added or dropped.

Parameters

name

The name of an installed extension.

new_version

The new version of the extension. The new_version can be either an identifier or a string literal. If not specified, the command attempts to update to the default version in the extension control file.

new_schema

The new schema for the extension.

object_name
aggregate_name
function_name
operator_name

The name of an object to be added to or removed from the extension. Names of tables, aggregates, domains, foreign tables, functions, operators, operator classes, operator families, sequences, text search objects, types, and views can be schema-qualified.

source_type

The name of the source data type of the cast.

target_type

The name of the target data type of the cast.

argmode

The mode of a function or aggregate argument: IN, OUT, INOUT, or VARIADIC. The default is IN.

The command ignores the OUT arguments. Only the input arguments are required to determine the function identity. It is sufficient to list the IN, INOUT, and VARIADIC arguments.
argname

The name of a function or aggregate argument.
The command ignores argument names, since only the argument data types are required to determine the function identity.

argtype

The data type of a function or aggregate argument.

left_type
right_type

The data types of the operator's arguments (optionally schema-qualified). Specify NONE for the missing argument of a prefix or postfix operator.

Examples

To update the hstore extension to version 2.0:

```sql
ALTER EXTENSION hstore UPDATE TO '2.0';
```

To change the schema of the hstore extension to utils:

```sql
ALTER EXTENSION hstore SET SCHEMA utils;
```

To add an existing function to the hstore extension:

```sql
ALTER EXTENSION hstore ADD FUNCTION populate_record(anyelement, hstore);
```

Compatibility

ALTER EXTENSION is a Greenplum Database extension.

See Also

CREATE EXTENSION, DROP EXTENSION

**ALTER EXTERNAL TABLE**

Changes the definition of an external table.

**Synopsis**

```sql
ALTER EXTERNAL TABLE name action [, ... ]
```

where *action* is one of:

- `ADD [COLUMN] new_column type`
- `DROP [COLUMN] column [RESTRICT|CASCADE]`
ALTER [COLUMN] column TYPE type
OWNER TO new_owner

Description
ALTER EXTERNAL TABLE changes the definition of an existing external table. These are the supported ALTER EXTERNAL TABLE actions:

• **ADD COLUMN** — Adds a new column to the external table definition.
• **DROP COLUMN** — Drops a column from the external table definition. If you drop readable external table columns, it only changes the table definition in Greenplum Database. The **CASCADE** keyword is required if anything outside the table depends on the column, such as a view that references the column.
• **ALTER COLUMN TYPE** — Changes the data type of a table column.
• **OWNER** — Changes the owner of the external table to the specified user.

Use the **ALTER TABLE** command to perform these actions on an external table.

• Set (change) the table schema.
• Rename the table.
• Rename a table column.

You must own the external table to use **ALTER EXTERNAL TABLE** or **ALTER TABLE**. To change the schema of an external table, you must also have CREATE privilege on the new schema. To alter the owner, you must also be a direct or indirect member of the new owning role, and that role must have CREATE privilege on the external table’s schema. A superuser has these privileges automatically.

Changes to the external table definition with either **ALTER EXTERNAL TABLE** or **ALTER TABLE** do not affect the external data.

The **ALTER EXTERNAL TABLE** and **ALTER TABLE** commands cannot modify the type external table (read, write, web), the table **FORMAT** information, or the location of the external data. To modify this information, you must drop and recreate the external table definition.

Parameters

- **name**
  The name (possibly schema-qualified) of an existing external table definition to alter.

- **column**
  Name of an existing column.

- **new_column**
  Name of a new column.

- **type**
  Data type of the new column, or new data type for an existing column.

- **new_owner**
  The role name of the new owner of the external table.

- **CASCADE**
  Automatically drop objects that depend on the dropped column, such as a view that references the column.

- **RESTRICT**
  Refuse to drop the column or constraint if there are any dependent objects. This is the default behavior.
Examples
Add a new column to an external table definition:

```
ALTER EXTERNAL TABLE ext_expenses ADD COLUMN manager text;
```

Change the owner of an external table:

```
ALTER EXTERNAL TABLE ext_data OWNER TO jojo;
```

Change the data type of an external table:

```
ALTER EXTERNAL TABLE ext_leads ALTER COLUMN acct_code TYPE integer
```

Compatibility
ALTER EXTERNAL TABLE is a Greenplum Database extension. There is no ALTER EXTERNAL TABLE statement in the SQL standard or regular PostgreSQL.

See Also
CREATE EXTERNAL TABLE, DROP EXTERNAL TABLE, ALTER TABLE

**ALTER FOREIGN DATA WRAPPER**
Changes the definition of a foreign-data wrapper.

**Synopsis**

```
ALTER FOREIGN DATA WRAPPER name
  [ HANDLER handler_function | NO HANDLER ]
  [ VALIDATOR validator_function | NO VALIDATOR ]
  [ OPTIONS ( [ ADD | SET | DROP ] option [ 'value' ] [, ... ] ) ]

ALTER FOREIGN DATA WRAPPER name OWNER TO new_owner
ALTER FOREIGN DATA WRAPPER name RENAME TO new_name
```

Description
ALTER FOREIGN DATA WRAPPER changes the definition of a foreign-data wrapper. The first form of the command changes the support functions or generic options of the foreign-data wrapper. Greenplum Database requires at least one clause. The second and third forms of the command change the owner or name of the foreign-data wrapper.

Only superusers can alter foreign-data wrappers. Additionally, only superusers can own foreign-data wrappers.

**Parameters**

`name`
The name of an existing foreign-data wrapper.

`HANDLER handler_function`
Specifies a new handler function for the foreign-data wrapper.

`NO HANDLER`
Specifies that the foreign-data wrapper should no longer have a handler function.
Note: You cannot access a foreign table that uses a foreign-data wrapper with no handler.

VALIDATOR validator_function

Specifies a new validator function for the foreign-data wrapper. Options to the foreign-data wrapper, servers, and user mappings may become invalid when you change the validator function. You must make sure that these options are correct before using the modified foreign-data wrapper. Note that Greenplum Database checks any options specified in this ALTER FOREIGN DATA WRAPPER command using the new validator.

NO VALIDATOR

Specifies that the foreign-data wrapper should no longer have a validator function.

OPTIONS ( [ ADD | SET | DROP ] option ['value'] [, ... ] )

Change the foreign-data wrapper's options. ADD, SET, and DROP specify the action to perform. If no operation is explicitly specified, the default operation is ADD. Option names must be unique. Greenplum Database validates names and values using the foreign-data wrapper's validator function, if any.

OWNER TO new_owner

Specifies the new owner of the foreign-data wrapper. Only superusers can own foreign-data wrappers.

RENAME TO new_name

Specifies the new name of the foreign-data wrapper.

Examples

Change the definition of a foreign-data wrapper named dbi by adding a new option named foo, and removing the option named bar:

```
ALTER FOREIGN DATA WRAPPER dbi OPTIONS (ADD foo '1', DROP 'bar');
```

Change the validator function for a foreign-data wrapper named dbi to bob.myvalidator:

```
ALTER FOREIGN DATA WRAPPER dbi VALIDATOR bob.myvalidator;
```

Compatibility

ALTER FOREIGN DATA WRAPPER conforms to ISO/IEC 9075-9 (SQL/MED), with the exception that the HANDLER, VALIDATOR, OWNER TO, and RENAME TO clauses are Greenplum Database extensions.

See Also

CREATE FOREIGN DATA WRAPPER, DROP FOREIGN DATA WRAPPER

ALTER FOREIGN TABLE

Changes the definition of a foreign table.

Synopsis

```
ALTER FOREIGN TABLE [ IF EXISTS ] name
  action [, ... ]
```

```
ALTER FOREIGN TABLE [ IF EXISTS ] name
```
ALTER FOREIGN TABLE changes the definition of an existing foreign table. There are several subforms of the command:

**ADD COLUMN**

This form adds a new column to the foreign table, using the same syntax as `CREATE FOREIGN TABLE`. Unlike the case when you add a column to a regular table, nothing happens to the underlying storage: this action simply declares that some new column is now accessible through the foreign table.

**DROP COLUMN [ IF EXISTS ]**

This form drops a column from a foreign table. You must specify `CASCADE` if any objects outside of the table depend on the column; for example, views. If you specify `IF EXISTS` and the column does not exist, no error is thrown. Greenplum Database issues a notice instead.

**IF EXISTS**

If you specify `IF EXISTS` and the foreign table does not exist, no error is thrown. Greenplum Database issues a notice instead.

**SET DATA TYPE**

This form changes the type of a column of a foreign table.

**SET/DROP DEFAULT**

These forms set or remove the default value for a column. Default values apply only in subsequent `INSERT` or `UPDATE` commands; they do not cause rows already in the table to change.

**SET/DROP NOT NULL**

Mark a column as allowing, or not allowing, null values.
SET STATISTICS

This form sets the per-column statistics-gathering target for subsequent ANALYZE operations. See the similar form of ALTER TABLE for more details.

SET ( attribute_option = value [, ... ] )
RESET ( attribute_option [, ... ] )

This form sets or resets per-attribute options. See the similar form of ALTER TABLE for more details.

DISABLE/ENABLE [ REPLICA | ALWAYS ] TRIGGER

These forms configure the firing of trigger(s) belonging to the foreign table. See the similar form of ALTER TABLE for more details.

OWNER

This form changes the owner of the foreign table to the specified user.

RENAME

The RENAME forms change the name of a foreign table or the name of an individual column in a foreign table.

SET SCHEMA

This form moves the foreign table into another schema.

OPTIONS ( [ ADD | SET | DROP ] option ['value'] [, ... ] )

Change options for the foreign table. ADD, SET, and DROP specify the action to perform. If no operation is explicitly specified, the default operation is ADD. Option names must be unique. Greenplum Database validates names and values using the server’s foreign-data wrapper.

You can combine all of the actions except RENAME and SET SCHEMA into a list of multiple alterations for Greenplum Database to apply in parallel. For example, it is possible to add several columns and/or alter the type of several columns in a single command.

You must own the table to use ALTER FOREIGN TABLE. To change the schema of a foreign table, you must also have CREATE privilege on the new schema. To alter the owner, you must also be a direct or indirect member of the new owning role, and that role must have CREATE privilege on the table’s schema. (These restrictions enforce that altering the owner doesn’t do anything you couldn't do by dropping and recreating the table. However, a superuser can alter ownership of any table anyway.) To add a column or to alter a column type, you must also have USAGE privilege on the data type.

Parameters

name

The name (possibly schema-qualified) of an existing foreign table to alter.

column_name

The name of a new or existing column.

new_column_name

The new name for an existing column.

new_name

The new name for the foreign table.

data_type

The data type of the new column, or new data type for an existing column.
CASCADE

Automatically drop objects that depend on the dropped column (for example, views referencing the column).

RESTRICT

Refuse to drop the column if there are any dependent objects. This is the default behavior.

trigger_name

Name of a single trigger to disable or enable.

ALL

Disable or enable all triggers belonging to the foreign table. (This requires superuser privilege if any of the triggers are internally generated triggers. The core system does not add such triggers to foreign tables, but add-on code could do so.)

USER

Disable or enable all triggers belonging to the foreign table except for internally generated triggers.

new_owner

The user name of the new owner of the foreign table.

new_schema

The name of the schema to which the foreign table will be moved.

Notes

The key word COLUMN is noise and can be omitted.

Consistency with the foreign server is not checked when a column is added or removed with ADD COLUMN or DROP COLUMN, a NOT NULL constraint is added, or a column type is changed with SET DATA TYPE. It is your responsibility to ensure that the table definition matches the remote side.

Refer to CREATE FOREIGN TABLE for a further description of valid parameters.

Examples

To mark a column as not-null:

```
ALTER FOREIGN TABLE distributors ALTER COLUMN street SET NOT NULL;
```

To change the options of a foreign table:

```
ALTER FOREIGN TABLE myschema.distributors
    OPTIONS (ADD opt1 'value', SET opt2 'value2', DROP opt3 'value3');
```

Compatibility

The forms ADD, DROP, and SET DATA TYPE conform with the SQL standard. The other forms are Greenplum Database extensions of the SQL standard. The ability to specify more than one manipulation in a single ALTER FOREIGN TABLE command is also a Greenplum Database extension.

You can use ALTER FOREIGN TABLE ... DROP COLUMN to drop the only column of a foreign table, leaving a zero-column table. This is an extension of SQL, which disallows zero-column foreign tables.

See Also

ALTER TABLE, CREATE FOREIGN TABLE, DROP FOREIGN TABLE
**ALTER FUNCTION**

Changes the definition of a function.

**Synopsis**

```
ALTER FUNCTION name ( [ [argmode] argname argtype [, ...] ] )
   action [, ... ] [RESTRICT]

ALTER FUNCTION name ( [ [argmode] argname argtype [, ...] ] )
   RENAME TO new_name

ALTER FUNCTION name ( [ [argmode] argname argtype [, ...] ] )
   OWNER TO new_owner

ALTER FUNCTION name ( [ [argmode] argname argtype [, ...] ] )
   SET SCHEMA new_schema
```

where `action` is one of:

```{CALLED ON NULL INPUT | RETURNS NULL ON NULL INPUT | STRICT}
{IMMUTABLE | STABLE | VOLATILE | [ NOT ] LEAKPROOF}
{[EXTERNAL] SECURITY INVOKER | [EXTERNAL] SECURITY DEFINER}
EXECUTE ON { ANY | MASTER | ALL SEGMENTS }
COST execution_cost
SET configuration_parameter { TO | = } { value | DEFAULT }
SET configuration_parameter FROM CURRENT
RESET configuration_parameter
RESET ALL```

**Description**

`ALTER FUNCTION` changes the definition of a function.

You must own the function to use `ALTER FUNCTION`. To change a function's schema, you must also have `CREATE` privilege on the new schema. To alter the owner, you must also be a direct or indirect member of the new owning role, and that role must have `CREATE` privilege on the function's schema. (These restrictions enforce that altering the owner does not do anything you could not do by dropping and recreating the function. However, a superuser can alter ownership of any function anyway.)

**Parameters**

**name**

The name (optionally schema-qualified) of an existing function.

**argmode**

The mode of an argument: either IN, OUT, INOUT, or VARIADIC. If omitted, the default is IN. Note that `ALTER FUNCTION` does not actually pay any attention to OUT arguments, since only the input arguments are needed to determine the function's identity. So it is sufficient to list the IN, INOUT, and VARIADIC arguments.

**argname**

The name of an argument. Note that `ALTER FUNCTION` does not actually pay any attention to argument names, since only the argument data types are needed to determine the function's identity.

**argtype**

The data type(s) of the function's arguments (optionally schema-qualified), if any.
The new name of the function.

The new owner of the function. Note that if the function is marked `SECURITY DEFINER`, it will subsequently execute as the new owner.

The new schema for the function.

`CALLED ON NULL INPUT`  `RETURNS NULL ON NULL INPUT`  `STRICT`

`CALLED ON NULL INPUT` changes the function so that it will be invoked when some or all of its arguments are null. `RETURNS NULL ON NULL INPUT` or `STRICT` changes the function so that it is not invoked if any of its arguments are null; instead, a null result is assumed automatically. See `CREATE FUNCTION` for more information.

`IMMUTABLE`  `STABLE`  `VOLATILE`

Change the volatility of the function to the specified setting. See `CREATE FUNCTION` for details.

`[ EXTERNAL ] SECURITY INVOKER`  `[ EXTERNAL ] SECURITY DEFINER`

Change whether the function is a security definer or not. The key word `EXTERNAL` is ignored for SQL conformance. See `CREATE FUNCTION` for more information about this capability.

`LEAKPROOF`

Change whether the function is considered leakproof or not. See `CREATE FUNCTION` for more information about this capability.

`EXECUTE ON ANY`  `EXECUTE ON MASTER`  `EXECUTE ON ALL SEGMENTS`

The `EXECUTE ON` attributes specify where (master or segment instance) a function executes when it is invoked during the query execution process.

`EXECUTE ON ANY` (the default) indicates that the function can be executed on the master, or any segment instance, and it returns the same result regardless of where it is executed. Greenplum Database determines where the function executes.

`EXECUTE ON MASTER` indicates that the function must execute only on the master instance.

`EXECUTE ON ALL SEGMENTS` indicates that the function must execute on all primary segment instances, but not the master, for each invocation. The overall result of the function is the `UNION ALL` of the results from all segment instances.

For more information about the `EXECUTE ON` attributes, see `CREATE FUNCTION`.

`COST`  `execution_cost`

Change the estimated execution cost of the function. See `CREATE FUNCTION` for more information.

`configuration_parameter`  `value`

Set or change the value of a configuration parameter when the function is called. If `value` is `DEFAULT` or, equivalently, `RESET` is used, the function-local setting is removed, and
the function executes with the value present in its environment. Use `RESET ALL` to clear all function-local settings. `SET FROM CURRENT` saves the value of the parameter that is current when `ALTER FUNCTION` is executed as the value to be applied when the function is entered.

**RESTRICT**

Ignored for conformance with the SQL standard.

**Notes**

Greenplum Database has limitations on the use of functions defined as `STABLE` or `VOLATILE`. See `CREATE FUNCTION` for more information.

**Examples**

To rename the function `sqrt` for type `integer` to `square_root`:

```
ALTER FUNCTION sqrt(integer) RENAME TO square_root;
```

To change the owner of the function `sqrt` for type `integer` to `joe`:

```
ALTER FUNCTION sqrt(integer) OWNER TO joe;
```

To change the `schema` of the function `sqrt` for type `integer` to `math`:

```
ALTER FUNCTION sqrt(integer) SET SCHEMA math;
```

To adjust the search path that is automatically set for a function:

```
ALTER FUNCTION check_password(text) RESET search_path;
```

**Compatibility**

This statement is partially compatible with the `ALTER FUNCTION` statement in the SQL standard. The standard allows more properties of a function to be modified, but does not provide the ability to rename a function, make a function a security definer, or change the owner, schema, or volatility of a function. The standard also requires the `RESTRICT` key word, which is optional in Greenplum Database.

**See Also**

`CREATE FUNCTION`, `DROP FUNCTION`

**ALTER GROUP**

Changes a role name or membership.

**Synopsis**

```
ALTER GROUP groupname ADD USER username [, ... ]
ALTER GROUP groupname DROP USER username [, ... ]
ALTER GROUP groupname RENAME TO newname
```
Description

ALTER GROUP changes the attributes of a user group. This is an obsolete command, though still accepted for backwards compatibility, because users and groups are superseded by the more general concept of roles. See ALTER ROLE for more information.

The first two variants add users to a group or remove them from a group. Any role can play the part of groupname or username. The preferred method for accomplishing these tasks is to use GRANT and REVOKE.

Parameters

- **groupname**
  - The name of the group (role) to modify.

- **username**
  - Users (roles) that are to be added to or removed from the group. The users (roles) must already exist.

- **newname**
  - The new name of the group (role).

Examples

To add users to a group:

```
ALTER GROUP staff ADD USER karl, john;
```

To remove a user from a group:

```
ALTER GROUP workers DROP USER beth;
```

Compatibility

There is no ALTER GROUP statement in the SQL standard.

See Also

ALTER ROLE, GRANT, REVOKE

**ALTER INDEX**

Changes the definition of an index.

Synopsis

```
ALTER INDEX [ IF EXISTS ] name RENAME TO new_name
ALTER INDEX [ IF EXISTS ] name SET TABLESPACE tablespace_name
ALTER INDEX [ IF EXISTS ] name SET (storage_parameter = value [, ...] )
ALTER INDEX [ IF EXISTS ] name RESET (storage_parameter [, ...] )
ALTER INDEX ALL IN TABLESPACE name [ OWNED BY role_name [, ... ] ]
  SET TABLESPACE new_tablespace [ NOWAIT ]
```
Description

ALTER INDEX changes the definition of an existing index. There are several subforms:

• **RENAME** — Changes the name of the index. There is no effect on the stored data.
• **SET TABLESPACE** — Changes the index's tablespace to the specified tablespace and moves the data file(s) associated with the index to the new tablespace. To change the tablespace of an index, you must own the index and have **CREATE** privilege on the new tablespace. All indexes in the current database in a tablespace can be moved by using the **ALL IN TABLESPACE** form, which will lock all indexes to be moved and then move each one. This form also supports **OWNED BY**, which will only move indexes owned by the roles specified. If the **NOWAIT** option is specified then the command will fail if it is unable to acquire all of the locks required immediately. Note that system catalogs will not be moved by this command, use **ALTER DATABASE** or explicit **ALTER INDEX** invocations instead if desired. See also **CREATE TABLESPACE**.
• **IF EXISTS** — Do not throw an error if the index does not exist. A notice is issued in this case.
• **SET** — Changes the index-method-specific storage parameters for the index. The built-in index methods all accept a single parameter: **fillfactor**. The fillfactor for an index is a percentage that determines how full the index method will try to pack index pages. Index contents will not be modified immediately by this command. Use **REINDEX** to rebuild the index to get the desired effects.
• **RESET** — Resets storage parameters for the index to their defaults. The built-in index methods all accept a single parameter: **fillfactor**. As with **SET**, a **REINDEX** may be needed to update the index entirely.

Parameters

**name**

The name (optionally schema-qualified) of an existing index to alter.

**new_name**

New name for the index.

**tablespace_name**

The tablespace to which the index will be moved.

**storage_parameter**

The name of an index-method-specific storage parameter.

**value**

The new value for an index-method-specific storage parameter. This might be a number or a word depending on the parameter.

Notes

These operations are also possible using **ALTER TABLE**.

Changing any part of a system catalog index is not permitted.

Examples

To rename an existing index:

```
ALTER INDEX distributors RENAME TO suppliers;
```

To move an index to a different tablespace:

```
ALTER INDEX distributors SET TABLESPACE fasttablespace;
```

To change an index's fill factor (assuming that the index method supports it):

```
ALTER INDEX distributors SET (fillfactor = 75);
```
REINDEX INDEX distributors;

**Compatibility**

ALTER INDEX is a Greenplum Database extension.

**See Also**

CREATE INDEX, REINDEX, ALTER TABLE

### ALTER LANGUAGE

Changes the name of a procedural language.

**Synopsis**

```
ALTER LANGUAGE name RENAME TO newname
ALTER LANGUAGE name OWNER TO new_owner
```

**Description**

ALTER LANGUAGE changes the definition of a procedural language for a specific database. Definition changes supported include renaming the language or assigning a new owner. You must be superuser or the owner of the language to use ALTER LANGUAGE.

**Parameters**

- **name**
  
  Name of a language.

- **newname**
  
  The new name of the language.

- **new_owner**
  
  The new owner of the language.

**Compatibility**

There is no ALTER LANGUAGE statement in the SQL standard.

**See Also**

CREATE LANGUAGE, DROP LANGUAGE

### ALTER OPERATOR

Changes the definition of an operator.

**Synopsis**

```
ALTER OPERATOR name ( {left_type | NONE} , {right_type | NONE} )
OWNER TO new_owner

ALTER OPERATOR name ( {left_type | NONE} , {right_type | NONE} )
SET SCHEMA new_schema
```
Description

`ALTER OPERATOR` changes the definition of an operator. The only currently available functionality is to change the owner of the operator.

You must own the operator to use `ALTER OPERATOR`. To alter the owner, you must also be a direct or indirect member of the new owning role, and that role must have `CREATE` privilege on the operator's schema. (These restrictions enforce that altering the owner does not do anything you could not do by dropping and recreating the operator. However, a superuser can alter ownership of any operator anyway.)

Parameters

- **name**
  - The name (optionally schema-qualified) of an existing operator.

- **left_type**
  - The data type of the operator's left operand; write `NONE` if the operator has no left operand.

- **right_type**
  - The data type of the operator's right operand; write `NONE` if the operator has no right operand.

- **new_owner**
  - The new owner of the operator.

- **new_schema**
  - The new schema for the operator.

Examples

Change the owner of a custom operator `a @@ b` for type `text`:

```sql
ALTER OPERATOR @@ (text, text) OWNER TO joe;
```

Compatibility

There is no `ALTER OPERATOR` statement in the SQL standard.

See Also

`CREATE OPERATOR`, `DROP OPERATOR`

### ALTER OPERATOR CLASS

Changes the definition of an operator class.

Synopsis

```sql
ALTER OPERATOR CLASS name USING index_method RENAME TO new_name
ALTER OPERATOR CLASS name USING index_method OWNER TO new_owner
ALTER OPERATOR CLASS name USING index_method SET SCHEMA new_schema
```

Description

`ALTER OPERATOR CLASS` changes the definition of an operator class.

You must own the operator class to use `ALTER OPERATOR CLASS`. To alter the owner, you must also be a direct or indirect member of the new owning role, and that role must have `CREATE` privilege on the
operator class’s schema. (These restrictions enforce that altering the owner does not do anything you could not do by dropping and recreating the operator class. However, a superuser can alter ownership of any operator class anyway.)

Parameters

name

The name (optionally schema-qualified) of an existing operator class.

index_method

The name of the index method this operator class is for.

new_name

The new name of the operator class.

new_owner

The new owner of the operator class.

new_schema

The new schema for the operator class.

Compatibility

There is no `ALTER OPERATOR CLASS` statement in the SQL standard.

See Also

`CREATE OPERATOR CLASS`, `DROP OPERATOR CLASS`

**ALTER OPERATOR FAMILY**

Changes the definition of an operator family.

Synopsis

```
ALTER OPERATOR FAMILY name USING index_method ADD
   {  OPERATOR strategy_number operator_name ( op_type, op_type ) [ FOR
      SEARCH | FOR ORDER BY sort_family_name ]
      | FUNCTION support_number [ ( op_type [, op_type ] ) ] funcname
      ( argument_type [, ... ] )
   } [, ... ]

ALTER OPERATOR FAMILY name USING index_method DROP
   {  OPERATOR strategy_number ( op_type, op_type )
      | FUNCTION support_number [ ( op_type [, op_type ] ) ]
   } [, ... ]

ALTER OPERATOR FAMILY name USING index_method RENAME TO new_name

ALTER OPERATOR FAMILY name USING index_method OWNER TO new_owner

ALTER OPERATOR FAMILY name USING index_method SET SCHEMA new_schema
```

Description

`ALTER OPERATOR FAMILY` changes the definition of an operator family. You can add operators and support functions to the family, remove them from the family, or change the family’s name or owner.

When operators and support functions are added to a family with `ALTER OPERATOR FAMILY`, they are not part of any specific operator class within the family, but are just “loose” within the family. This indicates that
these operators and functions are compatible with the family’s semantics, but are not required for correct functioning of any specific index. (Operators and functions that are so required should be declared as part of an operator class, instead; see \texttt{CREATE OPERATOR CLASS}.) You can drop loose members of a family from the family at any time, but members of an operator class cannot be dropped without dropping the whole class and any indexes that depend on it. Typically, single-data-type operators and functions are part of operator classes because they are needed to support an index on that specific data type, while cross-data-type operators and functions are made loose members of the family.

You must be a superuser to use \texttt{ALTER OPERATOR FAMILY}. (This restriction is made because an erroneous operator family definition could confuse or even crash the server.) \texttt{ALTER OPERATOR FAMILY} does not presently check whether the operator family definition includes all the operators and functions required by the index method, nor whether the operators and functions form a self-consistent set. It is the user's responsibility to define a valid operator family.

\texttt{OPERATOR} and \texttt{FUNCTION} clauses can appear in any order.

\textbf{Parameters}

\textit{name}

The name (optionally schema-qualified) of an existing operator family.

\textit{index\_method}

The name of the index method this operator family is for.

\textit{strategy\_number}

The index method's strategy number for an operator associated with the operator family.

\textit{operator\_name}

The name (optionally schema-qualified) of an operator associated with the operator family.

\textit{op\_type}

In an \texttt{OPERATOR} clause, the operand data type(s) of the operator, or \texttt{NONE} to signify a left-unary or right-unary operator. Unlike the comparable syntax in \texttt{CREATE OPERATOR CLASS}, the operand data types must always be specified. In an \texttt{ADD FUNCTION} clause, the operand data type(s) the function is intended to support, if different from the input data type(s) of the function. For B-tree comparison functions it is not necessary to specify \textit{op\_type} since the function's input data type(s) are always the correct ones to use. For B-tree sort support functions and all functions in GiST, SP-GiST, and GIN operator classes, it is necessary to specify the operand data type(s) the function is to be used with.

\textit{sort\_family\_name}

The name (optionally schema-qualified) of an existing \texttt{btree} operator family that describes the sort ordering associated with an ordering operator.

If neither \texttt{FOR SEARCH} nor \texttt{FOR ORDER BY} is specified, \texttt{FOR SEARCH} is the default.

\textit{support\_number}

The index method's support procedure number for a function associated with the operator family.

\textit{func\_name}

The name (optionally schema-qualified) of a function that is an index method support procedure for the operator family.

\textit{argument\_types}

The parameter data type(s) of the function.

\textit{new\_name}

The new name of the operator family.

\textit{new\_owner}
The new owner of the operator family.

new_schema
The new schema for the operator family.

Compatibility
There is no ALTER OPERATOR FAMILY statement in the SQL standard.

Notes
Notice that the DROP syntax only specifies the "slot" in the operator family, by strategy or support number and input data type(s). The name of the operator or function occupying the slot is not mentioned. Also, for DROP FUNCTION the type(s) to specify are the input data type(s) the function is intended to support; for GiST, SP_GiST, and GIN indexes this might have nothing to do with the actual input argument types of the function.

Because the index machinery does not check access permissions on functions before using them, including a function or operator in an operator family is tantamount to granting public execute permission on it. This is usually not an issue for the sorts of functions that are useful in an operator family.

The operators should not be defined by SQL functions. A SQL function is likely to be inlined into the calling query, which will prevent the optimizer from recognizing that the query matches an index.

Before Greenplum Database 6.0, the OPERATOR clause could include a RECHECK option. This option is no longer supported. Greenplum Database now determines whether an index operator is "lossy" on-the-fly at run time. This allows more efficient handling of cases where an operator might or might not be lossy.

Examples
The following example command adds cross-data-type operators and support functions to an operator family that already contains B-tree operator classes for data types int4 and int2.:  

```
ALTER OPERATOR FAMILY integer_ops USING btree ADD
  -- int4 vs int2  
  OPERATOR 1 < (int4, int2) ,
  OPERATOR 2 <= (int4, int2) ,
  OPERATOR 3 = (int4, int2) ,
  OPERATOR 4 >= (int4, int2) ,
  OPERATOR 5 > (int4, int2) ,
  FUNCTION 1 btint42cmp(int4, int2) ,

  -- int2 vs int4  
  OPERATOR 1 < (int2, int4) ,
  OPERATOR 2 <= (int2, int4) ,
  OPERATOR 3 = (int2, int4) ,
  OPERATOR 4 >= (int2, int4) ,
  OPERATOR 5 > (int2, int4) ,
  FUNCTION 1 btint24cmp(int2, int4) ;
```

To remove these entries:

```
ALTER OPERATOR FAMILY integer_ops USING btree DROP
  -- int4 vs int2
  OPERATOR 1 (int4, int2) ,
  OPERATOR 2 (int4, int2) ,
  OPERATOR 3 (int4, int2) ,
  OPERATOR 4 (int4, int2) ,
  OPERATOR 5 (int4, int2) ,
  FUNCTION 1 (int4, int2) ,
```
See Also

CREATE OPERATOR FAMILY, DROP OPERATOR FAMILY, ALTER OPERATOR CLASS, CREATE OPERATOR CLASS, DROP OPERATOR CLASS

ALTERT PROTOCOL

Changes the definition of a protocol.

Synopsis

ALTER PROTOCOL name RENAME TO newname
ALTER PROTOCOL name OWNER TO newowner

Description

ALTER PROTOCOL changes the definition of a protocol. Only the protocol name or owner can be altered. You must own the protocol to use ALTER PROTOCOL. To alter the owner, you must also be a direct or indirect member of the new owning role, and that role must have CREATE privilege on schema of the conversion.

These restrictions are in place to ensure that altering the owner only makes changes that could be made by dropping and recreating the protocol. Note that a superuser can alter ownership of any protocol.

Parameters

name
The name (optionally schema-qualified) of an existing protocol.

newname
The new name of the protocol.

newowner
The new owner of the protocol.

Examples

To rename the conversion GPDBauth to GPDB_authentication:

ALTER PROTOCOL GPDBauth RENAME TO GPDB_authentication;

To change the owner of the conversion GPDB_authentication to joe:

ALTER PROTOCOL GPDB_authentication OWNER TO joe;

Compatibility

There is no ALTER PROTOCOL statement in the SQL standard.
ALTER RESOURCE GROUP
Changes the limits of a resource group.

Synopsis

\[
\text{ALTER RESOURCE GROUP } \text{name SET } \text{group_attribute value}
\]

where \text{group_attribute} is one of:

- \text{CONCURRENCY integer}
- \text{CPU_RATE_LIMIT integer}
- \text{CPUSET tuple}
- \text{MEMORY_LIMIT integer}
- \text{MEMORY_SHARED_QUOTA integer}
- \text{MEMORY_SPILL_RATIO integer}

Description

\text{ALTER RESOURCE GROUP} changes the limits of a resource group. Only a superuser can alter a resource group.

You can set or reset the concurrency limit of a resource group that you create for roles to control the maximum number of active concurrent statements in that group. You can also reset the memory or CPU resources of a resource group to control the amount of memory or CPU resources that all queries submitted through the group can consume on each segment host.

When you alter the CPU resource management mode or limit of a resource group, the new mode or limit is immediately applied.

When you alter a memory limit of a resource group that you create for roles, the new resource limit is immediately applied if current resource usage is less than or equal to the new value and there are no running transactions in the resource group. If the current resource usage exceeds the new memory limit value, or if there are running transactions in other resource groups that hold some of the resource, then Greenplum Database defers assigning the new limit until resource usage falls within the range of the new value.

When you increase the memory limit of a resource group that you create for external components, the new resource limit is phased in as system memory resources become available. If you decrease the memory limit of a resource group that you create for external components, the behavior is component-specific. For example, if you decrease the memory limit of a resource group that you create for a PL/Container runtime, queries in a running container may fail with an out of memory error.

You can alter one limit type in a single \text{ALTER RESOURCE GROUP} call.

Parameters

\text{name}

The name of the resource group to alter.

\text{CONCURRENCY integer}

The maximum number of concurrent transactions, including active and idle transactions, that are permitted for resource groups that you assign to roles. Any transactions submitted after the \text{CONCURRENCY} value limit is reached are queued. When a running transaction completes, the earliest queued transaction is executed.
The **CONCURRENCY** value must be an integer in the range \([0 .. \text{max_connections}]\). The default **CONCURRENCY** value for a resource group that you create for roles is 20.

**Note:** You cannot set the **CONCURRENCY** value for the **admin_group** to zero (0).

**CPU_RATE_LIMIT integer**

The percentage of CPU resources to allocate to this resource group. The minimum CPU percentage for a resource group is 1. The maximum is 100. The sum of the **CPU_RATE_LIMITs** of all resource groups defined in the Greenplum Database cluster must not exceed 100.

If you alter the **CPU_RATE_LIMIT** of a resource group in which you previously configured a **CPUSET**, **CPUSET** is disabled, the reserved CPU cores are returned to Greenplum Database, and **CPUSET** is set to -1.

**CPUSET tuple**

The CPU cores to reserve for this resource group. The CPU cores that you specify in **tuple** must be available in the system and cannot overlap with any CPU cores that you specify for other resource groups.

**tuple** is a comma-separated list of single core numbers or core intervals. You must enclose **tuple** in single quotes, for example, ‘1,3-4’.

If you alter the **CPUSET** value of a resource group for which you previously configured a **CPU_RATE_LIMIT**, **CPU_RATE_LIMIT** is disabled, the reserved CPU resources are returned to Greenplum Database, and **CPU_RATE_LIMIT** is set to -1.

You can alter **CPUSET** for a resource group only after you have enabled resource group-based resource management for your Greenplum Database cluster.

**MEMORY_LIMIT integer**

The percentage of Greenplum Database memory resources to reserve for this resource group. The minimum memory percentage for a resource group is 0. The maximum is 100. The default value is 0.

When **MEMORY_LIMIT** is 0, Greenplum Database reserves no memory for the resource group, but uses global shared memory to fulfill all memory requests in the group. If **MEMORY_LIMIT** is 0, **MEMORY_SPILL_RATIO** must also be 0.

The sum of the **MEMORY_LIMITs** of all resource groups defined in the Greenplum Database cluster must not exceed 100. If this sum is less than 100, Greenplum Database allocates any unreserved memory to a resource group global shared memory pool.

**MEMORY_SHARED_QUOTA integer**

The percentage of memory resources to share among transactions in the resource group. The minimum memory shared quota percentage for a resource group is 0. The maximum is 100. The default **MEMORY_SHARED_QUOTA** value is 80.

**MEMORY_SPILL_RATIO integer**

The memory usage threshold for memory-intensive operators in a transaction. You can specify an integer percentage value from 0 to 100 inclusive. The default **MEMORY_SPILL_RATIO** value is 0. When **MEMORY_SPILL_RATIO** is 0, Greenplum Database uses the `statement_mem` server configuration parameter value to control initial query operator memory.

**Notes**

Use **CREATE ROLE** or **ALTER ROLE** to assign a specific resource group to a role (user).

You cannot submit an **ALTER RESOURCE GROUP** command in an explicit transaction or sub-transaction.
Examples
Change the active transaction limit for a resource group:

```
ALTER RESOURCE GROUP rgroup1 SET CONCURRENCY 13;
```

Update the CPU limit for a resource group:

```
ALTER RESOURCE GROUP rgroup2 SET CPU_RATE_LIMIT 45;
```

Update the memory limit for a resource group:

```
ALTER RESOURCE GROUP rgroup3 SET MEMORY_LIMIT 30;
```

Update the memory spill ratio for a resource group:

```
ALTER RESOURCE GROUP rgroup4 SET MEMORY_SPILL_RATIO 25;
```

Reserve CPU core 1 for a resource group:

```
ALTER RESOURCE GROUP rgroup5 SET CPUSET '1';
```

Compatibility
The `ALTER RESOURCE GROUP` statement is a Greenplum Database extension. This command does not exist in standard PostgreSQL.

See Also
`CREATE RESOURCE GROUP`, `DROP RESOURCE GROUP`, `CREATE ROLE`, `ALTER ROLE`

**ALTER RESOURCE QUEUE**
Changes the limits of a resource queue.

Synopsis

```
ALTER RESOURCE QUEUE name WITH ( queue_attribute=value [, ... ] )
```

where `queue_attribute` is:

```
ACTIVE_STATEMENTS=integer
MEMORY_LIMIT='memory_units'
MAX_COST=float
COST_OVERCOMMIT={TRUE|FALSE}
MIN_COST=float
PRIORITY={MIN|LOW|MEDIUM|HIGH|MAX}
```

```
ALTER RESOURCE QUEUE name WITHOUT ( queue_attribute [, ... ] )
```

where `queue_attribute` is:

```
ACTIVE_STATEMENTS
MEMORY_LIMIT
MAX_COST
COST_OVERCOMMIT
MIN_COST
```
Note: A resource queue must have either an ACTIVE_STATEMENTS or a MAX_COST value. Do not remove both these queue_attributes from a resource queue.

Description

ALTER RESOURCE QUEUE changes the limits of a resource queue. Only a superuser can alter a resource queue. A resource queue must have either an ACTIVE_STATEMENTS or a MAX_COST value (or it can have both). You can also set or reset priority for a resource queue to control the relative share of available CPU resources used by queries associated with the queue, or memory limit of a resource queue to control the amount of memory that all queries submitted through the queue can consume on a segment host.

ALTER RESOURCE QUEUE WITHOUT removes the specified limits on a resource that were previously set. A resource queue must have either an ACTIVE_STATEMENTS or a MAX_COST value. Do not remove both these queue_attributes from a resource queue.

Parameters

name

The name of the resource queue whose limits are to be altered.

ACTIVE_STATEMENTS integer

The number of active statements submitted from users in this resource queue allowed on the system at any one time. The value for ACTIVE_STATEMENTS should be an integer greater than 0. To reset ACTIVE_STATEMENTS to have no limit, enter a value of -1.

MEMORY_LIMIT 'memory_units'

Sets the total memory quota for all statements submitted from users in this resource queue. Memory units can be specified in kB, MB or GB. The minimum memory quota for a resource queue is 10MB. There is no maximum; however the upper boundary at query execution time is limited by the physical memory of a segment host. The default value is no limit (-1).

MAX_COST float

The total query optimizer cost of statements submitted from users in this resource queue allowed on the system at any one time. The value for MAX_COST is specified as a floating point number (for example 100.0) or can also be specified as an exponent (for example 1e+2). To reset MAX_COST to have no limit, enter a value of -1.0.

COST_OVERCOMMIT boolean

If a resource queue is limited based on query cost, then the administrator can allow cost overcommit (COST_OVERCOMMIT=TRUE, the default). This means that a query that exceeds the allowed cost threshold will be allowed to run but only when the system is idle. If COST_OVERCOMMIT=FALSE is specified, queries that exceed the cost limit will always be rejected and never allowed to run.

MIN_COST float

Queries with a cost under this limit will not be queued and run immediately. Cost is measured in units of disk page fetches; 1.0 equals one sequential disk page read. The value for MIN_COST is specified as a floating point number (for example 100.0) or can also be specified as an exponent (for example 1e+2). To reset MIN_COST to have no limit, enter a value of -1.0.

PRIORITY={MIN|LOW|MEDIUM|HIGH|MAX}

Sets the priority of queries associated with a resource queue. Queries or statements in queues with higher priority levels will receive a larger share of available CPU resources in case of contention. Queries in low-priority queues may be delayed while higher priority queries are executed.
Notes

GPORCA and the Postgres planner utilize different query costing models and may compute different costs for the same query. The Greenplum Database resource queue resource management scheme neither differentiates nor aligns costs between GPORCA and the Postgres Planner; it uses the literal cost value returned from the optimizer to throttle queries.

When resource queue-based resource management is active, use the MEMORY_LIMIT and ACTIVE_STATEMENTS limits for resource queues rather than configuring cost-based limits. Even when using GPORCA, Greenplum Database may fall back to using the Postgres Planner for certain queries, so using cost-based limits can lead to unexpected results.

Examples

Change the active query limit for a resource queue:

```
ALTER RESOURCE QUEUE myqueue WITH (ACTIVE_STATEMENTS=20);
```

Change the memory limit for a resource queue:

```
ALTER RESOURCE QUEUE myqueue WITH (MEMORY_LIMIT='2GB');
```

Reset the maximum and minimum query cost limit for a resource queue to no limit:

```
ALTER RESOURCE QUEUE myqueue WITH (MAX_COST=-1.0, MIN_COST=-1.0);
```

Reset the query cost limit for a resource queue to $10^3$ (or $30000000000.0$) and do not allow overcommit:

```
ALTER RESOURCE QUEUE myqueue WITH (MAX_COST=3e+10, COST_OVERCOMMIT=FALSE);
```

Reset the priority of queries associated with a resource queue to the minimum level:

```
ALTER RESOURCE QUEUE myqueue WITH (PRIORITY=MIN);
```

Remove the MAX_COST and MEMORY_LIMIT limits from a resource queue:

```
ALTER RESOURCE QUEUE myqueue WITHOUT (MAX_COST, MEMORY_LIMIT);
```

Compatibility

The ALTER RESOURCE QUEUE statement is a Greenplum Database extension. This command does not exist in standard PostgreSQL.

See Also

CREATE RESOURCE QUEUE, DROP RESOURCE QUEUE, CREATE ROLE, ALTER ROLE

ALTER ROLE

Changes a database role (user or group).

Synopsis

```
ALTER ROLE name [ [ WITH ] option [ ... ] ]
```

where option can be:
SUPERUSER | NOSUPERUSER
CREATEDB | NOCREATEDB
CREATEROLE | NOCREATEROLE
CREATEEXTTABLE | NOCREATEEXTTABLE

where attributes and values are:
- type='readable'/'writable'
- protocol='gpfdist'/'http'
- INHERIT | NOINHERIT
- LOGIN | NOLOGIN
- REPLICATION | NOREPLICATION
- CONNECTION LIMIT connlimit
- [ ENCRYPTED | UNENCRYPTED ] PASSWORD 'password'
- VALID UNTIL 'timestamp'

ALTER ROLE name RENAME TO new_name

ALTER ROLE { name | ALL } [ IN DATABASE database_name ]
  SET configuration_parameter { TO | = } { value | DEFAULT }
ALTER ROLE { name | ALL } [ IN DATABASE database_name ]
  SET configuration_parameter FROM CURRENT
ALTER ROLE { name | ALL } [ IN DATABASE database_name ]
  RESET configuration_parameter
ALTER ROLE { name | ALL } [ IN DATABASE database_name ] RESET ALL
ALTER ROLE name RESOURCE QUEUE { queue_name | NONE }
ALTER ROLE name RESOURCE GROUP { group_name | NONE }

Description

ALTER ROLE changes the attributes of a Greenplum Database role. There are several variants of this command.

WITH option

Changes many of the role attributes that can be specified in CREATE ROLE. (All of the possible attributes are covered, except that there are no options for adding or removing memberships; use GRANT and REVOKE for that.) Attributes not mentioned in the command retain their previous settings. Database superusers can change any of these settings for any role. Roles having CREATEROLE privilege can change any of these settings, but only for non-superuser and non-replication roles. Ordinary roles can only change their own password.

RENAME

Changes the name of the role. Database superusers can rename any role. Roles having CREATEROLE privilege can rename non-superuser roles. The current session user cannot be renamed (connect as a different user to rename a role). Because MD5-encrypted passwords use the role name as cryptographic salt, renaming a role clears its password if the password is MD5-encrypted.

SET | RESET

Changes a role’s session default for a specified configuration parameter, either for all databases or, when the IN DATABASE clause is specified, only for sessions in the named database. If ALL is specified instead of a role name, this changes the setting for all roles. Using ALL with IN DATABASE is effectively the same as using the command ALTER DATABASE...SET....

Whenever the role subsequently starts a new session, the specified value becomes the session default, overriding whatever setting is present in the server configuration file (postgresql.conf) or has been received from the postgres command line. This only happens at login time; executing SET ROLE or SET SESSION AUTHORIZATION does not cause new configuration values to be set.
Database-specific settings attached to a role override settings for all databases. Settings for specific databases or specific roles override settings for all roles.

For a role without LOGIN privilege, session defaults have no effect. Ordinary roles can change their own session defaults. Superusers can change anyone’s session defaults. Roles having CREATEROLE privilege can change defaults for non-superuser roles. Ordinary roles can only set defaults for themselves. Certain configuration variables cannot be set this way, or can only be set if a superuser issues the command. See the Greenplum Database Reference Guide for information about all user-settable configuration parameters. Only superusers can change a setting for all roles in all databases.

**RESOURCE QUEUE**
Assigns the role to a resource queue. The role would then be subject to the limits assigned to the resource queue when issuing queries. Specify NONE to assign the role to the default resource queue. A role can only belong to one resource queue. For a role without LOGIN privilege, resource queues have no effect. See CREATE RESOURCE QUEUE for more information.

**RESOURCE GROUP**
Assigns a resource group to the role. The role would then be subject to the concurrent transaction, memory, and CPU limits configured for the resource group. You can assign a single resource group to one or more roles. You cannot assign a resource group that you create for an external component to a role. See CREATE RESOURCE GROUP for additional information.

**Parameters**

*name*
The name of the role whose attributes are to be altered.

*new_name*
The new name of the role.

*database_name*
The name of the database in which to set the configuration parameter.

*config_parameter=value*
Set this role’s session default for the specified configuration parameter to the given value. If value is DEFAULT or if RESET is used, the role-specific parameter setting is removed, so the role will inherit the system-wide default setting in new sessions. Use RESET ALL to clear all role-specific settings. SET FROM CURRENT saves the session's current value of the parameter as the role-specific value. If IN DATABASE is specified, the configuration parameter is set or removed for the given role and database only. Whenever the role subsequently starts a new session, the specified value becomes the session default, overriding whatever setting is present in postgresql.conf or has been received from the postgres command line.

Role-specific variable settings take effect only at login; SET ROLE and SET SESSION AUTHORIZATION do not process role-specific variable settings.

See Server Configuration Parameters for information about user-settable configuration parameters.

*group_name*
The name of the resource group to assign to this role. Specifying the group_name NONE removes the role’s current resource group assignment and assigns a default resource group based on the role’s capability. SUPERUSER roles are assigned the admin_group resource group, while the default_group resource group is assigned to non-admin roles.

You cannot assign a resource group that you create for an external component to a role.
The name of the resource queue to which the user-level role is to be assigned. Only roles with LOGIN privilege can be assigned to a resource queue. To unassign a role from a resource queue and put it in the default resource queue, specify NONE. A role can only belong to one resource queue.

**SUPERUSER | NOSUPERUSER**

**CREATEDB | NOCREATEDB**

**CREATEROLE | NOCREATEROLE**

**CREATEUSER | NOCREATEUSER**

CREATEUSER and NOCREATEUSER are obsolete, but still accepted, spellings of SUPERUSER and NOSUPERUSER. Note that they are not equivalent to the CREATEROLE and NOCREATEROLE clauses.

**CREATEEXTTABLE | NOCREATEEXTTABLE [{attribute='value'}]**

If CREATEEXTTABLE is specified, the role being defined is allowed to create external tables. The default type is readable and the default protocol is gpfdist if not specified. NOCREATEEXTTABLE (the default) denies the role the ability to create external tables. Note that external tables that use the file or execute protocols can only be created by superusers.

**INHERIT | NOINHERIT**

**LOGIN | NOLOGIN**

**REPLICATION**

**NOREPLICATION**

**CONNECTION LIMIT connlimit**

**PASSWORD password**

**ENCRYPTED | UNENCRYPTED**

**VALID UNTIL 'timestamp'**

These clauses alter role attributes originally set by `CREATE ROLE`.

**DENY deny_point**

**DENY BETWEEN deny_point AND deny_point**

The `DENY` and `DENY BETWEEN` keywords set time-based constraints that are enforced at login. `DENY` sets a day or a day and time to deny access. `DENY BETWEEN` sets an interval during which access is denied. Both use the parameter `deny_point` that has following format:

```
DAY day [ TIME 'time' ]
```

The two parts of the `deny_point` parameter use the following formats:

For day:

```
{'Sunday' | 'Monday' | 'Tuesday' | 'Wednesday' | 'Thursday' |
'Sunday' | 'Monday' | 'Tuesday' | 'Wednesday' | 'Thursday' |
'Sunday' | 'Monday' | 'Tuesday' | 'Wednesday' | 'Thursday' }
```

For time:

```
{ 00-23 : 00-59 | 01-12 : 00-59 { AM | PM }}
```

The `DENY BETWEEN` clause uses two `deny_point` parameters.

**DROP DENY FOR deny_point**

For more information about time-based constraints and examples, see "Managing Roles and Privileges" in the Greenplum Database Administrator Guide.
The `DROP DENY FOR` clause removes a time-based constraint from the role. It uses the `deny_point` parameter described above.

For more information about time-based constraints and examples, see "Managing Roles and Privileges" in the *Greenplum Database Administrator Guide*.

**Notes**

Use `CREATE ROLE` to add new roles, and `DROP ROLE` to remove a role.

Use `GRANT` and `REVOKE` for adding and removing role memberships.

Caution must be exercised when specifying an unencrypted password with this command. The password will be transmitted to the server in clear text, and it might also be logged in the client's command history or the server log. The `psql` command-line client contains a meta-command `\password` that can be used to change a role's password without exposing the clear text password.

It is also possible to tie a session default to a specific database rather than to a role; see `ALTER DATABASE`. If there is a conflict, database-role-specific settings override role-specific ones, which in turn override database-specific ones.

**Examples**

Change the password for a role:

```
ALTER ROLE daria WITH PASSWORD 'passwd123';
```

Remove a role's password:

```
ALTER ROLE daria WITH PASSWORD NULL;
```

Change a password expiration date:

```
ALTER ROLE scott VALID UNTIL 'May 4 12:00:00 2015 +1';
```

Make a password valid forever:

```
ALTER ROLE luke VALID UNTIL 'infinity';
```

Give a role the ability to create other roles and new databases:

```
ALTER ROLE joelle CREATEROLE CREATEDB;
```

Give a role a non-default setting of the `maintenance_work_mem` parameter:

```
ALTER ROLE admin SET maintenance_work_mem = 100000;
```

Give a role a non-default, database-specific setting of the `client_min_messages` parameter:

```
ALTER ROLE fred IN DATABASE devel SET client_min_messages = DEBUG;
```

Assign a role to a resource queue:

```
ALTER ROLE sammy RESOURCE QUEUE poweruser;
```

Give a role permission to create writable external tables:

```
ALTER ROLE load CREATEEXTTABLE (type='writable');
```
Alter a role so it does not allow login access on Sundays:

```sql
ALTER ROLE user3 DENY DAY 'Sunday';
```

Alter a role to remove the constraint that does not allow login access on Sundays:

```sql
ALTER ROLE user3 DROP DENY FOR DAY 'Sunday';
```

Assign a new resource group to a role:

```sql
ALTER ROLE parttime_user RESOURCE GROUP rg_light;
```

**Compatibility**

The **ALTER ROLE** statement is a Greenplum Database extension.

`CREATE ROLE`, `DROP ROLE`, `ALTER DATABASE`, `SET`, `CREATE RESOURCE GROUP`, `CREATE RESOURCE QUEUE`, `GRANT`, `REVOKE`

---

**ALTER SCHEMA**

Changes the definition of a schema.

**Synopsis**

```sql
ALTER SCHEMA name RENAME TO newname
ALTER SCHEMA name OWNER TO newowner
```

**Description**

**ALTER SCHEMA** changes the definition of a schema.

You must own the schema to use **ALTER SCHEMA**. To rename a schema you must also have the **CREATE** privilege for the database. To alter the owner, you must also be a direct or indirect member of the new owning role, and you must have the **CREATE** privilege for the database. Note that superusers have all these privileges automatically.

**Parameters**

- **name**
  - The name of an existing schema.

- **newname**
  - The new name of the schema. The new name cannot begin with `pg_`, as such names are reserved for system schemas.

- **newowner**
  - The new owner of the schema.

**Compatibility**

There is no **ALTER SCHEMA** statement in the SQL standard.
ALTER SEQUENCE

Changes the definition of a sequence generator.

Synopsis

```
ALTER SEQUENCE [ IF EXISTS ] name [_INCREMENT [ BY ] increment]
[MINVALUE minvalue | NO MINVALUE]
[MAXVALUE maxvalue | NO MAXVALUE]
[START [ WITH ] start ]
[RESTART [ [ WITH ] restart ] ]
[CACHE cache] [[ NO ] CYCLE]
[OWNED BY {table.column | NONE}]
```

```
ALTER SEQUENCE [ IF EXISTS ] name OWNER TO new_owner

ALTER SEQUENCE [ IF EXISTS ] name RENAME TO new_name

ALTER SEQUENCE [ IF EXISTS ] name SET SCHEMA new_schema
```

Description

ALTER SEQUENCE changes the parameters of an existing sequence generator. Any parameters not specifically set in the ALTER SEQUENCE command retain their prior settings.

You must own the sequence to use ALTER SEQUENCE. To change a sequence's schema, you must also have CREATE privilege on the new schema. Note that superusers have all these privileges automatically.

To alter the owner, you must be a direct or indirect member of the new owning role, and that role must have CREATE privilege on the sequence's schema. (These restrictions enforce that altering the owner does not do anything you could not do by dropping and recreating the sequence. However, a superuser can alter ownership of any sequence anyway.)

Parameters

**name**

The name (optionally schema-qualified) of a sequence to be altered.

**IF EXISTS**

Do not throw an error if the sequence does not exist. A notice is issued in this case.

**increment**

The clause INCREMENT BY increment is optional. A positive value will make an ascending sequence, a negative one a descending sequence. If unspecified, the old increment value will be maintained.

**minvalue**

NO MINVALUE

The optional clause MINVALUE minvalue determines the minimum value a sequence can generate. If NO MINVALUE is specified, the defaults of 1 and -263-1 for ascending and descending sequences, respectively, will be used. If neither option is specified, the current minimum value will be maintained.

**maxvalue**

NO MAXVALUE
The optional clause `MAXVALUE maxvalue` determines the maximum value for the sequence. If `NO MAXVALUE` is specified, the defaults are 263-1 and -1 for ascending and descending sequences, respectively, will be used. If neither option is specified, the current maximum value will be maintained.

**start**

The optional clause `START WITH start` changes the recorded start value of the sequence. This has no effect on the current sequence value; it simply sets the value that future `ALTER SEQUENCE RESTART` commands will use.

**restart**

The optional clause `RESTART [ WITH restart ]` changes the current value of the sequence. This is equivalent to calling the `setval(sequence, start_val, is_called)` function with `is_called = false`. The specified value will be returned by the next call of the `nextval(sequence)` function. Writing `RESTART` with no `restart` value is equivalent to supplying the start value that was recorded by `CREATE SEQUENCE` or last set by `ALTER SEQUENCE START WITH`.

**new_owner**

The user name of the new owner of the sequence.

**cache**

The clause `CACHE cache` enables sequence numbers to be preallocated and stored in memory for faster access. The minimum value is 1 (only one value can be generated at a time, i.e., no cache). If unspecified, the old cache value will be maintained.

**CYCLE**

The optional `CYCLE` key word may be used to enable the sequence to wrap around when the `maxvalue` or `minvalue` has been reached by an ascending or descending sequence. If the limit is reached, the next number generated will be the respective `minvalue` or `maxvalue`.

**NO CYCLE**

If the optional `NO CYCLE` key word is specified, any calls to `nextval()` after the sequence has reached its maximum value will return an error. If neither `CYCLE` or `NO CYCLE` are specified, the old cycle behavior will be maintained.

**OWNED BY table.column**

**OWNED BY NONE**

The `OWNED BY` option causes the sequence to be associated with a specific table column, such that if that column (or its whole table) is dropped, the sequence will be automatically dropped as well. If specified, this association replaces any previously specified association for the sequence. The specified table must have the same owner and be in the same schema as the sequence. Specifying `OWNED BY NONE` removes any existing table column association.

**new_name**

The new name for the sequence.

**new_schema**

The new schema for the sequence.

**Notes**

To avoid blocking of concurrent transactions that obtain numbers from the same sequence, `ALTER SEQUENCE`’s effects on the sequence generation parameters are never rolled back; those changes take effect immediately and are not reversible. However, the `OWNED BY`, `OWNER TO`, `RENAME TO`, and `SET SCHEMA` clauses are ordinary catalog updates and can be rolled back.
**ALTER SEQUENCE** will not immediately affect *nextval()* results in sessions, other than the current one, that have preallocated (cached) sequence values. They will use up all cached values prior to noticing the changed sequence generation parameters. The current session will be affected immediately.

For historical reasons, **ALTER TABLE** can be used with sequences too; but the only variants of **ALTER TABLE** that are allowed with sequences are equivalent to the forms shown above.

**Examples**

Restart a sequence called serial at 105:

```
ALTER SEQUENCE serial RESTART WITH 105;
```

**Compatibility**

**ALTER SEQUENCE** conforms to the SQL standard, except for the **START WITH**, **OWNED BY**, **OWNER TO**, **RENAME TO**, and **SET SCHEMA** clauses, which are Greenplum Database extensions.

**See Also**

*CREATE SEQUENCE*, *DROP SEQUENCE*, *ALTER TABLE*

---

**ALTER SERVER**

Changes the definition of a foreign server.

**Synopsis**

```
ALTER SERVER server_name [ VERSION 'new_version' ]
    [ OPTIONS ( [ ADD | SET | DROP ] option ['value'] [, ... ] ) ]

ALTER SERVER server_name OWNER TO new_owner

ALTER SERVER server_name RENAME TO new_name
```

**Description**

**ALTER SERVER** changes the definition of a foreign server. The first form of the command changes the version string or the generic options of the server. Greenplum Database requires at least one clause. The second and third forms of the command change the owner or the name of the server.

To alter the server, you must be the owner of the server. To alter the owner you must:

- Own the server.
- Be a direct or indirect member of the new owning role.
- Have **USAGE** privilege on the server's foreign-data wrapper.

Superusers automatically satisfy all of these criteria.

**Parameters**

- **server_name**
  - The name of an existing server.
- **new_version**
  - The new server version.
- **OPTIONS ( [ ADD | SET | DROP ] option ['value'] [, ... ] )**
Change the server’s options. ADD, SET, and DROP specify the action to perform. If no operation is explicitly specified, the default operation is ADD. Option names must be unique. Greenplum Database validates names and values using the server’s foreign-data wrapper library.

**OWNER TO** *new_owner*

Specifies the new owner of the foreign server.

**RENAME TO** *new_name*

Specifies the new name of the foreign server.

### Examples

Change the definition of a server named `foo` by adding connection options:

```sql
ALTER SERVER foo OPTIONS (host 'foo', dbname 'foodb');
```

Change the option named `host` for a server named `foo`, and set the server version:

```sql
ALTER SERVER foo VERSION '9.1' OPTIONS (SET host 'baz');
```

### Compatibility

`ALTER SERVER` conforms to ISO/IEC 9075-9 (SQL/MED). The `OWNER TO` and `RENAME` forms are Greenplum Database extensions.

**ALTER TABLE**

Changes the definition of a table.

### Synopsis

```sql
ALTER TABLE [IF EXISTS] [ONLY] name 
  action [, ... ]

ALTER TABLE [IF EXISTS] [ONLY] name 
  RENAME [COLUMN] column_name TO new_column_name

ALTER TABLE [IF EXISTS ] [ ONLY ] name 
  RENAME CONSTRAINT constraint_name TO new_constraint_name

ALTER TABLE [IF EXISTS] name 
  RENAME TO new_name

ALTER TABLE [IF EXISTS] name 
  SET SCHEMA new_schema

ALTER TABLE ALL IN TABLESPACE name [ OWNED BY role_name [, ... ] ] 
  SET TABLESPACE new_tablespace [ NOWAIT ]

ALTER TABLE [IF EXISTS] [ONLY] name SET 
  WITH (REORGANIZE=true|false) 
    DISTRIBUTED BY (({column_name [opclass]} [, ... ] ) 
    DISTRIBUTED RANDOMLY 
    DISTRIBUTED REPLICATED
```
ALTER TABLE name
  [ ALTER PARTITION { partition_name | FOR (RANK(number))
   | FOR (value) } ] partition_action

where action is one of:

ADD [COLUMN] column_name data_type [ DEFAULT default_expr ]
  [column_constraint [ ... ]]
  [ COLLATE collation ]
  [ ENCODING ( storage_directive [, ... ] ) ]
DROP [COLUMN] [IF EXISTS] column_name [RESTRICT | CASCADE]
ALTER [COLUMN] column_name [ SET DATA ] TYPE type [COLLATE collation]

ENABLE TRIGGER [trigger_name | ALL | USER]
CLUSTER ON index_name
SET WITHOUT CLUSTER
SET WITHOUT OIDS
SET (storage_parameter = value)
RESET (storage_parameter [, ... ])
INHERIT parent_table
NO INHERIT parent_table
OF type_name
NOT OF
OWNER TO new_owner
SET TABLESPACE new_tablespace

where table_constraint_using_index is:

[ CONSTRAINT constraint_name ]
{ UNIQUE | PRIMARY KEY } USING INDEX index_name
[ DEFERRABLE | NOT DEFERRABLE ] [ INITIALLY DEFERRED | INITIALLY IMMEDIATE ]

where partition_action is one of:

ALTER DEFAULT PARTITION
DROP DEFAULT PARTITION [IF EXISTS]
DROP PARTITION [IF EXISTS] { partition_name | FOR (RANK(number)) | FOR (value) } [CASCADE]
TRUNCATE DEFAULT PARTITION
TRUNCATE PARTITION { partition_name | FOR (RANK(number)) | FOR (value) }
RENAME DEFAULT PARTITION TO new_partition_name
RENAME PARTITION { partition_name | FOR (RANK(number)) | FOR (value) } TO new_partition_name
ADD DEFAULT PARTITION name [ ( subpartition_spec ) ]
ADD PARTITION [partition_name] partition_element
[ ( subpartition_spec ) ]
EXCHANGE PARTITION { partition_name | FOR (RANK(number)) | FOR (value) } WITH TABLE table_name
[ WITH | WITHOUT VALIDATION ]
EXCHANGE DEFAULT PARTITION WITH TABLE table_name
[ WITH | WITHOUT VALIDATION ]
ALTER TABLE changes the definition of an existing table. There are several subforms:

- **ADD COLUMN** — Adds a new column to the table, using the same syntax as `CREATE TABLE`. The `ENCODING` clause is valid only for append-optimized, column-oriented tables.

- **DROP COLUMN [IF EXISTS]** — Drops a column from a table. Note that if you drop table columns that are being used as the Greenplum Database distribution key, the distribution policy for the table will be changed to `DISTRIBUTED RANDOMLY`. Indexes and table constraints involving the column are automatically dropped as well. You need to say `CASCADE` if anything outside the table depends on the column (such as views). If `IF EXISTS` is specified and the column does not exist, no error is thrown; a notice is issued instead.
• **IF EXISTS** — Do not throw an error if the table does not exist. A notice is issued in this case.
• **SET DATA TYPE** — This form changes the data type of a column of a table. Note that you cannot alter column data types that are being used as distribution or partitioning keys. Indexes and simple table constraints involving the column will be automatically converted to use the new column type by reparsing the originally supplied expression. The optional **COLLATE** clause specifies a collation for the new column; if omitted, the collation is the default for the new column type. The optional **USING** clause specifies how to compute the new column value from the old. If omitted, the default conversion is the same as an assignment cast from old data type to new. A **USING** clause must be provided if there is no implicit or assignment cast from old to new type.

**Note:** GPORCA supports collation only when all columns in the query use the same collation. If columns in the query use different collations, then Greenplum uses the Postgres Planner.

• **SET/DROP DEFAULT** — Sets or removes the default value for a column. Default values only apply in subsequent **INSERT** or **UPDATE** commands; they do not cause rows already in the table to change.

• **SET/DROP NOT NULL** — Changes whether a column is marked to allow null values or to reject null values. You can only use **SET NOT NULL** when the column contains no null values.

• **SET STATISTICS** — Sets the per-column statistics-gathering target for subsequent **ANALYZE** operations. The target can be set in the range 100 to 10000, or set to -1 to revert to using the system default statistics target (**default_statistics_target**).

• **SET (attribute_option = value [, ...])**

**RESET (attribute_option [, ...])** — Sets or resets per-attribute options. Currently, the only defined per-attribute options are **n_distinct** and **n_distinct_inherited**, which override the number-of-distinct-values estimates made by subsequent **ANALYZE** operations. **n_distinct** affects the statistics for the table itself, while **n_distinct_inherited** affects the statistics gathered for the table plus its inheritance children. When set to a positive value, **ANALYZE** will assume that the column contains exactly the specified number of distinct non-null values. When set to a negative value, which must be greater than or equal to -1, **ANALYZE** will assume that the number of distinct non-null values in the column is linear in the size of the table; the exact count is to be computed by multiplying the estimated table size by the absolute value of the given number. For example, a value of -1 implies that all values in the column are distinct, while a value of -0.5 implies that each value appears twice on the average. This can be useful when the size of the table changes over time, since the multiplication by the number of rows in the table is not performed until query planning time. Specify a value of 0 to revert to estimating the number of distinct values normally.

• **ADD table_constraint [NOT VALID]** — Adds a new constraint to a table (not just a partition) using the same syntax as **CREATE TABLE**. The **NOT VALID** option is currently only allowed for foreign key and **CHECK** constraints. If the constraint is marked **NOT VALID**, Greenplum Database skips the potentially-lengthy initial check to verify that all rows in the table satisfy the constraint. The constraint will still be enforced against subsequent inserts or updates (that is, they’ll fail unless there is a matching row in the referenced table, in the case of foreign keys; and they’ll fail unless the new row matches the specified check constraints). But the database will not assume that the constraint holds for all rows in the table, until it is validated by using the **VALIDATE CONSTRAINT** option. Constraint checks are skipped at create table time, so the **CREATE TABLE** syntax does not include this option.

• **VALIDATE CONSTRAINT** — This form validates a foreign key constraint that was previously created as **NOT VALID**, by scanning the table to ensure there are no rows for which the constraint is not satisfied. Nothing happens if the constraint is already marked valid. The advantage of separating validation from initial creation of the constraint is that validation requires a lesser lock on the table than constraint creation does.

• **ADD table_constraint_using_index** — Adds a new **PRIMARY KEY** or **UNIQUE** constraint to a table based on an existing unique index. All the columns of the index will be included in the constraint. The index cannot have expression columns nor be a partial index. Also, it must be a b-tree index with default sort ordering. These restrictions ensure that the index is equivalent to one that would be built by a regular **ADD PRIMARY KEY** or **ADD UNIQUE** command.

Adding a **PRIMARY KEY** or **UNIQUE** constraint to a table based on an existing unique index is not supported on a partitioned table.
If **PRIMARY KEY** is specified, and the index's columns are not already marked **NOT NULL**, then this command will attempt to do **ALTER COLUMN** **SET NOT NULL** against each such column. That requires a full table scan to verify the column(s) contain no nulls. In all other cases, this is a fast operation.

If a constraint name is provided then the index will be renamed to match the constraint name. Otherwise the constraint will be named the same as the index.

After this command is executed, the index is "owned" by the constraint, in the same way as if the index had been built by a regular **ADD PRIMARY KEY** or **ADD UNIQUE** command. In particular, dropping the constraint will make the index disappear too.

**DROP CONSTRAINT [IF EXISTS]** — Drops the specified constraint on a table. If **IF EXISTS** is specified and the constraint does not exist, no error is thrown. In this case a notice is issued instead.

**DISABLE/ENABLE TRIGGER** — Disables or enables trigger(s) belonging to the table. A disabled trigger is still known to the system, but is not executed when its triggering event occurs. For a deferred trigger, the enable status is checked when the event occurs, not when the trigger function is actually executed. One may disable or enable a single trigger specified by name, or all triggers on the table, or only user-created triggers. Disabling or enabling constraint triggers requires superuser privileges.

**Note**: triggers are not supported in Greenplum Database. Triggers in general have very limited functionality due to the parallelism of Greenplum Database.

**CLUSTER ON/SET WITHOUT CLUSTER** — Selects or removes the default index for future **CLUSTER** operations. It does not actually re-cluster the table. Note that **CLUSTER** is not the recommended way to physically reorder a table in Greenplum Database because it takes so long. It is better to recreate the table with **CREATE TABLE AS** and order it by the index column(s).

**Note**: **CLUSTER ON** is not supported on append-optimized tables.

**SET WITHOUT OIDS** — Removes the OID system column from the table.

**Warning**: Pivotal does not support using **SET WITH OIDS** or **oids=TRUE** to assign an OID system column. On large tables, such as those in a typical Greenplum Database system, using OIDs for table rows can cause wrap-around of the 32-bit OID counter. Once the counter wraps around, OIDs can no longer be assumed to be unique, which not only makes them useless to user applications, but can also cause problems in the Greenplum Database system catalog tables. In addition, excluding OIDs from a table reduces the space required to store the table on disk by 4 bytes per row, slightly improving performance. You cannot create OIDS on a partitioned or column-oriented table (an error is displayed). This syntax is deprecated and will be removed in a future Greenplum release.

**SET ( FILLFACTOR = value ) / RESET (FILLFACTOR)** — Changes the fillfactor for the table. The fillfactor for a table is a percentage between 10 and 100. 100 (complete packing) is the default. When a smaller fillfactor is specified, **INSERT** operations pack table pages only to the indicated percentage; the remaining space on each page is reserved for updating rows on that page. This gives **UPDATE** a chance to place the updated copy of a row on the same page as the original, which is more efficient than placing it on a different page. For a table whose entries are never updated, complete packing is the best choice, but in heavily updated tables smaller fillfactors are appropriate. Note that the table contents will not be modified immediately by this command. You will need to rewrite the table to get the desired effects. That can be done with **VACUUM** or one of the forms of **ALTER TABLE** that forces a table rewrite.

**SET DISTRIBUTED** — Changes the distribution policy of a table. Changing a hash distribution policy, or changing to or from a replicated policy, will cause the table data to be physically redistributed on disk, which can be resource intensive.

**INHERIT parent_table / NO INHERIT parent_table** — Adds or removes the target table as a child of the specified parent table. Queries against the parent will include records of its child table. To be added as a child, the target table must already contain all the same columns as the parent (it could have additional columns, too). The columns must have matching data types, and if they have **NOT NULL** constraints in the parent then they must also have **NOT NULL** constraints in the child. There must also be matching child-table constraints for all **CHECK** constraints of the parent, except those marked non-inheritable (that is, created with **ALTER TABLE ... ADD CONSTRAINT ... NO INHERIT**) in
the parent, which are ignored; all child-table constraints matched must not be marked non-inheritable. Currently UNIQUE, PRIMARY KEY, and FOREIGN KEY constraints are not considered, but this may change in the future.

- **OF type_name** — This form links the table to a composite type as though CREATE TABLE OF had formed it. The table's list of column names and types must precisely match that of the composite type; the presence of an oid system column is permitted to differ. The table must not inherit from any other table. These restrictions ensure that CREATE TABLE OF would permit an equivalent table definition.

- **NOT OF** — This form dissociates a typed table from its type.

- **OWNER** — Changes the owner of the table, sequence, or view to the specified user.

- **SET TABLESPACE** — Changes the table's tablespace to the specified tablespace and moves the data file(s) associated with the table to the new tablespace. Indexes on the table, if any, are not moved; but they can be moved separately with additional SET TABLESPACE commands. All tables in the current database in a tablespace can be moved by using the ALL IN TABLESPACE form, which will lock all tables to be moved first and then move each one. This form also supports OWNED BY, which will only move tables owned by the roles specified. If the NOWAIT option is specified then the command will fail if it is unable to acquire all of the locks required immediately. Note that system catalogs are not moved by this command, use ALTER DATABASE or explicit ALTER TABLE invocations instead if desired. The information_schema relations are not considered part of the system catalogs and will be moved. See also CREATE TABLESPACE. If changing the tablespace of a partitioned table, all child table partitions will also be moved to the new tablespace.

- **RENAME** — Changes the name of a table (or an index, sequence, or view), the name of an individual column in a table, or the name of a constraint of the table. There is no effect on the stored data. Note that Greenplum Database distribution key columns cannot be renamed.

- **SET SCHEMA** — Moves the table into another schema. Associated indexes, constraints, and sequences owned by table columns are moved as well.

- **ALTER PARTITION | DROP PARTITION | RENAME PARTITION | TRUNCATE PARTITION | ADD PARTITION | SPLIT PARTITION | EXCHANGE PARTITION | SET SUBPARTITION TEMPLATE** — Changes the structure of a partitioned table. In most cases, you must go through the parent table to alter one of its child table partitions.

  **Note:** If you add a partition to a table that has subpartition encodings, the new partition inherits the storage directives for the subpartitions. For more information about the precedence of compression settings, see “Using Compression” in the Greenplum Database Administrator Guide.

All the forms of ALTER TABLE that act on a single table, except RENAME and SET SCHEMA, can be combined into a list of multiple alterations to apply together. For example, it is possible to add several columns and/or alter the type of several columns in a single command. This is particularly useful with large tables, since only one pass over the table need be made.

You must own the table to use ALTER TABLE. To change the schema or tablespace of a table, you must also have CREATE privilege on the new schema or tablespace. To add the table as a new child of a parent table, you must own the parent table as well. To alter the owner, you must also be a direct or indirect member of the new owning role, and that role must have CREATE privilege on the table's schema. To add a column or alter a column type or use the OF clause, you must also have USAGE privilege on the data type. A superuser has these privileges automatically.

  **Note:** Memory usage increases significantly when a table has many partitions, if a table has compression, or if the blocksize for a table is large. If the number of relations associated with the table is large, this condition can force an operation on the table to use more memory. For example, if the table is a CO table and has a large number of columns, each column is a relation. An operation like ALTER TABLE ALTER COLUMN opens all the columns in the table allocates associated buffers. If a CO table has 40 columns and 100 partitions, and the columns are compressed and the blocksize is 2 MB (with a system factor of 3), the system attempts to allocate 24 GB, that is (40 ×100) × (2 ×3) MB or 24 GB.

**Parameters**

**ONLY**
Only perform the operation on the table name specified. If the **ONLY** keyword is not used, the operation will be performed on the named table and any child table partitions associated with that table.

**Note:** Adding or dropping a column, or changing a column's type, in a parent or descendant table only is not permitted. The parent table and its descendents must always have the same columns and types.

### name

The name (possibly schema-qualified) of an existing table to alter. If **ONLY** is specified, only that table is altered. If **ONLY** is not specified, the table and all its descendant tables (if any) are updated.

**Note:** Constraints can only be added to an entire table, not to a partition. Because of that restriction, the *name* parameter can only contain a table name, not a partition name.

### column_name

Name of a new or existing column. Note that Greenplum Database distribution key columns must be treated with special care. Altering or dropping these columns can change the distribution policy for the table.

### new_column_name

New name for an existing column.

### new_name

New name for the table.

### type

Data type of the new column, or new data type for an existing column. If changing the data type of a Greenplum distribution key column, you are only allowed to change it to a compatible type (for example, *text* to *varchar* is OK, but *text* to *int* is not).

### table_constraint

New table constraint for the table. Note that foreign key constraints are currently not supported in Greenplum Database. Also a table is only allowed one unique constraint and the uniqueness must be within the Greenplum Database distribution key.

### constraint_name

Name of an existing constraint to drop.

### CASCADE

Automatically drop objects that depend on the dropped column or constraint (for example, views referencing the column).

### RESTRICT

Refuse to drop the column or constraint if there are any dependent objects. This is the default behavior.

### trigger_name

Name of a single trigger to disable or enable. Note that Greenplum Database does not support triggers.

### ALL

Disable or enable all triggers belonging to the table including constraint related triggers. This requires superuser privilege if any of the triggers are internally generated constraint triggers such as those that are used to implement foreign key constraints or deferrable uniqueness and exclusion constraints.

### USER
Disable or enable all triggers belonging to the table except for internally generated constraint triggers such as those that are used to implement foreign key constraints or deferrable uniqueness and exclusion constraints.

**index_name**
The index name on which the table should be marked for clustering. Note that `CLUSTER` is not the recommended way to physically reorder a table in Greenplum Database because it takes so long. It is better to recreate the table with `CREATE TABLE AS` and order it by the index column(s).

**FILLFACTOR**
Set the fillfactor percentage for a table.

**value**
The new value for the `FILLFACTOR` parameter, which is a percentage between 10 and 100. 100 is the default.

**DISTRIBUTED BY ({{column_name [opclass]}}) | DISTRIBUTED RANDOMLY | DISTRIBUTED REPLICATED**
Specifies the distribution policy for a table. Changing a hash distribution policy causes the table data to be physically redistributed, which can be resource intensive. If you declare the same hash distribution policy or change from hash to random distribution, data will not be redistributed unless you declare `SET WITH (REORGANIZE=true)`.

Changing to or from a replicated distribution policy causes the table data to be redistributed.

**REORGANIZE=true|false**
Use `REORGANIZE=true` when the hash distribution policy has not changed or when you have changed from a hash to a random distribution, and you want to redistribute the data anyways.

**parent_table**
A parent table to associate or de-associate with this table.

**new_owner**
The role name of the new owner of the table.

**new_tablespace**
The name of the tablespace to which the table will be moved.

**new_schema**
The name of the schema to which the table will be moved.

**parent_table_name**
When altering a partitioned table, the name of the top-level parent table.

**ALTER [DEFAULT] PARTITION**
If altering a partition deeper than the first level of partitions, use `ALTER PARTITION` clauses to specify which subpartition in the hierarchy you want to alter. For each partition level in the table hierarchy that is above the target partition, specify the partition that is related to the target partition in an `ALTER PARTITION` clause.

**DROP [DEFAULT] PARTITION**
Drops the specified partition. If the partition has subpartitions, the subpartitions are automatically dropped as well.

**TRUNCATE [DEFAULT] PARTITION**
Truncates the specified partition. If the partition has subpartitions, the subpartitions are automatically truncated as well.

**RENAME [DEFAULT] PARTITION**
Changes the partition name of a partition (not the relation name). Partitioned tables are created using the naming convention: `<parentname>_` `<level>_prt_<partition_name>`.

**ADD DEFAULT PARTITION**

Adds a default partition to an existing partition design. When data does not match to an existing partition, it is inserted into the default partition. Partition designs that do not have a default partition will reject incoming rows that do not match to an existing partition. Default partitions must be given a name.

**ADD PARTITION**

*partition_element* - Using the existing partition type of the table (range or list), defines the boundaries of new partition you are adding.

*name* - A name for this new partition.

**VALUES** - For list partitions, defines the value(s) that the partition will contain.

**START** - For range partitions, defines the starting range value for the partition. By default, start values are INCLUSIVE. For example, if you declared a start date of '2016-01-01', then the partition would contain all dates greater than or equal to '2016-01-01'. Typically the data type of the START expression is the same type as the partition key column. If that is not the case, then you must explicitly cast to the intended data type.

**END** - For range partitions, defines the ending range value for the partition. By default, end values are EXCLUSIVE. For example, if you declared an end date of '2016-02-01', then the partition would contain all dates less than but not equal to '2016-02-01'. Typically the data type of the END expression is the same type as the partition key column. If that is not the case, then you must explicitly cast to the intended data type.

**WITH** - Sets the table storage options for a partition. For example, you may want older partitions to be append-optimized tables and newer partitions to be regular heap tables. See `CREATE TABLE` for a description of the storage options.

**TABLESPACE** - The name of the tablespace in which the partition is to be created.

*subpartition_spec* - Only allowed on partition designs that were created without a subpartition template. Declares a subpartition specification for the new partition you are adding. If the partitioned table was originally defined using a subpartition template, then the template will be used to generate the subpartitions automatically.

**EXCHANGE [DEFAULT] PARTITION**

Exchanges another table into the partition hierarchy into the place of an existing partition. In a multi-level partition design, you can only exchange the lowest level partitions (those that contain data).

The Greenplum Database server configuration parameter `gp_enable_exchange_default_partition` controls availability of the `EXCHANGE DEFAULT PARTITION` clause. The default value for the parameter is `off`. The clause is not available and Greenplum Database returns an error if the clause is specified in an `ALTER TABLE` command.

For information about the parameter, see [Server Configuration Parameters](#).

**Warning:** Before you exchange the default partition, you must ensure the data in the table to be exchanged, the new default partition, is valid for the default partition. For example, the data in the new default partition must not contain data that would be valid in other leaf child partitions of the partitioned table. Otherwise, queries against the partitioned table with the exchanged default partition that are executed by GPORCA might return incorrect results.

**WITH TABLE** *table_name* - The name of the table you are swapping into the partition design. You can exchange a table where the table data is stored in the database. For example, the table is created with the `CREATE TABLE` command. The table must have the
same number of columns, column order, column names, column types, and distribution policy as the parent table.

With the `EXCHANGE PARTITION` clause, you can also exchange a readable external table (created with the `CREATE EXTERNAL TABLE` command) into the partition hierarchy in the place of an existing leaf child partition. If you specify a readable external table, you must also specify the `WITHOUT VALIDATION` clause to skip table validation against the `CHECK` constraint of the partition you are exchanging.

Exchanging a leaf child partition with an external table is not supported if the partitioned table contains a column with a check constraint or a `NOT NULL` constraint.

You cannot exchange a partition with a replicated table. Exchanging a partition with a partitioned table or a child partition of a partitioned table is not supported.

**WITH | WITHOUT VALIDATION** - Validates that the data in the table matches the `CHECK` constraint of the partition you are exchanging. The default is to validate the data against the `CHECK` constraint.

**Warning:** If you specify the `WITHOUT VALIDATION` clause, you must ensure that the data in the table that you are exchanging for an existing child leaf partition is valid against the `CHECK` constraints on the partition. Otherwise, queries against the partitioned table might return incorrect results.

**SET SUBPARTITION TEMPLATE**

Modifies the subpartition template for an existing partition. After a new subpartition template is set, all new partitions added will have the new subpartition design (existing partitions are not modified).

**SPLIT DEFAULT PARTITION**

Splits a default partition. In a multi-level partition, only a range partition can be split, not a list partition, and you can only split the lowest level default partitions (those that contain data). Splitting a default partition creates a new partition containing the values specified and leaves the default partition containing any values that do not match to an existing partition.

**AT** - For list partitioned tables, specifies a single list value that should be used as the criteria for the split.

**START** - For range partitioned tables, specifies a starting value for the new partition.

**END** - For range partitioned tables, specifies an ending value for the new partition.

**INTO** - Allows you to specify a name for the new partition. When using the `INTO` clause to split a default partition, the second partition name specified should always be that of the existing default partition. If you do not know the name of the default partition, you can look it up using the `pg_partitions` view.

**SPLIT PARTITION**

Splits an existing partition into two partitions. In a multi-level partition, only a range partition can be split, not a list partition, and you can only split the lowest level partitions (those that contain data).

**AT** - Specifies a single value that should be used as the criteria for the split. The partition will be divided into two new partitions with the split value specified being the starting range for the latter partition.

**INTO** - Allows you to specify names for the two new partitions created by the split.

**partition_name**

The given name of a partition. The given partition name is the `partitionname` column value in the `pg_partitions` system view.

**FOR (RANK(number))**
For range partitions, the rank of the partition in the range.

FOR ('value')

Specifies a partition by declaring a value that falls within the partition boundary specification. If the value declared with FOR matches to both a partition and one of its subpartitions (for example, if the value is a date and the table is partitioned by month and then by day), then FOR will operate on the first level where a match is found (for example, the monthly partition). If your intent is to operate on a subpartition, you must declare so as follows: ALTER TABLE name ALTER PARTITION FOR ('2016-10-01') DROP PARTITION FOR ('2016-10-01');

Notes

The table name specified in the ALTER TABLE command cannot be the name of a partition within a table.

Take special care when altering or dropping columns that are part of the Greenplum Database distribution key as this can change the distribution policy for the table.

Greenplum Database does not currently support foreign key constraints. For a unique constraint to be enforced in Greenplum Database, the table must be hash-distributed (not DISTRIBUTED RANDOMLY), and all of the distribution key columns must be the same as the initial columns of the unique constraint columns.

Adding a CHECK or NOT NULL constraint requires scanning the table to verify that existing rows meet the constraint, but does not require a table rewrite.

When a column is added with ADD COLUMN, all existing rows in the table are initialized with the column's default value, or NULL if no DEFAULT clause is specified. Adding a column with a non-null default or changing the type of an existing column will require the entire table and indexes to be rewritten. As an exception, if the USING clause does not change the column contents and the old type is either binary coercible to the new type or an unconstrained domain over the new type, a table rewrite is not needed, but any indexes on the affected columns must still be rebuilt. Adding or removing a system oid column also requires rewriting the entire table. Table and/or index rebuilds may take a significant amount of time for a large table; and will temporarily require as much as double the disk space.

You can specify multiple changes in a single ALTER TABLE command, which will be done in a single pass over the table.

The DROP COLUMN form does not physically remove the column, but simply makes it invisible to SQL operations. Subsequent insert and update operations in the table will store a null value for the column. Thus, dropping a column is quick but it will not immediately reduce the on-disk size of your table, as the space occupied by the dropped column is not reclaimed. The space will be reclaimed over time as existing rows are updated. If you drop the system oid column, however, the table is rewritten immediately.

To force immediate reclamation of space occupied by a dropped column, you can execute one of the forms of ALTER TABLE that performs a rewrite of the whole table. This results in reconstructing each row with the dropped column replaced by a null value.

The rewriting forms of ALTER TABLE are not MVCC-safe. After a table rewrite, the table will appear empty to concurrent transactions, if they are using a snapshot taken before the rewrite occurred. See MVCC Caveats for more details.

The USING option of SET DATA TYPE can actually specify any expression involving the old values of the row; that is, it can refer to other columns as well as the one being converted. This allows very general conversions to be done with the SET DATA TYPE syntax. Because of this flexibility, the USING expression is not applied to the column's default value (if any); the result might not be a constant expression as required for a default. This means that when there is no implicit or assignment cast from old to new type, SET DATA TYPE might fail to convert the default even though a USING clause is supplied. In such cases, drop the default with DROP DEFAULT, perform the ALTER TYPE, and then use SET DEFAULT to add a suitable new default. Similar considerations apply to indexes and constraints involving the column.
If a table is partitioned or has any descendant tables, it is not permitted to add, rename, or change the type of a column, or rename an inherited constraint in the parent table without doing the same to the descendants. This ensures that the descendants always have columns matching the parent.

To see the structure of a partitioned table, you can use the view `pg_partitions`. This view can help identify the particular partitions you may want to alter.

A recursive `DROP COLUMN` operation will remove a descendant table’s column only if the descendant does not inherit that column from any other parents and never had an independent definition of the column. A nonrecursive `DROP COLUMN (ALTER TABLE ONLY ... DROP COLUMN)` never removes any descendant columns, but instead marks them as independently defined rather than inherited.

The `TRIGGER`, `CLUSTER`, `OWNER`, and `TABLESPACE` actions never recurse to descendant tables; that is, they always act as though `ONLY` were specified. Adding a constraint recurses only for `CHECK` constraints that are not marked `NO INHERIT`.

These `ALTER PARTITION` operations are supported if no data is changed on a partitioned table that contains a leaf child partition that has been exchanged to use an external table. Otherwise, an error is returned.

- Adding or dropping a column.
- Changing the data type of column.

These `ALTER PARTITION` operations are not supported for a partitioned table that contains a leaf child partition that has been exchanged to use an external table:

- Setting a subpartition template.
- Altering the partition properties.
- Creating a default partition.
- Setting a distribution policy.
- Setting or dropping a `NOT NULL` constraint of column.
- Adding or dropping constraints.
- Splitting an external partition.

Changing any part of a system catalog table is not permitted.

**Examples**

Add a column to a table:

```
ALTER TABLE distributors ADD COLUMN address varchar(30);
```

Rename an existing column:

```
ALTER TABLE distributors RENAME COLUMN address TO city;
```

Rename an existing table:

```
ALTER TABLE distributors RENAME TO suppliers;
```

Add a not-null constraint to a column:

```
ALTER TABLE distributors ALTER COLUMN street SET NOT NULL;
```
Add a check constraint to a table and all of its children:

```
ALTER TABLE distributors ADD CONSTRAINT zipchk CHECK (char_length(zipcode) = 5);
```

To add a check constraint only to a table and not to its children:

```
ALTER TABLE distributors ADD CONSTRAINT zipchk CHECK (char_length(zipcode) = 5) NO INHERIT;
```

(The check constraint will not be inherited by future children, either.)

Remove a check constraint from a table and all of its children:

```
ALTER TABLE distributors DROP CONSTRAINT zipchk;
```

Remove a check constraint from one table only:

```
ALTER TABLE ONLY distributors DROP CONSTRAINT zipchk;
```

(The check constraint remains in place for any child tables that inherit distributors.)

Move a table to a different schema:

```
ALTER TABLE myschema.distributors SET SCHEMA yourschema;
```

Change the distribution policy of a table to replicated:

```
ALTER TABLE myschema.distributors SET DISTRIBUTED REPLICATED;
```

Add a new partition to a partitioned table:

```
ALTER TABLE sales ADD PARTITION
    START (date '2017-02-01') INCLUSIVE
    END (date '2017-03-01') EXCLUSIVE;
```

Add a default partition to an existing partition design:

```
ALTER TABLE sales ADD DEFAULT PARTITION other;
```

Rename a partition:

```
ALTER TABLE sales RENAME PARTITION FOR ('2016-01-01') TO jan08;
```

Drop the first (oldest) partition in a range sequence:

```
ALTER TABLE sales DROP PARTITION FOR (RANK(1));
```

Exchange a table into your partition design:

```
ALTER TABLE sales EXCHANGE PARTITION FOR ('2016-01-01') WITH TABLE jan08;
```

Split the default partition (where the existing default partition's name is other) to add a new monthly partition for January 2017:

```
ALTER TABLE sales SPLIT DEFAULT PARTITION
    START ('2017-01-01') INCLUSIVE
```
END ('2017-02-01') EXCLUSIVE INTO (PARTITION jan09, PARTITION other);

Split a monthly partition into two with the first partition containing dates January 1-15 and the second partition containing dates January 16-31:

```sql
ALTER TABLE sales SPLIT PARTITION FOR ('2016-01-01') AT ('2016-01-16') INTO (PARTITION jan081to15, PARTITION jan0816to31);
```

For a multi-level partitioned table that consists of three levels, year, quarter, and region, exchange a leaf partition `region` with the table `region_new`:

```sql
ALTER TABLE sales ALTER PARTITION year_1 ALTER PARTITION quarter_4 EXCHANGE PARTITION region WITH TABLE region_new ;
```

In the previous command, the two `ALTER PARTITION` clauses identify which `region` partition to exchange. Both clauses are required to identify the specific partition to exchange.

**Compatibility**

The forms `ADD` (without `USING INDEX`), `DROP`, `SET DEFAULT`, and `SET DATA TYPE` (without `USING`) conform with the SQL standard. The other forms are Greenplum Database extensions of the SQL standard. Also, the ability to specify more than one manipulation in a single `ALTER TABLE` command is an extension.

`ALTER TABLE DROP COLUMN` can be used to drop the only column of a table, leaving a zero-column table. This is an extension of SQL, which disallows zero-column tables.

**See Also**

`CREATE TABLE`, `DROP TABLE`

**ALTER TABLESPACE**

Changes the definition of a tablespace.

**Synopsis**

- `ALTER TABLESPACE name RENAME TO new_name`
- `ALTER TABLESPACE name OWNER TO new_owner`
- `ALTER TABLESPACE name SET (tablespace_option = value [, ... ] )`
- `ALTER TABLESPACE name RESET (tablespace_option [, ... ] )`

**Description**

`ALTER TABLESPACE` changes the definition of a tablespace.

You must own the tablespace to use `ALTER TABLESPACE`. To alter the owner, you must also be a direct or indirect member of the new owning role. (Note that superusers have these privileges automatically.)

**Parameters**

- `name`
  - The name of an existing tablespace.
new_name

The new name of the tablespace. The new name cannot begin with `pg_` or `gp_` (reserved for system tablespaces).

new_owner

The new owner of the tablespace.

tablespace_parameter

A tablespace parameter to be set or reset. Currently, the only available parameters are `seq_page_cost` and `random_page_cost`. Setting either value for a particular tablespace will override the planner’s usual estimate of the cost of reading pages from tables in that tablespace, as established by the configuration parameters of the same name (see `seq-page-cost`, `random-page-cost`). This may be useful if one tablespace is located on a disk which is faster or slower than the remainder of the I/O subsystem.

Examples

Rename tablespace `index_space` to `fast_raid`:

```
ALTER TABLESPACE index_space RENAME TO fast_raid;
```

Change the owner of tablespace `index_space`:

```
ALTER TABLESPACE index_space OWNER TO mary;
```

Compatibility

There is no `ALTER TABLESPACE` statement in the SQL standard.

See Also

`CREATE TABLESPACE`, `DROP TABLESPACE`
Parameters

name
The name (optionally schema-qualified) of an existing text search configuration.

token_type
The name of a token type that is emitted by the configuration's parser.

dictionary_name
The name of a text search dictionary to be consulted for the specified token type(s). If multiple dictionaries are listed, they are consulted in the specified order.

old_dictionary
The name of a text search dictionary to be replaced in the mapping.

new_dictionary
The name of a text search dictionary to be substituted for old_dictionary.

new_name
The new name of the text search configuration.

new_owner
The new owner of the text search configuration.

new_schema
The new schema for the text search configuration.

The **ADD MAPPING FOR** form installs a list of dictionaries to be consulted for the specified token type(s); it is an error if there is already a mapping for any of the token types. The **ALTER MAPPING FOR** form does the same, but first removing any existing mapping for those token types. The **ALTER MAPPING REPLACE** forms substitute **new_dictionary** for **old_dictionary** anywhere the latter appears. This is done for only the specified token types when **FOR** appears, or for all mappings of the configuration when it doesn't. The **DROP MAPPING** form removes all dictionaries for the specified token type(s), causing tokens of those types to be ignored by the text search configuration. It is an error if there is no mapping for the token types, unless **IF EXISTS** appears.

Examples

The following example replaces the **english** dictionary with the **swedish** dictionary anywhere that **english** is used within **my_config**.

```
ALTER TEXT SEARCH CONFIGURATION my_config
  ALTER MAPPING REPLACE english WITH swedish;
```

Compatibility

There is no **ALTER TEXT SEARCH CONFIGURATION** statement in the SQL standard.

See Also

**CREATE TEXT SEARCH CONFIGURATION**, **DROP TEXT SEARCH CONFIGURATION**

**ALTER TEXT SEARCH DICTIONARY**

Changes the definition of a text search dictionary.

Synopsis

```
ALTER TEXT SEARCH DICTIONARY name {
```
Description

`ALTER TEXT SEARCH DICTIONARY` changes the definition of a text search dictionary. You can change the dictionary's template-specific options, or change the dictionary's name or owner.

You must be the owner of the dictionary to use `ALTER TEXT SEARCH DICTIONARY`.

Parameters

- **name**
  The name (optionally schema-qualified) of an existing text search dictionary.

- **option**
  The name of a template-specific option to be set for this dictionary.

- **value**
  The new value to use for a template-specific option. If the equal sign and value are omitted, then any previous setting for the option is removed from the dictionary, allowing the default to be used.

- **new_name**
  The new name of the text search dictionary.

- **new_owner**
  The new owner of the text search dictionary.

- **new_schema**
  The new schema for the text search dictionary.

Template-specific options can appear in any order.

Examples

The following example command changes the stopword list for a Snowball-based dictionary. Other parameters remain unchanged.

```
ALTER TEXT SEARCH DICTIONARY my_dict ( StopWords = newrussian );
```

The following example command changes the language option to `dutch`, and removes the stopword option entirely.

```
ALTER TEXT SEARCH DICTIONARY my_dict ( language = dutch, StopWords );
```

The following example command "updates" the dictionary's definition without actually changing anything.

```
ALTER TEXT SEARCH DICTIONARY my_dict ( dummy );
```

(The reason this works is that the option removal code doesn't complain if there is no such option.) This trick is useful when changing configuration files for the dictionary: the ALTER will force existing database sessions to re-read the configuration files, which otherwise they would never do if they had read them earlier.

Compatibility

There is no `ALTER TEXT SEARCH DICTIONARY` statement in the SQL standard.
See Also

CREATE TEXT SEARCH DICTIONARY, DROP TEXT SEARCH DICTIONARY

**ALTER TEXT SEARCH PARSER**

**Description**
Changes the definition of a text search parser.

**Synopsis**

```
ALTER TEXT SEARCH PARSER name RENAME TO new_name
ALTER TEXT SEARCH PARSER name SET SCHEMA new_schema
```

**Description**

ALTER TEXT SEARCH PARSER changes the definition of a text search parser. Currently, the only supported functionality is to change the parser’s name.

You must be a superuser to use ALTER TEXT SEARCH PARSER.

**Parameters**

- `name`
  The name (optionally schema-qualified) of an existing text search parser.

- `new_name`
  The new name of the text search parser.

- `new_schema`
  The new schema for the text search parser.

**Compatibility**

There is no ALTER TEXT SEARCH PARSER statement in the SQL standard.

**See Also**

CREATE TEXT SEARCH PARSER, DROP TEXT SEARCH PARSER

**ALTER TEXT SEARCH TEMPLATE**

**Description**
Changes the definition of a text search template.

**Synopsis**

```
ALTER TEXT SEARCH TEMPLATE name RENAME TO new_name
ALTER TEXT SEARCH TEMPLATE name SET SCHEMA new_schema
```

**Description**

ALTER TEXT SEARCH TEMPLATE changes the definition of a text search parser. Currently, the only supported functionality is to change the parser’s name.

You must be a superuser to use ALTER TEXT SEARCH TEMPLATE.
Parameters

**name**

The name (optionally schema-qualified) of an existing text search template.

**new_name**

The new name of the text search template.

**new_schema**

The new schema for the text search template.

Compatibility

There is no ALTER TEXT SEARCH TEMPLATE statement in the SQL standard.

See Also

CREATE TEXT SEARCH TEMPLATE, DROP TEXT SEARCH TEMPLATE

**ALTER TYPE**

Changes the definition of a data type.

Synopsis

```
ALTER TYPE name action [, ... ]
ALTER TYPE name OWNER TO new_owner
ALTER TYPE name RENAME ATTRIBUTE attribute_name TO new_attribute_name
    [ CASCADE | RESTRICT ]
ALTER TYPE name RENAME TO new_name
ALTER TYPE name SET SCHEMA new_schema
ALTER TYPE name ADD VALUE [ IF NOT EXISTS ] new_enum_value [ { BEFORE | AFTER } existing_enum_value ]
ALTER TYPE name SET DEFAULT ENCODING ( storage_directive )
```

where **action** is one of:

```
ADD ATTRIBUTE attribute_name data_type [ COLLATE collation ] [ CASCADE | RESTRICT ]
DROP ATTRIBUTE [ IF EXISTS ] attribute_name [ CASCADE | RESTRICT ]
ALTER ATTRIBUTE attribute_name [ SET DATA ] TYPE data_type [ COLLATE collation ] [ CASCADE | RESTRICT ]
```

where **storage Directive** is:

```
COMPRESSTYPE={ZLIB | ZSTD | QUICKLZ | RLE_TYPE | NONE}
COMPRESSLEVEL={0-19}
BLOCKSIZE={8192-2097152}
```

Description

**ALTER TYPE** changes the definition of an existing type. There are several subforms:

- **ADD ATTRIBUTE** — Adds a new attribute to a composite type, using the same syntax as CREATE TYPE.
- **DROP ATTRIBUTE [ IF EXISTS ]** — Drops an attribute from a composite type. If IF EXISTS is specified and the attribute does not exist, no error is thrown. In this case a notice is issued instead.
- **SET DATA TYPE** — Changes the type of an attribute of a composite type.
- **OWNER** — Changes the owner of the type.
• **RENAME** — Changes the name of the type or the name of an individual attribute of a composite type.

• **SET SCHEMA** — Moves the type into another schema.

• **ADD VALUE [ IF NOT EXISTS ] [ BEFORE | AFTER ]** — Adds a new value to an enum type. The new value's place in the enum's ordering can be specified as being **BEFORE** or **AFTER** one of the existing values. Otherwise, the new item is added at the end of the list of values.

  If **IF NOT EXISTS** is specified, it is not an error if the type already contains the new value; a notice is issued but no other action is taken. Otherwise, an error will occur if the new value is already present.

• **CASCADE** — Automatically propagate the operation to typed tables of the type being altered, and their descendants.

• **RESTRICT** — Refuse the operation if the type being altered is the type of a typed table. This is the default.

The **ADD ATTRIBUTE**, **DROP ATTRIBUTE**, and **ALTER ATTRIBUTE** actions can be combined into a list of multiple alterations to apply in parallel. For example, it is possible to add several attributes and/or alter the type of several attributes in a single command.

You can change the name, the owner, and the schema of a type. You can also add or update storage options for a scalar type.

  **Note:** Greenplum Database does not support adding storage options for row or composite types.

You must own the type to use **ALTER TYPE**. To change the schema of a type, you must also have **CREATE** privilege on the new schema. To alter the owner, you must also be a direct or indirect member of the new owning role, and that role must have **CREATE** privilege on the type's schema. (These restrictions enforce that altering the owner does not do anything that could be done by dropping and recreating the type. However, a superuser can alter ownership of any type.) To add an attribute or alter an attribute type, you must also have **USAGE** privilege on the data type.

**ALTER TYPE ... ADD VALUE** (the form that adds a new value to an enum type) cannot be executed inside a transaction block.

Comparisons involving an added enum value will sometimes be slower than comparisons involving only original members of the enum type. This will usually only occur if **BEFORE** or **AFTER** is used to set the new value's sort position somewhere other than at the end of the list. However, sometimes it will happen even though the new value is added at the end (this occurs if the OID counter "wrapped around" since the original creation of the enum type). The slowdown is usually insignificant; but if it matters, optimal performance can be regained by dropping and recreating the enum type, or by dumping and reloading the database.

### Parameters

**name**

The name (optionally schema-qualified) of an existing type to alter.

**new_name**

The new name for the type.

**new_owner**

The user name of the new owner of the type.

**new_schema**

The new schema for the type.

**attribute_name**

The name of the attribute to add, alter, or drop.

**new_attribute_name**

The new name of the attribute to be renamed.

**data_type**

The data type of the attribute to add, or the new type of the attribute to alter.
new_enum_value

The new value to be added to an enum type's list of values. Like all enum literals, it needs to be quoted.

existing_enum_value

The existing enum value that the new value should be added immediately before or after in the enum type's sort ordering. Like all enum literals, it needs to be quoted.

storage_directive

Identifies default storage options for the type when specified in a table column definition. Options include COMPRESSTYPE, COMPRESSLEVEL, and BLOCKSIZE.

COMPRESSTYPE — Set to ZLIB (the default), ZSTD, RLE_TYPE, or QUICKLZ\(^1\) to specify the type of compression used.

Note: \(^1\)QuickLZ compression is available only in the commercial release of Pivotal Greenplum Database.

COMPRESSLEVEL — For Zstd compression, set to an integer value from 1 (fastest compression) to 19 (highest compression ratio). For zlib compression, the valid range is from 1 to 9. The QuickLZ compression level can only be set to 1. For RLE_TYPE, the compression level can be set to an integer value from 1 (fastest compression) to 4 (highest compression ratio). The default compression level is 1.

BLOCKSIZE — Set to the size, in bytes, for each block in the column. The BLOCKSIZE must be between 8192 and 2097152 bytes, and be a multiple of 8192. The default block size is 32768.

Note: storage_directives defined at the table- or column-level override the default storage options defined for a type.

Examples

To rename the data type named electronic_mail:

```sql
ALTER TYPE electronic_mail RENAME TO email;
```

To change the owner of the user-defined type email to joe:

```sql
ALTER TYPE email OWNER TO joe;
```

To change the schema of the user-defined type email to customers:

```sql
ALTER TYPE email SET SCHEMA customers;
```

To set or alter the compression type and compression level of the user-defined type named int33:

```sql
ALTER TYPE int33 SET DEFAULT ENCODING (compresstype=zlib, compresslevel=7);
```

To add a new attribute to a type:

```sql
ALTER TYPE compfoo ADD ATTRIBUTE f3 int;
```

To add a new value to an enum type in a particular sort position:

```sql
ALTER TYPE colors ADD VALUE 'orange' AFTER 'red';
```
Compatibility
The variants to add and drop attributes are part of the SQL standard; the other variants are Greenplum Database extensions.

See Also
CREATE TYPE, DROP TYPE

**ALTER USER**

Changes the definition of a database role (user).

Synopsis

```
ALTER USER name RENAME TO newname
ALTER USER name SET config_parameter {TO | =} {value | DEFAULT}
ALTER USER name RESET config_parameter
ALTER USER name RESOURCE QUEUE {queue_name | NONE}
ALTER USER name RESOURCE GROUP {group_name | NONE}
ALTER USER name [ [WITH] option [ ... ] ]
```

where `option` can be:

```
SUPERUSER | NOSUPERUSER
CREATEDB | NOCREATEDB
CREATEROLE | NOCREATEROLE
CREATEUSER | NOCREATEUSER
CREATEEXTABLE | NOCREATEEXTABLE
[ ( attribute='value'[, ...] ) ]
  where attributes and value are:
  type='readable'|'writable'
  protocol='gpfdist'|'http'
INHERIT | NOINHERIT
LOGIN | NOLOGIN
REPLICATION | NOREPLICATION
CONNECTION LIMIT connlimit
[ [ENCRYPTED | UNENCRYPTED] PASSWORD 'password'
VALID UNTIL 'timestamp'
[ DENY deny_point ]
[ DENY BETWEEN deny_point AND deny_point]
[ DROP DENY FOR deny_point ]
```

Description

**ALTER USER** is an alias for **ALTER ROLE**. See **ALTER ROLE** for more information.

Compatibility

The **ALTER USER** statement is a Greenplum Database extension. The SQL standard leaves the definition of users to the implementation.

See Also

**ALTER ROLE**
**ALTER USER MAPPING**

Changes the definition of a user mapping for a foreign server.

**Synopsis**

```
ALTER USER MAPPING FOR { username | USER | CURRENT_USER | PUBLIC }
    SERVER servername
OPTIONS ( [ ADD | SET | DROP ] option ['value'] [, ... ] )
```

**Description**

`ALTER USER MAPPING` changes the definition of a user mapping for a foreign server. The owner of a foreign server can alter user mappings for that server for any user. Also, a user granted `USAGE` privilege on the server can alter a user mapping for their own user name.

**Parameters**

- `username`
  - User name of the mapping. `CURRENT_USER` and `USER` match the name of the current user. `PUBLIC` is used to match all present and future user names in the system.

- `servername`
  - Server name of the user mapping.

- `OPTIONS ( [ ADD | SET | DROP ] option ['value'] [, ... ] )`
  - Change options for the user mapping. The new options override any previously specified options. `ADD`, `SET`, and `DROP` specify the action to perform. If no operation is explicitly specified, the default operation is `ADD`. Option names must be unique. Greenplum Database validates names and values using the server’s foreign-data wrapper.

**Examples**

Change the password for user mapping `bob`, server `foo`:

```
ALTER USER MAPPING FOR bob SERVER foo OPTIONS (SET password 'public');
```

**Compatibility**

`ALTER USER MAPPING` conforms to ISO/IEC 9075-9 (SQL/MED). There is a subtle syntax issue: The standard omits the `FOR` key word. Since both `CREATE USER MAPPING` and `DROP USER MAPPING` use `FOR` in analogous positions, Greenplum Database diverges from the standard here in the interest of consistency and interoperability.

**See Also**

`CREATE USER MAPPING, DROP USER MAPPING`

---

**ALTER VIEW**

Changes properties of a view.
Synopsis

ALTER VIEW [ IF EXISTS ] name ALTER [ COLUMN ] column_name SET
  DEFAULT expression

ALTER VIEW [ IF EXISTS ] name ALTER [ COLUMN ] column_name DROP DEFAULT

ALTER VIEW [ IF EXISTS ] name OWNER TO new_owner

ALTER VIEW [ IF EXISTS ] name RENAME TO new_name

ALTER VIEW [ IF EXISTS ] name SET SCHEMA new_schema

ALTER VIEW [ IF EXISTS ] name SET ( view_option_name [= view_option_value] [, ... ] )

ALTER VIEW [ IF EXISTS ] name RESET ( view_option_name [, ... ] )

Description

ALTER VIEW changes various auxiliary properties of a view. (If you want to modify the view's defining
query, use CREATE OR REPLACE VIEW.

To execute this command you must be the owner of the view. To change a view's schema you must
also have CREATE privilege on the new schema. To alter the owner, you must also be a direct or indirect
member of the new owning role, and that role must have CREATE privilege on the view's schema. These
restrictions enforce that altering the owner does not do anything you could not do by dropping and
recreating the view. However, a superuser can alter ownership of any view.

Parameters

name

The name (optionally schema-qualified) of an existing view.

IF EXISTS

Do not throw an error if the view does not exist. A notice is issued in this case.

SET/DROP DEFAULT

These forms set or remove the default value for a column. A view column's default
value is substituted into any INSERT or UPDATE command whose target is the view,
before applying any rules or triggers for the view. The view's default will therefore take
precedence over any default values from underlying relations.

new_owner

The new owner for the view.

new_name

The new name of the view.

new_schema

The new schema for the view.

SET ( view_option_name [= view_option_value] [, ... ] )
RESET ( view_option_name [, ... ] )

Sets or resets a view option. Currently supported options are:

check_option (string)

Changes the check option of the view. The value must be local or cascaded.

security_barrier (boolean)

Changes the security-barrier property of the view. The value must be a Boolean value,
such as true or false.
Notes
For historical reasons, ALTER TABLE can be used with views, too; however, the only variants of ALTER TABLE that are allowed with views are equivalent to the statements shown above.

Rename the view myview to newview:

```
ALTER VIEW myview RENAME TO newview;
```

Examples
To rename the view foo to bar:

```
ALTER VIEW foo RENAME TO bar;
```

To attach a default column value to an updatable view:

```
CREATE TABLE base_table (id int, ts timestamptz);
CREATE VIEW a_view AS SELECT * FROM base_table;
ALTER VIEW a_view ALTER COLUMN ts SET DEFAULT now();
INSERT INTO base_table(id) VALUES(1);  -- ts will receive a NULL
INSERT INTO a_view(id) VALUES(2);  -- ts will receive the current time
```

Compatibility
ALTER VIEW is a Greenplum Database extension of the SQL standard.

CREATE VIEW, DROP VIEW in the Greenplum Database Utility Guide

ANALYZE
Collects statistics about a database.

Synopsis
```
ANALYZE [VERBOSE] [table [ (column [, ...] ) ]]
ANALYZE [VERBOSE] {root_partition|leaf_partition} [ (column [, ...] )]
ANALYZE [VERBOSE] ROOTPARTITION {ALL | root_partition [ (column [, ...] )]}
```

Description
ANALYZE collects statistics about the contents of tables in the database, and stores the results in the system table pg_statistic. Subsequently, Greenplum Database uses these statistics to help determine the most efficient execution plans for queries. For information about the table statistics that are collected, see Notes.

With no parameter, ANALYZE collects statistics for every table in the current database. You can specify a table name to collect statistics for a single table. You can specify a set of column names, in which case the statistics only for those columns are collected.

ANALYZE does not collect statistics on external tables.

For partitioned tables, ANALYZE collects additional statistics, HyperLogLog (HLL) statistics, on the leaf child partitions. HLL statistics are used are used to derive number of distinct values (NDV) for queries against partitioned tables.
• When aggregating NDV estimates across multiple leaf child partitions, HLL statistics generate a more accurate NDV estimates than the standard table statistics.

• When updating HLL statistics, `ANALYZE` operations are required only on leaf child partitions that have changed. For example, `ANALYZE` is required if the leaf child partition data has changed, or if the leaf child partition has been exchanged with another table. For more information about updating partitioned table statistics, see Notes.

**Important:** If you intend to execute queries on partitioned tables with GPORCA enabled (the default), then you must collect statistics on the root partition of the partitioned table with the `ANALYZE` or `ANALYZE ROOTPARTITION` command. For information about collecting statistics on partitioned tables and when the `ROOTPARTITION` keyword is required, see Notes. For information about GPORCA, see Overview of GPORCA in the Greenplum Database Administrator Guide.

**Note:** You can also use the Greenplum Database utility `analyzedb` to update table statistics. The `analyzedb` utility can update statistics for multiple tables concurrently. The utility can also check table statistics and update statistics only if the statistics are not current or do not exist. For information about the utility, see the Greenplum Database Utility Guide.

**Parameters**

```
{ root_partition | leaf_partition } [ (column [, ...] ) ]
```

Collect statistics for partitioned tables including HLL statistics. HLL statistics are collected only on leaf child partitions.

`ANALYZE root_partition`, collects statistics on all leaf child partitions and the root partition.

`ANALYZE leaf_partition`, collects statistics on the leaf child partition.

By default, if you specify a leaf child partition, and all other leaf child partitions have statistics, `ANALYZE` updates the root partition statistics. If not all leaf child partitions have statistics, `ANALYZE` logs information about the leaf child partitions that do not have statistics. For information about when root partition statistics are collected, see Notes.

**ROOTPARTITION [ALL]**

Collect statistics only on the root partition of partitioned tables based on the data in the partitioned table. If possible, `ANALYZE` uses leaf child partition statistics to generate root partition statistics. Otherwise, `ANALYZE` collects the statistics by sampling leaf child partition data. Statistics are not collected on the leaf child partitions, the data is only sampled. HLL statistics are not collected.

For information about when the `ROOTPARTITION` keyword is required, see Notes.

When you specify `ROOTPARTITION`, you must specify either `ALL` or the name of a partitioned table.

If you specify `ALL` with `ROOTPARTITION`, Greenplum Database collects statistics for the root partition of all partitioned tables in the database. If there are no partitioned tables in the database, a message stating that there are no partitioned tables is returned. For tables that are not partitioned tables, statistics are not collected.

If you specify a table name with `ROOTPARTITION` and the table is not a partitioned table, no statistics are collected for the table and a warning message is returned.

The `ROOTPARTITION` clause is not valid with `VACUUM ANALYZE`. The command `VACUUM ANALYZE ROOTPARTITION` returns an error.

The time to run `ANALYZE ROOTPARTITION` is similar to the time to analyze a non-partitioned table with the same data since `ANALYZE ROOTPARTITION` only samples the leaf child partition data.

For the partitioned table `sales_curr_yr`, this example command collects statistics only on the root partition of the partitioned table. `ANALYZE ROOTPARTITION sales_curr_yr;`
This example `ANALYZE` command collects statistics on the root partition of all the partitioned tables in the database.

```
ANALYZE ROOTPARTITION ALL;
```

**VERBOSE**

Enables display of progress messages. Enables display of progress messages. When specified, `ANALYZE` emits this information

- The table that is being processed.
- The query that is executed to generate the sample table.
- The column for which statistics is being computed.
- The queries that are issued to collect the different statistics for a single column.
- The statistics that are collected.

**table**

The name (possibly schema-qualified) of a specific table to analyze. If omitted, all regular tables (but not foreign tables) in the current database are analyzed.

**column**

The name of a specific column to analyze. Defaults to all columns.

**Notes**

Foreign tables are analyzed only when explicitly selected. Not all foreign data wrappers support `ANALYZE`. If the table’s wrapper does not support `ANALYZE`, the command prints a warning and does nothing.

It is a good idea to run `ANALYZE` periodically, or just after making major changes in the contents of a table. Accurate statistics helps Greenplum Database choose the most appropriate query plan, and thereby improve the speed of query processing. A common strategy for read-mostly databases is to run `VACUUM` and `ANALYZE` once a day during a low-usage time of day. (This will not be sufficient if there is heavy update activity.) You can check for tables with missing statistics using the `gp_stats_missing` view, which is in the `gp_toolkit` schema:

```
SELECT * from gp_toolkit.gp_stats_missing;
```

`ANALYZE` requires `SHARE UPDATE EXCLUSIVE` lock on the target table. This lock conflicts with these locks: `SHARE UPDATE EXCLUSIVE, SHARE, SHARE ROW EXCLUSIVE, EXCLUSIVE, ACCESS EXCLUSIVE`.

If you run `ANALYZE` on a table that does not contain data, statistics are not collected for the table. For example, if you perform a `TRUNCATE` operation on a table that has statistics, and then run `ANALYZE` on the table, the statistics do not change.

For a partitioned table, specifying which portion of the table to analyze, the root partition or subpartitions (leaf child partition tables) can be useful if the partitioned table has a large number of partitions that have been analyzed and only a few leaf child partitions have changed.

**Note:** When you create a partitioned table with the `CREATE TABLE` command, Greenplum Database creates the table that you specify (the root partition or parent table), and also creates a hierarchy of tables based on the partition hierarchy that you specified (the child tables).

- When you run `ANALYZE` on the root partitioned table, statistics are collected for all the leaf child partitions. Leaf child partitions are the lowest-level tables in the hierarchy of child tables created by Greenplum Database for use by the partitioned table.
- When you run `ANALYZE` on a leaf child partition, statistics are collected only for that leaf child partition and the root partition. If data in the leaf partition has changed (for example, you made significant updates to the leaf child partition data or you exchanged the leaf child partition), then you can run
ANALYZE on the leaf child partition to collect table statistics. By default, if all other leaf child partitions have statistics, the command updates the root partition statistics.

For example, if you collected statistics on a partitioned table with a large number of partitions and then updated data in only a few leaf child partitions, you can run `ANALYZE` only on those partitions to update statistics on the partitions and the statistics on the root partition.

- When you run `ANALYZE` on a child table that is not a leaf child partition, statistics are not collected.

For example, you can create a partitioned table with partitions for the years 2006 to 2016 and subpartitions for each month in each year. If you run `ANALYZE` on the child table for the year 2013 no statistics are collected. If you run `ANALYZE` on the leaf child partition for March of 2013, statistics are collected only for that leaf child partition.

For a partitioned table that contains a leaf child partition that has been exchanged to use an external table, `ANALYZE` does not collect statistics for the external table partition:

- If `ANALYZE` is run on an external table partition, the partition is not analyzed.
- If `ANALYZE` or `ANALYZE` `ROOTPARTITION` is run on the root partition, external table partitions are not sampled and root table statistics do not include external table partition.
- If the `VERBOSE` clause is specified, an informational message is displayed: skipping external table.

The Greenplum Database server configuration parameter `optimizer_analyze_root_partition` affects when statistics are collected on the root partition of a partitioned table. If the parameter is on (the default), the `ROOTPARTITION` keyword is not required to collect statistics on the root partition when you run `ANALYZE`. Root partition statistics are collected when you run `ANALYZE` on the root partition, or when you run `ANALYZE` on a child leaf partition of the partitioned table and the other child leaf partitions have statistics. If the parameter is off, you must run `ANALYZE` `ROOTPARTITION` to collect root partition statistics.

The statistics collected by `ANALYZE` usually include a list of some of the most common values in each column and a histogram showing the approximate data distribution in each column. One or both of these may be omitted if `ANALYZE` deems them uninteresting (for example, in a unique-key column, there are no common values) or if the column data type does not support the appropriate operators.

For large tables, `ANALYZE` takes a random sample of the table contents, rather than examining every row. This allows even very large tables to be analyzed in a small amount of time. Note, however, that the statistics are only approximate, and will change slightly each time `ANALYZE` is run, even if the actual table contents did not change. This may result in small changes in the planner's estimated costs shown by `EXPLAIN`. In rare situations, this non-determinism will cause the query optimizer to choose a different query plan between runs of `ANALYZE`. To avoid this, raise the amount of statistics collected by `ANALYZE` by adjusting the `default_statistics_target` configuration parameter, or on a column-by-column basis by setting the per-column statistics target with `ALTER TABLE ... ALTER COLUMN ... SET (n_distinct ...)` (see `ALTER TABLE`). The target value sets the maximum number of entries in the most-common-value list and the maximum number of bins in the histogram. The default target value is 100, but this can be adjusted up or down to trade off accuracy of planner estimates against the time taken for `ANALYZE` and the amount of space occupied in `pg_statistic`. In particular, setting the statistics target to zero disables collection of statistics for that column. It may be useful to do that for columns that are never used as part of the `WHERE`, `GROUP` BY, or `ORDER` BY clauses of queries, since the planner will have no use for statistics on such columns.

The largest statistics target among the columns being analyzed determines the number of table rows sampled to prepare the statistics. Increasing the target causes a proportional increase in the time and space needed to do `ANALYZE`.

One of the values estimated by `ANALYZE` is the number of distinct values that appear in each column. Because only a subset of the rows are examined, this estimate can sometimes be quite inaccurate, even with the largest possible statistics target. If this inaccuracy leads to bad query plans, a more accurate value can be determined manually and then installed with `ALTER TABLE ... ALTER COLUMN ... SET STATISTICS DISTINCT` (see `ALTER TABLE`).

```sql
ALTER TABLE ... ALTER COLUMN ... SET STATISTICS DISTINCT;
```
When Greenplum Database performs an `ANALYZE` operation to collect statistics for a table and detects that all the sampled table data pages are empty (do not contain valid data), Greenplum Database displays a message that a `VACUUM FULL` operation should be performed. If the sampled pages are empty, the table statistics will be inaccurate. Pages become empty after a large number of changes to the table, for example deleting a large number of rows. A `VACUUM FULL` operation removes the empty pages and allows an `ANALYZE` operation to collect accurate statistics.

If there are no statistics for the table, the server configuration parameter `gp_enable_relsize_collection` controls whether the Postgres Planner uses a default statistics file or estimates the size of a table using the `pg_relation_size` function. By default, the Postgres Planner uses the default statistics file to estimate the number of rows if statistics are not available.

**Examples**

Collect statistics for the table `mytable`:

```
ANALYZE mytable;
```

**Compatibility**

There is no `ANALYZE` statement in the SQL standard.

**See Also**

`ALTER TABLE`, `EXPLAIN`, `VACUUM`, `analyzedb` utility in the *Greenplum Database Utility Guide*.

**BEGIN**

Starts a transaction block.

**Synopsis**

```
BEGIN [WORK | TRANSACTION] [transaction_mode]
```

where `transaction_mode` is:

```
ISOLATION LEVEL {READ UNCOMMITTED | READ COMMITTED | REPEATABLE READ | SERIALIZABLE}
READ WRITE | READ ONLY
[ NOT ] DEFERRABLE
```

**Description**

`BEGIN` initiates a transaction block, that is, all statements after a `BEGIN` command will be executed in a single transaction until an explicit `COMMIT` or `ROLLBACK` is given. By default (without `BEGIN`), Greenplum Database executes transactions in autocommit mode, that is, each statement is executed in its own transaction and a commit is implicitly performed at the end of the statement (if execution was successful, otherwise a rollback is done).

Statements are executed more quickly in a transaction block, because transaction start/commit requires significant CPU and disk activity. Execution of multiple statements inside a transaction is also useful to ensure consistency when making several related changes: other sessions will be unable to see the intermediate states wherein not all the related updates have been done.

If the isolation level, read/write mode, or deferrable mode is specified, the new transaction has those characteristics, as if `SET TRANSACTION` was executed.
Parameters

**WORK**
**TRANSACTION**

Optional key words. They have no effect.

**SERIALIZABLE**
**READ COMMITTED**
**READ UNCOMMITTED**

The SQL standard defines four transaction isolation levels: READ UNCOMMITTED, READ COMMITTED, REPEATABLE READ, and SERIALIZABLE.

**READ UNCOMMITTED** allows transactions to see changes made by uncommitted concurrent transactions. This is not possible in Greenplum Database, so **READ UNCOMMITTED** is treated the same as **READ COMMITTED**.

**READ COMMITTED**, the default isolation level in Greenplum Database, guarantees that a statement can only see rows committed before it began. The same statement executed twice in a transaction can produce different results if another concurrent transaction commits after the statement is executed the first time.

The **REPEATABLE READ** isolation level guarantees that a transaction can only see rows committed before it began. **REPEATABLE READ** is the strictest transaction isolation level Greenplum Database supports. Applications that use the **REPEATABLE READ** isolation level must be prepared to retry transactions due to serialization failures.

The **SERIALIZABLE** transaction isolation level guarantees that executing multiple concurrent transactions produces the same effects as running the same transactions one at a time. If you specify **SERIALIZABLE**, Greenplum Database falls back to **REPEATABLE READ**.

Specifying **DEFERRABLE** has no effect in Greenplum Database, but the syntax is supported for compatibility with PostgreSQL. A transaction can only be deferred if it is **READ ONLY** and **SERIALIZABLE**, and Greenplum Database does not support **SERIALIZABLE** transactions.

Notes

**START TRANSACTION** has the same functionality as **BEGIN**.

Use **COMMIT** or **ROLLBACK** to terminate a transaction block.

Issuing **BEGIN** when already inside a transaction block will provoke a warning message. The state of the transaction is not affected. To nest transactions within a transaction block, use savepoints (see **SAVEPOINT**).

Examples

To begin a transaction block:

```sql
BEGIN;
```

To begin a transaction block with the repeatable read isolation level:

```sql
BEGIN TRANSACTION ISOLATION LEVEL REPEATABLE READ;
```

Compatibility

**BEGIN** is a Greenplum Database language extension. It is equivalent to the SQL-standard command **START TRANSACTION**.

**DEFERRABLE transaction_mode** is a Greenplum Database language extension.
Incidentally, the **BEGIN** key word is used for a different purpose in embedded SQL. You are advised to be careful about the transaction semantics when porting database applications.

**See Also**

COMMIT, ROLLBACK, START TRANSACTION, SAVEPOINT

### CHECKPOINT

Forces a transaction log checkpoint.

**Synopsis**

```
CHECKPOINT
```

**Description**

A checkpoint is a point in the transaction log sequence at which all data files have been updated to reflect the information in the log. All data files will be flushed to disk.

The **CHECKPOINT** command forces an immediate checkpoint when the command is issued, without waiting for a regular checkpoint scheduled by the system. **CHECKPOINT** is not intended for use during normal operation.

If executed during recovery, the **CHECKPOINT** command will force a restartpoint rather than writing a new checkpoint.

Only superusers may call **CHECKPOINT**.

**Compatibility**

The **CHECKPOINT** command is a Greenplum Database extension.

### CLOSE

Closes a cursor.

**Synopsis**

```
CLOSE cursor_name
```

**Description**

**CLOSE** frees the resources associated with an open cursor. After the cursor is closed, no subsequent operations are allowed on it. A cursor should be closed when it is no longer needed.

Every non-holdable open cursor is implicitly closed when a transaction is terminated by **COMMIT** or **ROLLBACK**. A holdable cursor is implicitly closed if the transaction that created it aborts via **ROLLBACK**. If the creating transaction successfully commits, the holdable cursor remains open until an explicit **CLOSE** is executed, or the client disconnects.

**Parameters**

`cursor_name`

The name of an open cursor to close.
Notes
Greenplum Database does not have an explicit `OPEN` cursor statement. A cursor is considered open when it is declared. Use the `DECLARE` statement to declare (and open) a cursor.
You can see all available cursors by querying the `pg_cursors` system view.
If a cursor is closed after a savepoint which is later rolled back, the `CLOSE` is not rolled back; that is the cursor remains closed.

Examples
Close the cursor `portala`:

```
CLOSE portala;
```

Compatibility
`CLOSE` is fully conforming with the SQL standard.

See Also
`DECLARE`, `FETCH`, `MOVE`

**CLUSTER**

Physically reorders a heap storage table on disk according to an index. Not a recommended operation in Greenplum Database.

Synopsis

```
CLUSTER indexname ON tablename

CLUSTER [VERBOSE] tablename

CLUSTER [VERBOSE]
```

Description

`CLUSTER` orders a heap storage table based on an index. `CLUSTER` is not supported on append-optimized storage tables. Clustering an index means that the records are physically ordered on disk according to the index information. If the records you need are distributed randomly on disk, then the database has to seek across the disk to get the records requested. If those records are stored more closely together, then the fetching from disk is more sequential. A good example for a clustered index is on a date column where the data is ordered sequentially by date. A query against a specific date range will result in an ordered fetch from the disk, which leverages faster sequential access.

Clustering is a one-time operation: when the table is subsequently updated, the changes are not clustered. That is, no attempt is made to store new or updated rows according to their index order. If you wish, you can periodically recluster by issuing the command again. Setting the table’s `FILLFACTOR` storage parameter to less than 100% can aid in preserving cluster ordering during updates, because updated rows are kept on the same page if enough space is available there.

When a table is clustered using this command, Greenplum Database remembers on which index it was clustered. The form `CLUSTER tablename` reclusters the table on the same index that it was clustered before. You can use the `CLUSTER` or `SET WITHOUT CLUSTER` forms of `ALTER TABLE` to set the index to use for future cluster operations, or to clear any previous setting. `CLUSTER` without any parameter reclusters all previously clustered tables in the current database that the calling user owns, or all tables if called by a superuser. This form of `CLUSTER` cannot be executed inside a transaction block.
When a table is being clustered, an **ACCESS EXCLUSIVE** lock is acquired on it. This prevents any other database operations (both reads and writes) from operating on the table until the **CLUSTER** is finished.

**Parameters**

*indexname*

The name of an index.

**VERBOSE**

Prints a progress report as each table is clustered.

*tablename*

The name (optionally schema-qualified) of a table.

**Notes**

In cases where you are accessing single rows randomly within a table, the actual order of the data in the table is unimportant. However, if you tend to access some data more than others, and there is an index that groups them together, you will benefit from using **CLUSTER**. If you are requesting a range of indexed values from a table, or a single indexed value that has multiple rows that match, **CLUSTER** will help because once the index identifies the table page for the first row that matches, all other rows that match are probably already on the same table page, and so you save disk accesses and speed up the query.

**CLUSTER** can re-sort the table using either an index scan on the specified index, or (if the index is a b-tree) a sequential scan followed by sorting. It will attempt to choose the method that will be faster, based on planner cost parameters and available statistical information.

When an index scan is used, a temporary copy of the table is created that contains the table data in the index order. Temporary copies of each index on the table are created as well. Therefore, you need free space on disk at least equal to the sum of the table size and the index sizes.

When a sequential scan and sort is used, a temporary sort file is also created, so that the peak temporary space requirement is as much as double the table size, plus the index sizes. This method is often faster than the index scan method, but if the disk space requirement is intolerable, you can disable this choice by temporarily setting the `enable_sort` configuration parameter to `off`.

It is advisable to set `maintenance_work_mem` configuration parameter to a reasonably large value (but not more than the amount of RAM you can dedicate to the **CLUSTER** operation) before clustering.

Because the query optimizer records statistics about the ordering of tables, it is advisable to run **ANALYZE** on the newly clustered table. Otherwise, the planner may make poor choices of query plans.

Because **CLUSTER** remembers which indexes are clustered, you can cluster the tables you want clustered manually the first time, then set up a periodic maintenance script that executes **CLUSTER** without any parameters, so that the desired tables are periodically reclustered.

**Note:** **CLUSTER** is not supported with append-optimized tables.

**Examples**

Cluster the table **employees** on the basis of its index **emp_ind**:

```
CLUSTER emp_ind ON emp;
```

Cluster a large table by recreating it and loading it in the correct index order:

```
CREATE TABLE newtable AS SELECT * FROM table ORDER BY column;
DROP table;
ALTER TABLE newtable RENAME TO table;
CREATE INDEX column_ix ON table (column);
VACUUM ANALYZE table;
```
Compatibility

There is no `CLUSTER` statement in the SQL standard.

See Also

`CREATE TABLE AS`, `CREATE INDEX`

**COMMENT**

Defines or changes the comment of an object.

**Synopsis**

```
COMMENT ON
    { TABLE object_name |
    COLUMN relation_name.column_name |
    AGGREGATE agg_name (agg_signature) |
    CAST (source_type AS target_type) |
    COLLATION object_name |
    CONSTRAINT constraint_name ON table_name |
    CONVERSION object_name |
    DATABASE object_name |
    DOMAIN object_name |
    EXTENSION object_name |
    FOREIGN DATA WRAPPER object_name |
    FOREIGN TABLE object_name |
    FUNCTION func_name ([[argmode] [argname] argtype [, ...]]) |
    INDEX object_name |
    LARGE OBJECT large_object oid |
    OPERATOR operator_name (left_type, right_type) |
    OPERATOR CLASS object_name USING index_method |
    [PROCEDURAL] LANGUAGE object_name |
    RESOURCE GROUP object_name |
    RESOURCE QUEUE object_name |
    ROLE object_name |
    RULE rule_name ON table_name |
    SCHEMA object_name |
    SEQUENCE object_name |
    SERVER object_name |
    TABLESPACE object_name |
    TRIGGER trigger_name ON table_name |
    TYPE object_name |
    VIEW object_name }
IS 'text'
```

where `agg_signature` is:

```
* |
[ [argmode] [argname] argtype [, ...] ]
[ [argmode] [argname] argtype [, ...] ] ORDER BY [argmode] [argname]
argtype [, ...]
```

**Description**

`COMMENT` stores a comment about a database object. Only one comment string is stored for each object. To remove a comment, write `NULL` in place of the text string. Comments are automatically dropped when the object is dropped.

For most kinds of object, only the object's owner can set the comment. Roles don't have owners, so the rule for `COMMENT ON ROLE` is that you must be superuser to comment on a superuser role, or have the
**CREATEROLE** privilege to comment on non-superuser roles. Of course, a superuser can comment on anything.

Comments can be easily retrieved with the `psql` meta-commands `\dd`, `\d+`, and `\l+`. Other user interfaces to retrieve comments can be built atop the same built-in functions that `psql` uses, namely `obj_description`, `col_description`, and `shobj_description`.

**Parameters**

- `object_name`  
  The name of the object to be commented. Names of tables, aggregates, collations, conversions, domains, foreign tables, functions, indexes, operators, operator classes, operator families, sequences, text search objects, types, and views can be schema-qualified. When commenting on a column, `relation_name` must refer to a table, view, composite type, or foreign table.

  **Note:** Greenplum Database does not support triggers.

- `relation_name.column_name`  
  The name of the source data type of the cast.

- `source_type`  
  The name of the target data type of the cast.

- `target_type`  
  The mode of a function or aggregate argument: either IN, OUT, INOUT, or VARIADIC. If omitted, the default is IN. Note that `COMMENT` does not actually pay any attention to OUT arguments, since only the input arguments are needed to determine the function's identity. So it is sufficient to list the IN, INOUT, and VARIADIC arguments.

- `argname`  
  The name of a function or aggregate argument. Note that `COMMENT` does not actually pay any attention to argument names, since only the argument data types are needed to determine the function's identity.

- `argtype`  
  The data type of a function or aggregate argument.

- `large_object_oid`  
  The OID of the large object.

  **Note:** Greenplum Database does not support the PostgreSQL large object facility for streaming user data that is stored in large-object structures.

- `left_type`  
  The data type(s) of the operator's arguments (optionally schema-qualified). Write `NONE` for the missing argument of a prefix or postfix operator.

- `right_type`  
  This is a noise word.

- `text`  
  The new comment, written as a string literal; or `NULL` to drop the comment.
Notes

There is presently no security mechanism for viewing comments: any user connected to a database can see all the comments for objects in that database. For shared objects such as databases, roles, and tablespaces, comments are stored globally so any user connected to any database in the cluster can see all the comments for shared objects. Therefore, do not put security-critical information in comments.

Examples

Attach a comment to the table `mytable`:

```sql
COMMENT ON TABLE mytable IS 'This is my table.';
```

Remove it again:

```sql
COMMENT ON TABLE mytable IS NULL;
```

Some more examples:

```sql
COMMENT ON AGGREGATE my_aggregate (double precision) IS 'Computes sample variance';
COMMENT ON CAST (text AS int4) IS 'Allow casts from text to int4';
COMMENT ON COLLATION "fr_CA" IS 'Canadian French';
COMMENT ON COLUMN my_table.my_column IS 'Employee ID number';
COMMENT ON CONVERSION my_conv IS 'Conversion to UTF8';
COMMENT ON CONSTRAINT bar_col_cons ON bar IS 'Constrains column col';
COMMENT ON DATABASE my_database IS 'Development Database';
COMMENT ON DOMAIN my_domain IS 'Email Address Domain';
COMMENT ON EXTENSION hstore IS 'implements the hstore data type';
COMMENT ON FOREIGN DATA WRAPPER mywrapper IS 'my foreign data wrapper';
COMMENT ON FOREIGN TABLE my_foreign_table IS 'Employee Information in other database';
COMMENT ON FUNCTION my_function (timestamp) IS 'Returns Roman Numeral';
COMMENT ON INDEX my_index IS 'Enforces uniqueness on employee ID';
COMMENT ON LANGUAGE plpython IS 'Python support for stored procedures';
COMMENT ON LARGE OBJECT 346344 IS 'Planning document';
COMMENT ON OPERATOR ^ (text, text) IS 'Performs intersection of two texts';
COMMENT ON OPERATOR - (NONE, integer) IS 'Unary minus';
COMMENT ON OPERATOR CLASS int4ops USING btree IS '4 byte integer operators for btrees';
COMMENT ON OPERATOR FAMILY integer_ops USING btree IS 'all integer operators for btrees';
COMMENT ON ROLE my_role IS 'Administration group for finance tables';
COMMENT ON RULE my_rule ON my_table IS 'Logs updates of employee records';
COMMENT ON SCHEMA my_schema IS 'Departmental data';
COMMENT ON SEQUENCE my_sequence IS 'Used to generate primary keys';
COMMENT ON SERVER myserver IS 'my foreign server';
COMMENT ON TABLE my_schema.my_table IS 'Employee Information';
COMMENT ON TABLESPACE my_tablespace IS 'Tablespace for indexes';
COMMENT ON TEXT SEARCH CONFIGURATION my_config IS 'Special word filtering';
COMMENT ON TEXT SEARCH DICTIONARY swedish IS 'Snowball stemmer for Swedish language';
COMMENT ON TEXT SEARCH PARSER my_parser IS 'Splits text into words';
COMMENT ON TEXT SEARCH TEMPLATE snowball IS 'Snowball stemmer';
COMMENT ON TRIGGER my_trigger ON my_table IS 'Used for RI';
COMMENT ON TYPE complex IS 'Complex number data type';
COMMENT ON VIEW my_view IS 'View of departmental costs';
```

Compatibility

There is no `COMMENT` statement in the SQL standard.
**COMMIT**

Commits the current transaction.

**Synopsis**

```
COMMIT [WORK | TRANSACTION]
```

**Description**

COMMIT commits the current transaction. All changes made by the transaction become visible to others and are guaranteed to be durable if a crash occurs.

**Parameters**

- **WORK**
- **TRANSACTION**

Optional key words. They have no effect.

**Notes**

Use **ROLLBACK** to abort a transaction.

Issuing **COMMIT** when not inside a transaction does no harm, but it will provoke a warning message.

**Examples**

To commit the current transaction and make all changes permanent:

```
COMMIT;
```

**Compatibility**

The SQL standard only specifies the two forms **COMMIT** and **COMMIT WORK**. Otherwise, this command is fully conforming.

**See Also**

**BEGIN, END, START TRANSACTION, ROLLBACK**

**COPY**

Copies data between a file and a table.

**Synopsis**

```
COPY table_name [((column_name [, ...])] FROM {filename | PROGRAM 'command' | STDIN)
   [ [ WITH ] (option [, ...] ) ]
   [ ON SEGMENT ]
COPY {table_name [((column_name [, ...])] | (query)} TO {filename | PROGRAM 'command' | STDOUT)
   [ [ WITH ] (option [, ...] ) ]
   [ ON SEGMENT ]
```
where option can be one of:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>

<tr>
<td>IGNORE EXTERNAL PARTITIONS</td>
<td></td>
</tr>
</tbody>
</table>

**Description**

COPY moves data between Greenplum Database tables and standard file-system files. COPY TO copies the contents of a table to a file (or multiple files based on the segment ID if copying ON SEGMENT), while COPY FROM copies data from a file to a table (appending the data to whatever is in the table already). COPY TO can also copy the results of a SELECT query.

If a list of columns is specified, COPY will only copy the data in the specified columns to or from the file. If there are any columns in the table that are not in the column list, COPY FROM will insert the default values for those columns.

COPY with a file name instructs the Greenplum Database master host to directly read from or write to a file. The file must be accessible to the master host and the name must be specified from the viewpoint of the master host.

When COPY is used with the ON SEGMENT clause, the COPY TO causes segments to create individual segment-oriented files, which remain on the segment hosts. The filename argument for ON SEGMENT takes the string literal <SEGID> (required) and uses either the absolute path or the <SEG_DATA_DIR> string literal. When the COPY operation is run, the segment IDs and the paths of the segment data directories are substituted for the string literal values.

Using COPY TO with a replicated table (DISTRIBUTED REPLICATED) as source creates a file with rows from a single segment so that the target file contains no duplicate rows. Using COPY TO with the ON SEGMENT clause with a replicated table as source creates target files on segment hosts containing all table rows.

The ON SEGMENT clause allows you to copy table data to files on segment hosts for use in operations such as migrating data between clusters or performing a backup. Segment data created by the ON SEGMENT clause can be restored by tools such as gpfdist, which is useful for high speed data loading.

**Warning:** Use of the ON SEGMENT clause is recommended for expert users only.

When PROGRAM is specified, the server executes the given command and reads from the standard output of the program, or writes to the standard input of the program. The command must be specified from the viewpoint of the server, and be executable by the gpadmin user.

When STDIN or STDOUT is specified, data is transmitted via the connection between the client and the master. STDIN and STDOUT cannot be used with the ON SEGMENT clause.

If SEGMENT REJECT LIMIT is used, then a COPY FROM operation will operate in single row error isolation mode. In this release, single row error isolation mode only applies to rows in the input file with format errors — for example, extra or missing attributes, attributes of a wrong data type, or invalid client encoding sequences. Constraint errors such as violation of a NOT NULL, CHECK, or UNIQUE constraint will still be handled in 'all-or-nothing' input mode. The user can specify the number of error rows acceptable (on a per-
segment basis), after which the entire COPY FROM operation will be aborted and no rows will be loaded. The count of error rows is per-segment, not per entire load operation. If the per-segment reject limit is not reached, then all rows not containing an error will be loaded and any error rows discarded. To keep error rows for further examination, specify the LOG ERRORS clause to capture error log information. The error information and the row is stored internally in Greenplum Database.

Outputs
On successful completion, a COPY command returns a command tag of the form, where count is the number of rows copied:

```
COPY count
```

If running a COPY FROM command in single row error isolation mode, the following notice message will be returned if any rows were not loaded due to format errors, where count is the number of rows rejected:

```
NOTICE: Rejected count badly formatted rows.
```

Parameters

table_name
The name (optionally schema-qualified) of an existing table.

column_name
An optional list of columns to be copied. If no column list is specified, all columns of the table will be copied.

When copying in text format, the default, a row of data in a column of type bytea can be up to 256MB.

query
A SELECT or VALUES command whose results are to be copied. Note that parentheses are required around the query.

filename
The path name of the input or output file. An input file name can be an absolute or relative path, but an output file name must be an absolute path. Windows users might need to use an E'' string and double any backslashes used in the path name.

PROGRAM 'command'
Specify a command to execute. In COPY FROM, the input is read from standard output of the command, and in COPY TO, the output is written to the standard input of the command. The command must be specified from the viewpoint of the Greenplum Database master host system, and must be executable by the Greenplum Database administrator user (gpadmin).

The command is invoked by a shell. When passing arguments to the shell, strip or escape any special characters that have a special meaning for the shell. For security reasons, it is best to use a fixed command string, or at least avoid passing any user input in the string.

When ON SEGMENT is specified, the command must be executable on all Greenplum Database primary segment hosts by the Greenplum Database administrator user (gpadmin). The command is executed by each Greenplum segment instance. The <SEGID> is required in the command.

See the ON SEGMENT clause for information about command syntax requirements and the data that is copied when the clause is specified.

STDIN
Specifies that input comes from the client application. The ON SEGMENT clause is not supported with STDIN.
STDOUT

Specifies that output goes to the client application. The ON SEGMENT clause is not supported with STDOUT.

boolean

Specifies whether the selected option should be turned on or off. You can write TRUE, ON, or 1 to enable the option, and FALSE, OFF, or 0 to disable it. The boolean value can also be omitted, in which case TRUE is assumed.

FORMAT

Selects the data format to be read or written: text, csv (Comma Separated Values), or binary. The default is text.

OIDS

Specifies copying the OID for each row. (An error is raised if OIDS is specified for a table that does not have OIDs, or in the case of copying a query.)

FREEZE

Requests copying the data with rows already frozen, just as they would be after running the VACUUM FREEZE command. This is intended as a performance option for initial data loading. Rows will be frozen only if the table being loaded has been created or truncated in the current subtransaction, there are no cursors open, and there are no older snapshots held by this transaction.

Note that all other sessions will immediately be able to see the data once it has been successfully loaded. This violates the normal rules of MVCC visibility and users specifying this option should be aware of the potential problems this might cause.

DELIMITER

Specifies the character that separates columns within each row (line) of the file. The default is a tab character in text format, a comma in CSV format. This must be a single one-byte character. This option is not allowed when using binary format.

NULL

Specifies the string that represents a null value. The default is \N (backslash-N) in text format, and an unquoted empty string in CSV format. You might prefer an empty string even in text format for cases where you don't want to distinguish nulls from empty strings. This option is not allowed when using binary format.

Note: When using COPY FROM, any data item that matches this string will be stored as a null value, so you should make sure that you use the same string as you used with COPY TO.

HEADER

Specifies that a file contains a header line with the names of each column in the file. On output, the first line contains the column names from the table, and on input, the first line is ignored. This option is allowed only when using CSV format.

QUOTE

Specifies the quoting character to be used when a data value is quoted. The default is double-quote. This must be a single one-byte character. This option is allowed only when using CSV format.

ESCAPE

Specifies the character that should appear before a data character that matches the QUOTE value. The default is the same as the QUOTE value (so that the quoting character is doubled if it appears in the data). This must be a single one-byte character. This option is allowed only when using CSV format.

FORCE_QUOTE
Forces quoting to be used for all non-NULL values in each specified column. NULL output is never quoted. If * is specified, non-NULL values will be quoted in all columns. This option is allowed only in COPY TO, and only when using CSV format.

**FORCE_NOT_NULL**

Do not match the specified columns' values against the null string. In the default case where the null string is empty, this means that empty values will be read as zero-length strings rather than nulls, even when they are not quoted. This option is allowed only in COPY FROM, and only when using CSV format.

**ENCODING**

Specifies that the file is encoded in the `encoding_name`. If this option is omitted, the current client encoding is used. See the Notes below for more details.

**ON SEGMENT**

Specify individual, segment data files on the segment hosts. Each file contains the table data that is managed by the primary segment instance. For example, when copying data to files from a table with a COPY TO...ON SEGMENT command, the command creates a file on the segment host for each segment instance on the host. Each file contains the table data that is managed by the segment instance.

The COPY command does not copy data from or to mirror segment instances and segment data files.

The keywords STDIN and STDOUT are not supported with ON SEGMENT.

The `<SEG_DATA_DIR>` and `<SEGID>` string literals are used to specify an absolute path and file name with the following syntax:

```
COPY table [TO|FROM] '<SEG_DATA_DIR>/gpdumpname<SEGID>_suffix' ON SEGMENT;
```

**<SEG_DATA_DIR>**

The string literal representing the absolute path of the segment instance data directory for ON SEGMENT copying. The angle brackets (< and >) are part of the string literal used to specify the path. COPY replaces the string literal with the segment path(s) when COPY is run. An absolute path can be used in place of the `<SEG_DATA_DIR>` string literal.

**<SEGID>**

The string literal representing the content ID number of the segment instance to be copied when copying ON SEGMENT. `<SEGID>` is a required part of the file name when ON SEGMENT is specified. The angle brackets are part of the string literal used to specify the file name.

With COPY TO, the string literal is replaced by the content ID of the segment instance when the COPY command is run.

With COPY FROM, specify the segment instance content ID in the name of the file and place that file on the segment instance host. There must be a file for each primary segment instance on each host. When the COPY FROM command is run, the data is copied from the file to the segment instance.

When the PROGRAM command clause is specified, the `<SEGID>` string literal is required in the command, the `<SEG_DATA_DIR>` string literal is optional. See Examples.

For a COPY FROM...ON SEGMENT command, the table distribution policy is checked when data is copied into the table. By default, an error is returned if a data row violates the table distribution policy. You can disable the distribution policy check with the server configuration parameter `gp_enable_segment_copy_checking`. See Notes.
Specifies the newline used in your data files — LF (Line feed, 0x0A), CR (Carriage return, 0x0D), or CRLF (Carriage return plus line feed, 0x0D 0x0A). If not specified, a Greenplum Database segment will detect the newline type by looking at the first row of data it receives and using the first newline type encountered.

**CSV**

Selects Comma Separated Value (CSV) mode. See [CSV Format](#).

**FILL MISSING FIELDS**

In COPY FROM more for both TEXT and CSV, specifying FILL MISSING FIELDS will set missing trailing field values to NULL (instead of reporting an error) when a row of data has missing data fields at the end of a line or row. Blank rows, fields with a NOT NULL constraint, and trailing delimiters on a line will still report an error.

**LOG ERRORS**

This is an optional clause that can precede a SEGMENT REJECT LIMIT clause to capture error log information about rows with formatting errors.

Error log information is stored internally and is accessed with the Greenplum Database built-in SQL function gp_read_error_log().

See [Notes](#) for information about the error log information and built-in functions for viewing and managing error log information.

**SEGMENT REJECT LIMIT count [ROWS | PERCENT]**

Runs a COPY FROM operation in single row error isolation mode. If the input rows have format errors they will be discarded provided that the reject limit count is not reached on any Greenplum Database segment instance during the load operation. The reject limit count can be specified as number of rows (the default) or percentage of total rows (1-100).

If PERCENT is used, each segment starts calculating the bad row percentage only after the number of rows specified by the parameter gp_reject_percent_threshold has been processed. The default for gp_reject_percent_threshold is 300 rows. Constraint errors such as violation of a NOT NULL, CHECK, or UNIQUE constraint will still be handled in 'all-or-nothing' input mode. If the limit is not reached, all good rows will be loaded and any error rows discarded.

**Note:** Greenplum Database limits the initial number of rows that can contain formatting errors if the SEGMENT REJECT LIMIT is not triggered first or is not specified. If the first 1000 rows are rejected, the COPY operation is stopped and rolled back.

The limit for the number of initial rejected rows can be changed with the Greenplum Database server configuration parameter `gp_initial_bad_row_limit`. See [Server Configuration Parameters](#) for information about the parameter.

**IGNORE EXTERNAL PARTITIONS**

When copying data from partitioned tables, data are not copied from leaf child partitions that are external tables. A message is added to the log file when data are not copied.

If this clause is not specified and Greenplum Database attempts to copy data from a leaf child partition that is an external table, an error is returned.

See the next section "Notes" for information about specifying an SQL query to copy data from leaf child partitions that are external tables.

**Notes**

COPY can only be used with tables, not with external tables or views. However, you can write COPY (SELECT * FROM viewname) TO ...
COPY only deals with the specific table named; it does not copy data to or from child tables. Thus for example COPY table TO shows the same data as SELECT * FROM ONLY table. But COPY (SELECT * FROM table) TO ... can be used to dump all of the data in an inheritance hierarchy.

Similarly, to copy data from a partitioned table with a leaf child partition that is an external table, use an SQL query to select the data to copy. For example, if the table my_sales contains a leaf child partition that is an external table, this command COPY my_sales TO stdout returns an error. This command sends the data to stdout:

```
COPY (SELECT * FROM my_sales) TO stdout
```

The BINARY keyword causes all data to be stored/read as binary format rather than as text. It is somewhat faster than the normal text mode, but a binary-format file is less portable across machine architectures and Greenplum Database versions. Also, you cannot run COPY FROM in single row error isolation mode if the data is in binary format.

You must have SELECT privilege on the table whose values are read by COPY TO, and INSERT privilege on the table into which values are inserted by COPY FROM. It is sufficient to have column privileges on the columns listed in the command.

Files named in a COPY command are read or written directly by the database server, not by the client application. Therefore, they must reside on or be accessible to the Greenplum Database master host machine, not the client. They must be accessible to and readable or writable by the Greenplum Database system user (the user ID the server runs as), not the client. Only database superusers are permitted to name files with COPY, because this allows reading or writing any file that the server has privileges to access.

COPY FROM will invoke any triggers and check constraints on the destination table. However, it will not invoke rewrite rules. Note that in this release, violations of constraints are not evaluated for single row error isolation mode.

COPY input and output is affected by DateStyle. To ensure portability to other Greenplum Database installations that might use non-default DateStyle settings, DateStyle should be set to ISO before using COPY TO. It is also a good idea to avoid dumping data with IntervalStyle set to sql_standard, because negative interval values might be misinterpreted by a server that has a different setting for IntervalStyle.

Input data is interpreted according to ENCODING option or the current client encoding, and output data is encoded in ENCODING or the current client encoding, even if the data does not pass through the client but is read from or written to a file directly by the server.

When copying XML data from a file in text mode, the server configuration parameter xmloption affects the validation of the XML data that is copied. If the value is content (the default), XML data is validated as an XML content fragment. If the parameter value is document, XML data is validated as an XML document. If the XML data is not valid, COPY returns an error.

By default, COPY stops operation at the first error. This should not lead to problems in the event of a COPY TO, but the target table will already have received earlier rows in a COPY FROM. These rows will not be visible or accessible, but they still occupy disk space. This may amount to a considerable amount of wasted disk space if the failure happened well into a large COPY FROM operation. You may wish to invoke VACUUM to recover the wasted space. Another option would be to use single row error isolation mode to filter out error rows while still loading good rows.

When a COPY FROM...ON SEGMENT command is run, the server configuration parameter gp_enable_segment_copy_checking controls whether the table distribution policy (from the table DISTRIBUTED clause) is checked when data is copied into the table. The default is to check the distribution policy. An error is returned if the row of data violates the distribution policy for the segment instance. For information about the parameter, see Server Configuration Parameters.

Data from a table that is generated by a COPY TO...ON SEGMENT command can be used to restore table data with COPY FROM...ON SEGMENT. However, data restored to the segments is distributed according
to the table distribution policy at the time the files were generated with the COPY TO command. The COPY command might return table distribution policy errors, if you attempt to restore table data and the table distribution policy was changed after the COPY FROM...ON SEGMENT was run.

**Note:** If you run COPY FROM...ON SEGMENT and the server configuration parameter gp_enable_segment_copy_checking is false, manual redistribution of table data might be required. See the ALTER TABLE clause with REORGANIZE.

When you specify the LOG ERRORS clause, Greenplum Database captures errors that occur while reading the external table data. You can view and manage the captured error log data.

- Use the built-in SQL function `gp_read_error_log('table_name')`. It requires SELECT privilege on `table_name`. This example displays the error log information for data loaded into table `ext_expenses` with a COPY command:

  ```sql
  SELECT * from gp_read_error_log('ext_expenses');
  ```

  For information about the error log format, see Viewing Bad Rows in the Error Log in the Greenplum Database Administrator Guide.

  The function returns FALSE if `table_name` does not exist.

- If error log data exists for the specified table, the new error log data is appended to existing error log data. The error log information is not replicated to mirror segments.

- Use the built-in SQL function `gp_truncate_error_log('table_name')` to delete the error log data for `table_name`. It requires the table owner privilege. This example deletes the error log information captured when moving data into the table `ext_expenses`:

  ```sql
  SELECT gp_truncate_error_log('ext_expenses');
  ```

  The function returns FALSE if `table_name` does not exist.

Specify the * wildcard character to delete error log information for existing tables in the current database. Specify the string *.* to delete all database error log information, including error log information that was not deleted due to previous database issues. If * is specified, database owner privilege is required. If *.* is specified, operating system super-user privilege is required.

When a Greenplum Database user who is not a superuser runs a COPY command, the command can be controlled by a resource queue. The resource queue must be configured with the ACTIVE_STATEMENTS parameter that specifies a maximum limit on the number of queries that can be executed by roles assigned to that queue. Greenplum Database does not apply a cost value or memory value to a COPY command, resource queues with only cost or memory limits do not affect the running of COPY commands.

A non-superuser can run only these types of COPY commands:

- COPY FROM command where the source is stdin
- COPY TO command where the destination is stdout

For information about resource queues, see "Resource Management with Resource Queues" in the Greenplum Database Administrator Guide.

### File Formats

File formats supported by COPY.

#### Text Format

When the text format is used, the data read or written is a text file with one line per table row. Columns in a row are separated by the delimiter_character (tab by default). The column values themselves are strings generated by the output function, or acceptable to the input function, of each attribute's data type. The specified null string is used in place of columns that are null. COPY FROM will raise an error if any line of the input file contains more or fewer columns than are expected. If OIDS is specified, the OID is read or written as the first column, preceding the user data columns.
The data file has two reserved characters that have special meaning to `COPY`:

- The designated delimiter character (tab by default), which is used to separate fields in the data file.
- A UNIX-style line feed (`\n` or `0x0a`), which is used to designate a new row in the data file. It is strongly recommended that applications generating `COPY` data convert data line feeds to UNIX-style line feeds rather than Microsoft Windows style carriage return line feeds (`\r\n` or `0x0a 0x0d`).

If your data contains either of these characters, you must escape the character so `COPY` treats it as data and not as a field separator or new row.

By default, the escape character is a \ (backslash) for text-formatted files and a " (double quote) for csv-formatted files. If you want to use a different escape character, you can do so using the `ESCAPE AS` clause. Make sure to choose an escape character that is not used anywhere in your data file as an actual data value. You can also disable escaping in text-formatted files by using `ESCAPE 'OFF'`.

For example, suppose you have a table with three columns and you want to load the following three fields using `COPY`.

- percentage sign = %
- vertical bar = |
- backslash = \n
Your designated `delimiter_character` is | (pipe character), and your designated `escape` character is * (asterisk). The formatted row in your data file would look like this:

```
percentage sign = % | vertical bar = *| | backslash = \n```

Notice how the pipe character that is part of the data has been escaped using the asterisk character (*). Also notice that we do not need to escape the backslash since we are using an alternative escape character.

The following characters must be preceded by the escape character if they appear as part of a column value: the escape character itself, newline, carriage return, and the current delimiter character. You can specify a different escape character using the `ESCAPE AS` clause.

**CSV Format**

This format option is used for importing and exporting the Comma Separated Value (CSV) file format used by many other programs, such as spreadsheets. Instead of the escaping rules used by Greenplum Database standard text format, it produces and recognizes the common CSV escaping mechanism.

The values in each record are separated by the `DELIMITER` character. If the value contains the delimiter character, the `QUOTE` character, the `ESCAPE` character (which is double quote by default), the `NULL` string, a carriage return, or line feed character, then the whole value is prefixed and suffixed by the `QUOTE` character. You can also use `FORCE_QUOTE` to force quotes when outputting non-`NULL` values in specific columns.

The CSV format has no standard way to distinguish a `NULL` value from an empty string. Greenplum Database `COPY` handles this by quoting. A `NULL` is output as the `NULL` parameter string and is not quoted, while a non-`NULL` value matching the `NULL` string is quoted. For example, with the default settings, a `NULL` is written as an unquoted empty string, while an empty string data value is written with double quotes (" "). Reading values follows similar rules. You can use `FORCE_NOT_NULL` to prevent `NULL` input comparisons for specific columns.

Because backslash is not a special character in the CSV format, \. the end-of-data marker, could also appear as a data value. To avoid any misinterpretation, a \. data value appearing as a lone entry on a line is automatically quoted on output, and on input, if quoted, is not interpreted as the end-of-data marker. If you are loading a file created by another application that has a single unquoted column and might have a value of \. you might need to quote that value in the input file.

**Note:** In CSV format, all characters are significant. A quoted value surrounded by white space, or any characters other than `DELIMITER`, will include those characters. This can cause errors if you
import data from a system that pads CSV lines with white space out to some fixed width. If such a situation arises you might need to preprocess the CSV file to remove the trailing white space, before importing the data into Greenplum Database.

**CSV** format will both recognize and produce CSV files with quoted values containing embedded carriage returns and line feeds. Thus the files are not strictly one line per table row like text-format files

**Note:** Many programs produce strange and occasionally perverse CSV files, so the file format is more a convention than a standard. Thus you might encounter some files that cannot be imported using this mechanism, and COPY might produce files that other programs cannot process.

**Binary Format**

The **binary** format option causes all data to be stored/read as binary format rather than as text. It is somewhat faster than the text and **csv** formats, but a binary-format file is less portable across machine architectures and Greenplum Database versions. Also, the binary format is very data type specific; for example it will not work to output binary data from a smallint column and read it into an integer column, even though that would work fine in text format.

The binary file format consists of a file header, zero or more tuples containing the row data, and a file trailer. Headers and data are in network byte order.

- **File Header** — The file header consists of 15 bytes of fixed fields, followed by a variable-length header extension area. The fixed fields are:
  - **Signature** — 11-byte sequence PGCOPY\n\n\n\n\n\n— note that the zero byte is a required part of the signature. (The signature is designed to allow easy identification of files that have been munged by a non-8-bit-clean transfer. This signature will be changed by end-of-line-translation filters, dropped zero bytes, dropped high bits, or parity changes.)
  - **Flags field** — 32-bit integer bit mask to denote important aspects of the file format. Bits are numbered from 0 (LSB) to 31 (MSB). Note that this field is stored in network byte order (most significant byte first), as are all the integer fields used in the file format. Bits 16-31 are reserved to denote critical file format issues; a reader should abort if it finds an unexpected bit set in this range. Bits 0-15 are reserved to signal backwards-compatible format issues; a reader should simply ignore any unexpected bits set in this range. Currently only one flag is defined, and the rest must be zero (Bit 16: 1 if data has OIDs, 0 if not).
  - **Header extension area length** — 32-bit integer, length in bytes of remainder of header, not including self. Currently, this is zero, and the first tuple follows immediately. Future changes to the format might allow additional data to be present in the header. A reader should silently skip over any header extension data it does not know what to do with. The header extension area is envisioned to contain a sequence of self-identifying chunks. The flags field is not intended to tell readers what is in the extension area. Specific design of header extension contents is left for a later release.
  - **Tuples** — Each tuple begins with a 16-bit integer count of the number of fields in the tuple. (Presently, all tuples in a table will have the same count, but that might not always be true.) Then, repeated for each field in the tuple, there is a 32-bit length word followed by that many bytes of field data. (The length word does not include itself, and can be zero.) As a special case, -1 indicates a NULL field value. No value bytes follow in the NULL case.

There is no alignment padding or any other extra data between fields.

Presently, all data values in a binary-format file are assumed to be in binary format (format code one). It is anticipated that a future extension may add a header field that allows per-column format codes to be specified.

If OIDs are included in the file, the OID field immediately follows the field-count word. It is a normal field except that it is not included in the field-count. In particular it has a length word — this will allow handling of 4-byte vs. 8-byte OIDs without too much pain, and will allow OIDs to be shown as null if that ever proves desirable.

- **File Trailer** — The file trailer consists of a 16-bit integer word containing -1. This is easily distinguished from a tuple's field-count word. A reader should report an error if a field-count word is neither -1 nor the
expected number of columns. This provides an extra check against somehow getting out of sync with the data.

**Examples**

Copy a table to the client using the vertical bar (|) as the field delimiter:

```
COPY country TO STDOUT (DELIMITER '|');
```

Copy data from a file into the `country` table:

```
COPY country FROM '/home/usr1/sql/country_data';
```

Copy into a file just the countries whose names start with 'A':

```
COPY (SELECT * FROM country WHERE country_name LIKE 'A%') TO
'/home/usr1/sql/a_list_countries.copy';
```

Copy data from a file into the `sales` table using single row error isolation mode and log errors:

```
COPY sales FROM '/home/usr1/sql/sales_data' LOG ERRORS
SEGMENT REJECT LIMIT 10 ROWS;
```

To copy segment data for later use, use the `ON SEGMENT` clause. Use of the `COPY TO ON SEGMENT` command takes the form:

```
COPY table TO '<SEG_DATA_DIR>/gpbackup<SEGID>.txt' ON SEGMENT;
```

The `<SEGID>` is required. However, you can substitute an absolute path for the `<SEG_DATA_DIR>` string literal in the path.

When you pass in the string literal `<SEG_DATA_DIR>` and `<SEGID>` to `COPY`, `COPY` will fill in the appropriate values when the operation is run.

For example, if you have `mytable` with the segments and mirror segments like this:

<table>
<thead>
<tr>
<th>contentid</th>
<th>dbid</th>
<th>file segment location</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>1</td>
<td>/home/usr1/data1/gpsegdir0</td>
</tr>
<tr>
<td>0</td>
<td>3</td>
<td>/home/usr1/data_mirror1/gpsegdir0</td>
</tr>
<tr>
<td>1</td>
<td>4</td>
<td>/home/usr1/data2/gpsegdir1</td>
</tr>
<tr>
<td>1</td>
<td>2</td>
<td>/home/usr1/data_mirror2/gpsegdir1</td>
</tr>
</tbody>
</table>

running the command:

```
COPY mytable TO '<SEG_DATA_DIR>/gpbackup<SEGID>.txt' ON SEGMENT;
```

would result in the following files:

```
/home/usr1/data1/gpsegdir0/gpbackup0.txt
/home/usr1/data2/gpsegdir1/gpbackup1.txt
```

The content ID in the first column is the identifier inserted into the file path (for example, `gpsegdir0/gpbackup0.txt` above) Files are created on the segment hosts, rather than on the master, as they would be in a standard `COPY` operation. No data files are created for the mirror segments when using `ON SEGMENT` copying.

If an absolute path is specified, instead of `<SEG_DATA_DIR>`, such as in the statement

```
COPY mytable TO '/tmp/gpdir/gpbackup_<SEGID>.txt' ON SEGMENT;
```
files would be placed in /tmp/gpdir on every segment. The gpfdist tool can also be used to restore data files generated with COPY TO with the ON SEGMENT option if redistribution is necessary.

Note: Tools such as gpfdist can be used to restore data. The backup/restore tools will not work with files that were manually generated with COPY TO ON SEGMENT.

This example uses a SELECT statement to copy data to files on each segment:

```sql
COPY (SELECT * FROM testtbl) TO '/tmp/mytst<SEGID>' ON SEGMENT;
```

This example copies the data from the lineitem table and uses the PROGRAM clause to add the data to the /tmp/lineitem_program.csv file with cat utility. The file is placed on the Greenplum Database master.

```sql
COPY LINEITEM TO PROGRAM 'cat > /tmp/lineitem.csv' CSV;
```

This example uses the PROGRAM and ON SEGMENT clauses to copy data to files on the segment hosts. On the segment hosts, the COPY command replaces <SEGID> with the segment content ID to create a file for each segment instance on the segment host.

```sql
COPY LINEITEM TO PROGRAM 'cat > /tmp/lineitem_program<SEGID>.csv' ON SEGMENT CSV;
```

This example uses the PROGRAM and ON SEGMENT clauses to copy data from files on the segment hosts. The COPY command replaces <SEGID> with the segment content ID when copying data from the files. On the segment hosts, there must be a file for each segment instance where the file name contains the segment content ID on the segment host.

```sql
COPY LINEITEM_4 FROM PROGRAM 'cat /tmp/lineitem_program<SEGID>.csv' ON SEGMENT CSV;
```

**Compatibility**

There is no COPY statement in the SQL standard.

The following syntax was used in earlier versions of Greenplum Database and is still supported:

```sql
COPY table_name [(column_name [, ...])] FROM {filename | PROGRAM 'command' | STDIN) [ [WITH] [ON SEGMENT] [BINARY] [OIDS] [HEADER] [DELIMITER [ AS ] 'delimiter_character'] [NULL [ AS ] 'null string'] [ESCAPE [ AS ] 'escape' | 'OFF'] [NEWLINE [ AS ] 'LF' | 'CR' | 'CRLF'] [CSV [QUOTE [ AS ] 'quote'] [FORCE NOT NULL column_name [, ...]] [FILL MISSING FIELDS] [LOG ERRORS] [SEGMENT REJECT LIMIT count [ROWS | PERCENT] ]
COPY { table_name [(column_name [, ...])] | (query)} TO {filename | PROGRAM 'command' | STDOUT) [ [WITH] [ON SEGMENT] [BINARY] [OIDS] [HEADER]
```
Note that in this syntax, `BINARY` and `CSV` are treated as independent keywords, not as arguments of a `FORMAT` option.

**See Also**

`CREATE EXTERNAL TABLE`

**CREATE AGGREGATE**

Defines a new aggregate function.

**Synopsis**

```sql
```

```sql
```

or the old syntax

```sql
CREATE AGGREGATE name ( BASETYPE = base_type, SFUNC = statefunc, STYPE = state_data_type [, SSPACE = state_data_size ]
```
CREATE AGGREGATE defines a new aggregate function. Some basic and commonly-used aggregate functions such as `count`, `min`, `max`, `sum`, `avg` and so on are already provided in Greenplum Database. If you define new types or need an aggregate function not already provided, you can use CREATE AGGREGATE to provide the desired features.

If a schema name is given (for example, CREATE AGGREGATE myschema.myagg ...) then the aggregate function is created in the specified schema. Otherwise it is created in the current schema.

An aggregate function is identified by its name and input data types. Two aggregate functions in the same schema can have the same name if they operate on different input types. The name and input data types of an aggregate function must also be distinct from the name and input data types of every ordinary function in the same schema. This behavior is identical to overloading of ordinary function names. See CREATE FUNCTION.

A simple aggregate function is made from one, two, or three ordinary functions (which must be IMMUTABLE functions):

- a state transition function `statefunc`
- an optional final calculation function `ffunc`
- an optional combine function `combinefunc`

These functions are used as follows:

- `statefunc( internal-state, next-data-values ) ---> next-internal-state`
- `ffunc( internal-state ) ---> aggregate-value`
- `combinefunc( internal-state, internal-state ) ---> next-internal-state`

Greenplum Database creates a temporary variable of data type `state_data_type` to hold the current internal state of the aggregate function. At each input row, the aggregate argument values are calculated and the state transition function is invoked with the current state value and the new argument values to calculate a new internal state value. After all the rows have been processed, the final function is invoked once to calculate the aggregate return value. If there is no final function then the ending state value is returned as-is.

**Note:** If you write a user-defined aggregate in C, and you declare the state value (`state_data_type`) as type `internal`, there is a risk of an out-of-memory error occurring. If `internal` state values are not properly managed and a query acquires too much memory for state values, an out-of-memory error could occur. To prevent this, use `mpool_alloc(mpool, size)` to have Greenplum manage and allocate memory for non-temporary state values, that is, state values that have a lifespan for the entire aggregation. The argument `mpool` of the `mpool_alloc()` function is `aggstate->hhashtable->group_buf`. For an example, see the implementation of the numeric data type aggregates in `src/backend/utils/adt/numeric.c` in the Greenplum Database open source code.
You can specify `combinefunc` as a method for optimizing aggregate execution. By specifying `combinefunc`, the aggregate can be executed in parallel on segments first and then on the master. When a two-level execution is performed, the `statefunc` is executed on the segments to generate partial aggregate results, and `combinefunc` is executed on the master to aggregate the partial results from segments. If single-level aggregation is performed, all the rows are sent to the master and the `statefunc` is applied to the rows.

Single-level aggregation and two-level aggregation are equivalent execution strategies. Either type of aggregation can be implemented in a query plan. When you implement the functions `combinefunc` and `statefunc`, you must ensure that the invocation of the `statefunc` on the segment instances followed by `combinefunc` on the master produce the same result as single-level aggregation that sends all the rows to the master and then applies only the `statefunc` to the rows.

An aggregate function can provide an optional initial condition, an initial value for the internal state value. This is specified and stored in the database as a value of type `text`, but it must be a valid external representation of a constant of the state value data type. If it is not supplied then the state value starts out NULL.

If `statefunc` is declared `STRICT`, then it cannot be called with `NULL` inputs. With such a transition function, aggregate execution behaves as follows. Rows with any null input values are ignored (the function is not called and the previous state value is retained). If the initial state value is `NULL`, then at the first row with all non-null input values, the first argument value replaces the state value, and the transition function is invoked at subsequent rows with all non-null input values. This is useful for implementing aggregates like `max`. Note that this behavior is only available when `state_data_type` is the same as the first `arg_data_type`. When these types are different, you must supply a non-null initial condition or use a nonstrict transition function.

If `statefunc` is not declared `STRICT`, then it will be called unconditionally at each input row, and must deal with `NULL` inputs and `NULL` state values for itself. This allows the aggregate author to have full control over the aggregate's handling of `NULL` values.

If the final function (`ffunc`) is declared `STRICT`, then it will not be called when the ending state value is `NULL`; instead a `NULL` result will be returned automatically. (This is the normal behavior of `STRICT` functions.) In any case the final function has the option of returning a `NULL` value. For example, the final function for `avg` returns `NULL` when it sees there were zero input rows.

Sometimes it is useful to declare the final function as taking not just the state value, but extra parameters corresponding to the aggregate's input values. The main reason for doing this is if the final function is polymorphic and the state value's data type would be inadequate to pin down the result type. These extra parameters are always passed as `NULL` (and so the final function must not be strict when the `FINALFUNC_EXTRA` option is used), but nonetheless they are valid parameters. The final function could for example make use of `get_fn_expr_argtype` to identify the actual argument type in the current call.

An aggregate can optionally support moving-aggregate mode, as described in Moving-Aggregate Mode in the PostgreSQL documentation. This requires specifying the `msfunc`, `mminvfunc`, and `mstype` functions, and optionally the `mspace`, `mfinalfunc`, `mfinalfunc_extra`, and `minitcond` functions. Except for `mminvfunc`, these functions work like the corresponding simple-aggregate functions without `m`; they define a separate implementation of the aggregate that includes an inverse transition function.

The syntax with `ORDER BY` in the parameter list creates a special type of aggregate called an ordered-set aggregate; or if `HYPOTHETICAL` is specified, then a hypothetical-set aggregate is created. These aggregates operate over groups of sorted values in order-dependent ways, so that specification of an input sort order is an essential part of a call. Also, they can have `direct` arguments, which are arguments that are evaluated only once per aggregation rather than once per input row. Hypothetical-set aggregates are a subclass of ordered-set aggregates in which some of the direct arguments are required to match, in number and data types, the aggregated argument columns. This allows the values of those direct arguments to be added to the collection of aggregate-input rows as an additional "hypothetical" row.

Single argument aggregate functions, such as `min` or `max`, can sometimes be optimized by looking into an index instead of scanning every input row. If this aggregate can be so optimized, indicate it by specifying a
**sort operator**. The basic requirement is that the aggregate must yield the first element in the sort ordering induced by the operator; in other words:

```
SELECT agg(col) FROM tab;
```

must be equivalent to:

```
SELECT col FROM tab ORDER BY col USING sortop LIMIT 1;
```

Further assumptions are that the aggregate function ignores NULL inputs, and that it delivers a NULL result if and only if there were no non-null inputs. Ordinarily, a data type’s < operator is the proper sort operator for MIN, and > is the proper sort operator for MAX. Note that the optimization will never actually take effect unless the specified operator is the "less than" or "greater than" strategy member of a B-tree index operator class.

To be able to create an aggregate function, you must have USAGE privilege on the argument types, the state type(s), and the return type, as well as EXECUTE privilege on the transition and final functions.

### Parameters

**name**

The name (optionally schema-qualified) of the aggregate function to create.

**argmode**

The mode of an argument: IN or VARIADIC. (Aggregate functions do not support OUT arguments.) If omitted, the default is IN. Only the last argument can be marked VARIADIC.

**argname**

The name of an argument. This is currently only useful for documentation purposes. If omitted, the argument has no name.

**arg_data_type**

An input data type on which this aggregate function operates. To create a zero-argument aggregate function, write * in place of the list of argument specifications. (An example of such an aggregate is count(*).)

**base_type**

In the old syntax for `CREATE AGGREGATE`, the input data type is specified by a `basetype` parameter rather than being written next to the aggregate name. Note that this syntax allows only one input parameter. To define a zero-argument aggregate function with this syntax, specify the `basetype` as "ANY" (not *). Ordered-set aggregates cannot be defined with the old syntax.

**statefunc**

The name of the state transition function to be called for each input row. For a normal N-argument aggregate function, the state transition function `statefunc` must take N+1 arguments, the first being of type `state_data_type` and the rest matching the declared input data types of the aggregate. The function must return a value of type `state_data_type`. This function takes the current state value and the current input data values, and returns the next state value.

For ordered-set (including hypothetical-set) aggregates, the state transition function `statefunc` receives only the current state value and the aggregated arguments, not the direct arguments. Otherwise it is the same.

**state_data_type**

The data type for the aggregate's state value.

**state_data_size**
The approximate average size (in bytes) of the aggregate’s state value. If this parameter is omitted or is zero, a default estimate is used based on the \textit{state\_data\_type}. The planner uses this value to estimate the memory required for a grouped aggregate query. Large values of this parameter discourage use of hash aggregation.

\textbf{ffunc}

The name of the final function called to compute the aggregate result after all input rows have been traversed. The function must take a single argument of type \textit{state\_data\_type}. The return data type of the aggregate is defined as the return type of this function. If \textit{ffunc} is not specified, then the ending state value is used as the aggregate result, and the return type is \textit{state\_data\_type}.

For ordered-set (including hypothetical-set) aggregates, the final function receives not only the final state value, but also the values of all the direct arguments.

If \texttt{FINALFUNC\_EXTRA} is specified, then in addition to the final state value and any direct arguments, the final function receives extra NULL values corresponding to the aggregate’s regular (aggregated) arguments. This is mainly useful to allow correct resolution of the aggregate result type when a polymorphic aggregate is being defined.

\textbf{combinefunc}

The name of a combine function. This is a function of two arguments, both of type \textit{state\_data\_type}. It must return a value of \textit{state\_data\_type}. A combine function takes two transition state values and returns a new transition state value representing the combined aggregation. In Greenplum Database, if the result of the aggregate function is computed in a segment mode, the combine function is invoked on the individual internal states in order to combine them into an ending internal state.

Note that this function is called in hash aggregate mode within a segment. Therefore, if you call this aggregate function without a combine function, hash aggregate is never chosen. Since hash aggregate is efficient, consider defining a combine function whenever possible.

\textbf{serialfunc}

An aggregate function whose \textit{state\_data\_type} is \texttt{internal} can participate in parallel aggregation only if it has a \texttt{serialfunc} function, which must serialize the aggregate state into a \texttt{bytea} value for transmission to another process. This function must take a single argument of type \texttt{internal} and return type \texttt{bytea}. A corresponding \texttt{deserialfunc} is also required.

\textbf{deserialfunc}

Deserializes a previously serialized aggregate state back into \textit{state\_data\_type}. This function must take two arguments of types \texttt{bytea} and \texttt{internal}, and produce a result of type \texttt{internal}. (Note: the second, \texttt{internal} argument is unused, but is required for type safety reasons.)

\textbf{initial\_condition}

The initial setting for the state value. This must be a string constant in the form accepted for the data type \textit{state\_data\_type}. If not specified, the state value starts out null.

\textbf{msfunc}

The name of the forward state transition function to be called for each input row in moving-aggregate mode. This is exactly like the regular transition function, except that its first argument and result are of type \textit{mstate\_data\_type}, which might be different from \textit{state\_data\_type}.

\textbf{minvfunc}

The name of the inverse state transition function to be used in moving-aggregate mode. This function has the same argument and result types as \texttt{msfunc}, but it is used to remove a value from the current aggregate state, rather than add a value to it. The inverse
transition function must have the same strictness attribute as the forward state transition function.

**mstate_data_type**

The data type for the aggregate's state value, when using moving-aggregate mode.

**mstate_data_size**

The approximate average size (in bytes) of the aggregate's state value, when using moving-aggregate mode. This works the same as `state_data_size`.

**mffunc**

The name of the final function called to compute the aggregate's result after all input rows have been traversed, when using moving-aggregate mode. This works the same as `ffunc`, except that its first argument's type is `mstate_data_type` and extra dummy arguments are specified by writing `MFINALFUNC_EXTRA`. The aggregate result type determined by `mffunc` or `mstate_data_type` must match that determined by the aggregate's regular implementation.

**minitial_condition**

The initial setting for the state value, when using moving-aggregate mode. This works the same as `initial_condition`.

**sort_operator**

The associated sort operator for a `MIN`- or `MAX`-like aggregate. This is just an operator name (possibly schema-qualified). The operator is assumed to have the same input data types as the aggregate (which must be a single-argument normal aggregate).

**HYPOTHETICAL**

For ordered-set aggregates only, this flag specifies that the aggregate arguments are to be processed according to the requirements for hypothetical-set aggregates: that is, the last few direct arguments must match the data types of the aggregated (`WITHIN GROUP`) arguments. The `HYPOTHETICAL` flag has no effect on run-time behavior, only on parse-time resolution of the data types and collations of the aggregate's arguments.

**Notes**

The ordinary functions used to define a new aggregate function must be defined first. Note that in this release of Greenplum Database, it is required that the `statefunc`, `ffunc`, and `combinefunc` functions used to create the aggregate are defined as `IMMUTABLE`.

If the value of the Greenplum Database server configuration parameter `gp_enable_multiphase_agg` is `off`, only single-level aggregation is performed.

Any compiled code (shared library files) for custom functions must be placed in the same location on every host in your Greenplum Database array (master and all segments). This location must also be in the `LD_LIBRARY_PATH` so that the server can locate the files.

In previous versions of Greenplum Database, there was a concept of ordered aggregates. Since version 6, any aggregate can be called as an ordered aggregate, using the syntax:

```
name ( arg [ , ... ] [ORDER BY sortspec [ , ...]] )
```

The `ORDERED` keyword is accepted for backwards compatibility, but is ignored.

In previous versions of Greenplum Database, the `COMBINEFUNC` option was called `PREFUNC`. It is still accepted for backwards compatibility, as a synonym for `COMBINEFUNC`.

**Example**

The following simple example creates an aggregate function that computes the sum of two columns.
Before creating the aggregate function, create two functions that are used as the statefunc and combinefunc functions of the aggregate function.

This function is specified as the statefunc function in the aggregate function.

```sql
CREATE FUNCTION mysfunc_accum(numeric, numeric, numeric) 
  RETURNS numeric 
  AS 'select $1 + $2 + $3'
  LANGUAGE SQL
  IMMUTABLE
  RETURNS NULL ON NULL INPUT;
```

This function is specified as the combinefunc function in the aggregate function.

```sql
CREATE FUNCTION mycombine_accum(numeric, numeric) 
  RETURNS numeric 
  AS 'select $1 + $2'
  LANGUAGE SQL
  IMMUTABLE
  RETURNS NULL ON NULL INPUT;
```

This `CREATE AGGREGATE` command creates the aggregate function that adds two columns.

```sql
CREATE AGGREGATE agg_prefunc(numeric, numeric) (
  SFUNC = mysfunc_accum,
  STYPE = numeric,
  COMBINEFUNC = mycombine_accum,
  INITCOND = 0);
```

The following commands create a table, adds some rows, and runs the aggregate function.

```sql
create table t1 (a int, b int) DISTRIBUTED BY (a);
insert into t1 values
  (10, 1),
  (20, 2),
  (30, 3);
select agg_prefunc(a, b) from t1;
```

This `EXPLAIN` command shows two phase aggregation.

```sql
explain select agg_prefunc(a, b) from t1;
```

```
QUERY PLAN

-------------------------------------------------------------------------
Aggregate (cost=1.10..1.11 rows=1 width=32) 
  -> Gather Motion 2:1 (slice1; segments: 2) (cost=1.04..1.08 rows=1 width=32) 
    -> Aggregate (cost=1.04..1.05 rows=1 width=32) 
      -> Seq Scan on t1 (cost=0.00..1.03 rows=2 width=8) 
(4 rows)
```

**Compatibility**

`CREATE AGGREGATE` is a Greenplum Database language extension. The SQL standard does not provide for user-defined aggregate functions.

**See Also**

`ALTER AGGREGATE, DROP AGGREGATE, CREATE FUNCTION`
**CREATE CAST**

Defines a new cast.

**Synopsis**

```
CREATE CAST (sourcetype AS targettype)
    WITH FUNCTION funcname (argtype [, ...])
    [AS ASSIGNMENT | AS IMPLICIT]

CREATE CAST (sourcetype AS targettype)
    WITHOUT FUNCTION
    [AS ASSIGNMENT | AS IMPLICIT]

CREATE CAST (sourcetype AS targettype)
    WITH INOUT
    [AS ASSIGNMENT | AS IMPLICIT]
```

**Description**

CREATE CAST defines a new cast. A cast specifies how to perform a conversion between two data types. For example,

```
SELECT CAST(42 AS float8);
```

converts the integer constant 42 to type float8 by invoking a previously specified function, in this case float8(int4). If no suitable cast has been defined, the conversion fails.

Two types may be binary coercible, which means that the types can be converted into one another without invoking any function. This requires that corresponding values use the same internal representation. For instance, the types text and varchar are binary coercible in both directions. Binary coercibility is not necessarily a symmetric relationship. For example, the cast from xml to text can be performed for free in the present implementation, but the reverse direction requires a function that performs at least a syntax check. (Two types that are binary coercible both ways are also referred to as binary compatible.)

You can define a cast as an I/O conversion cast by using the WITH INOUT syntax. An I/O conversion cast is performed by invoking the output function of the source data type, and passing the resulting string to the input function of the target data type. In many common cases, this feature avoids the need to write a separate cast function for conversion. An I/O conversion cast acts the same as a regular function-based cast; only the implementation is different.

By default, a cast can be invoked only by an explicit cast request, that is an explicit `CAST(x AS typename)` or `x:: typename` construct.

If the cast is marked AS ASSIGNMENT then it can be invoked implicitly when assigning a value to a column of the target data type. For example, supposing that `foo.f1` is a column of type text, then:

```
INSERT INTO foo (f1) VALUES (42);
```

will be allowed if the cast from type integer to type text is marked AS ASSIGNMENT, otherwise not. The term assignment cast is typically used to describe this kind of cast.

If the cast is marked AS IMPLICIT then it can be invoked implicitly in any context, whether assignment or internally in an expression. The term implicit cast is typically used to describe this kind of cast. For example, consider this query:

```
SELECT 2 + 4.0;
```
The parser initially marks the constants as being of type \texttt{integer} and \texttt{numeric}, respectively. There is no \texttt{integer + numeric} operator in the system catalogs, but there is a \texttt{numeric + numeric} operator. This query succeeds if a cast from \texttt{integer to numeric} exists (it does) and is marked \texttt{AS IMPLICIT}, which in fact it is. The parser applies only the implicit cast and resolves the query as if it had been written as the following:

\begin{verbatim}
SELECT CAST ( 2 AS numeric ) + 4.0;
\end{verbatim}

The catalogs also provide a cast from \texttt{numeric to integer}. If that cast were marked \texttt{AS IMPLICIT}, which it is not, then the parser would be faced with choosing between the above interpretation and the alternative of casting the \texttt{numeric} constant to \texttt{integer} and applying the \texttt{integer + integer} operator. Lacking any knowledge of which choice to prefer, the parser would give up and declare the query ambiguous. The fact that only one of the two casts is implicit is the way in which we teach the parser to prefer resolution of a mixed \texttt{numeric-and-integer} expression as \texttt{numeric}; the parser has no built-in knowledge about that.

It is wise to be conservative about marking casts as implicit. An overabundance of implicit casting paths can cause Greenplum Database to choose surprising interpretations of commands, or to be unable to resolve commands at all because there are multiple possible interpretations. A good rule of thumb is to make a cast implicitly invokable only for information-preserving transformations between types in the same general type category. For example, the cast from \texttt{int2} to \texttt{int4} can reasonably be implicit, but the cast from \texttt{float8} to \texttt{int4} should probably be assignment-only. Cross-type-category casts, such as \texttt{text to int4}, are best made explicit-only.

\textbf{Note:} Sometimes it is necessary for usability or standards-compliance reasons to provide multiple implicit casts among a set of types, resulting in ambiguity that cannot be avoided as described above. The parser uses a fallback heuristic based on type categories and preferred types that helps to provide desired behavior in such cases. See \texttt{CREATE TYPE} for more information.

To be able to create a cast, you must own the source or the target data type and have \texttt{USAGE} privilege on the other type. To create a binary-coercible cast, you must be superuser. (This restriction is made because an erroneous binary-coercible cast conversion can easily crash the server.)

\textbf{Parameters}

\textit{source\texttt{type}}

The name of the source data type of the cast.

\textit{target\texttt{type}}

The name of the target data type of the cast.

\textit{func\texttt{name}\texttt{(arg\texttt{type} [, \ldots])}}

The function used to perform the cast. The function name may be schema-qualified. If it is not, Greenplum Database looks for the function in the schema search path. The function's result data type must match the target type of the cast.

Cast implementation functions may have one to three arguments. The first argument type must be identical to or binary-coercible from the cast's source type. The second argument, if present, must be type \texttt{integer}; it receives the type modifier associated with the destination type, or \texttt{-1} if there is none. The third argument, if present, must be type \texttt{boolean}; it receives \texttt{true} if the cast is an explicit cast, \texttt{false} otherwise. The SQL specification demands different behaviors for explicit and implicit casts in some cases. This argument is supplied for functions that must implement such casts. It is not recommended that you design your own data types this way.

The return type of a cast function must be identical to or binary-coercible to the cast's target type.

Ordinarily a cast must have different source and target data types. However, you are permitted to declare a cast with identical source and target types if it has a cast implementation function that takes more than one argument. This is used to represent
type-specific length coercion functions in the system catalogs. The named function is used to coerce a value of the type to the type modifier value given by its second argument.

When a cast has different source and target types and a function that takes more than one argument, the cast converts from one type to another and applies a length coercion in a single step. When no such entry is available, coercion to a type that uses a type modifier involves two steps, one to convert between data types and a second to apply the modifier.

A cast to or from a domain type currently has no effect. Casting to or from a domain uses the casts associated with its underlying type.

WITHOUT FUNCTION
Indicates that the source type is binary-coercible to the target type, so no function is required to perform the cast.

WITH INOUT
Indicates that the cast is an I/O conversion cast, performed by invoking the output function of the source data type, and passing the resulting string to the input function of the target data type.

AS ASSIGNMENT
Indicates that the cast may be invoked implicitly in assignment contexts.

AS IMPLICIT
Indicates that the cast may be invoked implicitly in any context.

Notes
Note that in this release of Greenplum Database, user-defined functions used in a user-defined cast must be defined as IMMUTABLE. Any compiled code (shared library files) for custom functions must be placed in the same location on every host in your Greenplum Database array (master and all segments). This location must also be in the LD_LIBRARY_PATH so that the server can locate the files.

Remember that if you want to be able to convert types both ways you need to declare casts both ways explicitly.

It is normally not necessary to create casts between user-defined types and the standard string types (text, varchar, and char(n), as well as user-defined types that are defined to be in the string category). Greenplum Database provides automatic I/O conversion casts for these. The automatic casts to string types are treated as assignment casts, while the automatic casts from string types are explicit-only. You can override this behavior by declaring your own cast to replace an automatic cast, but usually the only reason to do so is if you want the conversion to be more easily invokeable than the standard assignment-only or explicit-only setting. Another possible reason is that you want the conversion to behave differently from the type's I/O function - think twice before doing this. (A small number of the built-in types do indeed have different behaviors for conversions, mostly because of requirements of the SQL standard.)

It is recommended that you follow the convention of naming cast implementation functions after the target data type, as the built-in cast implementation functions are named. Many users are used to being able to cast data types using a function-style notation, that is $typename(x)$.

There are two cases in which a function-call construct is treated as a cast request without having matched it to an actual function. If a function call $name(x)$ does not exactly match any existing function, but $name$ is the name of a data type and $pg_cast$ provides a binary-coercible cast to this type from the type of $x$, then the call will be construed as a binary-coercible cast. Greenplum Database makes this exception so that binary-coercible casts can be invoked using functional syntax, even though they lack any function. Likewise, if there is no $pg_cast$ entry but the cast would be to or from a string type, the call is construed as an I/O conversion cast. This exception allows I/O conversion casts to be invoked using functional syntax.

There is an exception to the exception above: I/O conversion casts from composite types to string types cannot be invoked using functional syntax, but must be written in explicit cast syntax (either CAST or ::
notation). This exception exists because after the introduction of automatically-provided I/O conversion casts, it was found to be too easy to accidentally invoke such a cast when you intended a function or column reference.

Examples

To create an assignment cast from type bigint to type int4 using the function int4(bigint) (This cast is already predefined in the system):

```sql
CREATE CAST (bigint AS int4) WITH FUNCTION int4(bigint) AS ASSIGNMENT;
```

Compatibility

The CREATE CAST command conforms to the SQL standard, except that SQL does not make provisions for binary-coercible types or extra arguments to implementation functions. AS IMPLICIT is a Greenplum Database extension, too.

See Also

CREATE FUNCTION, CREATE TYPE, DROP CAST

CREATE COLLATION

Defines a new collation using the specified operating system locale settings, or by copying an existing collation.

Synopsis

```sql
CREATE COLLATION name (  
    [ LOCALE = locale, ]  
    [ LC_COLLATE = lc_collate, ]  
    [ LC_CTYPE = lc_ctype ]
)  
CREATE COLLATION name FROM existing_collation
```

Description

To be able to create a collation, you must have CREATE privilege on the destination schema.

Parameters

name

The name of the collation. The collation name can be schema-qualified. If it is not, the collation is defined in the current schema. The collation name must be unique within that schema. (The system catalogs can contain collations with the same name for other encodings, but these are ignored if the database encoding does not match.)

locale

This is a shortcut for setting LC_COLLATE and LC_CTYPE at once. If you specify this, you cannot specify either of those parameters.

lc_collate

Use the specified operating system locale for the LC_COLLATE locale category. The locale must be applicable to the current database encoding. (See CREATE DATABASE for the precise rules.)

lc_ctype
Use the specified operating system locale for the `LC_CTYPE` locale category. The locale must be applicable to the current database encoding. (See `CREATE DATABASE` for the precise rules.)

`existing_collation`

The name of an existing collation to copy. The new collation will have the same properties as the existing one, but it will be an independent object.

**Notes**

To be able to create a collation, you must have `CREATE` privilege on the destination schema.

Use `DROP COLLATION` to remove user-defined collations.

See `Collation Support` in the PostgreSQL documentation for more information about collation support in Greenplum Database.

**Examples**

To create a collation from the operating system locale `fr_FR.utf8` (assuming the current database encoding is `UTF8`):

```
CREATE COLLATION french (LOCALE = 'fr_FR.utf8');
```

To create a collation from an existing collation:

```
CREATE COLLATION german FROM "de_DE";
```

This can be convenient to be able to use operating-system-independent collation names in applications.

**Compatibility**

There is a `CREATE COLLATION` statement in the SQL standard, but it is limited to copying an existing collation. The syntax to create a new collation is a Greenplum Database extension.

**See Also**

`ALTER COLLATION, DROP COLLATION`

---

**CREATE CONVERSION**

Defines a new encoding conversion.

**Synopsis**

```
CREATE [DEFAULT] CONVERSION name FOR source_encoding TO dest_encoding FROM funcname
```

**Description**

`CREATE CONVERSION` defines a new conversion between character set encodings. Conversion names may be used in the `convert` function to specify a particular encoding conversion. Also, conversions that are marked `DEFAULT` can be used for automatic encoding conversion between client and server. For this purpose, two conversions, from encoding A to B and from encoding B to A, must be defined.

To create a conversion, you must have `EXECUTE` privilege on the function and `CREATE` privilege on the destination schema.
**Parameters**

**DEFAULT**

Indicates that this conversion is the default for this particular source to destination encoding. There should be only one default encoding in a schema for the encoding pair.

**name**

The name of the conversion. The conversion name may be schema-qualified. If it is not, the conversion is defined in the current schema. The conversion name must be unique within a schema.

**source_encoding**

The source encoding name.

**dest_encoding**

The destination encoding name.

**funcname**

The function used to perform the conversion. The function name may be schema-qualified. If it is not, the function will be looked up in the path. The function must have the following signature:

```c
conv_proc(
    integer,  -- source encoding ID
    integer,  -- destination encoding ID
    cstring,  -- source string (null terminated C string)
    internal, -- destination (fill with a null terminated C string)
    integer   -- source string length
) RETURNS void;
```

**Notes**

Note that in this release of Greenplum Database, user-defined functions used in a user-defined conversion must be defined as **IMMUTABLE**. Any compiled code (shared library files) for custom functions must be placed in the same location on every host in your Greenplum Database array (master and all segments). This location must also be in the **LD_LIBRARY_PATH** so that the server can locate the files.

**Examples**

To create a conversion from encoding **UTF8** to **LATIN1** using **myfunc**:

```sql
CREATE CONVERSION myconv FOR 'UTF8' TO 'LATIN1' FROM myfunc;
```

**Compatibility**

There is no **CREATE CONVERSION** statement in the SQL standard, but there is a **CREATE TRANSLATION** statement that is very similar in purpose and syntax.

**See Also**

**ALTER CONVERSION, CREATE FUNCTION, DROP CONVERSION**

**CREATE DATABASE**

Creates a new database.
Synopsis

CREATE DATABASE name [ [WITH] [OWNER [=] user_name] [TEMPLATE [=] template] [ENCODING [=] encoding] [LC_COLLATE [=] lc_collate] [LC_CTYPE [=] lc_ctype] [TABLESPACE [=] tablespace] [CONNECTION LIMIT [=] connlimit ] ]

Description

CREATE DATABASE creates a new database. To create a database, you must be a superuser or have the special CREATEDB privilege.

The creator becomes the owner of the new database by default. Superusers can create databases owned by other users by using the OWNER clause. They can even create databases owned by users with no special privileges. Non-superusers with CREATEDB privilege can only create databases owned by themselves.

By default, the new database will be created by cloning the standard system database template1. A different template can be specified by writing TEMPLATE name. In particular, by writing TEMPLATE template0, you can create a clean database containing only the standard objects predefined by Greenplum Database. This is useful if you wish to avoid copying any installation-local objects that may have been added to template1.

Parameters

name

The name of a database to create.

user_name

The name of the database user who will own the new database, or DEFAULT to use the default owner (the user executing the command).

template

The name of the template from which to create the new database, or DEFAULT to use the default template (template1).

encoding

Character set encoding to use in the new database. Specify a string constant (such as 'SQL_ASCII'), an integer encoding number, or DEFAULT to use the default encoding. For more information, see Character Set Support.

lc_collate

The collation order (LC_COLLATE) to use in the new database. This affects the sort order applied to strings, e.g. in queries with ORDER BY, as well as the order used in indexes on text columns. The default is to use the collation order of the template database. See the Notes section for additional restrictions.

lc_ctype

The character classification (LC_CTYPE) to use in the new database. This affects the categorization of characters, e.g. lower, upper and digit. The default is to use the character classification of the template database. See below for additional restrictions.

tablespace

The name of the tablespace that will be associated with the new database, or DEFAULT to use the template database's tablespace. This tablespace will be the default tablespace used for objects created in this database.

connlimit

The maximum number of concurrent connections possible. The default of -1 means there is no limitation.

Notes

CREATE DATABASE cannot be executed inside a transaction block.

When you copy a database by specifying its name as the template, no other sessions can be connected to the template database while it is being copied. New connections to the template database are locked out until CREATE DATABASE completes.

The CONNECTION LIMIT is not enforced against superusers.

The character set encoding specified for the new database must be compatible with the chosen locale settings (LC_COLLATE and LC_CTYPE). If the locale is C (or equivalently POSIX), then all encodings are allowed, but for other locale settings there is only one encoding that will work properly. CREATE DATABASE will allow superusers to specify SQL_ASCII encoding regardless of the locale settings, but this choice is deprecated and may result in misbehavior of character-string functions if data that is not encoding-compatible with the locale is stored in the database.

The encoding and locale settings must match those of the template database, except when template0 is used as template. This is because COLLATE and CTYPE affect the ordering in indexes, so that any indexes copied from the template database would be invalid in the new database with different settings. template0, however, is known to not contain any data or indexes that would be affected.

Examples

To create a new database:

```
CREATE DATABASE gpdb;
```

To create a database sales owned by user salesapp with a default tablespace of salesspace:

```
CREATE DATABASE sales OWNER salesapp TABLESPACE salesspace;
```

To create a database music which supports the ISO-8859-1 character set:

```
CREATE DATABASE music ENCODING 'LATIN1' TEMPLATE template0;
```

In this example, the TEMPLATE template0 clause would only be required if template1’s encoding is not ISO-8859-1. Note that changing encoding might require selecting new LC_COLLATE and LC_CTYPE settings as well.

Compatibility

There is no CREATE DATABASE statement in the SQL standard. Databases are equivalent to catalogs, whose creation is implementation-defined.

See Also

ALTER DATABASE, DROP DATABASE

CREATE DOMAIN

Defines a new domain.

Synopsis

```
CREATE DOMAIN name [AS] data_type [DEFAULT expression]
```
[ COLLATE collation ]
[ CONSTRAINT constraint_name ]
| NOT NULL | NULL |
| CHECK (expression) | [...] |

Description

CREATE DOMAIN creates a new domain. A domain is essentially a data type with optional constraints (restrictions on the allowed set of values). The user who defines a domain becomes its owner. The domain name must be unique among the data types and domains existing in its schema.

If a schema name is given (for example, CREATE DOMAIN myschema.mydomain ...) then the domain is created in the specified schema. Otherwise it is created in the current schema.

Domains are useful for abstracting common constraints on fields into a single location for maintenance. For example, several tables might contain email address columns, all requiring the same CHECK constraint to verify the address syntax. It is easier to define a domain rather than setting up a column constraint for each table that has an email column.

To be able to create a domain, you must have USAGE privilege on the underlying type.

Parameters

name
The name (optionally schema-qualified) of a domain to be created.

data_type
The underlying data type of the domain. This may include array specifiers.

DEFAULT expression
Specifies a default value for columns of the domain data type. The value is any variable-free expression (but subqueries are not allowed). The data type of the default expression must match the data type of the domain. If no default value is specified, then the default value is the null value. The default expression will be used in any insert operation that does not specify a value for the column. If a default value is defined for a particular column, it overrides any default associated with the domain. In turn, the domain default overrides any default value associated with the underlying data type.

COLLATE collation
An optional collation for the domain. If no collation is specified, the underlying data type’s default collation is used. The underlying type must be collatable if COLLATE is specified.

CONSTRAINT constraint_name
An optional name for a constraint. If not specified, the system generates a name.

NOT NULL
Values of this domain are normally prevented from being null. However, it is still possible for a domain with this constraint to take a null value if it is assigned a matching domain type that has become null, e.g. via a left outer join, or a command such as INSERT INTO tab (domcol) VALUES ((SELECT domcol FROM tab WHERE false)).

NULL
Values of this domain are allowed to be null. This is the default. This clause is only intended for compatibility with nonstandard SQL databases. Its use is discouraged in new applications.

CHECK (expression)
CHECK clauses specify integrity constraints or tests which values of the domain must satisfy. Each constraint must be an expression producing a Boolean result. It should use the key word VALUE to refer to the value being tested. Currently, CHECK expressions cannot contain subqueries nor refer to variables other than VALUE.
Examples

Create the `us_zip_code` data type. A regular expression test is used to verify that the value looks like a valid US zip code.

```sql
CREATE DOMAIN us_zip_code AS TEXT CHECK
  ( VALUE ~ '^\d{5}$' OR VALUE ~ '^\d{5}-\d{4}$' );
```

Compatibility

CREATE DOMAIN conforms to the SQL standard.

See Also

`ALTER DOMAIN`, `DROP DOMAIN`

CREATE EXTENSION

Registers an extension in a Greenplum database.

Synopsis

```sql
CREATE EXTENSION [ IF NOT EXISTS ] extension_name
  [ WITH ] [ SCHEMA schema_name ]
  [ VERSION version ]
  [ FROM old_version ]
  [ CASCADE ]
```

Description

CREATE EXTENSION loads a new extension into the current database. There must not be an extension of the same name already loaded.

Loading an extension essentially amounts to running the extension script file. The script typically creates new SQL objects such as functions, data types, operators and index support methods. The CREATE EXTENSION command also records the identities of all the created objects, so that they can be dropped again if DROP EXTENSION is issued.

Loading an extension requires the same privileges that would be required to create the component extension objects. For most extensions this means superuser or database owner privileges are required. The user who runs CREATE EXTENSION becomes the owner of the extension for purposes of later privilege checks, as well as the owner of any objects created by the extension script.

Parameters

**IF NOT EXISTS**

Do not throw an error if an extension with the same name already exists. A notice is issued in this case. There is no guarantee that the existing extension is similar to the extension that would have been installed.

**extension_name**

The name of the extension to be installed. The name must be unique within the database. An extension is created from the details in the extension control file `SHAREDIR/extension/extension_name.control`.

`SHAREDIR` is the installation shared-data directory, for example `/usr/local/greenplum-db/share/postgresql`. The command `pg_config --sharedir` displays the directory.
**SCHEMA** `schema_name`

The name of the schema in which to install the extension objects. This assumes that the extension allows its contents to be relocated. The named schema must already exist. If not specified, and the extension control file does not specify a schema, the current default object creation schema is used.

If the extension specifies a schema parameter in its control file, then that schema cannot be overridden with a `SCHEMA` clause. Normally, an error is raised if a `SCHEMA` clause is given and it conflicts with the extension schema parameter. However, if the `CASCADE` clause is also given, then `schema_name` is ignored when it conflicts. The given `schema_name` is used for the installation of any needed extensions that do not a specify schema in their control files.

The extension itself is not within any schema. Extensions have unqualified names that must be unique within the database. But objects belonging to the extension can be within a schema.

**VERSION** `version`

The version of the extension to install. This can be written as either an identifier or a string literal. The default version is value that is specified in the extension control file.

**FROM** `old_version`

Specify `FROM` `old_version` only if you are attempting to install an extension that replaces an `old-style` module that is a collection of objects that is not packaged into an extension. If specified, `CREATE EXTENSION` runs an alternative installation script that absorbs the existing objects into the extension, instead of creating new objects. Ensure that `SCHEMA` clause specifies the schema containing these pre-existing objects.

The value to use for `old_version` is determined by the extension author, and might vary if there is more than one version of the `old-style` module that can be upgraded into an extension. For the standard additional modules supplied with pre-9.1 PostgreSQL, specify `unpackaged` for the `old_version` when updating a module to extension style.

**CASCADE**

Automatically install dependent extensions are not already installed. Dependent extensions are checked recursively and those dependencies are also installed automatically. If the `SCHEMA` clause is specified, the schema applies to the extension and all dependent extensions that are installed. Other options that are specified are not applied to the automatically-installed dependent extensions. In particular, default versions are always selected when installing dependent extensions.

**Notes**

The extensions currently available for loading can be identified from the `pg_available_extensions` or `pg_available_extension_versions` system views.

Before you use `CREATE EXTENSION` to load an extension into a database, the supporting extension files must be installed including an extension control file and at least one least one SQL script file. The support files must be installed in the same location on all Greenplum Database hosts. For information about creating new extensions, see PostgreSQL information about *Packaging Related Objects into an Extension*.

**Compatibility**

`CREATE EXTENSION` is a Greenplum Database extension.
CREATE EXTERNAL TABLE

Defines a new external table.

Synopsis

CREATE [READABLE] EXTERNAL [TEMPORARY | TEMP] TABLE table_name
   ( column_name data_type [, ...] | LIKE other_table )
   LOCATION ('file://seghost[:port]/path/file' [, ...])

Description

CREATE EXTERNAL TABLE or CREATE EXTERNAL WEB TABLE creates a new readable external table definition in Greenplum Database. Readable external tables are typically used for fast, parallel data loading. Once an external table is defined, you can query its data directly (and in parallel) using SQL commands. For example, you can select, join, or sort external table data. You can also create views for external tables. DML operations (UPDATE, INSERT, DELETE, or TRUNCATE) are not allowed on readable external tables, and you cannot create indexes on readable external tables.

CREATE WRITABLE EXTERNAL TABLE or CREATE WRITABLE EXTERNAL WEB TABLE creates a new writable external table definition in Greenplum Database. Writable external tables are typically used for unloading data from the database into a set of files or named pipes. Writable external web tables can also be used to output data to an executable program. Writable external tables can also be used as output targets for Greenplum parallel MapReduce calculations. Once a writable external table is defined, data can be selected from database tables and inserted into the writable external table. Writable external tables only allow INSERT operations – SELECT, UPDATE, DELETE or TRUNCATE are not allowed.

The main difference between regular external tables and external web tables is their data sources. Regular readable external tables access static flat files, whereas external web tables access dynamic data sources – either on a web server or by executing OS commands or scripts.

See Working with External Data for detailed information about working with external tables.

Parameters

READABLE | WRITABLE
Specifies the type of external table, readable being the default. Readable external tables are used for loading data into Greenplum Database. Writable external tables are used for unloading data.

WEB
Creates a readable or writable external web table definition in Greenplum Database. There are two forms of readable external web tables – those that access files via the http:// protocol or those that access data by executing OS commands. Writable external web tables output data to an executable program that can accept an input stream of data. External web tables are not rescannable during query execution.

The s3 protocol does not support external web tables. You can, however, create an external web table that executes a third-party tool to read data from or write data to S3 directly.

TEMPORARY | TEMP
If specified, creates a temporary readable or writable external table definition in Greenplum Database. Temporary external tables exist in a special schema; you cannot specify a schema name when you create the table. Temporary external tables are automatically dropped at the end of a session.

An existing permanent table with the same name is not visible to the current session while the temporary table exists, unless you reference the permanent table with its schema-qualified name.

table_name
The name of the new external table.

column_name
The name of a column to create in the external table definition. Unlike regular tables, external tables do not have column constraints or default values, so do not specify those.

LIKE other_table
The LIKE clause specifies a table from which the new external table automatically copies all column names, data types and Greenplum distribution policy. If the original table
specifies any column constraints or default column values, those will not be copied over to the new external table definition.

**data_type**

The data type of the column.

**LOCATION ('protocol://[host[[:port]]/path/file' [, ...])**

If you use the `pxf` protocol to access an external data source, refer to the PXF Creating an External Table documentation for detailed information about the `pxf` protocol LOCATION clause syntax.

If you use the `s3` protocol to read or write to S3, refer to About the S3 Protocol URL for additional information about the `s3` protocol LOCATION clause syntax.

For readable external tables, specifies the URI of the external data source(s) to be used to populate the external table or web table. Regular readable external tables allow the `gpfdist` or `file` protocols. External web tables allow the `http` protocol. If `port` is omitted, port 8080 is assumed for `http` and `gpfdist` protocols. If using the `gpfdist` protocol, the `path` is relative to the directory from which `gpfdist` is serving files (the directory specified when you started the `gpfdist` program). Also, `gpfdist` can use wildcards or other C-style pattern matching (for example, a whitespace character is `[:space:]`) to denote multiple files in a directory. For example:

```
'gpfdist://filehost:8081/*'
'gpfdist://masterhost/my_load_file'
'file://seghost1/dbfast1/external/myfile.txt'
'http://intranet.example.com/finance/expenses.csv'
```

For writable external tables, specifies the URI location of the `gpfdist` process or S3 protocol that will collect data output from the Greenplum segments and write it to one or more named files. For `gpfdist` the `path` is relative to the directory from which `gpfdist` is serving files (the directory specified when you started the `gpfdist` program). If multiple `gpfdist` locations are listed, the segments sending data will be evenly divided across the available output locations. For example:

```
'gpfdist://outputhost:8081/data1.out',
'gpfdist://outputhost:8081/data2.out'
```

With two `gpfdist` locations listed as in the above example, half of the segments would send their output data to the `data1.out` file and the other half to the `data2.out` file.

With the option `#transform=trans_name`, you can specify a transform to apply when loading or extracting data. The `trans_name` is the name of the transform in the YAML configuration file you specify with the you run the `gpfdist` utility. For information about specifying a transform, see `gpfdist` in the Greenplum Utility Guide.

**ON MASTER**

Restricts all table-related operations to the Greenplum master segment. Permitted only on readable and writable external tables created with the `s3` or custom protocols. The `gpfdist`, `gpfdists`, `pxf`, and `file` protocols do not support `ON MASTER`.

**Note:** Be aware of potential resource impacts when reading from or writing to external tables you create with the ON MASTER clause. You may encounter performance issues when you restrict table operations solely to the Greenplum master segment.

**EXECUTE 'command' [ON ...]**

Allowed for readable external web tables or writable external tables only. For readable external web tables, specifies the OS command to be executed by the segment instances.
The *command* can be a single OS command or a script. The *ON* clause is used to specify which segment instances will execute the given command.

- **ON ALL** is the default. The command will be executed by every active (primary) segment instance on all segment hosts in the Greenplum Database system. If the command executes a script, that script must reside in the same location on all of the segment hosts and be executable by the Greenplum superuser (*gpadmin*).
- **ON MASTER** runs the command on the master host only.

  **Note:** Logging is not supported for external web tables when the *ON* MASTER clause is specified.

- **ON number** means the command will be executed by the specified number of segments. The particular segments are chosen randomly at runtime by the Greenplum Database system. If the command executes a script, that script must reside in the same location on all of the segment hosts and be executable by the Greenplum superuser (*gpadmin*).
- **HOST** means the command will be executed by one segment on each segment host (once per segment host), regardless of the number of active segment instances per host.
- **HOST segment_hostname** means the command will be executed by all active (primary) segment instances on the specified segment host.
- **SEGMENT segment_id** means the command will be executed only once by the specified segment. You can determine a segment instance's ID by looking at the content number in the system catalog table *gp_segment_configuration*. The content ID of the Greenplum Database master is always -1.

For writable external tables, the *command* specified in the *EXECUTE* clause must be prepared to have data piped into it. Since all segments that have data to send will write their output to the specified command or program, the only available option for the *ON* clause is *ON ALL*.

**FORMAT 'TEXT | CSV' (options)**

When the *FORMAT* clause identifies delimited text (*TEXT*) or comma separated values (*CSV*) format, formatting options are similar to those available with the PostgreSQL *COPY* command. If the data in the file does not use the default column delimiter, escape character, null string and so on, you must specify the additional formatting options so that the data in the external file is read correctly by Greenplum Database. For information about using a custom format, see “Loading and Unloading Data” in the *Greenplum Database Administrator Guide*.

If you use the *pxf* protocol to access an external data source, refer to the PXF Creating an External Table documentation for detailed information about the *pxf* protocol *FORMAT* clause syntax.

**FORMAT 'CUSTOM' (formatter=formatter_specification)**

Specifies a custom data format. The *formatter_specification* specifies the function to use to format the data, followed by comma-separated parameters to the formatter function. The length of the formatter specification, the string including *Formatter=*, can be up to approximately 50K bytes.

If you use the *pxf* protocol to access an external data source, refer to the PXF Creating an External Table documentation for detailed information about the *pxf* protocol *FORMAT* clause syntax.

For general information about using a custom format, see “Loading and Unloading Data” in the *Greenplum Database Administrator Guide*.

**DELIMITER**

Specifies a single ASCII character that separates columns within each row (line) of data. The default is a tab character in *TEXT* mode, a comma in *CSV* mode. In *TEXT* mode for
readable external tables, the delimiter can be set to `OFF` for special use cases in which unstructured data is loaded into a single-column table.

For the `s3` protocol, the delimiter cannot be a newline character (`\n`) or a carriage return character (`\r`).

**NULL**

Specifies the string that represents a **NULL** value. The default is `\N` (backslash-N) in **TEXT** mode, and an empty value with no quotations in **CSV** mode. You might prefer an empty string even in **TEXT** mode for cases where you do not want to distinguish **NULL** values from empty strings. When using external and web tables, any data item that matches this string will be considered a **NULL** value.

As an example for the **text** format, this **FORMAT** clause can be used to specify that the string of two single quotes (`''`) is a **NULL** value.

```sql
FORMAT 'text' (delimiter ',' null '''''
```}

**ESCAPE**

Specifies the single character that is used for C escape sequences (such as `\n`, `\t`, `\100`, and so on) and for escaping data characters that might otherwise be taken as row or column delimiters. Make sure to choose an escape character that is not used anywhere in your actual column data. The default escape character is a `\` (backslash) for text-formatted files and a `"` (double quote) for csv-formatted files, however it is possible to specify another character to represent an escape. It is also possible to disable escaping in text-formatted files by specifying the value `OFF` as the escape value. This is very useful for data such as text-formatted web log data that has many embedded backslashes that are not intended to be escapes.

**NEWLINE**

Specifies the newline used in your data files – `LF` (Line feed, 0x0A), `CR` (Carriage return, 0x0D), or `CRLF` (Carriage return plus line feed, 0x0D 0x0A). If not specified, a Greenplum Database segment will detect the newline type by looking at the first row of data it receives and using the first newline type encountered.

**HEADER**

For readable external tables, specifies that the first line in the data file(s) is a header row (contains the names of the table columns) and should not be included as data for the table. If using multiple data source files, all files must have a header row.

For the `s3` protocol, the column names in the header row cannot contain a newline character (`\n`) or a carriage return (`\r`).

The `pxf` protocol does not support the **HEADER** formatting option.

**QUOTE**

Specifies the quotation character for **CSV** mode. The default is double-quote (`"`).

**FORCE NOT NULL**

In **CSV** mode, processes each specified column as though it were quoted and hence not a **NULL** value. For the default null string in **CSV** mode (nothing between two delimiters), this causes missing values to be evaluated as zero-length strings.

**FORCE QUOTE**

In **CSV** mode for writable external tables, forces quoting to be used for all non-**NULL** values in each specified column. If `*` is specified then non-**NULL** values will be quoted in all columns. **NULL** output is never quoted.

**FILL MISSING FIELDS**

In both **TEXT** and **CSV** mode for readable external tables, specifying **FILL MISSING FIELDS** will set missing trailing field values to **NULL** (instead of reporting an error) when a
A row of data has missing data fields at the end of a line or row. Blank rows, fields with a NOT NULL constraint, and trailing delimiters on a line will still report an error.

ENCODING 'encoding'

Character set encoding to use for the external table. Specify a string constant (such as 'SQL_ASCII'), an integer encoding number, or DEFAULT to use the default client encoding. See Character Set Support.

LOG ERRORS

This is an optional clause that can precede a SEGMENT REJECT LIMIT clause to log information about rows with formatting errors. The error log information is stored internally and is accessed with the Greenplum Database built-in SQL function gp_read_error_log().

See Notes for information about the error log information and built-in functions for viewing and managing error log information.

SEGMENT REJECT LIMIT count [ROWS | PERCENT]

Runs a COPY FROM operation in single row error isolation mode. If the input rows have format errors they will be discarded provided that the reject limit count is not reached on any Greenplum segment instance during the load operation. The reject limit count can be specified as number of rows (the default) or percentage of total rows (1-100). If PERCENT is used, each segment starts calculating the bad row percentage only after the number of rows specified by the parameter gp_reject_percent_threshold has been processed. The default for gp_reject_percent_threshold is 300 rows. Constraint errors such as violation of a NOT NULL, CHECK, or UNIQUE constraint will still be handled in "all-or-nothing" input mode. If the limit is not reached, all good rows will be loaded and any error rows discarded.

Note: When reading an external table, Greenplum Database limits the initial number of rows that can contain formatting errors if the SEGMENT REJECT LIMIT is not triggered first or is not specified. If the first 1000 rows are rejected, the COPY operation is stopped and rolled back.

The limit for the number of initial rejected rows can be changed with the Greenplum Database server configuration parameter gp_initial_bad_row_limit. See Server Configuration Parameters for information about the parameter.

DISTRIBUTED BY ({column [opclass]}, [ ... ] )

DISTRIBUTED RANDOMLY

Used to declare the Greenplum Database distribution policy for a writable external table. By default, writable external tables are distributed randomly. If the source table you are exporting data from has a hash distribution policy, defining the same distribution key column(s) and operator class(es), opclass, for the writable external table will improve unload performance by eliminating the need to move rows over the interconnect. When you issue an unload command such as INSERT INTO wex_table SELECT * FROM source_table, the rows that are unloaded can be sent directly from the segments to the output location if the two tables have the same hash distribution policy.

Examples

Start the gpfdist file server program in the background on port 8081 serving files from directory /var/data/staging:

```
gpdist -p 8081 -d /var/data/staging -l /home/gpadmin/log &
```

Create a readable external table named ext_customer using the gpfdist protocol and any text formatted files (*.txt) found in the gpfdist directory. The files are formatted with a pipe (|) as the
column delimiter and an empty space as `NULL`. Also access the external table in single row error isolation mode:

```sql
CREATE EXTERNAL TABLE ext_customer
(id int, name text, sponsor text)
LOCATION ('gpfdist://filehost:8081/*.txt')
FORMAT 'TEXT' (DELIMITER '|' NULL ' ')
LOG ERRORS SEGMENT REJECT LIMIT 5;
```

Create the same readable external table definition as above, but with CSV formatted files:

```sql
CREATE EXTERNAL TABLE ext_customer
(id int, name text, sponsor text)
LOCATION ('gpfdist://filehost:8081/*.csv')
FORMAT 'CSV' (DELIMITER ',');
```

Create a readable external table named `ext_expenses` using the file protocol and several CSV formatted files that have a header row:

```sql
CREATE EXTERNAL TABLE ext_expenses (name text, date date, amount float4, category text, description text)
LOCATION ('file://seghost1/dbfast/external/expenses1.csv',
          'file://seghost1/dbfast/external/expenses2.csv',
          'file://seghost2/dbfast/external/expenses3.csv',
          'file://seghost2/dbfast/external/expenses4.csv',
          'file://seghost3/dbfast/external/expenses5.csv',
          'file://seghost3/dbfast/external/expenses6.csv')
FORMAT 'CSV' (HEADER);
```

Create a readable external web table that executes a script once per segment host:

```sql
CREATE EXTERNAL WEB TABLE log_output (linenum int, message text)
EXECUTE '/var/load_scripts/get_log_data.sh' ON HOST
FORMAT 'TEXT' (DELIMITER '|');
```

Create a writable external table named `sales_out` that uses `gpfdist` to write output data to a file named `sales.out`. The files are formatted with a pipe (`|`) as the column delimiter and an empty space as `NULL`.

```sql
CREATE WRITABLE EXTERNAL TABLE sales_out (LIKE sales)
LOCATION ('gpfdist://etl1:8081/sales.out')
FORMAT 'TEXT' (DELIMITER '|' NULL ' ')
DISTRIBUTED BY (txn_id);
```

Create a writable external web table that pipes output data received by the segments to an executable script named `to_adreport_etl.sh`:

```sql
CREATE WRITABLE EXTERNAL WEB TABLE campaign_out (LIKE campaign)
EXECUTE '/var/unload_scripts/to_adreport_etl.sh'
FORMAT 'TEXT' (DELIMITER '|');
```

Use the writable external table defined above to unload selected data:

```sql
INSERT INTO campaign_out SELECT * FROM campaign WHERE customer_id=123;
```
Notes

When you specify the `LOG ERRORS` clause, Greenplum Database captures errors that occur while reading the external table data. You can view and manage the captured error log data.

- Use the built-in SQL function `gp_read_error_log('table_name')`. It requires `SELECT` privilege on `table_name`. This example displays the error log information for data loaded into table `ext_expenses` with a `COPY` command:

  ```sql
  SELECT * from gp_read_error_log('ext_expenses');
  ```

For information about the error log format, see Viewing Bad Rows in the Error Log in the Greenplum Database Administrator Guide.

The function returns `FALSE` if `table_name` does not exist.
- If error log data exists for the specified table, the new error log data is appended to existing error log data. The error log information is not replicated to mirror segments.
- Use the built-in SQL function `gp_truncate_error_log('table_name')` to delete the error log data for `table_name`. It requires the table owner privilege. This example deletes the error log information captured when moving data into the table `ext_expenses`:

  ```sql
  SELECT gp_truncate_error_log('ext_expenses');
  ```

The function returns `FALSE` if `table_name` does not exist.

Specify the `*` wildcard character to delete error log information for existing tables in the current database. Specify the string `*.*` to delete all database error log information, including error log information that was not deleted due to previous database issues. If `*` is specified, database owner privilege is required. If `*.*` is specified, operating system super-user privilege is required.

Compatibility

`CREATE EXTERNAL TABLE` is a Greenplum Database extension. The SQL standard makes no provisions for external tables.

See Also

`CREATE TABLE AS`, `CREATE TABLE`, `COPY`, `SELECT INTO`, `INSERT`

CREATE FOREIGN DATA WRAPPER

Defines a new foreign-data wrapper.

Synopsis

```
CREATE FOREIGN DATA WRAPPER name
  [ HANDLER handler_function | NO HANDLER ]
  [ VALIDATOR validator_function | NO VALIDATOR ]
  [ OPTIONS ( [ mpp_execute { 'master' | 'any' | 'all segments' } ]
[ , ] ] option 'value' [ , ... ] ) ]
```

Description

`CREATE FOREIGN DATA WRAPPER` creates a new foreign-data wrapper in the current database. The user who defines the foreign-data wrapper becomes its owner.
Only superusers can create foreign-data wrappers.

**Parameters**

`name`

The name of the foreign-data wrapper to create. The name must be unique within the database.

**HANDLER** `handler_function`

The name of a previously registered function that Greenplum Database calls to retrieve the execution functions for foreign tables. `handler_function` must take no arguments, and its return type must be `fdw_handler`.

It is possible to create a foreign-data wrapper with no handler function, but you can only declare, not access, foreign tables using such a wrapper.

**VALIDATOR** `validator_function`

The name of a previously registered function that Greenplum Database calls to check the options provided to the foreign-data wrapper. This function also checks the options for foreign servers, user mappings, and foreign tables that use the foreign-data wrapper. If no validator function or `NO VALIDATOR` is specified, Greenplum Database does not check options at creation time. (Depending upon the implementation, foreign-data wrappers may ignore or reject invalid options at runtime.)

`validator_function` must take two arguments: one of type `text[]`, which contains the array of options as stored in the system catalogs, and one of type `oid`, which identifies the OID of the system catalog containing the options.

The return type is ignored; `validator_function` should report invalid options using the `ereport(ERROR)` function.

**OPTIONS** ( `option 'value' [, ... ]` )

The options for the new foreign-data wrapper. Option names must be unique. The option names and values are foreign-data wrapper-specific and are validated using the foreign-data wrappers' `validator_function`.

`mpp_execute { 'master' | 'any' | 'all segments' }`

An option that identifies the host from which the foreign data-wrapper requests data:

- `master` (the default)—Request data from the master host.
- `any`—Request data from either the master host or any one segment, depending on which path costs less.
- `all segments`—Request data from all segments. To support this option value, the foreign data-wrapper must have a policy that matches the segments to data.

The `mpp_execute` option can be specified in multiple commands: `CREATE FOREIGN TABLE`, `CREATE SERVER`, and `CREATE FOREIGN DATA WRAPPER`. The foreign table setting takes precedence over the foreign server setting, followed by the foreign data wrapper setting.

**Notes**

The foreign-data wrapper functionality is still under development. Optimization of queries is primitive (and mostly left to the wrapper).
### Examples

Create a useless foreign-data wrapper named `dummy`:

```sql
CREATE FOREIGN DATA WRAPPER dummy;
```

Create a foreign-data wrapper named `file` with a handler function named `file_fdw_handler`:

```sql
CREATE FOREIGN DATA WRAPPER file HANDLER file_fdw_handler;
```

Create a foreign-data wrapper named `mywrapper` that includes an option:

```sql
CREATE FOREIGN DATA WRAPPER mywrapper OPTIONS (debug 'true');
```

### Compatibility

`CREATE FOREIGN DATA WRAPPER` conforms to ISO/IEC 9075-9 (SQL/MED), with the exception that the `HANDLER` and `VALIDATOR` clauses are extensions, and the standard clauses `LIBRARY` and `LANGUAGE` are not implemented in Greenplum Database.

Note, however, that the SQL/MED functionality as a whole is not yet conforming.

### See Also

`ALTER FOREIGN DATA WRAPPER`, `DROP FOREIGN DATA WRAPPER`, `CREATE SERVER`, `CREATE USER MAPPING`.

---

**CREATE FOREIGN TABLE**

Defines a new foreign table.

### Synopsis

```sql
CREATE FOREIGN TABLE [ IF NOT EXISTS ] table_name ( [ column_name data_type [ OPTIONS ( option 'value' [, ... ] ) ] [ COLLATE collation ] [ column_constraint [ ... ] ] [, ... ] ) ] SERVER server_name [ OPTIONS { mpp_execute { 'master' | 'any' | 'all segments' } [, ] option 'value' [, ... ] } ]
```

where `column_constraint` is:

```sql
[ CONSTRAINT constraint_name ]
{ NOT NULL | NULL | DEFAULT default_expr }
```

### Description

`CREATE FOREIGN TABLE` creates a new foreign table in the current database. The user who creates the foreign table becomes its owner.

If you schema-qualify the table name (for example, `CREATE FOREIGN TABLE myschema.mytable ...`), Greenplum Database creates the table in the specified schema. Otherwise, the foreign table is created in the current schema. The name of the foreign table must be distinct from the name of any other foreign table, table, sequence, index, or view in the same schema.
Because `CREATE FOREIGN TABLE` automatically creates a data type that represents the composite type corresponding to one row of the foreign table, foreign tables cannot have the same name as any existing data type in the same schema.

To create a foreign table, you must have `USAGE` privilege on the foreign server, as well as `USAGE` privilege on all column types used in the table.

**Parameters**

**IF NOT EXISTS**

Do not throw an error if a relation with the same name already exists. Greenplum Database issues a notice in this case. Note that there is no guarantee that the existing relation is anything like the one that would have been created.

`table_name`

The name (optionally schema-qualified) of the foreign table to create.

`column_name`

The name of a column to create in the new foreign table.

`data_type`

The data type of the column, including array specifiers.

**NOT NULL**

The column is not allowed to contain null values.

**NULL**

The column is allowed to contain null values. This is the default.

This clause is provided only for compatibility with non-standard SQL databases. Its use is discouraged in new applications.

**DEFAULT** `default_expr`

The `DEFAULT` clause assigns a default value for the column whose definition it appears within. The value is any variable-free expression; Greenplum Database does not allow subqueries and cross-references to other columns in the current table. The data type of the default expression must match the data type of the column.

Greenplum Database uses the default expression in any insert operation that does not specify a value for the column. If there is no default for a column, then the default is null.

`server_name`

The name of an existing server to use for the foreign table. For details on defining a server, see `CREATE SERVER`.

**OPTIONS ( option 'value' [, ... ] )**

The options for the new foreign table or one of its columns. While option names must be unique, a table option and a column option may have the same name. The option names and values are foreign-data wrapper-specific. Greenplum Database validates the options and values using the foreign-data wrapper's `validator_function`.

**mpp_execute { 'master' | 'any' | 'all segments' }**

An option that identifies the host from which the foreign data-wrapper requests data:

- `master` (the default)—Request data from the master host.
- `any`—Request data from either the master host or any one segment, depending on which path costs less.
• all segments—Request data from all segments. To support this option value, the foreign data-wrapper must have a policy that matches the segments to data.

Use of the foreign table `mpp_execute` option, and the specific modes supported, is foreign data-wrapper-specific.

The `mpp_execute` option can be specified in multiple commands: `CREATE FOREIGN TABLE`, `CREATE SERVER`, and `CREATE FOREIGN DATA WRAPPER`. The foreign table setting takes precedence over the foreign server setting, followed by the foreign data wrapper setting.

### Notes

The Pivotal Query Optimizer, GPORCA, does not support foreign tables. A query on a foreign table always falls back to the Postgres Planner.

### Examples

Create a foreign table named `films` with the server named `film_server`:

```sql
CREATE FOREIGN TABLE films (  
  code        char(5) NOT NULL,  
  title       varchar(40) NOT NULL,  
  did         integer NOT NULL,  
  date_prod   date,  
  kind        varchar(10),  
  len         interval hour to minute  
)  
SERVER film_server;
```

### Compatibility

`CREATE FOREIGN TABLE` largely conforms to the SQL standard; however, much as with `CREATE TABLE`, Greenplum Database permits NULL constraints and zero-column foreign tables. The ability to specify a default value is a Greenplum Database extension, as is the `mpp_execute` option.

### CREATE FUNCTION

Defines a new function.

### Synopsis

```
CREATE [OR REPLACE] FUNCTION name  
  ( [ [argmode] [argname] argtype [ { DEFAULT | = } default_expr ]  
  [, ...] ] )  
[ RETURNS rettype  
  | RETURNS TABLE ( column_name column_type [, ...] ) ]  
{  
  LANGUAGE langname  
  | WINDOW  
  | IMMUTABLE | STABLE | VOLATILE | [NOT] LEAKPROOF  
  | CALLED ON NULL INPUT | RETURNS NULL ON NULL INPUT | STRICT  
  | [EXTERNAL] SECURITY INVOKER | [EXTERNAL] SECURITY DEFINER  
  | EXECUTE ON { ANY | MASTER | ALL SEGMENTS }  
  | COST execution_cost  
  | SET configuration_parameter { TO value | = value | FROM CURRENT }  
AS 'definition'
```

**Description**

CREATE FUNCTION defines a new function. CREATE OR REPLACE FUNCTION either creates a new function, or replaces an existing definition.

The name of the new function must not match any existing function with the same input argument types in the same schema. However, functions of different argument types may share a name (overloading).

To update the definition of an existing function, use CREATE OR REPLACE FUNCTION. It is not possible to change the name or argument types of a function this way (this would actually create a new, distinct function). Also, CREATE OR REPLACE FUNCTION will not let you change the return type of an existing function. To do that, you must drop and recreate the function. When using OUT parameters, that means you cannot change the types of any OUT parameters except by dropping the function. If you drop and then recreate a function, you will have to drop existing objects (rules, views, triggers, and so on) that refer to the old function. Use CREATE OR REPLACE FUNCTION to change a function definition without breaking objects that refer to the function.

The user that creates the function becomes the owner of the function.

To be able to create a function, you must have USAGE privilege on the argument types and the return type.

For more information about creating functions, see the User Defined Functions section of the PostgreSQL documentation.

**Limited Use of VOLATILE and STABLE Functions**

To prevent data from becoming out-of-sync across the segments in Greenplum Database, any function classified as STABLE or VOLATILE cannot be executed at the segment level if it contains SQL or modifies the database in any way. For example, functions such as random() or gettimeofday() are not allowed to execute on distributed data in Greenplum Database because they could potentially cause inconsistent data between the segment instances.

To ensure data consistency, VOLATILE and STABLE functions can safely be used in statements that are evaluated on and execute from the master. For example, the following statements are always executed on the master (statements without a FROM clause):

```sql
SELECT setval('myseq', 201);
SELECT foo();
```

In cases where a statement has a FROM clause containing a distributed table and the function used in the FROM clause simply returns a set of rows, execution may be allowed on the segments:

```sql
SELECT * FROM foo();
```

One exception to this rule are functions that return a table reference (rangeFuncs) or functions that use the refCursor data type. Note that you cannot return a refcursor from any kind of function in Greenplum Database.

**Function Volatility and EXECUTE ON Attributes**

Volatility attributes (IMMUTABLE, STABLE, VOLATILE) and EXECUTE ON attributes specify two different aspects of function execution. In general, volatility indicates when the function is executed, and EXECUTE ON indicates where it is executed.

For example, a function defined with the IMMUTABLE attribute can be executed at query planning time, while a function with the VOLATILE attribute must be executed for every row in the query. A function with the EXECUTE ON MASTER attribute is executed only on the master segment and a function with the EXECUTE ON ALL SEGMENTS attribute is executed on all primary segment instances (not the master).
See Using Functions and Operators in the Greenplum Database Administrator Guide.

Functions And Replicated Tables

A user-defined function that executes only SELECT commands on replicated tables can run on segments. Replicated tables, created with the DISTRIBUTED REPLICATED clause, store all of their rows on every segment. It is safe for a function to read them on the segments, but updates to replicated tables must execute on the master instance.

Parameters

**name**

The name (optionally schema-qualified) of the function to create.

**argmode**

The mode of an argument: either IN, OUT, INOUT, or VARIADIC. If omitted, the default is IN. Only OUT arguments can follow an argument declared as VARIADIC. Also, OUT and INOUT arguments cannot be used together with the RETURNS TABLE notation.

**argname**

The name of an argument. Some languages (currently only SQL and PL/pgSQL) let you use the name in the function body. For other languages the name of an input argument is just extra documentation, so far as the function itself is concerned; but you can use input argument names when calling a function to improve readability. In any case, the name of an output argument is significant, since it defines the column name in the result row type. (If you omit the name for an output argument, the system will choose a default column name.)

**argtype**

The data type(s) of the function's arguments (optionally schema-qualified), if any. The argument types may be base, composite, or domain types, or may reference the type of a table column.

Depending on the implementation language it may also be allowed to specify pseudotypes such as cstring. Pseudotypes indicate that the actual argument type is either incompletely specified, or outside the set of ordinary SQL data types.

The type of a column is referenced by writing `tablename.columnname%TYPE`. Using this feature can sometimes help make a function independent of changes to the definition of a table.

**default_expr**

An expression to be used as the default value if the parameter is not specified. The expression must be coercible to the argument type of the parameter. Only IN and INOUT parameters can have a default value. Each input parameter in the argument list that follows a parameter with a default value must have a default value as well.

**rettype**

The return data type (optionally schema-qualified). The return type can be a base, composite, or domain type, or may reference the type of a table column. Depending on the implementation language it may also be allowed to specify pseudotypes such as cstring. If the function is not supposed to return a value, specify void as the return type.

When there are OUT or INOUT parameters, the RETURNS clause may be omitted. If present, it must agree with the result type implied by the output parameters: RECORD if there are multiple output parameters, or the same type as the single output parameter.

The SETOF modifier indicates that the function will return a set of items, rather than a single item.

The type of a column is referenced by writing `tablename.columnname%TYPE`.

**column_name**
The name of an output column in the `RETURNS TABLE` syntax. This is effectively another way of declaring a named `OUT` parameter, except that `RETURNS TABLE` also implies `RETURNS SETOF`.

**column_type**
The data type of an output column in the `RETURNS TABLE` syntax.

**langname**
The name of the language that the function is implemented in. May be SQL, C, `internal`, or the name of a user-defined procedural language. See `CREATE LANGUAGE` for the procedural languages supported in Greenplum Database. For backward compatibility, the name may be enclosed by single quotes.

**WINDOW**
`WINDOW` indicates that the function is a window function rather than a plain function. This is currently only useful for functions written in C. The `WINDOW` attribute cannot be changed when replacing an existing function definition.

**IMMUTABLE**
**STABLE**
**VOLATILE**
**LEAKPROOF**
These attributes inform the query optimizer about the behavior of the function. At most one choice may be specified. If none of these appear, `VOLATILE` is the default assumption. Since Greenplum Database currently has limited use of `VOLATILE` functions, if a function is truly `IMMUTABLE`, you must declare it as so to be able to use it without restrictions.

`IMMUTABLE` indicates that the function cannot modify the database and always returns the same result when given the same argument values. It does not do database lookups or otherwise use information not directly present in its argument list. If this option is given, any call of the function with all-constant arguments can be immediately replaced with the function value.

`STABLE` indicates that the function cannot modify the database, and that within a single table scan it will consistently return the same result for the same argument values, but that its result could change across SQL statements. This is the appropriate selection for functions whose results depend on database lookups, parameter values (such as the current time zone), and so on. Also note that the `current_timestamp` family of functions qualify as stable, since their values do not change within a transaction.

`VOLATILE` indicates that the function value can change even within a single table scan, so no optimizations can be made. Relatively few database functions are volatile in this sense; some examples are `random()`, `timeofday()`. But note that any function that has side-effects must be classified volatile, even if its result is quite predictable, to prevent calls from being optimized away; an example is `setval()`.

`LEAKPROOF` indicates that the function has no side effects. It reveals no information about its arguments other than by its return value. For example, a function that throws an error message for some argument values but not others, or that includes the argument values in any error message, is not leakproof. The query planner may push leakproof functions (but not others) into views created with the `security_barrier` option. See `CREATE VIEW` and `CREATE RULE`. This option can only be set by the superuser.

**CALLED ON NULL INPUT**
**RETURNS NULL ON NULL INPUT**
**STRICT**
`CALLED ON NULL INPUT` (the default) indicates that the function will be called normally when some of its arguments are null. It is then the function author's responsibility to check for null values if necessary and respond appropriately. `RETURNS NULL ON NULL INPUT` or `STRICT` indicates that the function always returns null whenever any of its arguments
are null. If this parameter is specified, the function is not executed when there are null arguments; instead a null result is assumed automatically.

**[EXTERNAL] SECURITY INVOKER**

**[EXTERNAL] SECURITY DEFINER**

SECURITY INVOKER (the default) indicates that the function is to be executed with the privileges of the user that calls it. SECURITY DEFINER specifies that the function is to be executed with the privileges of the user that created it. The key word EXTERNAL is allowed for SQL conformance, but it is optional since, unlike in SQL, this feature applies to all functions not just external ones.

EXECUTE ON ANY
EXECUTE ON MASTER
EXECUTE ON ALL SEGMENTS

The EXECUTE ON attributes specify where (master or segment instance) a function executes when it is invoked during the query execution process.

EXECUTE ON ANY (the default) indicates that the function can be executed on the master, or any segment instance, and it returns the same result regardless of where it is executed. Greenplum Database determines where the function executes.

EXECUTE ON MASTER indicates that the function must execute only on the master instance.

EXECUTE ON ALL SEGMENTS indicates that the function must execute on all primary segment instances, but not the master, for each invocation. The overall result of the function is the **UNION ALL** of the results from all segment instances.

For information about using EXECUTE ON attributes, see **Notes**.

**COST execution_cost**

A positive number identifying the estimated execution cost for the function, in cpu_operator_cost units. If the function returns a set, execution_cost identifies the cost per returned row. If the cost is not specified, C-language and internal functions default to 1 unit, while functions in other languages default to 100 units. The planner tries to evaluate the function less often when you specify larger execution_cost values.

**configuration_parameter value**

The SET clause applies a value to a session configuration parameter when the function is entered. The configuration parameter is restored to its prior value when the function exits. SET FROM CURRENT saves the value of the parameter that is current when CREATE FUNCTION is executed as the value to be applied when the function is entered.

**definition**

A string constant defining the function; the meaning depends on the language. It may be an internal function name, the path to an object file, an SQL command, or text in a procedural language.

**obj_file, link_symbol**

This form of the **AS** clause is used for dynamically loadable C language functions when the function name in the C language source code is not the same as the name of the SQL function. The string **obj_file** is the name of the file containing the dynamically loadable object, and **link_symbol** is the name of the function in the C language source code. If the link symbol is omitted, it is assumed to be the same as the name of the SQL function being defined. The C names of all functions must be different, so you must give overloaded SQL functions different C names (for example, use the argument types as part of the C names).

It is recommended to locate shared libraries either relative to **$libdir** (which is located at **$GPHOME/lib**) or through the dynamic library path (set by the dynamic_library_path
server configuration parameter). This simplifies version upgrades if the new installation is at a different location.

**describe_function**

The name of a callback function to execute when a query that calls this function is parsed. The callback function returns a tuple descriptor that indicates the result type.

**Notes**

Any compiled code (shared library files) for custom functions must be placed in the same location on every host in your Greenplum Database array (master and all segments). This location must also be in the `LD_LIBRARY_PATH` so that the server can locate the files. It is recommended to locate shared libraries either relative to `$libdir` (which is located at `$GPHOME/lib`) or through the dynamic library path (set by the `dynamic_library_path` server configuration parameter) on all master segment instances in the Greenplum array.

The full SQL type syntax is allowed for input arguments and return value. However, some details of the type specification (such as the precision field for type `numeric`) are the responsibility of the underlying function implementation and are not recognized or enforced by the `CREATE FUNCTION` command.

Greenplum Database allows function overloading. The same name can be used for several different functions so long as they have distinct input argument types. However, the C names of all functions must be different, so you must give overloaded C functions different C names (for example, use the argument types as part of the C names).

Two functions are considered the same if they have the same names and input argument types, ignoring any `OUT` parameters. Thus for example these declarations conflict:

```
CREATE FUNCTION foo(int) ...
CREATE FUNCTION foo(int, out text) ...
```

Functions that have different argument type lists are not considered to conflict at creation time, but if argument defaults are provided, they might conflict in use. For example, consider:

```
CREATE FUNCTION foo(int) ...
CREATE FUNCTION foo(int, int default 42) ...
```

The call `foo(10)`, will fail due to the ambiguity about which function should be called.

When repeated `CREATE FUNCTION` calls refer to the same object file, the file is only loaded once. To unload and reload the file, use the `LOAD` command.

You must have the `USAGE` privilege on a language to be able to define a function using that language.

It is often helpful to use dollar quoting to write the function definition string, rather than the normal single quote syntax. Without dollar quoting, any single quotes or backslashes in the function definition must be escaped by doubling them. A dollar-quoted string constant consists of a dollar sign (`$`), an optional tag of zero or more characters, another dollar sign, an arbitrary sequence of characters that makes up the string content, a dollar sign, the same tag that began this dollar quote, and a dollar sign. Inside the dollar-quoted string, single quotes, backslashes, or any character can be used without escaping. The string content is always written literally. For example, here are two different ways to specify the string "Dianne's horse" using dollar quoting:

```
$$Dianne's horse$$
$SomeTag$Dianne's horse$SomeTag$
```

If a `SET` clause is attached to a function, the effects of a `SET LOCAL` command executed inside the function for the same variable are restricted to the function; the configuration parameter's prior value is still restored when the function exits. However, an ordinary `SET` command (without `LOCAL`) overrides the
CREATE FUNCTION SET clause, much as it would for a previous SET LOCAL command. The effects of such a command will persist after the function exits, unless the current transaction is rolled back.

If a function with a VARIADIC argument is declared as STRICT, the strictness check tests that the variadic array as a whole is non-null. PL/pgSQL will still call the function if the array has null elements.

When replacing an existing function with CREATE OR REPLACE FUNCTION, there are restrictions on changing parameter names. You cannot change the name already assigned to any input parameter (although you can add names to parameters that had none before). If there is more than one output parameter, you cannot change the names of the output parameters, because that would change the column names of the anonymous composite type that describes the function's result. These restrictions are made to ensure that existing calls of the function do not stop working when it is replaced.

Using Functions with Queries on Distributed Data

In some cases, Greenplum Database does not support using functions in a query where the data in a table specified in the FROM clause is distributed over Greenplum Database segments. As an example, this SQL query contains the function `func()`:

```
SELECT func(a) FROM table1;
```

The function is not supported for use in the query if all of the following conditions are met:

- The data of table `table1` is distributed over Greenplum Database segments.
- The function `func()` reads or modifies data from distributed tables.
- The function `func()` returns more than one row or takes an argument (`a`) that comes from `table1`.

If any of the conditions are not met, the function is supported. Specifically, the function is supported if any of the following conditions apply:

- The function `func()` does not access data from distributed tables, or accesses data that is only on the Greenplum Database master.
- The table `table1` is a master only table.
- The function `func()` returns only one row and only takes input arguments that are constant values. The function is supported if it can be changed to require no input arguments.

Using EXECUTE ON attributes

Most functions that execute queries to access tables can only execute on the master. However, functions that execute only SELECT queries on replicated tables can run on segments. If the function accesses a hash-distributed table or a randomly distributed table, the function should be defined with the EXECUTE ON MASTER attribute. Otherwise, the function might return incorrect results when the function is used in a complicated query. Without the attribute, planner optimization might determine it would be beneficial to push the function invocation to segment instances.

These are limitations for functions defined with the EXECUTE ON MASTER or EXECUTE ON ALL SEGMENTS attribute:

- The function must be a set-returning function.
- The function cannot be in the FROM clause of a query.
- The function cannot be in the SELECT list of a query with a FROM clause.
- A query that includes the function falls back from GPORCA to the Postgres Planner.

Examples

A very simple addition function:

```
CREATE FUNCTION add(integer, integer) RETURNS integer
AS 'select $1 + $2;'
LANGUAGE SQL
IMMUTABLE
```
RETURNS NULL ON NULL INPUT;

Increment an integer, making use of an argument name, in PL/pgSQL:

```sql
CREATE OR REPLACE FUNCTION increment(i integer) RETURNS integer AS $$
BEGIN
    RETURN i + 1;
END;
$$ LANGUAGE plpgsql;
```

Increase the default segment host memory per query for a PL/pgSQL function:

```sql
CREATE OR REPLACE FUNCTION function_with_query() RETURNS SETOF text AS $$
BEGIN
    RETURN QUERY
    EXPLAIN ANALYZE SELECT * FROM large_table;
END;
$$ LANGUAGE plpgsql;

SET statement_mem='256MB';
```

Use polymorphic types to return an ENUM array:

```sql
CREATE TYPE rainbow AS
    ENUM('red','orange','yellow','green','blue','indigo','violet');
CREATE FUNCTION return_enum_as_array( anyenum, anyelement, anyelement )
RETURNS TABLE (ae anyenum, aa anyarray) AS $$
SELECT $1, array[$2, $3]
$$ LANGUAGE SQL STABLE;

SELECT * FROM return_enum_as_array('red'::rainbow, 'green'::rainbow, 'blue'::rainbow);
```

Return a record containing multiple output parameters:

```sql
CREATE FUNCTION dup(in int, out f1 int, out f2 text)
AS $$ SELECT $1, CAST($1 AS text) || ' is text' $$
LANGUAGE SQL;

SELECT * FROM dup(42);
```

You can do the same thing more verbosely with an explicitly named composite type:

```sql
CREATE TYPE dup_result AS (f1 int, f2 text);
CREATE FUNCTION dup(int) RETURNS dup_result
AS $$ SELECT $1, CAST($1 AS text) || ' is text' $$
LANGUAGE SQL;

SELECT * FROM dup(42);
```

Another way to return multiple columns is to use a TABLE function:

```sql
CREATE FUNCTION dup(int) RETURNS TABLE(f1 int, f2 text)
AS $$ SELECT $1, CAST($1 AS text) || ' is text' $$
LANGUAGE SQL;

SELECT * FROM dup(4);
This function is defined with the `EXECUTE ON ALL SEGMENTS` to run on all primary segment instances. The `SELECT` command executes the function that returns the time it was run on each segment instance.

```sql
CREATE FUNCTION run_on_segs (text) returns setof text as $$
begin
    return next ($1 || ' - ' || now()::text);
end;
$$ language plpgsql VOLATILE EXECUTE ON ALL SEGMENTS;

SELECT run_on_segs('my test');
```

This function looks up a part name in the parts table. The parts table is replicated, so the function can execute on the master or on the primary segments.

```sql
CREATE OR REPLACE FUNCTION get_part_name(partno int) RETURNS text AS $$
DECLARE
    result text := ' ';
BEGIN
    SELECT part_name INTO result FROM parts WHERE part_id = partno;
    RETURN result;
END;
$$ LANGUAGE plpgsql;
```

If you execute `SELECT get_part_name(100);` at the master the function executes on the master. (The master instance directs the query to a single primary segment.) If orders is a distributed table and you execute the following query, the `get_part_name()` function executes on the primary segments.

```sql
SELECT order_id, get_part_name(orders.part_no) FROM orders;
```

### Compatibility

`CREATE FUNCTION` is defined in SQL:1999 and later. The Greenplum Database version is similar but not fully compatible. The attributes are not portable, neither are the different available languages.

For compatibility with some other database systems, `argmode` can be written either before or after `argname`. But only the first way is standard-compliant.

For parameter defaults, the SQL standard specifies only the syntax with the `DEFAULT` key word. The syntax with `=` is used in T-SQL and Firebird.

`ALTER FUNCTION`, `DROP FUNCTION`, `LOAD`

---

**CREATE GROUP**

Defines a new database role.

### Synopsis

```sql
CREATE GROUP name [[WITH] option [ ... ]]
```

where `option` can be:

- `SUPERUSER | NOSUPERUSER`
- `CREATEDB | NOCREATEDB`
- `CREATEROLE | NOCREATEROLE`
- `CREATEUSER | NOCREATEUSER`
CREATE EXTERNAL TABLE | NOCREATEEXTTABLE
[ ( attribute='value',[ ...] ) ]
where attributes and value are:
type='readable'|'writable'
protocol='gpfdist'|'http'
INHERIT | NOINHERIT
LOGIN | NOLOGIN
CONNECTION LIMIT conllimit
[ ENCRYPTED | UNENCRIPTED ] PASSWORD 'password'
VALID UNTIL 'timestamp'
IN ROLE rolename [, ...]
ROLE rolename [, ...]
ADMIN rolename [, ...]
RESOURCE QUEUE queue_name
RESOURCE GROUP group_name
[ DENY deny_point ]
[ DENY BETWEEN deny_point AND deny_point]

Description
CREATE GROUP is an alias for CREATE ROLE.

Compatibility
There is no CREATE GROUP statement in the SQL standard.

See Also
CREATE ROLE

CREATE INDEX
Defines a new index.

Synopsis
CREATE [UNIQUE] INDEX [name] ON table_name [USING method]
( (column_name | (expression)) [COLLATE parameter] [opclass] [ ASC | DESC ] [ NULLS [ FIRST | LAST ] ] [, ... ] )
[ WITH ( storageParameter = value [, ... ] ) ]
[ TABLESPACE tablespace ]
[ WHERE predicate ]

Description
CREATE INDEX constructs an index on the specified column(s) of the specified table. Indexes are primarily used to enhance database performance (though inappropriate use can result in slower performance).

The key field(s) for the index are specified as column names, or alternatively as expressions written in parentheses. Multiple fields can be specified if the index method supports multicolumn indexes.

An index field can be an expression computed from the values of one or more columns of the table row. This feature can be used to obtain fast access to data based on some transformation of the basic data. For example, an index computed on upper(col) would allow the clause WHERE upper(col) = 'JIM' to use an index.

Greenplum Database provides the index methods B-tree, bitmap, GiST, SP-GiST, and GIN. Users can also define their own index methods, but that is fairly complicated.
When the `WHERE` clause is present, a partial index is created. A partial index is an index that contains entries for only a portion of a table, usually a portion that is more useful for indexing than the rest of the table. For example, if you have a table that contains both billed and unbilled orders where the unbilled orders take up a small fraction of the total table and yet is most often selected, you can improve performance by creating an index on just that portion.

The expression used in the `WHERE` clause may refer only to columns of the underlying table, but it can use all columns, not just the ones being indexed. Subqueries and aggregate expressions are also forbidden in `WHERE`. The same restrictions apply to index fields that are expressions.

All functions and operators used in an index definition must be immutable. Their results must depend only on their arguments and never on any outside influence (such as the contents of another table or a parameter value). This restriction ensures that the behavior of the index is well-defined. To use a user-defined function in an index expression or `WHERE` clause, remember to mark the function `IMMUTABLE` when you create it.

**Parameters**

**UNIQUE**
Checks for duplicate values in the table when the index is created and each time data is added. Duplicate entries will generate an error. Unique indexes only apply to B-tree indexes. In Greenplum Database, unique indexes are allowed only if the columns of the index key are the same as (or a superset of) the Greenplum distribution key. On partitioned tables, a unique index is only supported within an individual partition - not across all partitions.

**name**
The name of the index to be created. The index is always created in the same schema as its parent table. If the name is omitted, Greenplum Database chooses a suitable name based on the parent table's name and the indexed column name(s).

**table_name**
The name (optionally schema-qualified) of the table to be indexed.

**method**
The name of the index method to be used. Choices are `btree`, `bitmap`, `gist`, `spgist`, and `gin`. The default method is `btree`.

Currently, only the B-tree, GiST, and GIN index methods support multicolumn indexes. Up to 32 fields can be specified by default. Only B-tree currently supports unique indexes.

GPORCA supports only B-tree, bitmap, GiST, and GIN indexes. GPORCA ignores indexes created with unsupported indexing methods.

**column_name**
The name of a column of the table on which to create the index. Only the B-tree, bitmap, GiST, and GIN index methods support multicolumn indexes.

**expression**
An expression based on one or more columns of the table. The expression usually must be written with surrounding parentheses, as shown in the syntax. However, the parentheses may be omitted if the expression has the form of a function call.

**collation**
The name of the collation to use for the index. By default, the index uses the collation declared for the column to be indexed or the result collation of the expression to be indexed. Indexes with non-default collations can be useful for queries that involve expressions using non-default collations.

**opclass**
The name of an operator class. The operator class identifies the operators to be used by the index for that column. For example, a B-tree index on four-byte integers would use the `int4_ops` class (this operator class includes comparison functions for four-byte integers). In practice the default operator class for the column's data type is usually sufficient. The main point of having operator classes is that for some data types, there could be more than one meaningful ordering. For example, a complex-number data type could be sorted by either absolute value or by real part. We could do this by defining two operator classes for the data type and then selecting the proper class when making an index.

**ASC**

Specifies ascending sort order (which is the default).

**DESC**

Specifies descending sort order.

**NULLS FIRST**

Specifies that nulls sort before non-nulls. This is the default when `DESC` is specified.

**NULLS LAST**

Specifies that nulls sort after non-nulls. This is the default when `DESC` is not specified.

**storage_parameter**

The name of an index-method-specific storage parameter. Each index method has its own set of allowed storage parameters.

**FILLFACTOR**

- B-tree, bitmap, GiST, and SP-GiST index methods all accept this parameter. The `FILLFACTOR` for an index is a percentage that determines how full the index method will try to pack index pages. For B-trees, leaf pages are filled to this percentage during initial index build, and also when extending the index at the right (adding new largest key values). If pages subsequently become completely full, they will be split, leading to gradual degradation in the index's efficiency. B-trees use a default fillfactor of 90, but any integer value from 10 to 100 can be selected. If the table is static then fillfactor 100 is best to minimize the index's physical size, but for heavily updated tables a smaller fillfactor is better to minimize the need for page splits. The other index methods use fillfactor in different but roughly analogous ways; the default fillfactor varies between methods.

**BUFFERING**

- In addition to `FILLFACTOR`, GiST indexes additionally accept the `BUFFERING` parameter. `BUFFERING` determines whether Greenplum Database builds the index using the buffering build technique described in *GiST buffering build* in the PostgreSQL documentation. With `OFF` it is disabled, with `ON` it is enabled, and with `AUTO` it is initially disabled, but turned on on-the-fly once the index size reaches `effective-cache-size`. The default is `AUTO`.

**FASTUPDATE**

- The GIN index method accepts the `FASTUPDATE` storage parameter. `FASTUPDATE` is a Boolean parameter that disables or enables the GIN index fast update technique. A value of `ON` enables fast update (the default), and `OFF` disables it. See *GIN fast update technique* in the PostgreSQL documentation for more information.

Note: Turning `FASTUPDATE` off via `ALTER INDEX` prevents future insertions from going into the list of pending index entries, but does not in itself flush previous entries. You might want to `VACUUM` the table afterward to ensure the pending list is emptied.

**tablespace_name**

The tablespace in which to create the index. If not specified, the default tablespace is used, or `temp_tablespaces` for indexes on temporary tables.

**predicate**

The constraint expression for a partial index.
Notes

An operator class can be specified for each column of an index. The operator class identifies the operators to be used by the index for that column. For example, a B-tree index on four-byte integers would use the int4_ops class; this operator class includes comparison functions for four-byte integers. In practice the default operator class for the column's data type is usually sufficient. The main point of having operator classes is that for some data types, there could be more than one meaningful ordering. For example, we might want to sort a complex-number data type either by absolute value or by real part. We could do this by defining two operator classes for the data type and then selecting the proper class when making an index.

For index methods that support ordered scans (currently, only B-tree), the optional clauses ASC, DESC, NULLS FIRST, and/or NULLS LAST can be specified to modify the sort ordering of the index. Since an ordered index can be scanned either forward or backward, it is not normally useful to create a single-column DESC index — that sort ordering is already available with a regular index. The value of these options is that multicolumn indexes can be created that match the sort ordering requested by a mixed-ordering query, such as SELECT ... ORDER BY x ASC, y DESC. The NULLS options are useful if you need to support "nulls sort low" behavior, rather than the default "nulls sort high", in queries that depend on indexes to avoid sorting steps.

For most index methods, the speed of creating an index is dependent on the setting of maintenance_work_mem. Larger values will reduce the time needed for index creation, so long as you don't make it larger than the amount of memory really available, which would drive the machine into swapping.

When an index is created on a partitioned table, the index is propagated to all the child tables created by Greenplum Database. Creating an index on a table that is created by Greenplum Database for use by a partitioned table is not supported.

UNIQUE indexes are allowed only if the index columns are the same as (or a superset of) the Greenplum distribution key columns.

UNIQUE indexes are not allowed on append-optimized tables.

A UNIQUE index can be created on a partitioned table. However, uniqueness is enforced only within a partition; uniqueness is not enforced between partitions. For example, for a partitioned table with partitions that are based on year and a subpartitions that are based on quarter, uniqueness is enforced only on each individual quarter partition. Uniqueness is not enforced between quarter partitions.

Indexes are not used for IS NULL clauses by default. The best way to use indexes in such cases is to create a partial index using an IS NULL predicate.

Bitmap indexes perform best for columns that have between 100 and 100,000 distinct values. For a column with more than 100,000 distinct values, the performance and space efficiency of a bitmap index decline. The size of a bitmap index is proportional to the number of rows in the table times the number of distinct values in the indexed column.

Columns with fewer than 100 distinct values usually do not benefit much from any type of index. For example, a gender column with only two distinct values for male and female would not be a good candidate for an index.

Prior releases of Greenplum Database also had an R-tree index method. This method has been removed because it had no significant advantages over the GiST method. If USING rtree is specified, CREATE INDEX will interpret it as USING gist.

For more information on the GiST index type, refer to the PostgreSQL documentation.

The use of hash indexes has been disabled in Greenplum Database.
Examples

To create a B-tree index on the column title in the table films:

```sql
CREATE UNIQUE INDEX title_idx ON films (title);
```

To create a bitmap index on the column gender in the table employee:

```sql
CREATE INDEX gender_bmp_idx ON employee USING bitmap (gender);
```

To create an index on the expression lower(title), allowing efficient case-insensitive searches:

```sql
CREATE INDEX ON films ((lower(title)));
```

(In this example we have chosen to omit the index name, so the system will choose a name, typically films_lower_idx.)

To create an index with non-default collation:

```sql
CREATE INDEX title_idx_german ON films (title COLLATE "de_DE");
```

To create an index with non-default fill factor:

```sql
CREATE UNIQUE INDEX title_idx ON films (title) WITH (fillfactor = 70);
```

To create a GIN index with fast updates disabled:

```sql
CREATE INDEX gin_idx ON documents_table USING gin (locations) WITH (fastupdate = off);
```

To create an index on the column code in the table films and have the index reside in the tablespace indexspace:

```sql
CREATE INDEX code_idx ON films(code) TABLESPACE indexspace;
```

To create a GiST index on a point attribute so that we can efficiently use box operators on the result of the conversion function:

```sql
CREATE INDEX pointloc ON points USING gist (box(location,location));
SELECT * FROM points WHERE box(location,location) && '(0,0),(1,1)::box;
```

Compatibility

CREATE INDEX is a Greenplum Database language extension. There are no provisions for indexes in the SQL standard.

Greenplum Database does not support the concurrent creation of indexes (CONCURRENTLY keyword not supported).

CREATE LANGUAGE

Defines a new procedural language.
Synopsis

CREATE [ OR REPLACE ] [ PROCEDURAL ] LANGUAGE name

CREATE [ OR REPLACE ] [ TRUSTED ] [ PROCEDURAL ] LANGUAGE name
   HANDLER call_handler [ INLINE inline_handler ]
   [ VALIDATOR valfunction ]

Description

CREATE LANGUAGE registers a new procedural language with a Greenplum database. Subsequently, functions and trigger procedures can be defined in this new language.

Note: Procedural languages for Greenplum Database have been made into "extensions," and should therefore be installed with CREATE EXTENSION, not CREATE LANGUAGE. Using CREATE LANGUAGE directly should be restricted to extension installation scripts. If you have a "bare" language in your database, perhaps as a result of an upgrade, you can convert it to an extension using CREATE EXTENSION langname FROM unpackaged.

Superusers can register a new language with a Greenplum database. A database owner can also register within that database any language listed in the pg_pltemplate catalog in which the tmpldbacreate field is true. The default configuration allows only trusted languages to be registered by database owners. The creator of a language becomes its owner and can later drop it, rename it, or assign ownership to a new owner.

CREATE OR REPLACE LANGUAGE will either create a new language, or replace an existing definition. If the language already exists, its parameters are updated according to the values specified or taken from pg_pltemplate, but the language's ownership and permissions settings do not change, and any existing functions written in the language are assumed to still be valid. In addition to the normal privilege requirements for creating a language, the user must be superuser or owner of the existing language. The REPLACE case is mainly meant to be used to ensure that the language exists. If the language has a pg_pltemplate entry then REPLACE will not actually change anything about an existing definition, except in the unusual case where the pg_pltemplate entry has been modified since the language was created.

CREATE LANGUAGE effectively associates the language name with handler function(s) that are responsible for executing functions written in that language. For a function written in a procedural language (a language other than C or SQL), the database server has no built-in knowledge about how to interpret the function's source code. The task is passed to a special handler that knows the details of the language. The handler could either do all the work of parsing, syntax analysis, execution, and so on or it could serve as a bridge between Greenplum Database and an existing implementation of a programming language. The handler itself is a C language function compiled into a shared object and loaded on demand, just like any other C function. Therese procedural language packages are included in the standard Greenplum Database distribution: PL/pgSQL, PL/Perl, and PL/Python. Language handlers have also been added for PL/Java and PL/R, but those languages are not pre-installed with Greenplum Database. See the topic on Procedural Languages in the PostgreSQL documentation for more information on developing functions using these procedural languages.

The PL/Perl, PL/Java, and PL/R libraries require the correct versions of Perl, Java, and R to be installed, respectively.

On RHEL and SUSE platforms, download the appropriate extensions from Pivotal Network, then install the extensions using the Greenplum Package Manager (gppkg) utility to ensure that all dependencies are installed as well as the extensions. See the Greenplum Database Utility Guide for details about gppkg.

There are two forms of the CREATE LANGUAGE command. In the first form, the user specifies the name of the desired language and the Greenplum Database server uses the pg_pltemplate system catalog to determine the correct parameters. In the second form, the user specifies the language parameters as well as the language name. You can use the second form to create a language that is not defined in pg_pltemplate.
When the server finds an entry in the `pg_pltemplate` catalog for the given language name, it will use the catalog data even if the command includes language parameters. This behavior simplifies loading of old dump files, which are likely to contain out-of-date information about language support functions.

**Parameters**

**TRUSTED**

`TRUSTED` specifies that the language does not grant access to data that the user would not otherwise have. If this key word is omitted when registering the language, only users with the Greenplum Database superuser privilege can use this language to create new functions.

**PROCEDURAL**

This is a noise word.

**name**

The name of the new procedural language. The name must be unique among the languages in the database. Built-in support is included for `plpgsql`, `plperl`, and `plpythonu`. The languages `plpgsql` (PL/pgSQL) and `plpythonu` (PL/Python) are installed by default in Greenplum Database.

**HANDLER** `call_handler`

Ignored if the server has an entry for the specified language name in `pg_pltemplate`. The name of a previously registered function that will be called to execute the procedural language functions. The call handler for a procedural language must be written in a compiled language such as C with version 1 call convention and registered with Greenplum Database as a function taking no arguments and returning the `language_handler` type, a placeholder type that is simply used to identify the function as a call handler.

**INLINE** `inline_handler`

The name of a previously registered function that is called to execute an anonymous code block in this language that is created with the `DO` command. If an `inline_handler` function is not specified, the language does not support anonymous code blocks. The handler function must take one argument of type `internal`, which is the `DO` command internal representation. The function typically return `void`. The return value of the handler is ignored.

**VALIDATOR** `valfunction`

Ignored if the server has an entry for the specified language name in `pg_pltemplate`. The name of a previously registered function that will be called to execute the procedural language functions. The call handler for a procedural language must be written in a compiled language such as C with version 1 call convention and registered with Greenplum Database as a function taking no arguments and returning the `language_handler` type, a placeholder type that is simply used to identify the function as a call handler.

**Notes**

The PL/pgSQL language is already registered in all databases by default. The PL/Python language extension is installed but not registered.

The system catalog `pg_language` records information about the currently installed languages.

To create functions in a procedural language, a user must have the `USAGE` privilege for the language. By default, `USAGE` is granted to `PUBLIC` (everyone) for trusted languages. This may be revoked if desired.

Procedural languages are local to individual databases. You create and drop languages for individual databases.
The call handler function and the validator function (if any) must already exist if the server does not have an entry for the language in `pg_pltemplate`. But when there is an entry, the functions need not already exist; they will be automatically defined if not present in the database.

Any shared library that implements a language must be located in the same `LD_LIBRARY_PATH` location on all segment hosts in your Greenplum Database array.

**Examples**

The preferred way of creating any of the standard procedural languages is to use `CREATE EXTENSION` instead of `CREATE LANGUAGE`. For example:

```
CREATE EXTENSION plperl;
```

For a language not known in the `pg_pltemplate` catalog:

```
CREATE FUNCTION plsample_call_handler() RETURNS language_handler
  AS '$libdir/plsample'
  LANGUAGE C;
CREATE LANGUAGE plsample
  HANDLER plsample_call_handler;
```

**Compatibility**

`CREATE LANGUAGE` is a Greenplum Database extension.

**See Also**

`ALTER LANGUAGE`, `CREATE EXTENSION`, `CREATE FUNCTION`, `DROP EXTENSION`, `DROP LANGUAGE`, `GRANT DO`

**CREATE OPERATOR**

Defines a new operator.

**Synopsis**

```
CREATE OPERATOR name (  
  PROCEDURE = funcname  
  [, LEFTARG = lefttype] [, RIGHTARG = righttype]  
  [, COMMUTATOR = com_op] [, NEGATOR = neg_op]  
  [, RESTRICT = res_proc] [, JOIN = join_proc]  
  [, HASHES] [, MERGES] )
```

**Description**

`CREATE OPERATOR` defines a new operator. The user who defines an operator becomes its owner.

The operator name is a sequence of up to `NAMEDATALEN-1` (63 by default) characters from the following list: `+ - * / < > = ~ @ # % ^ & | ` ?

There are a few restrictions on your choice of name:

- `--` and `/` cannot appear anywhere in an operator name, since they will be taken as the start of a comment.
- A multicharacter operator name cannot end in `+` or `--`, unless the name also contains at least one of these characters: `~ ! @ # % ^ & | ` ?
For example, `@-` is an allowed operator name, but `*-` is not. This restriction allows Greenplum Database to parse SQL-compliant commands without requiring spaces between tokens.

The use of `=>` as an operator name is deprecated. It may be disallowed altogether in a future release.

The operator `!=` is mapped to `<>` on input, so these two names are always equivalent.

At least one of `LEFTARG` and `RIGHTARG` must be defined. For binary operators, both must be defined. For right unary operators, only `LEFTARG` should be defined, while for left unary operators only `RIGHTARG` should be defined.

The `funcname` procedure must have been previously defined using `CREATE FUNCTION`, must be `IMMUTABLE`, and must be defined to accept the correct number of arguments (either one or two) of the indicated types.

The other clauses specify optional operator optimization clauses. These clauses should be provided whenever appropriate to speed up queries that use the operator. But if you provide them, you must be sure that they are correct. Incorrect use of an optimization clause can result in server process crashes, subtly wrong output, or other unexpected results. You can always leave out an optimization clause if you are not sure about it.

To be able to create an operator, you must have `USAGE` privilege on the argument types and the return type, as well as `EXECUTE` privilege on the underlying function. If a commutator or negator operator is specified, you must own these operators.

**Parameters**

**name**

The (optionally schema-qualified) name of the operator to be defined. Two operators in the same schema can have the same name if they operate on different data types.

**funcname**

The function used to implement this operator (must be an `IMMUTABLE` function).

**lefttype**

The data type of the operator's left operand, if any. This option would be omitted for a left-unary operator.

**righttype**

The data type of the operator's right operand, if any. This option would be omitted for a right-unary operator.

**com_op**

The optional `COMMUTATOR` clause names an operator that is the commutator of the operator being defined. We say that operator A is the commutator of operator B if `(x A y)` equals `(y B x)` for all possible input values `x`, `y`. Notice that B is also the commutator of A. For example, operators `<` and `>` for a particular data type are usually each others commutators, and operator `+` is usually commutative with itself. But operator `-` is usually not commutative with anything. The left operand type of a commutable operator is the same as the right operand type of its commutator, and vice versa. So the name of the commutator operator is all that needs to be provided in the `COMMUTATOR` clause.

**neg_op**

The optional `NEGATOR` clause names an operator that is the negator of the operator being defined. We say that operator A is the negator of operator B if both return Boolean results and `(x A y)` equals NOT `(x B y)` for all possible inputs `x`, `y`. Notice that B is also the negator of A. For example, `<` and `>=` are a negator pair for most data types. An operator's negator must have the same left and/or right operand types as the operator to be defined, so only the operator name need be given in the `NEGATOR` clause.

**res_proc**
The optional `RESTRICT` names a restriction selectivity estimation function for the operator. Note that this is a function name, not an operator name. `RESTRICT` clauses only make sense for binary operators that return `boolean`. The idea behind a restriction selectivity estimator is to guess what fraction of the rows in a table will satisfy a `WHERE`-clause condition of the form:

```
column OP constant
```

for the current operator and a particular constant value. This assists the optimizer by giving it some idea of how many rows will be eliminated by `WHERE` clauses that have this form.

You can usually just use one of the following system standard estimator functions for many of your own operators:

- `eqsel` for `=`
- `neqsel` for `<>`
- `scalarltssel` for `< or` `<=`
- `scalargtssel` for `>` or `>=`

`join_proc`

The optional `JOIN` clause names a join selectivity estimation function for the operator. Note that this is a function name, not an operator name. `JOIN` clauses only make sense for binary operators that return `boolean`. The idea behind a join selectivity estimator is to guess what fraction of the rows in a pair of tables will satisfy a `WHERE`-clause condition of the form:

```
table1.column1 OP table2.column2
```

for the current operator. This helps the optimizer by letting it figure out which of several possible join sequences is likely to take the least work.

You can usually just use one of the following system standard join selectivity estimator functions for many of your own operators:

- `eqjoinsel` for `=`
- `neqjoinsel` for `<>`
- `scalarltjoinsel` for `< or` `<=`
- `scalargtjoinsel` for `>` or `>=`
- `areajoinsel` for 2D area-based comparisons
- `positionjoinsel` for 2D position-based comparisons
- `contjoinsel` for 2D containment-based comparisons

**HASHES**

The optional `HASHES` clause tells the system that it is permissible to use the hash join method for a join based on this operator. `HASHES` only makes sense for a binary operator that returns `boolean`. The hash join operator can only return true for pairs of left and right values that hash to the same hash code. If two values are put in different hash buckets, the join will never compare them, implicitly assuming that the result of the join operator must be false. Because of this, it never makes sense to specify `HASHES` for operators that do not represent equality.

In most cases, it is only practical to support hashing for operators that take the same data type on both sides. However, you can design compatible hash functions for two or more data types, which are functions that will generate the same hash codes for “equal” values, even if the values are differently represented.
To be marked \texttt{HASHES}, the join operator must appear in a hash index operator class. Attempts to use the operator in hash joins will fail at run time if no such operator class exists. The system needs the operator class to find the data-type-specific hash function for the operator's input data type. You must also supply a suitable hash function before you can create the operator class. Exercise care when preparing a hash function, as there are machine-dependent ways in which it could fail to function correctly. For example, on machines that meet the IEEE floating-point standard, negative zero and positive zero are different values (different bit patterns) but are defined to compare as equal. If a float value could contain a negative zero, define it to generate the same hash value as positive zero.

A hash-joinable operator must have a commutator (itself, if the two operand data types are the same, or a related equality operator if they are different) that appears in the same operator family. Otherwise, planner errors can occur when the operator is used. For better optimization, a hash operator family that supports multiple data types should provide equality operators for every combination of the data types.

\textbf{Note:} The function underlying a hash-joinable operator must be marked immutable or stable; an operator marked as volatile will not be used. If a hash-joinable operator has an underlying function that is marked strict, the function must also be complete, returning true or false, and not null, for any two non-null inputs.

\texttt{MERGES}

The \texttt{MERGES} clause, if present, tells the system that it is permissible to use the merge-join method for a join based on this operator. \texttt{MERGES} only makes sense for a binary operator that returns boolean, and in practice the operator must represent equality for some data type or pair of data types.

Merge join is based on the idea of sorting the left- and right-hand tables into order and then scanning them in parallel. This means both data types must be capable of being fully ordered, and the join operator must be one that can only succeed for pairs of values that fall at equivalent places in the sort order. In practice, this means that the join operator must behave like an equality operator. However, you can merge-join two distinct data types so long as they are logically compatible. For example, the \texttt{smallint-versus-integer} equality operator is merge-joinable. Only sorting operators that bring both data types into a logically compatible sequence are needed.

To be marked \texttt{MERGES}, the join operator must appear as an equality member of a btree index operator family. This is not enforced when you create the operator, because the referencing operator family does not exist until later. However, the operator will not actually be used for merge joins unless a matching operator family can be found. The \texttt{MERGE} flag thus acts as a suggestion to the planner to look for a matching operator family.

A merge-joinable operator must have a commutator that appears in the same operator family. This would be itself, if the two operand data types are the same, or a related equality operator if the data types are different. Without an appropriate commutator, planner errors can occur when the operator is used. Also, although not strictly required, a btree operator family that supports multiple data types should be able to provide equality operators for every combination of the data types; this allows better optimization.

\textbf{Note:} \texttt{SORT1}, \texttt{SORT2}, \texttt{LTCMP}, and \texttt{GTCMP} were formerly used to specify the names of sort operators associated with a merge-joinable operator. Information about associated operators is now found by looking at B-tree operator families; specifying any of these operators will be ignored, except that it will implicitly set \texttt{MERGES} to true.

\textbf{Notes}

Any functions used to implement the operator must be defined as \texttt{IMMUTABLE}.
It is not possible to specify an operator's lexical precedence in `CREATE OPERATOR`, because the parser's precedence behavior is hard-wired. See `Operator Precedence` in the PostgreSQL documentation for precedence details.

Use `DROP OPERATOR` to delete user-defined operators from a database. Use `ALTER OPERATOR` to modify operators in a database.

**Examples**

Here is an example of creating an operator for adding two complex numbers, assuming we have already created the definition of type `complex`. First define the function that does the work, then define the operator:

```
CREATE FUNCTION complex_add(complex, complex)
    RETURNS complex
    AS 'filename', 'complex_add'
    LANGUAGE C IMMUTABLE STRICT;
CREATE OPERATOR + (
    leftarg = complex,
    rightarg = complex,
    procedure = complex_add,
    commutator = +
);
```

To use this operator in a query:

```
SELECT (a + b) AS c FROM test_complex;
```

**Compatibility**

`CREATE OPERATOR` is a Greenplum Database language extension. The SQL standard does not provide for user-defined operators.

**See Also**

`CREATE FUNCTION`, `CREATE TYPE`, `ALTER OPERATOR`, `DROP OPERATOR`
All the operators and functions used by an operator class must be defined before the operator class is created. Any functions used to implement the operator class must be defined as `IMMUTABLE`.

`CREATE OPERATOR CLASS` does not presently check whether the operator class definition includes all the operators and functions required by the index method, nor whether the operators and functions form a self-consistent set. It is the user’s responsibility to define a valid operator class.

You must be a superuser to create an operator class.

**Parameters**

*name*

The (optionally schema-qualified) name of the operator class to be defined. Two operator classes in the same schema can have the same name only if they are for different index methods.

*DEFAULT*

Makes the operator class the default operator class for its data type. At most one operator class can be the default for a specific data type and index method.

*data_type*

The column data type that this operator class is for.

*index_method*

The name of the index method this operator class is for. Choices are `btree`, `bitmap`, and `gist`.

*family_name*

The name of the existing operator family to add this operator class to. If not specified, a family named the same as the operator class is used (creating it, if it doesn't already exist).

*strategy_number*

The operators associated with an operator class are identified by `strategy numbers`, which serve to identify the semantics of each operator within the context of its operator class. For example, B-trees impose a strict ordering on keys, lesser to greater, and so operators like `less than` and `greater than or equal` to are interesting with respect to a B-tree. These strategies can be thought of as generalized operators. Each operator class specifies which actual operator corresponds to each strategy for a particular data type and interpretation of the index semantics. The corresponding strategy numbers for each index method are as follows:

**Table 80: B-tree and Bitmap Strategies**

<table>
<thead>
<tr>
<th>Operation</th>
<th>Strategy Number</th>
</tr>
</thead>
<tbody>
<tr>
<td>less than</td>
<td>1</td>
</tr>
<tr>
<td>less than or equal</td>

</tr>
</tbody>
</table>

### sort_family_name

The name (optionally schema-qualified) of an existing `btree` operator family that describes the sort ordering associated with an ordering operator.

If neither `FOR SEARCH` nor `FOR ORDER BY` is specified, `FOR SEARCH` is the default.

### operator_name

The name (optionally schema-qualified) of an operator associated with the operator class.

### op_type

In an `OPERATOR` clause, the operand data type(s) of the operator, or `NONE` to signify a left-unary or right-unary operator. The operand data types can be omitted in the normal case where they are the same as the operator class's data type.

In a `FUNCTION` clause, the operand data type(s) the function is intended to support, if different from the input data type(s) of the function (for B-tree comparison functions and hash functions) or the class's data type (for B-tree sort support functions and all functions in GiST, SP-GiST, and GIN operator classes). These defaults are correct, and so `op_type` need not be specified in `FUNCTION` clauses, except for the case of a B-tree sort support function that is meant to support cross-data-type comparisons.

### support_number

Index methods require additional support routines in order to work. These operations are administrative routines used internally by the index methods. As with strategies, the operator class identifies which specific functions should play each of these roles for a given data type and semantic interpretation. The index method defines the set of functions it needs, and the operator class identifies the correct functions to use by assigning them to the `support function numbers` as follows:

### Table 82: B-tree and Bitmap Support Functions

<table>
<thead>
<tr>
<th>Function</th>
<th>Support Number</th>
</tr>
</thead>
<tbody>
<tr>
<td>Compare two keys and return an integer less than zero, zero, or greater than zero, indicating whether the first key is less than, equal to, or greater than the second.</td>
<td>1</td>
</tr>
</tbody>
</table>
### Table 83: GiST Support Functions

<table>
<thead>
<tr>
<th>Function</th>
<th>Support Number</th>
</tr>
</thead>
<tbody>
<tr>
<td>consistent - determine whether key satisfies the query qualifier.</td>
<td>1</td>
</tr>
<tr>
<td>union - compute union of a set of keys.</td>
<td>2</td>
</tr>
<tr>
<td>compress - compute a compressed representation of a key or value to be indexed.</td>
<td>3</td>
</tr>
<tr>
<td>decompress - compute a decompressed representation of a compressed key.</td>
<td>4</td>
</tr>
<tr>
<td>penalty - compute penalty for inserting new key into subtree with given subtree's key.</td>
<td>5</td>
</tr>
<tr>
<td>picksplit - determine which entries of a page are to be moved to the new page and compute the union keys for resulting pages.</td>
<td>6</td>
</tr>
<tr>
<td>equal - compare two keys and return true if they are equal.</td>
<td>7</td>
</tr>
</tbody>
</table>

**funcname**

The name (optionally schema-qualified) of a function that is an index method support procedure for the operator class.

**argument_types**

The parameter data type(s) of the function.

**storage_type**

The data type actually stored in the index. Normally this is the same as the column data type, but some index methods (currently GiST and GIN) allow it to be different. The `STORAGE` clause must be omitted unless the index method allows a different type to be used.

### Notes

Because the index machinery does not check access permissions on functions before using them, including a function or operator in an operator class is the same as granting public execute permission on it. This is usually not an issue for the sorts of functions that are useful in an operator class.

The operators should not be defined by SQL functions. A SQL function is likely to be inlined into the calling query, which will prevent the optimizer from recognizing that the query matches an index.

Any functions used to implement the operator class must be defined as `IMMUTABLE`.

Before Greenplum Database 6.0, the `OPERATOR` clause could include a `RECHECK` option. This option is no longer supported. Greenplum Database now determines whether an index operator is "lossy" on-the-fly at run time. This allows more efficient handling of cases where an operator might or might not be lossy.

### Examples

The following example command defines a GiST index operator class for the data type `_int4` (array of `int4`). See the `intarray` contrib module for the complete example.

```
CREATE OPERATOR CLASS gist__int_ops
    DEFAULT FOR TYPE _int4 USING gist AS
```
OPERATOR 3 &&,
OPERATOR 6 = (anyarray, anyarray),
OPERATOR 7 @>,
OPERATOR 8 <@,
OPERATOR 20 @@ (_int4, query_int),
FUNCTION 1 g_int_consistent (internal, _int4, int, oid, internal),
FUNCTION 2 g_int_union (internal, internal),
FUNCTION 3 g_int_compress (internal),
FUNCTION 4 g_int_decompress (internal),
FUNCTION 5 g_int_penalty (internal, internal, internal),
FUNCTION 6 g_int_picksplit (internal, internal),
FUNCTION 7 g_int_same (_int4, _int4, internal);

Compatibility

CREATE OPERATOR CLASS is a Greenplum Database extension. There is no CREATE OPERATOR CLASS statement in the SQL standard.

See Also

ALTER OPERATOR CLASS, DROP OPERATOR CLASS, CREATE FUNCTION

CREATE OPERATOR FAMILY

Defines a new operator family.

Synopsis

CREATE OPERATOR FAMILY name USING index_method

Description

CREATE OPERATOR FAMILY creates a new operator family. An operator family defines a collection of related operator classes, and perhaps some additional operators and support functions that are compatible with these operator classes but not essential for the functioning of any individual index. (Operators and functions that are essential to indexes should be grouped within the relevant operator class, rather than being “loose” in the operator family. Typically, single-data-type operators are bound to operator classes, while cross-data-type operators can be loose in an operator family containing operator classes for both data types.)

The new operator family is initially empty. It should be populated by issuing subsequent CREATE OPERATOR CLASS commands to add contained operator classes, and optionally ALTER OPERATOR FAMILY commands to add “loose” operators and their corresponding support functions.

If a schema name is given then the operator family is created in the specified schema. Otherwise it is created in the current schema. Two operator families in the same schema can have the same name only if they are for different index methods.

The user who defines an operator family becomes its owner. Presently, the creating user must be a superuser. (This restriction is made because an erroneous operator family definition could confuse or even crash the server.)

Parameters

name

The (optionally schema-qualified) name of the operator family to be defined. The name can be schema-qualified.

index_method
The name of the index method this operator family is for.

**Compatibility**

CREATE OPERATOR FAMILY is a Greenplum Database extension. There is no CREATE OPERATOR FAMILY statement in the SQL standard.

**See Also**

ALTER OPERATOR FAMILY, DROP OPERATOR FAMILY, CREATE FUNCTION, ALTER OPERATOR CLASS, CREATE OPERATOR CLASS, DROP OPERATOR CLASS

**CREATE PROTOCOL**

Registers a custom data access protocol that can be specified when defining a Greenplum Database external table.

**Synopsis**

```sql
CREATE [TRUSTED] PROTOCOL name (  
   [readfunc='read_call_handler'] [, writefunc='write_call_handler']  
   [, validatorfunc='validate_handler' ]
)
```

**Description**

CREATE PROTOCOL associates a data access protocol name with call handlers that are responsible for reading from and writing data to an external data source. You must be a superuser to create a protocol.

The CREATE PROTOCOL command must specify either a read call handler or a write call handler. The call handlers specified in the CREATE PROTOCOL command must be defined in the database.

The protocol name can be specified in a CREATE EXTERNAL TABLE command.

For information about creating and enabling a custom data access protocol, see "Example Custom Data Access Protocol" in the Greenplum Database Administrator Guide.

**Parameters**

**TRUSTED**

If not specified, only superusers and the protocol owner can create external tables using the protocol. If specified, superusers and the protocol owner can GRANT permissions on the protocol to other database roles.

**name**

The name of the data access protocol. The protocol name is case sensitive. The name must be unique among the protocols in the database.

**readfunc= 'read_call_handler'**

The name of a previously registered function that Greenplum Database calls to read data from an external data source. The command must specify either a read call handler or a write call handler.

**writefunc= 'write_call_handler'**

The name of a previously registered function that Greenplum Database calls to write data to an external data source. The command must specify either a read call handler or a write call handler.

**validatorfunc='validate_handler'**

An optional validator function that validates the URL specified in the CREATE EXTERNAL TABLE command.
Notes

Greenplum Database handles external tables of type file, gpfdist, and gpfdists internally. See Configuring and Using S3 External Tables for information about enabling the s3 protocol. See the Greenplum Platform Extension Framework (PXF) documentation for information about configuring the PXF extension and using the pxf protocol.

Any shared library that implements a data access protocol must be located in the same location on all Greenplum Database segment hosts. For example, the shared library can be in a location specified by the operating system environment variable LD_LIBRARY_PATH on all hosts. You can also specify the location when you define the handler function. For example, when you define the s3 protocol in the CREATE PROTOCOL command, you specify $libdir/gps3ext.so as the location of the shared object, where $libdir is located at $GPHOME/lib.

Compatibility

CREATE PROTOCOL is a Greenplum Database extension.

ALTER PROTOCOL, CREATE EXTERNAL TABLE, DROP PROTOCOL, GRANT

CREATE RESOURCE GROUP

Defines a new resource group.

Synopsis

```
CREATE RESOURCE GROUP name WITH (group_attribute=value [, ... ])
```

where `group_attribute` is:

```
CPU_RATE_LIMIT=integer  |  CPUSET=tuple
[ MEMORY_LIMIT=integer ]
[ CONCURRENCY=integer ]
[ MEMORY_SHARED_QUOTA=integer ]
[ MEMORY_SPILL_RATIO=integer ]
[ MEMORY_AUDITOR= {vmtracker | cgroup} ]
```

Description

Creates a new resource group for Greenplum Database resource management. You can create resource groups to manage resources for roles or to manage the resources of a Greenplum Database external component such as PL/Container.

A resource group that you create to manage a user role identifies concurrent transaction, memory, and CPU limits for the role when resource groups are enabled. You may assign such resource groups to one or more roles.

A resource group that you create to manage the resources of a Greenplum Database external component such as PL/Container identifies the memory and CPU limits for the component when resource groups are enabled. These resource groups use cgroups for both CPU and memory management. Assignment of resource groups to external components is component-specific. For example, you assign a PL/Container resource group when you configure a PL/Container runtime. You cannot assign a resource group that you create for external components to a role, nor can you assign a resource group that you create for roles to an external component.

You must have SUPERUSER privileges to create a resource group. The maximum number of resource groups allowed in your Greenplum Database cluster is 100.
Greenplum Database pre-defines two default resource groups: `admin_group` and `default_group`. These group names, as well as the group name `none`, are reserved.

To set appropriate limits for resource groups, the Greenplum Database administrator must be familiar with the queries typically executed on the system, as well as the users/roles executing those queries and the external components they may be using, such as PL/Containers.

After creating a resource group for a role, assign the group to one or more roles using the `ALTER ROLE` or `CREATE ROLE` commands.

After you create a resource group to manage the CPU and memory resources of an external component, configure the external component to use the resource group. For example, configure the PL/Container runtime `resource_group_id`.

**Parameters**

**name**

The name of the resource group.

**CONCURRENCY integer**

The maximum number of concurrent transactions, including active and idle transactions, that are permitted for this resource group. The `CONCURRENCY` value must be an integer in the range `[0 .. max_connections]`. The default `CONCURRENCY` value for resource groups defined for roles is 20.

You must set `CONCURRENCY` to zero (0) for resource groups that you create for external components.

*Note:* You cannot set the `CONCURRENCY` value for the `admin_group` to zero (0).

**CPU_RATE_LIMIT integer**

**CPUSET tuple**

Required. You must specify only one of `CPU_RATE_LIMIT` or `CPUSET` when you create a resource group.

`CPU_RATE_LIMIT` is the percentage of CPU resources to allocate to this resource group. The minimum CPU percentage you can specify for a resource group is 1. The maximum is 100. The sum of the `CPU_RATE_LIMIT` values specified for all resource groups defined in the Greenplum Database cluster must be less than or equal to 100.

`CPUSET` identifies the CPU cores to reserve for this resource group. The CPU cores that you specify in `tuple` must be available in the system and cannot overlap with any CPU cores that you specify for other resource groups.

`tuple` is a comma-separated list of single core numbers or core number intervals. You must enclose `tuple` in single quotes, for example, `‘1,3-4’`.

*Note:* You can configure `CPUSET` for a resource group only after you have enabled resource group-based resource management for your Greenplum Database cluster.

**MEMORY_LIMIT integer**

The total percentage of Greenplum Database memory resources to reserve for this resource group. The minimum memory percentage you can specify for a resource group is 0. The maximum is 100. The default value is 0.

When you specify a `MEMORY_LIMIT` of 0, Greenplum Database reserves no memory for the resource group, but uses global shared memory to fulfill all memory requests in the group. If `MEMORY_LIMIT` is 0, `MEMORY_SPILL_RATIO` must also be 0.

The sum of the `MEMORY_LIMIT` values specified for all resource groups defined in the Greenplum Database cluster must be less than or equal to 100.
MEMORY_SHARED_QUOTA integer

The quota of shared memory in the resource group. Resource groups with a MEMORY_SHARED_QUOTA threshold set aside a percentage of memory allotted to the resource group to share across transactions. This shared memory is allocated on a first-come, first-served basis as available. A transaction may use none, some, or all of this memory. The minimum memory shared quota percentage you can specify for a resource group is 0. The maximum is 100. The default MEMORY_SHARED_QUOTA value is 80.

MEMORY_SPILL_RATIO integer

The memory usage threshold for memory-intensive operators in a transaction. When this threshold is reached, a transaction spills to disk. You can specify an integer percentage value from 0 to 100 inclusive. The default MEMORY_SPILL_RATIO value is 0. When MEMORY_SPILL_RATIO is 0, Greenplum Database uses the statement_mem server configuration parameter value to control initial query operator memory.

MEMORY_AUDITOR {vmtracker | cgroup}

The memory auditor for the resource group. Greenplum Database employs virtual memory tracking for role resources and cgroup memory tracking for resources used by external components. The default MEMORY_AUDITOR is vmtracker. When you create a resource group with vmtracker memory auditing, Greenplum Database tracks that resource group's memory internally.

When you create a resource group specifying the cgroup MEMORY_AUDITOR, Greenplum Database defers the accounting of memory used by that resource group to cgroups. CONCURRENCY must be zero (0) for a resource group that you create for external components such as PL/Container. You cannot assign a resource group that you create for external components to a Greenplum Database role.

Notes

You cannot submit a CREATE RESOURCE GROUP command in an explicit transaction or sub-transaction.

Use the gp_toolkit.gp_resgroup_config system view to display the limit settings of all resource groups:

```sql
SELECT * FROM gp_toolkit.gp_resgroup_config;
```

Examples

Create a resource group with CPU and memory limit percentages of 35:

```sql
CREATE RESOURCE GROUP rgroup1 WITH (CPU_RATE_LIMIT=35, MEMORY_LIMIT=35);
```

Create a resource group with a concurrent transaction limit of 20, a memory limit of 15, and a CPU limit of 25:

```sql
CREATE RESOURCE GROUP rgroup2 WITH (CONCURRENCY=20,
                                      MEMORY_LIMIT=15, CPU_RATE_LIMIT=25);
```

Create a resource group to manage PL/Container resources specifying a memory limit of 10, and a CPU limit of 10:

```sql
CREATE RESOURCE GROUP plc_run1 WITH (MEMORY_LIMIT=10, CPU_RATE_LIMIT=10,
                                      CONCURRENCY=0, MEMORY_AUDITOR=cgroup);
```

Create a resource group with a memory limit percentage of 11 to which you assign CPU cores 1 to 3:

```sql
CREATE RESOURCE GROUP rgroup3 WITH (CPUSET='1-3', MEMORY_LIMIT=11);
```
Compatibility

`CREATE RESOURCE GROUP` is a Greenplum Database extension. There is no provision for resource
groups or resource management in the SQL standard.

`ALTER ROLE`, `CREATE ROLE`, `ALTER RESOURCE GROUP`, `DROP RESOURCE GROUP`

**CREATE RESOURCE QUEUE**

Defines a new resource queue.

**Synopsis**

```
CREATE RESOURCE QUEUE name WITH (queue_attribute=value [, ... ])
```

where `queue_attribute` is:

```
ACTIVE_STATEMENTS=integer
    [ MAX_COST=float [COST_OVERCOMMIT={TRUE|FALSE}] ]
    [ MIN_COST=float ]
    [ PRIORITY={MIN|LOW|MEDIUM|HIGH|MAX} ]
    [ MEMORY_LIMIT='memory_units' ]

| MAX_COST=float [COST_OVERCOMMIT={TRUE|FALSE}] |
    [ ACTIVE_STATEMENTS=integer ]
    [ MIN_COST=float ]
    [ PRIORITY={MIN|LOW|MEDIUM|HIGH|MAX} ]
    [ MEMORY_LIMIT='memory_units' ]
```

**Description**

Creates a new resource queue for Greenplum Database resource management. A resource queue must
have either an `ACTIVE_STATEMENTS` or a `MAX_COST` value (or it can have both). Only a superuser can
create a resource queue.

Resource queues with an `ACTIVE_STATEMENTS` threshold set a maximum limit on the number of queries
that can be executed by roles assigned to that queue. It controls the number of active queries that are
allowed to run at the same time. The value for `ACTIVE_STATEMENTS` should be an integer greater than 0.

Resource queues with a `MAX_COST` threshold set a maximum limit on the total cost of queries that
can be executed by roles assigned to that queue. Cost is measured in the estimated total cost for the
query as determined by the query planner (as shown in the `EXPLAIN` output for a query). Therefore,
an administrator must be familiar with the queries typically executed on the system in order to set an
appropriate cost threshold for a queue. Cost is measured in units of disk page fetches; 1.0 equals one
sequential disk page read. The value for `MAX_COST` is specified as a floating point number (for example
100.0) or can also be specified as an exponent (for example 1e+2). If a resource queue is limited based
on a cost threshold, then the administrator can allow `COST_OVERCOMMIT=TRUE` (the default). This means
that a query that exceeds the allowed cost threshold will be allowed to run but only when the system is idle.

If `COST_OVERCOMMIT=FALSE` is specified, queries that exceed the cost limit will always be rejected and
never allowed to run. Specifying a value for `MIN_COST` allows the administrator to define a cost for small
queries that will be exempt from resource queuing.

**Note:** GPORCA and the Postgres Planner utilize different query costing models and may
compute different costs for the same query. The Greenplum Database resource queue resource
management scheme neither differentiates nor aligns costs between GPORCA and the Postgres
Planner; it uses the literal cost value returned from the optimizer to throttle queries.
When resource queue-based resource management is active, use the MEMORY_LIMIT and ACTIVE_STATEMENTS limits for resource queues rather than configuring cost-based limits. Even when using GPORCA, Greenplum Database may fall back to using the Postgres Planner for certain queries, so using cost-based limits can lead to unexpected results.

If a value is not defined for ACTIVE_STATEMENTS or MAX_COST, it is set to -1 by default (meaning no limit). After defining a resource queue, you must assign roles to the queue using the ALTER ROLE or CREATE ROLE command.

You can optionally assign a PRIORITY to a resource queue to control the relative share of available CPU resources used by queries associated with the queue in relation to other resource queues. If a value is not defined for PRIORITY, queries associated with the queue have a default priority of MEDIUM.

Resource queues with an optional MEMORY_LIMIT threshold set a maximum limit on the amount of memory that all queries submitted through a resource queue can consume on a segment host. This determines the total amount of memory that all worker processes of a query can consume on a segment host during query execution. Greenplum recommends that MEMORY_LIMIT be used in conjunction with ACTIVE_STATEMENTS rather than with MAX_COST. The default amount of memory allotted per query on statement-based queues is: MEMORY_LIMIT / ACTIVE_STATEMENTS. The default amount of memory allotted per query on cost-based queues is: MEMORY_LIMIT * (query_cost / MAX_COST).

The default memory allotment can be overridden on a per-query basis using the statement_mem server configuration parameter, provided that MEMORY_LIMIT or max_statement_mem is not exceeded. For example, to allocate more memory to a particular query:

```sql
=> SET statement_mem='2GB';
=> SELECT * FROM my_big_table WHERE column='value' ORDER BY id;
=> RESET statement_mem;
```

The MEMORY_LIMIT value for all of your resource queues should not exceed the amount of physical memory of a segment host. If workloads are staggered over multiple queues, memory allocations can be oversubscribed. However, queries can be cancelled during execution if the segment host memory limit specified in gp_vmem_protect_limit is exceeded.

For information about statement_mem, max_statement, and gp_vmem_protect_limit, see Server Configuration Parameters.

**Parameters**

<table>
<thead>
<tr>
<th>name</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>The name of the resource queue.</td>
</tr>
<tr>
<td>ACTIVE_STATEMENTS integer</td>
<td>Resource queues with an ACTIVE_STATEMENTS threshold limit the number of queries that can be executed by roles assigned to that queue. It controls the number of active queries that are allowed to run at the same time. The value for ACTIVE_STATEMENTS should be an integer greater than 0.</td>
</tr>
<tr>
<td>MEMORY_LIMIT 'memory_units'</td>
<td>Sets the total memory quota for all statements submitted from users in this resource queue. Memory units can be specified in kB, MB or GB. The minimum memory quota for a resource queue is 10MB. There is no maximum, however the upper boundary at query execution time is limited by the physical memory of a segment host. The default is no limit (-1).</td>
</tr>
<tr>
<td>MAX_COST float</td>
<td>Resource queues with a MAX_COST threshold set a maximum limit on the total cost of queries that can be executed by roles assigned to that queue. Cost is measured in the estimated total cost for the query as determined by the Greenplum Database query optimizer (as shown in the EXPLAIN output for a query). Therefore, an administrator must</td>
</tr>
</tbody>
</table>
be familiar with the queries typically executed on the system in order to set an appropriate cost threshold for a queue. Cost is measured in units of disk page fetches; 1.0 equals one sequential disk page read. The value for `MAX_COST` is specified as a floating point number (for example 100.0) or can also be specified as an exponent (for example 1e+2).

**COST_OVERCOMMIT** boolean

If a resource queue is limited based on `MAX_COST`, then the administrator can allow `COST_OVERCOMMIT` (the default). This means that a query that exceeds the allowed cost threshold will be allowed to run but only when the system is idle. If `COST_OVERCOMMIT=FALSE` is specified, queries that exceed the cost limit will always be rejected and never allowed to run.

**MIN_COST** float

The minimum query cost limit of what is considered a small query. Queries with a cost under this limit will not be queued and run immediately. Cost is measured in the estimated total cost for the query as determined by the query planner (as shown in the `EXPLAIN` output for a query). Therefore, an administrator must be familiar with the queries typically executed on the system in order to set an appropriate cost for what is considered a small query. Cost is measured in units of disk page fetches; 1.0 equals one sequential disk page read. The value for `MIN_COST` is specified as a floating point number (for example 100.0) or can also be specified as an exponent (for example 1e+2).

**PRIORITY={MIN|LOW|MEDIUM|HIGH|MAX}**

Sets the priority of queries associated with a resource queue. Queries or statements in queues with higher priority levels will receive a larger share of available CPU resources in case of contention. Queries in low-priority queues may be delayed while higher priority queries are executed. If no priority is specified, queries associated with the queue have a priority of `MEDIUM`.

**Notes**

Use the `gp_toolkit.gp_resqueue_status` system view to see the limit settings and current status of a resource queue:

```sql
SELECT * FROM gp_toolkit.gp_resqueue_status WHERE rsqname='queue_name';
```

There is also another system view named `pg_stat_resqueues` which shows statistical metrics for a resource queue over time. To use this view, however, you must enable the `stats_queue_level` server configuration parameter. See "Managing Workload and Resources" in the Greenplum Database Administrator Guide for more information about using resource queues.

**CREATE RESOURCE QUEUE** cannot be run within a transaction.

Also, an SQL statement that is run during the execution of an `EXPLAIN ANALYZE` command is excluded from resource queues.

**Examples**

Create a resource queue with an active query limit of 20:

```sql
CREATE RESOURCE QUEUE myqueue WITH (ACTIVE_STATEMENTS=20);
```

Create a resource queue with an active query limit of 20 and a total memory limit of 2000MB (each query will be allocated 100MB of segment host memory at execution time):

```sql
CREATE RESOURCE QUEUE myqueue WITH (ACTIVE_STATEMENTS=20, MEMORY_LIMIT='2000MB');
```
Create a resource queue with a query cost limit of 3000.0:

```
CREATE RESOURCE QUEUE myqueue WITH (MAX_COST=3000.0);
```

Create a resource queue with a query cost limit of 3e10 (or 30000000000.0) and do not allow overcommit. Allow small queries with a cost under 500 to run immediately:

```
CREATE RESOURCE QUEUE myqueue WITH (MAX_COST=3e10,
  COST_OVERCOMMIT=FALSE, MIN_COST=500.0);
```

Create a resource queue with both an active query limit and a query cost limit:

```
CREATE RESOURCE QUEUE myqueue WITH (ACTIVE_STATEMENTS=30,
  MAX_COST=5000.00);
```

Create a resource queue with an active query limit of 5 and a maximum priority setting:

```
CREATE RESOURCE QUEUE myqueue WITH (ACTIVE_STATEMENTS=5,
  PRIORITY=MAX);
```

**Compatibility**

`CREATE RESOURCE QUEUE` is a Greenplum Database extension. There is no provision for resource queues or resource management in the SQL standard.

**See Also**

`ALTER ROLE, CREATE ROLE, ALTER RESOURCE QUEUE, DROP RESOURCE QUEUE`

---

**CREATE ROLE**

Defines a new database role (user or group).

**Synopsis**

```
CREATE ROLE name [[WITH] option [ ... ]]
```

where `option` can be:

- `SUPERUSER | NOSUPERUSER`
- `CREATEDB | NOCREATEDB`
- `CREATEROLE | NOCREATEROLE`
- `CREATEUSER | NOCREATEUSER`
- `CREATEEXTABLE | NOCREATEEXTABLE`
- `[ ( attribute='value'[, ...] ) ]`
  where attributes and value are:
  - `type='readable' | 'writable'`
  - `protocol='gpfdist' | 'http'`
- `INHERIT | NOINHERIT`
- `LOGIN | NOLOGIN`
- `REPLICATION | NOREPLICATION`
- `CONNECTION LIMIT conllimit`
- `[ ENCRYPTED | UNENCRYPTED ] PASSWORD 'password'`
- `VALID UNTIL 'timestamp'`
- `IN ROLE rolename [, ...]`
- `ROLE rolename [, ...]`
- `ADMIN rolename [, ...]`
- `USER rolename [, ...]`
- `SYSID uid [, ...]`
Description

CREATE ROLE adds a new role to a Greenplum Database system. A role is an entity that can own database objects and have database privileges. A role can be considered a user, a group, or both depending on how it is used. You must have CREATEROLE privilege or be a database superuser to use this command.

Note that roles are defined at the system-level and are valid for all databases in your Greenplum Database system.

Parameters

\textit{name}

The name of the new role.

\textbf{SUPERUSER}

\textbf{NOSUPERUSER}

If \textbf{SUPERUSER} is specified, the role being defined will be a superuser, who can override all access restrictions within the database. Superuser status is dangerous and should be used only when really needed. You must yourself be a superuser to create a new superuser. \textbf{NOSUPERUSER} is the default.

\textbf{CREATEDB}

\textbf{NOCREATEDB}

If \textbf{CREATEDB} is specified, the role being defined will be allowed to create new databases. \textbf{NOCREATEDB} (the default) will deny a role the ability to create databases.

\textbf{CREATEROLE}

\textbf{NOCREATEROLE}

If \textbf{CREATEROLE} is specified, the role being defined will be allowed to create new roles, alter other roles, and drop other roles. \textbf{NOCREATEROLE} (the default) will deny a role the ability to create roles or modify roles other than their own.

\textbf{CREATEUSER}

\textbf{NOCREATEUSER}

These clauses are obsolete, but still accepted, spellings of \textbf{SUPERUSER} and \textbf{NOSUPERUSER}. Note that they are not equivalent to the \textbf{CREATEROLE} and \textbf{NOCREATEROLE} clauses.

\textbf{CREATEEXTTABLE}

\textbf{NOCREATEEXTTABLE}

If \textbf{CREATEEXTTABLE} is specified, the role being defined is allowed to create external tables. The default type is \texttt{readable} and the default protocol is \texttt{gpfdist}, if not specified. Valid types are \texttt{gpfdist}, \texttt{gpfdisst}, \texttt{http}, and \texttt{https}. \textbf{NOCREATEEXTTABLE} (the default type) denies the role the ability to create external tables. Note that external tables that use the \texttt{file} or \texttt{execute} protocols can only be created by superusers.

Use the \texttt{GRANT...ON PROTOCOL} command to allow users to create and use external tables with a custom protocol type, including the \texttt{s3} and \texttt{pxf} protocols included with Greenplum Database.

\textbf{INHERIT}

\textbf{NOINHERIT}
If specified, **INHERIT** (the default) allows the role to use whatever database privileges have been granted to all roles it is directly or indirectly a member of. With **NOINHERIT**, membership in another role only grants the ability to **SET ROLE** to that other role.

**LOGIN**
**NOLOGIN**

If specified, **LOGIN** allows a role to log in to a database. A role having the **LOGIN** attribute can be thought of as a user. Roles with **NOLOGIN** are useful for managing database privileges, and can be thought of as groups. If not specified, **NOLOGIN** is the default, except when **CREATE ROLE** is invoked through its alternative spelling **CREATE USER**.

**REPLICATION**
**NOREPLICATION**

These clauses determine whether a role is allowed to initiate streaming replication or put the system in and out of backup mode. A role having the **REPLICATION** attribute is a very highly privileged role, and should only be used on roles actually used for replication. If not specified, **NOREPLICATION** is the default.

**CONNECTION LIMIT** *connlimit*

The number maximum of concurrent connections this role can make. The default of -1 means there is no limitation.

**PASSWORD** *password*

Sets the user password for roles with the **LOGIN** attribute. If you do not plan to use password authentication you can omit this option. If no password is specified, the password will be set to null and password authentication will always fail for that user. A null password can optionally be written explicitly as **PASSWORD NULL**.

**ENCRYPTED**
**UNENCRYPTED**

These key words control whether the password is stored encrypted in the system catalogs. (If neither is specified, the default behavior is determined by the configuration parameter **password_encryption**.) If the presented password string is already in MD5-encrypted format, then it is stored encrypted as-is, regardless of whether **ENCRYPTED** or **UNENCRYPTED** is specified (since the system cannot decrypt the specified encrypted password string). This allows reloading of encrypted passwords during dump/restore.

**VALID UNTIL** *'timestamp'*

The **VALID UNTIL** clause sets a date and time after which the role's password is no longer valid. If this clause is omitted the password will never expire.

**IN ROLE** *rolename*

Adds the new role as a member of the named roles. Note that there is no option to add the new role as an administrator; use a separate **GRANT** command to do that.

**ROLE** *rolename*

Adds the named roles as members of this role, making this new role a group.

**ADMIN** *rolename*

The **ADMIN** clause is like **ROLE**, but the named roles are added to the new role with **ADMIN OPTION**, giving them the right to grant membership in this role to others.

**RESOURCE GROUP** *group_name*

The name of the resource group to assign to the new role. The role will be subject to the concurrent transaction, memory, and CPU limits configured for the resource group. You can assign a single resource group to one or more roles.

If you do not specify a resource group for a new role, the role is automatically assigned the default resource group for the role's capability, **admin_group** for **SUPERUSER** roles, **default_group** for non-admin roles.
You can assign the `admin_group` resource group to any role having the `SUPERUSER` attribute.

You can assign the `default_group` resource group to any role.

You cannot assign a resource group that you create for an external component to a role.

**RESOURCE QUEUE queue_name**

The name of the resource queue to which the new user-level role is to be assigned. Only roles with `LOGIN` privilege can be assigned to a resource queue. The special keyword `NONE` means that the role is assigned to the default resource queue. A role can only belong to one resource queue.

Roles with the `SUPERUSER` attribute are exempt from resource queue limits. For a superuser role, queries always run immediately regardless of limits imposed by an assigned resource queue.

**DENY deny_point**

**DENY BETWEEN deny_point AND deny_point**

The `DENY` and `DENY BETWEEN` keywords set time-based constraints that are enforced at login. `DENY` sets a day or a day and time to deny access. `DENY BETWEEN` sets an interval during which access is denied. Both use the parameter `deny_point` that has the following format:

```
DAY day [ TIME 'time' ]
```

The two parts of the `deny_point` parameter use the following formats:

For `day`:

```
{'Sunday' | 'Monday' | 'Tuesday' | 'Wednesday' | 'Thursday' |
'Friday' | 'Saturday' | 0-6 }
```

For `time`:

```
{ 00-23 : 00-59 | 01-12 : 00-59 { AM | PM }}
```

The `DENY BETWEEN` clause uses two `deny_point` parameters:

**DENY BETWEEN deny_point AND deny_point**

For more information and examples about time-based constraints, see "Managing Roles and Privileges" in the *Greenplum Database Administrator Guide*.

**Notes**

The preferred way to add and remove role members (manage groups) is to use `GRANT` and `REVOKE`.

The `VALID UNTIL` clause defines an expiration time for a password only, not for the role. The expiration time is not enforced when logging in using a non-password-based authentication method.

The `INHERIT` attribute governs inheritance of grantable privileges (access privileges for database objects and role memberships). It does not apply to the special role attributes set by `CREATE ROLE` and `ALTER ROLE`. For example, being a member of a role with `CREATEDB` privilege does not immediately grant the ability to create databases, even if `INHERIT` is set. These privileges/attributes are never inherited: `SUPERUSER`, `CREATEDB`, `CREATEROLE`, `CREATEEXTTABLE`, `LOGIN`, `RESOURCE GROUP`, and `RESOURCE QUEUE`. The attributes must be set on each user-level role.
The **INHERIT** attribute is the default for reasons of backwards compatibility. In prior releases of Greenplum Database, users always had access to all privileges of groups they were members of. However, **NOINHERIT** provides a closer match to the semantics specified in the SQL standard.

Be careful with the **CREATEROLE** privilege. There is no concept of inheritance for the privileges of a **CREATEROLE**-role. That means that even if a role does not have a certain privilege but is allowed to create other roles, it can easily create another role with different privileges than its own (except for creating roles with superuser privileges). For example, if a role has the **CREATEROLE** privilege but not the **CREATEDB** privilege, it can create a new role with the **CREATEDB** privilege. Therefore, regard roles that have the **CREATEROLE** privilege as almost-superuser-roles.

The **CONNECTION LIMIT** option is never enforced for superusers.

Caution must be exercised when specifying an unencrypted password with this command. The password will be transmitted to the server in clear-text, and it might also be logged in the client's command history or the server log. The client program **createuser**, however, transmits the password encrypted. Also, **psql** contains a command `\password` that can be used to safely change the password later.

**Examples**

Create a role that can log in, but don't give it a password:

```sql
CREATE ROLE jonathan LOGIN;
```

Create a role that belongs to a resource queue:

```sql
CREATE ROLE jonathan LOGIN RESOURCE QUEUE poweruser;
```

Create a role with a password that is valid until the end of 2016 (**CREATE USER** is the same as **CREATE ROLE** except that it implies **LOGIN**):

```sql
CREATE USER joelle WITH PASSWORD 'jw8s0F4' VALID UNTIL '2017-01-01';
```

Create a role that can create databases and manage other roles:

```sql
CREATE ROLE admin WITH CREATEDB CREATEROLE;
```

Create a role that does not allow login access on Sundays:

```sql
CREATE ROLE user3 DENY DAY 'Sunday';
```

Create a role that can create readable and writable external tables of type 'gpfdist':

```sql
CREATE ROLE jan WITH CREATEEXTTABLE(type='readable', protocol='gpfdist') CREATEEXTTABLE(type='writable', protocol='gpfdist');
```

Create a role, assigning a resource group:

```sql
CREATE ROLE bill RESOURCE GROUP rg_light;
```

**Compatibility**

The SQL standard defines the concepts of users and roles, but it regards them as distinct concepts and leaves all commands defining users to be specified by the database implementation. In Greenplum Database users and roles are unified into a single type of object. Roles therefore have many more optional attributes than they do in the standard.
CREATE ROLE is in the SQL standard, but the standard only requires the syntax:

```
CREATE ROLE name [WITH ADMIN rolename]
```

Allowing multiple initial administrators, and all the other options of CREATE ROLE, are Greenplum Database extensions. The behavior specified by the SQL standard is most closely approximated by giving users the NOINHERIT attribute, while roles are given the INHERIT attribute.

---

**CREATE RULE**

Defines a new rewrite rule.

**Synopsis**

```
CREATE [OR REPLACE] RULE name AS ON event
to table_name [WHERE condition]
DO [ALSO | INSTEAD] { NOTHING | command | (command; command
... ) }
```

**Description**

CREATE RULE defines a new rule applying to a specified table or view. CREATE OR REPLACE RULE will either create a new rule, or replace an existing rule of the same name for the same table.

The Greenplum Database rule system allows one to define an alternate action to be performed on insertions, updates, or deletions in database tables. A rule causes additional or alternate commands to be executed when a given command on a given table is executed. An INSTEAD rule can replace a given command by another, or cause a command to not be executed at all. Rules can be used to implement SQL views as well. It is important to realize that a rule is really a command transformation mechanism, or command macro. The transformation happens before the execution of the command starts. It does not operate independently for each physical row as does a trigger.

ON SELECT rules must be unconditional INSTEAD rules and must have actions that consist of a single SELECT command. Thus, an ON SELECT rule effectively turns the table into a view, whose visible contents are the rows returned by the rule's SELECT command rather than whatever had been stored in the table (if anything). It is considered better style to write a CREATE VIEW command than to create a real table and define an ON SELECT rule for it.

You can create the illusion of an updatable view by defining ON INSERT, ON UPDATE, and ON DELETE rules to replace update actions on the view with appropriate updates on other tables. If you want to support INSERT RETURNING and so on, be sure to put a suitable RETURNING clause into each of these rules.

There is a catch if you try to use conditional rules for view updates: there must be an unconditional INSTEAD rule for each action you wish to allow on the view. If the rule is conditional, or is not INSTEAD, then the system will still reject attempts to perform the update action, because it thinks it might end up trying to perform the action on the dummy table of the view in some cases. If you want to handle all the useful cases in conditional rules, add an unconditional DO INSTEAD NOTHING rule to ensure that the system understands it will never be called on to update the dummy table. Then make the conditional rules non-INSTEAD; in the cases where they are applied, they add to the default INSTEAD NOTHING action. (This method does not currently work to support RETURNING queries, however.)

**Note:**
A view that is simple enough to be automatically updatable (see `CREATE VIEW`) does not require a user-created rule in order to be updatable. While you can create an explicit rule anyway, the automatic update transformation will generally outperform an explicit rule.

### Parameters

**name**

The name of a rule to create. This must be distinct from the name of any other rule for the same table. Multiple rules on the same table and same event type are applied in alphabetical name order.

**event**

The event is one of `SELECT`, `INSERT`, `UPDATE`, or `DELETE`.

**table_name**

The name (optionally schema-qualified) of the table or view the rule applies to.

**condition**

Any SQL conditional expression (returning boolean). The condition expression may not refer to any tables except `NEW` and `OLD`, and may not contain aggregate functions. `NEW` and `OLD` refer to values in the referenced table. `NEW` is valid in `ON INSERT` and `ON UPDATE` rules to refer to the new row being inserted or updated. `OLD` is valid in `ON UPDATE` and `ON DELETE` rules to refer to the existing row being updated or deleted.

**INSTEAD**

`INSTEAD NOTHING` indicates that the commands should be executed instead of the original command.

**ALSO**

`ALSO` indicates that the commands should be executed in addition to the original command. If neither `ALSO` nor `INSTEAD` is specified, `ALSO` is the default.

**command**

The command or commands that make up the rule action. Valid commands are `SELECT`, `INSERT`, `UPDATE`, or `DELETE`. The special table names `NEW` and `OLD` may be used to refer to values in the referenced table. `NEW` is valid in `ON INSERT` and `ON UPDATE` rules to refer to the new row being inserted or updated. `OLD` is valid in `ON UPDATE` and `ON DELETE` rules to refer to the existing row being updated or deleted.

### Notes

You must be the owner of a table to create or change rules for it.

It is very important to take care to avoid circular rules. Recursive rules are not validated at rule create time, but will report an error at execution time.

### Examples

Create a rule that inserts rows into the child table `b2001` when a user tries to insert into the partitioned parent table `rank`:

```
CREATE RULE b2001 AS ON INSERT TO rank WHERE gender='M' and year='2001' DO INSTEAD INSERT INTO b2001 VALUES (NEW.id, NEW.rank, NEW.year, NEW.gender, NEW.count);
```

### Compatibility

`CREATE RULE` is a Greenplum Database language extension, as is the entire query rewrite system.

ALTER RULE DROP RULE, CREATE TABLE, CREATE VIEW

CREATE SCHEMA

Defines a new schema.

Synopsis

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
</table>
| **CREATE SCHEMA** | `schema_name` [AUTHORIZATION `username`]
| | `[schema_element [ ... ]]`
| **CREATE SCHEMA AUTHORIZATION** | `rolename` `[schema_element [ ... ]]`
| **CREATE SCHEMA IF NOT EXISTS** | `schema_name` [ AUTHORIZATION `user_name` ]
| **CREATE SCHEMA IF NOT EXISTS AUTHORIZATION** | `user_name`

Description

CREATE SCHEMA enters a new schema into the current database. The schema name must be distinct from the name of any existing schema in the current database.

A schema is essentially a namespace: it contains named objects (tables, data types, functions, and operators) whose names may duplicate those of other objects existing in other schemas. Named objects are accessed either by qualifying their names with the schema name as a prefix, or by setting a search path that includes the desired schema(s). A CREATE command specifying an unqualified object name creates the object in the current schema (the one at the front of the search path, which can be determined with the function `current_schema`).

 Optionally, CREATE SCHEMA can include subcommands to create objects within the new schema. The subcommands are treated essentially the same as separate commands issued after creating the schema, except that if the AUTHORIZATION clause is used, all the created objects will be owned by that role.

Parameters

- **schema_name**
  The name of a schema to be created. If this is omitted, the user name is used as the schema name. The name cannot begin with `pg_`, as such names are reserved for system catalog schemas.

- **user_name**
  The name of the role who will own the schema. If omitted, defaults to the role executing the command. Only superusers may create schemas owned by roles other than themselves.

- **schema_element**
  An SQL statement defining an object to be created within the schema. Currently, only CREATE TABLE, CREATE VIEW, CREATE INDEX, CREATE SEQUENCE, CREATE TRIGGER and GRANT are accepted as clauses within CREATE SCHEMA. Other kinds of objects may be created in separate commands after the schema is created.

  **Note:** Greenplum Database does not support triggers.

- **IF NOT EXISTS**
  Do nothing (except issuing a notice) if a schema with the same name already exists.

  `schema_element` subcommands cannot be included when this option is used.
Notes
To create a schema, the invoking user must have the CREATE privilege for the current database or be a superuser.

Examples
Create a schema:

```sql
CREATE SCHEMA myschema;
```

Create a schema for role joe (the schema will also be named joe):

```sql
CREATE SCHEMA AUTHORIZATION joe;
```

Create a schema named test that will be owned by user joe, unless there already is a schema named test. (It does not matter whether joe owns the pre-existing schema.)

```sql
CREATE SCHEMA IF NOT EXISTS test AUTHORIZATION joe;
```

Compatibility
The SQL standard allows a DEFAULT CHARACTER SET clause in CREATE SCHEMA, as well as more subcommand types than are presently accepted by Greenplum Database.

The SQL standard specifies that the subcommands in CREATE SCHEMA may appear in any order. The present Greenplum Database implementation does not handle all cases of forward references in subcommands; it may sometimes be necessary to reorder the subcommands in order to avoid forward references.

According to the SQL standard, the owner of a schema always owns all objects within it. Greenplum Database allows schemas to contain objects owned by users other than the schema owner. This can happen only if the schema owner grants the CREATE privilege on the schema to someone else, or a superuser chooses to create objects in it.

The IF NOT EXISTS option is a Greenplum Database extension.

ALTER SCHEMA, DROP SCHEMA

CREATE SEQUENCE
Defines a new sequence generator.

Synopsis

```sql
CREATE [TEMPORARY | TEMP] SEQUENCE name
    [INCREMENT [BY] value]
    [MINVALUE minvalue | NO MINVALUE]
    [MAXVALUE maxvalue | NO MAXVALUE]
    [START [ WITH ] start]
    [CACHE cache]
    [[NO] CYCLE]
    [OWNED BY { table.column | NONE }]
```
Description

CREATE SEQUENCE creates a new sequence number generator. This involves creating and initializing a new special single-row table. The generator will be owned by the user issuing the command.

If a schema name is given, then the sequence is created in the specified schema. Otherwise it is created in the current schema. Temporary sequences exist in a special schema, so a schema name may not be given when creating a temporary sequence. The sequence name must be distinct from the name of any other sequence, table, index, view, or foreign table in the same schema.

After a sequence is created, you use the `nextval()` function to operate on the sequence. For example, to insert a row into a table that gets the next value of a sequence:

```
INSERT INTO distributors VALUES (nextval('myserial'), 'acme');
```

You can also use the function `setval()` to operate on a sequence, but only for queries that do not operate on distributed data. For example, the following query is allowed because it resets the sequence counter value for the sequence generator process on the master:

```
SELECT setval('myserial', 201);
```

But the following query will be rejected in Greenplum Database because it operates on distributed data:

```
INSERT INTO product VALUES (setval('myserial', 201), 'gizmo');
```

In a regular (non-distributed) database, functions that operate on the sequence go to the local sequence table to get values as they are needed. In Greenplum Database, however, keep in mind that each segment is its own distinct database process. Therefore the segments need a single point of truth to go for sequence values so that all segments get incremented correctly and the sequence moves forward in the right order. A sequence server process runs on the master and is the point-of-truth for a sequence in a Greenplum distributed database. Segments get sequence values at runtime from the master.

Because of this distributed sequence design, there are some limitations on the functions that operate on a sequence in Greenplum Database:

- `lastval()` and `currval()` functions are not supported.
- `setval()` can only be used to set the value of the sequence generator on the master, it cannot be used in subqueries to update records on distributed table data.
- `nextval()` sometimes grabs a block of values from the master for a segment to use, depending on the query. So values may sometimes be skipped in the sequence if all of the block turns out not to be needed at the segment level. Note that a regular PostgreSQL database does this too, so this is not something unique to Greenplum Database.

Although you cannot update a sequence directly, you can use a query like:

```
SELECT * FROM sequence_name;
```

to examine the parameters and current state of a sequence. In particular, the `last_value` field of the sequence shows the last value allocated by any session.

Parameters

<table>
<thead>
<tr>
<th>TEMPORARY</th>
<th>TEMP</th>
</tr>
</thead>
</table>

If specified, the sequence object is created only for this session, and is automatically dropped on session exit. Existing permanent sequences with the same name are not visible (in this session) while the temporary sequence exists, unless they are referenced with schema-qualified names.

`name`

The name (optionally schema-qualified) of the sequence to be created.
increment

Specifies which value is added to the current sequence value to create a new value. A positive value will make an ascending sequence, a negative one a descending sequence. The default value is 1.

minvalue

NO MINVALUE

Determines the minimum value a sequence can generate. If this clause is not supplied or NO MINVALUE is specified, then defaults will be used. The defaults are 1 and -263-1 for ascending and descending sequences, respectively.

maxvalue

NO MAXVALUE

Determines the maximum value for the sequence. If this clause is not supplied or NO MAXVALUE is specified, then default values will be used. The defaults are 263-1 and -1 for ascending and descending sequences, respectively.

start

Allows the sequence to begin anywhere. The default starting value is minvalue for ascending sequences and maxvalue for descending ones.

cache

Specifies how many sequence numbers are to be preallocated and stored in memory for faster access. The minimum (and default) value is 1 (no cache).

CYCLE

NO CYCLE

Allows the sequence to wrap around when the maxvalue (for ascending) or minvalue (for descending) has been reached. If the limit is reached, the next number generated will be the minvalue (for ascending) or maxvalue (for descending). If NO CYCLE is specified, any calls to nextval() after the sequence has reached its maximum value will return an error. If not specified, NO CYCLE is the default.

OWNED BY table.column

OWNED BY NONE

Causes the sequence to be associated with a specific table column, such that if that column (or its whole table) is dropped, the sequence will be automatically dropped as well. The specified table must have the same owner and be in the same schema as the sequence. OWNED BY NONE, the default, specifies that there is no such association.

Notes

Sequences are based on bigint arithmetic, so the range cannot exceed the range of an eight-byte integer (-922372036854775808 to 9223372036854775807).

Although multiple sessions are guaranteed to allocate distinct sequence values, the values may be generated out of sequence when all the sessions are considered. For example, session A might reserve values 1..10 and return nextval=1, then session B might reserve values 11..20 and return nextval=11 before session A has generated nextval=2. Thus, you should only assume that the nextval() values are all distinct, not that they are generated purely sequentially. Also, last_value will reflect the latest value reserved by any session, whether or not it has yet been returned by nextval().

Examples

Create a sequence named myseq:

```
CREATE SEQUENCE myseq START 101;
```
Insert a row into a table that gets the next value of the sequence named `idseq`:

```sql
INSERT INTO distributors VALUES (nextval('idseq'), 'acme');
```

Reset the sequence counter value on the master:

```sql
SELECT setval('myseq', 201);
```

Illegal use of `setval()` in Greenplum Database (setting sequence values on distributed data):

```sql
INSERT INTO product VALUES (setval('myseq', 201), 'gizmo');
```

**Compatibility**

`CREATE SEQUENCE` conforms to the SQL standard, with the following exceptions:

- The `AS data_type` expression specified in the SQL standard is not supported.
- Obtaining the next value is done using the `nextval()` function instead of the `NEXT VALUE FOR` expression specified in the SQL standard.
- The `OWNED BY` clause is a Greenplum Database extension.

`ALTER SEQUENCE`, `DROP SEQUENCE`

---

**CREATE SERVER**

Defines a new foreign server.

**Synopsis**

```sql
CREATE SERVER server_name [ TYPE 'server_type' ] [ VERSION 'server_version' ]
FOREIGN DATA WRAPPER fdw_name
[ OPTIONS ( [ mpp_execute { 'master' | 'any' | 'all segments' } [, ... ] ) ]
[ [ , ] option 'value' [, ... ] ] ]
```

**Description**

`CREATE SERVER` defines a new foreign server. The user who defines the server becomes its owner.

A foreign server typically encapsulates connection information that a foreign-data wrapper uses to access an external data source. Additional user-specific connection information may be specified by means of user mappings.

Creating a server requires the `USAGE` privilege on the foreign-data wrapper specified.

**Parameters**

- **server_name**
  
  The name of the foreign server to create. The server name must be unique within the database.

- **server_type**
  
  Optional server type, potentially useful to foreign-data wrappers.

- **server_version**
  
  Optional server version, potentially useful to foreign-data wrappers.
**fdw_name**

Name of the foreign-data wrapper that manages the server.

**OPTIONS ( option 'value' [, ... ] )**

The options for the new foreign server. The options typically define the connection details of the server, but the actual names and values are dependent upon the server's foreign-data wrapper.

**mpp_execute { 'master' | 'any' | 'all segments' }**

An option that identifies the host from which the foreign data-wrapper requests data:

- **master** (the default)—Request data from the master host.
- **any**—Request data from either the master host or any one segment, depending on which path costs less.
- **all segments**—Request data from all segments. To support this option value, the foreign data-wrapper must have a policy that matches the segments to data.

The `mpp_execute` option can be specified in multiple commands: `CREATE FOREIGN TABLE`, `CREATE SERVER`, and `CREATE FOREIGN DATA WRAPPER`. The foreign table setting takes precedence over the foreign server setting, followed by the foreign data wrapper setting.

**Notes**

When using the `dblink` module (see `dblink`), you can use the foreign server name as an argument of the `dblink_connect()` function to provide the connection parameters. You must have the `USAGE` privilege on the foreign server to use it in this manner.

**Examples**

Create a foreign server named `myserver` that uses the foreign wrapper named `pgsql` and includes connection options:

```sql
CREATE SERVER myserver FOREIGN DATA WRAPPER pgsql
  OPTIONS (host 'foo', dbname 'foodb', port '5432');
```

**Compatibility**

`CREATE SERVER` conforms to ISO/IEC 9075-9 (SQL/MED).

[oids=FALSE]
```

**Description**

`CREATE TABLE` creates an initially empty table in the current database. The user who issues the command owns the table.

To be able to create a table, you must have `USAGE` privilege on all column types or the type in the `OF` clause, respectively.

If you specify a schema name, Greenplum creates the table in the specified schema. Otherwise Greenplum creates the table in the current schema. Temporary tables exist in a special schema, so you cannot specify a schema name when creating a temporary table. Table names must be distinct from the name of any other table, external table, sequence, index, view, or foreign table in the same schema.

`CREATE TABLE` also automatically creates a data type that represents the composite type corresponding to one row of the table. Therefore, tables cannot have the same name as any existing data type in the same schema.

The optional constraint clauses specify conditions that new or updated rows must satisfy for an insert or update operation to succeed. A constraint is an SQL object that helps define the set of valid values in the table in various ways. Constraints apply to tables, not to partitions. You cannot add a constraint to a partition or subpartition.

Referential integrity constraints (foreign keys) are accepted but not enforced. The information is kept in the system catalogs but is otherwise ignored.

There are two ways to define constraints: table constraints and column constraints. A column constraint is defined as part of a column definition. A table constraint definition is not tied to a particular column, and it can encompass more than one column. Every column constraint can also be written as a table constraint; a column constraint is only a notational convenience for use when the constraint only affects one column.

When creating a table, there is an additional clause to declare the Greenplum Database distribution policy. If a `DISTRIBUTED BY`, `DISTRIBUTED RANDOMLY`, or `DISTRIBUTED REPLICATED` clause is
not supplied, then Greenplum Database assigns a hash distribution policy to the table using either the
**PRIMARY KEY** (if the table has one) or the first column of the table as the distribution key. Columns of
geometric or user-defined data types are not eligible as Greenplum distribution key columns. If a table
does not have a column of an eligible data type, the rows are distributed based on a round-robin or
random distribution. To ensure an even distribution of data in your Greenplum Database system, you
want to choose a distribution key that is unique for each record, or if that is not possible, then choose
**DISTRIBUTED RANDOMLY**.

If the **DISTRIBUTED REPLICATED** clause is supplied, Greenplum Database distributes all rows of the
table to all segments in the Greenplum Database system. This option can be used in cases where user-
defined functions must execute on the segments, and the functions require access to all rows of the table.
Replicated functions can also be used to improve query performance by preventing broadcast motions
for the table. The **DISTRIBUTED REPLICATED** clause cannot be used with the **PARTITION BY** clause
or the **INHERITS** clause. A replicated table also cannot be inherited by another table. The hidden system
columns (*ctid*, *cmin*, *cmax*, *xmin*, *xmax*, and *gp_segment_id*) cannot be referenced in user queries
on replicated tables because they have no single, unambiguous value. Greenplum Database returns a
column does not exist error for the query.

The **PARTITION BY** clause allows you to divide the table into multiple sub-tables (or parts) that,
taken together, make up the parent table and share its schema. Though the sub-tables exist as
independent tables, the Greenplum Database restricts their use in important ways. Internally, partitioning
is implemented as a special form of inheritance. Each child table partition is created with a distinct
**CHECK** constraint which limits the data the table can contain, based on some defining criteria. The **CHECK**
constraints are also used by the query optimizer to determine which table partitions to scan in order to
satisfy a given query predicate. These partition constraints are managed automatically by the Greenplum
Database.

**Parameters**

**GLOBAL | LOCAL**

These keywords are present for SQL standard compatibility, but have no effect in
Greenplum Database and are deprecated.

**TEMPORARY | TEMP**

If specified, the table is created as a temporary table. Temporary tables are automatically
dropped at the end of a session, or optionally at the end of the current transaction (see
**ON COMMIT**). Existing permanent tables with the same name are not visible to the current
session while the temporary table exists, unless they are referenced with schema-qualified
names. Any indexes created on a temporary table are automatically temporary as well.

**UNLOGGED**

If specified, the table is created as an unlogged table. Data written to unlogged tables
is not written to the write-ahead (WAL) log, which makes them considerably faster than
ordinary tables. However, the contents of an unlogged table are not replicated to mirror
segment instances. Also an unlogged table is not crash-safe. After a segment instance
flush or unclean shutdown, the data for the unlogged table on that segment is truncated.
Any indexes created on an unlogged table are automatically unlogged as well.

**table_name**

The name (optionally schema-qualified) of the table to be created.

**OF type_name**

Creates a typed table, which takes its structure from the specified composite type (name
optionally schema-qualified). A typed table is tied to its type; for example the table will be
dropped if the type is dropped (with **DROP TYPE ... CASCADE**).

When a typed table is created, the data types of the columns are determined by the
underlying composite type and are not specified by the **CREATE TABLE** command. But the
CREATE TABLE command can add defaults and constraints to the table and can specify storage parameters.

```
column_name
```
The name of a column to be created in the new table.

```
data_type
```
The data type of the column. This may include array specifiers.

For table columns that contain textual data, Specify the data type VARCHAR or TEXT. Specifying the data type CHAR is not recommended. In Greenplum Database, the data types VARCHAR or TEXT handles padding added to the data (space characters added after the last non-space character) as significant characters, the data type CHAR does not. See Notes.

```
cOLLATE collation
```
The COLLATE clause assigns a collation to the column (which must be of a collatable data type). If not specified, the column data type's default collation is used.

**Note:** GPORCA supports collation only when all columns in the query use the same collation. If columns in the query use different collations, then Greenplum uses the Postgres Planner.

```
DEFAULT default_expr
```
The DEFAULT clause assigns a default data value for the column whose column definition it appears within. The value is any variable-free expression (subqueries and cross-references to other columns in the current table are not allowed). The data type of the default expression must match the data type of the column. The default expression will be used in any insert operation that does not specify a value for the column. If there is no default for a column, then the default is null.

```
ENCODING ( storage_directive [, ...] )
```
For a column, the optional ENCODING clause specifies the type of compression and block size for the column data. See storage_options for compresstype, compresslevel, and blocksize values.

The clause is valid only for append-optimized, column-oriented tables.

Column compression settings are inherited from the table level to the partition level to the subpartition level. The lowest-level settings have priority.

```
INHERITS ( parent_table [, ...] )
```
The optional INHERITS clause specifies a list of tables from which the new table automatically inherits all columns. Use of INHERITS creates a persistent relationship between the new child table and its parent table(s). Schema modifications to the parent(s) normally propagate to children as well, and by default the data of the child table is included in scans of the parent(s).

In Greenplum Database, the INHERITS clause is not used when creating partitioned tables. Although the concept of inheritance is used in partition hierarchies, the inheritance structure of a partitioned table is created using the PARTITION BY clause.

If the same column name exists in more than one parent table, an error is reported unless the data types of the columns match in each of the parent tables. If there is no conflict, then the duplicate columns are merged to form a single column in the new table. If the column name list of the new table contains a column name that is also inherited, the data type must likewise match the inherited column(s), and the column definitions are merged into one. If the new table explicitly specifies a default value for the column, this default overrides any defaults from inherited declarations of the column. Otherwise, any parents that specify default values for the column must all specify the same default, or an error will be reported.
CHECK constraints are merged in essentially the same way as columns: if multiple parent tables or the new table definition contain identically-named constraints, these constraints must all have the same check expression, or an error will be reported. Constraints having the same name and expression will be merged into one copy. A constraint marked NO INHERIT in a parent will not be considered. Notice that an unnamed CHECK constraint in the new table will never be merged, since a unique name will always be chosen for it.

Column STORAGE settings are also copied from parent tables.

LIKE source_table like_option ...]

The LIKE clause specifies a table from which the new table automatically copies all column names, their data types, not-null constraints, and distribution policy. Storage properties like append-optimized or partition structure are not copied. Unlike INHERITS, the new table and original table are completely decoupled after creation is complete.

Default expressions for the copied column definitions will only be copied if INCLUDING DEFAULTS is specified. The default behavior is to exclude default expressions, resulting in the copied columns in the new table having null defaults.

Not-null constraints are always copied to the new table. CHECK constraints will be copied only if INCLUDING CONSTRAINTS is specified. No distinction is made between column constraints and table constraints.

Indexes, PRIMARY KEY, and UNIQUE constraints on the original table will be created on the new table only if the INCLUDING INDEXES clause is specified. Names for the new indexes and constraints are chosen according to the default rules, regardless of how the originals were named. (This behavior avoids possible duplicate-name failures for the new indexes.)

Any indexes on the original table will not be created on the new table, unless the INCLUDING INDEXES clause is specified.

STORAGE settings for the copied column definitions will be copied only if INCLUDING STORAGE is specified. The default behavior is to exclude STORAGE settings, resulting in the copied columns in the new table having type-specific default settings.

Comments for the copied columns, constraints, and indexes will be copied only if INCLUDING COMMENTS is specified. The default behavior is to exclude comments, resulting in the copied columns and constraints in the new table having no comments.

INCLUDING ALL is an abbreviated form of including DEFAULTS including CONSTRAINTS including INDEXES including STORAGE including COMMENTS.

Note that unlike INHERITS, columns and constraints copied by LIKE are not merged with similarly named columns and constraints. If the same name is specified explicitly or in another LIKE clause, an error is signaled.

The LIKE clause can also be used to copy columns from views, foreign tables, or composite types. Inapplicable options (e.g., INCLUDING INDEXES from a view) are ignored.

CONSTRAINT constraint_name

An optional name for a column or table constraint. If the constraint is violated, the constraint name is present in error messages, so constraint names like column must be positive can be used to communicate helpful constraint information to client applications. (Double-quotes are needed to specify constraint names that contain spaces.) If a constraint name is not specified, the system generates a name.

Note: The specified constraint_name is used for the constraint, but a system-generated unique name is used for the index name. In some prior releases, the provided name was used for both the constraint name and the index name.
NULL | NOT NULL

Specifies if the column is or is not allowed to contain null values. NULL is the default.

CHECK (expression) [ NO INHERIT ]

The CHECK clause specifies an expression producing a Boolean result which new or updated rows must satisfy for an insert or update operation to succeed. Expressions evaluating to TRUE or UNKNOWN succeed. Should any row of an insert or update operation produce a FALSE result an error exception is raised and the insert or update does not alter the database. A check constraint specified as a column constraint should reference that column's value only, while an expression appearing in a table constraint can reference multiple columns.

A constraint marked with NO INHERIT will not propagate to child tables.

Currently, CHECK expressions cannot contain subqueries nor refer to variables other than columns of the current row.

UNIQUE (column_constraint)
UNIQUE (column_name [, ... ]) (table_constraint)

The UNIQUE constraint specifies that a group of one or more columns of a table may contain only unique values. The behavior of the unique table constraint is the same as that for column constraints, with the additional capability to span multiple columns. For the purpose of a unique constraint, null values are not considered equal. The column(s) that are unique must contain all the columns of the Greenplum distribution key. In addition, the <key> must contain all the columns in the partition key if the table is partitioned. Note that a <key> constraint in a partitioned table is not the same as a simple UNIQUE INDEX.

For information about unique constraint management and limitations, see Notes.

PRIMARY KEY (column_constraint)
PRIMARY KEY (column_name [, ... ]) (table_constraint)

The PRIMARY KEY constraint specifies that a column or columns of a table may contain only unique (non-duplicate), non-null values. Only one primary key can be specified for a table, whether as a column constraint or a table constraint.

For a table to have a primary key, it must be hash distributed (not randomly distributed), and the primary key, the column(s) that are unique, must contain all the columns of the Greenplum distribution key. In addition, the <key> must contain all the columns in the partition key if the table is partitioned. Note that a <key> constraint in a partitioned table is not the same as a simple UNIQUE INDEX.

PRIMARY KEY enforces the same data constraints as a combination of UNIQUE and NOT NULL, but identifying a set of columns as the primary key also provides metadata about the design of the schema, since a primary key implies that other tables can rely on this set of columns as a unique identifier for rows.

For information about primary key management and limitations, see Notes.

REFERENCES ref_table [ ( ref_column ) ]
[ MATCH FULL | MATCH PARTIAL | MATCH SIMPLE ]
[ON DELETE | ON UPDATE] [key_action]
FOREIGN KEY (column_name [, ...])

The REFERENCES and FOREIGN KEY clauses specify referential integrity constraints (foreign key constraints). Greenplum accepts referential integrity constraints as specified in PostgreSQL syntax but does not enforce them. See the PostgreSQL documentation for information about referential integrity constraints.

DEFERRABLE
NOT DEFERRABLE

The [NOT] DEFERRABLE clause controls whether the constraint can be deferred. A constraint that is not deferrable will be checked immediately after every command.
Checking of constraints that are deferrable can be postponed until the end of the transaction (using the `SET CONSTRAINTS` command). NOT DEFERRABLE is the default. Currently, only UNIQUE and PRIMARY KEY constraints are deferrable. NOT NULL and CHECK constraints are not deferrable. REFERENCES (foreign key) constraints accept this clause but are not enforced.

**INITIALLY IMMEDIATE**

If a constraint is deferrable, this clause specifies the default time to check the constraint. If the constraint is INITIALLY IMMEDIATE, it is checked after each statement. This is the default. If the constraint is INITIALLY DEFERRED, it is checked only at the end of the transaction. The constraint check time can be altered with the `SET CONSTRAINTS` command.

**INITIALLY DEFERRED**

With `(storage_parameter=value)`

The `WITH` clause can specify storage parameters for tables, and for indexes associated with a UNIQUE or PRIMARY constraint. Note that you can also set storage parameters on a particular partition or subpartition by declaring the `WITH` clause in the partition specification. The lowest-level settings have priority.

The defaults for some of the table storage options can be specified with the server configuration parameter `gp_default_storage_options`. For information about setting default storage options, see Notes.

The following storage options are available:

- **appendoptimized** — Set to `TRUE` to create the table as an append-optimized table. If `FALSE` or not declared, the table will be created as a regular heap-storage table.
- **blocksize** — Set to the size, in bytes, for each block in a table. The blocksize must be between 8192 and 2097152 bytes, and be a multiple of 8192. The default is 32768.
- **orientation** — Set to `column` for column-oriented storage, or `row` (the default) for row-oriented storage. This option is only valid if `appendoptimized=TRUE`. Heap-storage tables can only be row-oriented.
- **checksum** — This option is valid only for append-optimized tables (appendoptimized=TRUE). The value `TRUE` is the default and enables CRC checksum validation for append-optimized tables. The checksum is calculated during block creation and is stored on disk. Checksum validation is performed during block reads. If the checksum calculated during the read does not match the stored checksum, the transaction is aborted. If you set the value to `FALSE` to disable checksum validation, checking the table data for on-disk corruption will not be performed.
- **compressstype** — Set to `ZLIB` (the default), `ZSTD`, `RLE_TYPE`, or `QUICKLZ`¹ to specify the type of compression used. The value `NONE` disables compression. Zstd provides for both speed or a good compression ratio, tunable with the `compresslevel` option. QuickLZ and zlib are provided for backwards-compatibility. Zstd outperforms these compression types on usual workloads. The `compressstype` option is only valid if `appendoptimized=TRUE`.

**Note:** ¹QuickLZ compression is available only in the commercial release of Pivotal Greenplum Database.

The value `RLE_TYPE`, which is supported only if `orientation=column` is specified, enables the run-length encoding (RLE) compression algorithm. RLE compresses data better than the Zstd, zlib, or QuickLZ compression algorithms when the same data value occurs in many consecutive rows.

For columns of type `BIGINT`, `INTEGER`, `DATE`, `TIME`, or `TIMESTAMP`, delta compression is also applied if the `compressstype` option is set to `RLE_TYPE` compression. The delta compression algorithm is based on the delta between column values in consecutive
rows and is designed to improve compression when data is loaded in sorted order or the compression is applied to column data that is in sorted order.

For information about using table compression, see “Choosing the Table Storage Model” in the *Greenplum Database Administrator Guide*.

**compresslevel** — For Zstd compression of append-optimized tables, set to an integer value from 1 (fastest compression) to 19 (highest compression ratio). For zlib compression, the valid range is from 1 to 9. QuickLZ compression level can only be set to 1. If not declared, the default is 1. For **RLE_TYPE**, the compression level can be an integer value from 1 (fastest compression) to 4 (highest compression ratio).

The **compresslevel** option is valid only if **appendoptimized=TRUE**.

**fillfactor** — See **CREATE INDEX** for more information about this index storage parameter.

**oids=FALSE** — This setting is the default, and it ensures that rows do not have object identifiers assigned to them. Pivotal does not support using **WITH OIDS** or **oids=TRUE** to assign an OID system column. On large tables, such as those in a typical Greenplum Database system, using OIDs for table rows can cause wrap-around of the 32-bit OID counter. Once the counter wraps around, OIDs can no longer be assumed to be unique, which not only makes them useless to user applications, but can also cause problems in the Greenplum Database system catalog tables. In addition, excluding OIDs from a table reduces the space required to store the table on disk by 4 bytes per row, slightly improving performance. You cannot create OIDS on a partitioned or column-oriented table (an error is displayed). This syntax is deprecated and will be removed in a future Greenplum release.

**ON COMMIT**

The behavior of temporary tables at the end of a transaction block can be controlled using **ON COMMIT**. The three options are:

- **PRESERVE ROWS** - No special action is taken at the ends of transactions for temporary tables. This is the default behavior.
- **DELETE ROWS** - All rows in the temporary table will be deleted at the end of each transaction block. Essentially, an automatic **TRUNCATE** is done at each commit.
- **DROP** - The temporary table will be dropped at the end of the current transaction block.

**TABLESPACE** *tablespace*

The name of the tablespace in which the new table is to be created. If not specified, the database’s default tablespace is used, or **temp_tablespaces** if the table is temporary.

**USING INDEX TABLESPACE** *tablespace*

This clause allows selection of the tablespace in which the index associated with a **UNIQUE** or **PRIMARY KEY** constraint will be created. If not specified, the database’s default tablespace is used, or **temp_tablespaces** if the table is temporary.

**DISTRIBUTED BY (column [opclass], [ ... ] )**

**DISTRIBUTED RANDOMLY**

**DISTRIBUTED REPLICATED**

Used to declare the Greenplum Database distribution policy for the table. **DISTRIBUTED** by uses hash distribution with one or more columns declared as the distribution key. For the most even data distribution, the distribution key should be the primary key of the table or a unique column (or set of columns). If that is not possible, then you may choose **DISTRIBUTED RANDOMLY**, which will send the data round-robin to the segment instances. Additionally, an operator class, **opclass**, can be specified, to use a non-default hash function.

The Greenplum Database server configuration parameter **gp_create_table_random_default_distribution** controls the default table
distribution policy if the DISTRIBUTED BY clause is not specified when you create a table. Greenplum Database follows these rules to create a table if a distribution policy is not specified.

If the value of the parameter is off (the default), Greenplum Database chooses the table distribution key based on the command:

- If a LIKE or INHERITS clause is specified, then Greenplum copies the distribution key from the source or parent table.
- If a PRIMARY KEY or UNIQUE constraints are specified, then Greenplum chooses the largest subset of all the key columns as the distribution key.
- If neither constraints nor a LIKE or INHERITS clause is specified, then Greenplum chooses the first suitable column as the distribution key. (Columns with geometric or user-defined data types are not eligible as Greenplum distribution key columns.)

If the value of the parameter is set to on, Greenplum Database follows these rules:

- If PRIMARY KEY or UNIQUE columns are not specified, the distribution of the table is random (DISTRIBUTED RANDOMLY). Table distribution is random even if the table creation command contains the LIKE or INHERITS clause.
- If PRIMARY KEY or UNIQUE columns are specified, a DISTRIBUTED BY clause must also be specified. If a DISTRIBUTED BY clause is not specified as part of the table creation command, the command fails.

For more information about setting the default table distribution policy, see gp_create_table_random_default_distribution.

The DISTRIBUTED REPLICATED clause replicates the entire table to all Greenplum Database segment instances. It can be used when it is necessary to execute user-defined functions on segments when the functions require access to all rows in the table, or to improve query performance by preventing broadcast motions.

PARTITION BY

Declares one or more columns by which to partition the table.

When creating a partitioned table, Greenplum Database creates the root partitioned table (the root partition) with the specified table name. Greenplum Database also creates a hierarchy of tables, child tables, that are the subpartitions based on the partitioning options that you specify. The Greenplum Database pg_partition* system views contain information about the subpartition tables.

For each partition level (each hierarchy level of tables), a partitioned table can have a maximum of 32,767 partitions.

**Note:** Greenplum Database stores partitioned table data in the leaf child tables, the lowest-level tables in the hierarchy of child tables for use by the partitioned table.

**partition_type**

Declares partition type: LIST (list of values) or RANGE (a numeric or date range).

**partition_specification**

Declares the individual partitions to create. Each partition can be defined individually or, for range partitions, you can use the EVERY clause (with a START and optional END clause) to define an increment pattern to use to create the individual partitions.

**DEFAULT PARTITION name** — Declares a default partition. When data does not match to an existing partition, it is inserted into the default partition. Partition designs that do not have a default partition will reject incoming rows that do not match to an existing partition.

**PARTITION name** — Declares a name to use for the partition. Partitions are created using the following naming convention: parentname_level#_prt_givenname.
VALUES — For list partitions, defines the value(s) that the partition will contain.

START — For range partitions, defines the starting range value for the partition. By default, start values are INCLUSIVE. For example, if you declared a start date of '2016-01-01', then the partition would contain all dates greater than or equal to '2016-01-01'. Typically the data type of the START expression is the same type as the partition key column. If that is not the case, then you must explicitly cast to the intended data type.

END — For range partitions, defines the ending range value for the partition. By default, end values are EXCLUSIVE. For example, if you declared an end date of '2016-02-01', then the partition would contain all dates less than but not equal to '2016-02-01'. Typically the data type of the END expression is the same type as the partition key column. If that is not the case, then you must explicitly cast to the intended data type.

EVERY — For range partitions, defines how to increment the values from START to END to create individual partitions. Typically the data type of the EVERY expression is the same type as the partition key column. If that is not the case, then you must explicitly cast to the intended data type.

WITH — Sets the table storage options for a partition. For example, you may want older partitions to be append-optimized tables and newer partitions to be regular heap tables.

TABLESPACE — The name of the tablespace in which the partition is to be created.

SUBPARTITION BY

Declares one or more columns by which to subpartition the first-level partitions of the table. The format of the subpartition specification is similar to that of a partition specification described above.

SUBPARTITION TEMPLATE

Instead of declaring each subpartition definition individually for each partition, you can optionally declare a subpartition template to be used to create the subpartitions (lower level child tables). This subpartition specification would then apply to all parent partitions.

Notes

• In Greenplum Database (a Postgres-based system) the data types VARCHAR or TEXT handle padding added to the textual data (space characters added after the last non-space character) as significant characters; the data type CHAR does not.

In Greenplum Database, values of type CHAR(n) are padded with trailing spaces to the specified width n. The values are stored and displayed with the spaces. However, the padding spaces are treated as semantically insignificant. When the values are distributed, the trailing spaces are disregarded. The trailing spaces are also treated as semantically insignificant when comparing two values of data type CHAR, and the trailing spaces are removed when converting a character value to one of the other string types.

• Pivotal does not support using WITH OIDS or oids=TRUE to assign an OID system column. This syntax is deprecated and will be removed in a future Greenplum release. As an alternative, use a SERIAL or other sequence generator as the table’s primary key. However, if your application does make use of OIDs to identify specific rows of a table, it is recommended to create a unique constraint on the OID column of that table, to ensure that OIDs in the table will indeed uniquely identify rows even after counter wrap-around. Avoid assuming that OIDs are unique across tables; if you need a database-wide unique identifier, use the combination of table OID and row OID for that purpose.

• Greenplum Database has some special conditions for primary key and unique constraints with regards to columns that are the distribution key in a Greenplum table. For a unique constraint to be enforced in Greenplum Database, the table must be hash-distributed (not DISTRIBUTED RANDOMLY), and the constraint columns must be the same as (or a superset of) the table’s distribution key columns.

Replicated tables (DISTRIBUTED REPLICATED) can have both PRIMARY KEY and UNIQUE column constraints.
A primary key constraint is simply a combination of a unique constraint and a not-null constraint.

Greenplum Database automatically creates a **UNIQUE** index for each **UNIQUE** or **PRIMARY KEY** constraint to enforce uniqueness. Thus, it is not necessary to create an index explicitly for primary key columns. **UNIQUE** and **PRIMARY KEY** constraints are not allowed on append-optimized tables because the **UNIQUE** indexes that are created by the constraints are not allowed on append-optimized tables.

Foreign key constraints are not supported in Greenplum Database.

For inherited tables, unique constraints, primary key constraints, indexes and table privileges are **not** inherited in the current implementation.

- For append-optimized tables, **UPDATE** and **DELETE** are not allowed in a repeatable read or serializable transaction and will cause the transaction to abort. **CLUSTER**, **DECLARE...FOR UPDATE**, and triggers are not supported with append-optimized tables.
- To insert data into a partitioned table, you specify the root partitioned table, the table created with the **CREATE TABLE** command. You also can specify a leaf child table of the partitioned table in an **INSERT** command. An error is returned if the data is not valid for the specified leaf child table. Specifying a child table that is not a leaf child table in the **INSERT** command is not supported. Execution of other DML commands such as **UPDATE** and **DELETE** on any child table of a partitioned table is not supported. These commands must be executed on the root partitioned table, the table created with the **CREATE TABLE** command.
- The default values for these table storage options can be specified with the server configuration parameter **gp_default_storage_option**.
  - **appendoptimized**
  - **blocksize**
  - **checksum**
  - **compressstype**
  - **compresslevel**
  - **orientation**

The defaults can be set for the system, a database, or a user. For information about setting storage options, see the server configuration parameter **gp_default_storage_options**.

**Important**: The current Postgres Planner allows list partitions with multi-column (composite) partition keys. GPORCA does not support composite keys, so using composite partition keys is **not** recommended.

### Examples

Create a table named **rank** in the schema named **baby** and distribute the data using the columns **rank**, **gender**, and **year**:

```
CREATE TABLE baby.rank (id int, rank int, year smallint, gender char(1), count int ) DISTRIBUTED BY (rank, gender, year);
```

Create table **films** and table distributors (the primary key will be used as the Greenplum distribution key by default):

```
CREATE TABLE films (  
  code char(5) CONSTRAINT firstkey PRIMARY KEY,  
  title varchar(40) NOT NULL,  
  did integer NOT NULL,  
  date_prod date,  
  kind varchar(10),  
  len interval hour to minute
);```
CREATE TABLE distributors (  
did integer PRIMARY KEY DEFAULT nextval('serial'),  
nname varchar(40) NOT NULL CHECK (name <> '')  
);

Create a gzip-compressed, append-optimized table:

CREATE TABLE sales (txn_id int, qty int, date date)  
WITH (appendoptimized=true, compresslevel=5)  
DISTRIBUTED BY (txn_id);

Create a three level partitioned table using subpartition templates and default partitions at each level:

CREATE TABLE sales (id int, year int, month int, day int,  
region text)  
DISTRIBUTED BY (id)  
PARTITION BY RANGE (year)  
  SUBPARTITION BY RANGE (month)  
      SUBPARTITION TEMPLATE (  
          START (1) END (13) EVERY (1),  
          DEFAULT SUBPARTITION other_months )  
  SUBPARTITION BY LIST (region)  
      SUBPARTITION TEMPLATE (  
          SUBPARTITION usa VALUES ('usa'),  
          SUBPARTITION europe VALUES ('europe'),  
          SUBPARTITION asia VALUES ('asia'),  
          DEFAULT SUBPARTITION other_regions)  
( START (2008) END (2016) EVERY (1),  
  DEFAULT PARTITION outlying_years);

**Compatibility**

CREATE TABLE command conforms to the SQL standard, with the following exceptions:

- **Temporary Tables** — In the SQL standard, temporary tables are defined just once and automatically exist (starting with empty contents) in every session that needs them. Greenplum Database instead requires each session to issue its own CREATE TEMPORARY TABLE command for each temporary table to be used. This allows different sessions to use the same temporary table name for different purposes, whereas the standard's approach constrains all instances of a given temporary table name to have the same table structure.

  The standard's distinction between global and local temporary tables is not in Greenplum Database. Greenplum Database will accept the `GLOBAL` and `LOCAL` keywords in a temporary table declaration, but they have no effect and are deprecated.

  If the `ON COMMIT` clause is omitted, the SQL standard specifies that the default behavior as `ON COMMIT DELETE ROWS`. However, the default behavior in Greenplum Database is `ON COMMIT PRESERVE ROWS`. The `ON COMMIT DROP` option does not exist in the SQL standard.

- **Column Check Constraints** — The SQL standard says that CHECK column constraints may only refer to the column they apply to; only CHECK table constraints may refer to multiple columns. Greenplum Database does not enforce this restriction; it treats column and table check constraints alike.

- **NULL Constraint** — The NULL constraint is a Greenplum Database extension to the SQL standard that is included for compatibility with some other database systems (and for symmetry with the NOT NULL constraint). Since it is the default for any column, its presence is not required.

- **Inheritance** — Multiple inheritance via the INHERITS clause is a Greenplum Database language extension. SQL:1999 and later define single inheritance using a different syntax and different semantics. SQL:1999-style inheritance is not yet supported by Greenplum Database.
- **Partitioning** — Table partitioning via the PARTITION BY clause is a Greenplum Database language extension.
- **Zero-column tables** — Greenplum Database allows a table of no columns to be created (for example, CREATE TABLE foo();). This is an extension from the SQL standard, which does not allow zero-column tables. Zero-column tables are not in themselves very useful, but disallowing them creates odd special cases for ALTER TABLE DROP COLUMN, so Greenplum decided to ignore this spec restriction.
- **LIKE** — While a LIKE clause exists in the SQL standard, many of the options that Greenplum Database accepts for it are not in the standard, and some of the standard's options are not implemented by Greenplum Database.
- **WITH clause** — The WITH clause is a Greenplum Database extension; neither storage parameters nor OIDs are in the standard.
- **Tablespaces** — The Greenplum Database concept of tablespaces is not part of the SQL standard. The clauses TABLESPACE and USING INDEX TABLESPACE are extensions.
- **Data Distribution** — The Greenplum Database concept of a parallel or distributed database is not part of the SQL standard. The DISTRIBUTED clauses are extensions.

**See Also**

ALTER TABLE, DROP TABLE, CREATE EXTERNAL TABLE, CREATE TABLE AS

---

**CREATE TABLE AS**

Defines a new table from the results of a query.

**Synopsis**

CREATE [ [ GLOBAL | LOCAL ] { TEMPORARY | TEMP } | UNLOGGED ]
TABLE table_name
    [ (column_name [, ...] ) ]
    [ WITH ( storage_parameter [= value] [, ... ] ) | WITHOUT OIDS ]
    [ ON COMMIT { PRESERVE ROWS | DELETE ROWS | DROP } ]
    [ TABLESPACE tablespace_name ]
AS query
    [ WITH [ NO ] DATA ]
    [ DISTRIBUTED BY (column [, ...] ) ] | DISTRIBUTED RANDOMLY |
    DISTRIBUTED REPLICATED ]

where storage_parameter is:

appendoptimized={TRUE|FALSE}
blocksize={8192-2097152}
orientation={COLUMN|ROW}
compresstype={ZLIB|ZSTD|QUICKLZ}
compresslevel={1-19 | 1}
fillfactor={10-100}
[oids=FALSE]

**Description**

CREATE TABLE AS creates a table and fills it with data computed by a SELECT command. The table columns have the names and data types associated with the output columns of the SELECT, however you can override the column names by giving an explicit list of new column names.

CREATE TABLE AS creates a new table and evaluates the query just once to fill the new table initially. The new table will not track subsequent changes to the source tables of the query.
Parameters

GLOBAL | LOCAL
Ignored for compatibility. These keywords are deprecated; refer to `CREATE TABLE` for details.

TEMPORARY | TEMP
If specified, the new table is created as a temporary table. Temporary tables are automatically dropped at the end of a session, or optionally at the end of the current transaction (see ON COMMIT). Existing permanent tables with the same name are not visible to the current session while the temporary table exists, unless they are referenced with schema-qualified names. Any indexes created on a temporary table are automatically temporary as well.

UNLOGGED
If specified, the table is created as an unlogged table. Data written to unlogged tables is not written to the write-ahead (WAL) log, which makes them considerably faster than ordinary tables. However, the contents of an unlogged table are not replicated to mirror segment instances. Also an unlogged table is not crash-safe. After a segment instance crash or unclean shutdown, the data for the unlogged table on that segment is truncated. Any indexes created on an unlogged table are automatically unlogged as well.

table_name
The name (optionally schema-qualified) of the new table to be created.

column_name
The name of a column in the new table. If column names are not provided, they are taken from the output column names of the query.

WITH ( storage_parameter=value )
The `WITH` clause can be used to set storage options for the table or its indexes. Note that you can also set different storage parameters on a particular partition or subpartition by declaring the `WITH` clause in the partition specification. The following storage options are available:

appendoptimized — Set to `TRUE` to create the table as an append-optimized table. If `FALSE` or not declared, the table will be created as a regular heap-storage table.

blocksize — Set to the size, in bytes for each block in a table. The `blocksize` must be between 8192 and 2097152 bytes, and be a multiple of 8192. The default is 32768.

orientation — Set to `column` for column-oriented storage, or `row` (the default) for row-oriented storage. This option is only valid if `appendoptimized=TRUE`. Heap-storage tables can only be row-oriented.

compressstype — Set to `ZLIB` (the default), `ZSTD`, or `QUICKLZ`\(^\text{1}\) to specify the type of compression used. The value `NONE` disables compression. Zstd provides for both speed or a good compression ratio, tunable with the `compresslevel` option. QuickLZ and zlib are provided for backwards-compatibility. Zstd outperforms these compression types on usual workloads. The `compressstype` option is valid only if `appendoptimized=TRUE`.

Note: \(^\text{1}\)QuickLZ compression is available only in the commercial release of Pivotal Greenplum Database.

compresslevel — For Zstd compression of append-optimized tables, set to an integer value from 1 (fastest compression) to 19 (highest compression ratio). For zlib compression, the valid range is from 1 to 9. QuickLZ compression level can only be set to 1. If not declared, the default is 1. The `compresslevel` option is valid only if `appendoptimized=TRUE`.

fillfactor — See `CREATE INDEX` for more information about this index storage parameter.
oids=FALSE — This setting is the default, and it ensures that rows do not have object
idifiers assigned to them. Pivotal does not support using WITH OIDS or oids=TRUE
to assign an OID system column. On large tables, such as those in a typical Greenplum
Database system, using OIDs for table rows can cause wrap-around of the 32-bit OID
counter. Once the counter wraps around, OIDs can no longer be assumed to be unique,
which not only makes them useless to user applications, but can also cause problems in
the Greenplum Database system catalog tables. In addition, excluding OIDs from a table
reduces the space required to store the table on disk by 4 bytes per row, slightly improving
performance. You cannot create OIDS on a partitioned or column-oriented table (an
error is displayed). This syntax is deprecated and will be removed in a future Greenplum
release.

ON COMMIT
The behavior of temporary tables at the end of a transaction block can be controlled using
ON COMMIT. The three options are:

PRESERVE ROWS — No special action is taken at the ends of transactions for temporary
tables. This is the default behavior.

DELETE ROWS — All rows in the temporary table will be deleted at the end of each
transaction block. Essentially, an automatic TRUNCATE is done at each commit.

DROP — The temporary table will be dropped at the end of the current transaction block.

TABLESPACE tablespace_name
The tablespace_name parameter is the name of the tablespace in which the new
table is to be created. If not specified, the database’s default tablespace is used, or
temp_tablespaces if the table is temporary.

AS query
A SELECT, TABLE, or VALUES command, or an EXECUTE command that runs a prepared
SELECT or VALUES query.

DISTRIBUTED BY ({column [opclass]}, [ ... ])
DISTRIBUTED RANDOMLY
DISTRIBUTED REPLICATED
Used to declare the Greenplum Database distribution policy for the table. DISTRIBUTED
BY uses hash distribution with one or more columns declared as the distribution key.
For the most even data distribution, the distribution key should be the primary key of the
table or a unique column (or set of columns). If that is not possible, then you may choose
DISTRIBUTED RANDOMLY, which will send the data round-robin to the segment instances.

DISTRIBUTED REPLICATED replicates all rows in the table to all Greenplum Database
segments. It cannot be used with partitioned tables or with tables that inherit from other
tables.

The Greenplum Database server configuration parameter
gp_create_table_random_default_distribution controls the default table
distribution policy if the DISTRIBUTED BY clause is not specified when you create a table.
Greenplum Database follows these rules to create a table if a distribution policy is not
specified.

- If the Postgres Planner creates the table, and the value of the parameter is off, the
table distribution policy is determined based on the command.
- If the Postgres Planner creates the table, and the value of the parameter is on, the
table distribution policy is random.
- If GPORCA creates the table, the table distribution policy is random. The parameter
value has no effect.

For more information about setting the default table distribution policy, see
gp_create_table_random_default_distribution. For information about
the Postgres Planner and GPORCA, see Querying Data in the Greenplum Database Administrator Guide.

Notes
This command is functionally similar to SELECT INTO, but it is preferred since it is less likely to be confused with other uses of the SELECT INTO syntax. Furthermore, CREATE TABLE AS offers a superset of the functionality offered by SELECT INTO.

CREATE TABLE AS can be used for fast data loading from external table data sources. See CREATE EXTERNAL TABLE.

Examples
Create a new table films_recent consisting of only recent entries from the table films:

CREATE TABLE films_recent AS SELECT * FROM films WHERE date_prod >= '2007-01-01';

Create a new temporary table films_recent, consisting of only recent entries from the table films, using a prepared statement. The new table will be dropped at commit:

PREPARE recentfilms(date) AS SELECT * FROM films WHERE date_prod > $1;
CREATE TEMP TABLE films_recent ON COMMIT DROP AS EXECUTE recentfilms('2007-01-01');

Compatibility
CREATE TABLE AS conforms to the SQL standard, with the following exceptions:

- The standard requires parentheses around the subquery clause; in Greenplum Database, these parentheses are optional.
- The standard defines a WITH [NO] DATA clause; this is not currently implemented by Greenplum Database. The behavior provided by Greenplum Database is equivalent to the standard's WITH DATA case. WITH NO DATA can be simulated by appending LIMIT 0 to the query.
- Greenplum Database handles temporary tables differently from the standard; see CREATE TABLE for details.
- The WITH clause is a Greenplum Database extension; neither storage parameters nor OIDs are in the standard. The syntax for creating OID system columns is deprecated and will be removed in a future Greenplum release.
- The Greenplum Database concept of tablespaces is not part of the standard. The TABLESPACE clause is an extension.

CREATE TABLESPACE
Defines a new tablesapce.

Synopsis
CREATE TABLESPACE tablespace_name [OWNER username] LOCATION '/path/to/dir' [WITH (content_ID_1='/path/to/dir1', content_ID_2='/path/to/dir2' ... )]

1061
Description

CREATE TABLESPACE registers and configures a new tablespace for your Greenplum Database system. The tablespace name must be distinct from the name of any existing tablespace in the system. A tablespace is a Greenplum Database system object (a global object), you can use a tablespace from any database if you have appropriate privileges.

A tablespace allows superusers to define an alternative host file system location where the data files containing database objects (such as tables and indexes) reside.

A user with appropriate privileges can pass a tablespace name to CREATE DATABASE, CREATE TABLE, or CREATE INDEX to have the data files for these objects stored within the specified tablespace.

In Greenplum Database, the file system location must exist on all hosts including the hosts running the master, standby mirror, each primary segment, and each mirror segment.

Parameters

tablespace

The name of a tablespace to be created. The name cannot begin with pg_ or gp_, as such names are reserved for system tablespaces.

OWNER username

The name of the user who will own the tablespace. If omitted, defaults to the user executing the command. Only superusers can create tablespaces, but they can assign ownership of tablespaces to non-superusers.

LOCATION '/path/to/dir'

The absolute path to the directory (host system file location) that will be the root directory for the tablespace. When registering a tablespace, the directory should be empty and must be owned by the Greenplum Database system user. The directory must be specified by an absolute path name of no more than 100 characters. (The location is used to create a symlink target in the pg_tblspc directory, and symlink targets are truncated to 100 characters when sending to tar from utilities such as pg_basebackup.)

For each segment instance, you can specify a different directory for the tablespace in the WITH clause.

content ID_i='/path/to/dir_i'

The value ID_i is the content ID for the segment instance. /path/to/dir_i is the absolute path to the host system file location that the segment instance uses as the root directory for the tablespace. You cannot specify the content ID of the master instance (-1). You can specify the same directory for multiple segments.

If a segment instance is not listed in the WITH clause, Greenplum Database uses the directory specified in the LOCATION clause.

When registering a tablespace, the directories should be empty and must be owned by the Greenplum Database system user. Each directory must be specified by an absolute path name of no more than 100 characters.

Notes

Tablespaces are only supported on systems that support symbolic links.

CREATE TABLESPACE cannot be executed inside a transaction block.

When creating tablespaces, ensure that file system locations have sufficient I/O speed and available disk space.

CREATE TABLESPACE creates symbolic links from the pg_tblspc directory in the master and segment instance data directory to the directories specified in the command.
The system catalog table `pg_tablespace` stores tablespace information. This command displays the tablespace OID values, names, and owner.

```
SELECT oid, spcname, spcowner FROM pg_tablespace ;
```

The Greenplum Database built-in function `gp_tablespace_location(tablespace_oid)` displays the tablespace host system file locations for all segment instances. This command lists the segment database IDs and host system file locations for the tablespace with OID 16385.

```
SELECT * FROM gp_tablespace_location(16385)
```

**Examples**

Create a new tablespace and specify the file system location for the master and all segment instances:

```
CREATE TABLESPACE mytblspace LOCATION '/gpdbtspc/mytestspace' ;
```

Create a new tablespace and specify a location for segment instances with content ID 0 and 1. For the master and segment instances not listed in the `WITH` clause, the file system location for the tablespace is specified in the `LOCATION` clause.

```
CREATE TABLESPACE mytblspace LOCATION '/gpdbtspc/mytestspace' WITH (content0='/temp/mytest', content1='/temp/mytest');
```

The example specifies the same location for the two segment instances. You can specify different locations for each segment.

**Compatibility**

`CREATE TABLESPACE` is a Greenplum Database extension.

`CREATE DATABASE`, `CREATE TABLE`, `CREATE INDEX`, `DROP TABLESPACE`, `ALTER TABLESPACE`  

**CREATE TEXT SEARCH CONFIGURATION**

Defines a new text search configuration.

**Synopsis**

```
CREATE TEXT SEARCH CONFIGURATION name (  
  PARSER = parser_name  |  
  COPY = source_config  
)
```

**Description**

`CREATE TEXT SEARCH CONFIGURATION` creates a new text search configuration. A text search configuration specifies a text search parser that can divide a string into tokens, plus dictionaries that can be used to determine which tokens are of interest for searching.

If only the parser is specified, then the new text search configuration initially has no mappings from token types to dictionaries, and therefore will ignore all words. Subsequent `ALTER TEXT SEARCH CONFIGURATION` commands must be used to create mappings to make the configuration useful. Alternatively, an existing text search configuration can be copied.
If a schema name is given then the text search configuration is created in the specified schema. Otherwise it is created in the current schema.

The user who defines a text search configuration becomes its owner.

Refer to *Using Full Text Search* for further information.

**Parameters**

*name*

The name of the text search configuration to be created. The name can be schema-qualified.

*parser_name*

The name of the text search parser to use for this configuration.

*source_config*

The name of an existing text search configuration to copy.

**Notes**

The `PARSER` and `COPY` options are mutually exclusive, because when an existing configuration is copied, its parser selection is copied too.

**Compatibility**

There is no `CREATE TEXT SEARCH CONFIGURATION` statement in the SQL standard.

**See Also**

`ALTER TEXT SEARCH CONFIGURATION`, `DROP TEXT SEARCH CONFIGURATION`

---

**CREATE TEXT SEARCH DICTIONARY**

Defines a new text search dictionary.

**Synopsis**

```
CREATE TEXT SEARCH DICTIONARY name (    
    TEMPLATE = template 
    [, option = value [, ... ]] 
)
```

**Description**

`CREATE TEXT SEARCH DICTIONARY` creates a new text search dictionary. A text search dictionary specifies a way of recognizing interesting or uninteresting words for searching. A dictionary depends on a text search template, which specifies the functions that actually perform the work. Typically the dictionary provides some options that control the detailed behavior of the template's functions.

If a schema name is given then the text search dictionary is created in the specified schema. Otherwise it is created in the current schema.

The user who defines a text search dictionary becomes its owner.

Refer to *Using Full Text Search* for further information.

**Parameters**

*name*

The name of the text search dictionary to be created. The name can be schema-qualified.
**template**
The name of the text search template that will define the basic behavior of this dictionary.

**option**
The name of a template-specific option to be set for this dictionary.

**value**
The value to use for a template-specific option. If the value is not a simple identifier or number, it must be quoted (but you can always quote it, if you wish).

The options can appear in any order.

**Examples**
The following example command creates a Snowball-based dictionary with a nonstandard list of stop words.

```
CREATE TEXT SEARCH DICTIONARY my_russian (
    template = snowball,
    language = russian,
    stopwords = myrussian
);
```

**Compatibility**
There is no `CREATE TEXT SEARCH DICTIONARY` statement in the SQL standard.

**See Also**
`ALTER TEXT SEARCH DICTIONARY`, `DROP TEXT SEARCH DICTIONARY`

---

**CREATE TEXT SEARCH PARSER**

**Description**
Defines a new text search parser.

**Synopsis**

```
CREATE TEXT SEARCH PARSER name (  
    START = start_function ,  
    GETTOKEN = gettoken_function ,  
    END = end_function ,  
    LEXTYPES = lextypes_function  
    [, HEADLINE = headline_function ]
)
```

**Description**
`CREATE TEXT SEARCH PARSER` creates a new text search parser. A text search parser defines a method for splitting a text string into tokens and assigning types (categories) to the tokens. A parser is not particularly useful by itself, but must be bound into a text search configuration along with some text search dictionaries to be used for searching.

If a schema name is given then the text search parser is created in the specified schema. Otherwise it is created in the current schema.

You must be a superuser to use `CREATE TEXT SEARCH PARSER`. (This restriction is made because an erroneous text search parser definition could confuse or even crash the server.)
Refer to *Using Full Text Search* for further information.

**Parameters**

`name`

The name of the text search parser to be created. The name can be schema-qualified.

`start_function`

The name of the start function for the parser.

`gettoken_function`

The name of the get-next-token function for the parser.

`end_function`

The name of the end function for the parser.

`lextypes_function`

The name of the lextypes function for the parser (a function that returns information about the set of token types it produces).

`headline_function`

The name of the headline function for the parser (a function that summarizes a set of tokens).

The function names can be schema-qualified if necessary. Argument types are not given, since the argument list for each type of function is predetermined. All except the headline function are required. The arguments can appear in any order, not only the one shown above.

**Compatibility**

There is no `CREATE TEXT SEARCH PARSER` statement in the SQL standard.

**See Also**

`ALTER TEXT SEARCH PARSER`, `DROP TEXT SEARCH PARSER`

---

**CREATE TEXT SEARCH TEMPLATE**

**Description**

Defines a new text search template.

**Synopsis**

```sql
CREATE TEXT SEARCH TEMPLATE name ( [ INIT = init_function , ] LEXIZE = lexize_function )
```

**Description**

`CREATE TEXT SEARCH TEMPLATE` creates a new text search template. Text search templates define the functions that implement text search dictionaries. A template is not useful by itself, but must be instantiated as a dictionary to be used. The dictionary typically specifies parameters to be given to the template functions.

If a schema name is given then the text search template is created in the specified schema. Otherwise it is created in the current schema.
You must be a superuser to use `CREATE TEXT SEARCH TEMPLATE`. This restriction is made because an erroneous text search template definition could confuse or even crash the server. The reason for separating templates from dictionaries is that a template encapsulates the "unsafe" aspects of defining a dictionary. The parameters that can be set when defining a dictionary are safe for unprivileged users to set, and so creating a dictionary need not be a privileged operation.

Refer to *Using Full Text Search* for further information.

**Parameters**

- **name**
  The name of the text search template to be created. The name can be schema-qualified.

- **init_function**
  The name of the init function for the template.

- **lexize_function**
  The name of the lexize function for the template.

The function names can be schema-qualified if necessary. Argument types are not given, since the argument list for each type of function is predetermined. The lexize function is required, but the init function is optional.

The arguments can appear in any order, not only the order shown above.

**Compatibility**

There is no `CREATE TEXT SEARCH TEMPLATE` statement in the SQL standard.

**See Also**

  [, INTERNALLENGTH = {internallength | VARIABLE}]
  [, PASSEDBYVALUE]`
CREATE TYPE name

Description

CREATE TYPE registers a new data type for use in the current database. The user who defines a type becomes its owner.

If a schema name is given then the type is created in the specified schema. Otherwise it is created in the current schema. The type name must be distinct from the name of any existing type or domain in the same schema. The type name must also be distinct from the name of any existing table in the same schema.

There are five forms of CREATE TYPE, as shown in the syntax synopsis above. They respectively create a composite type, an enum type, a range type, a base type, or a shell type. The first four of these are discussed in turn below. A shell type is simply a placeholder for a type to be defined later; it is created by issuing CREATE TYPE with no parameters except for the type name. Shell types are needed as forward references when creating range types and base types, as discussed in those sections.

Composite Types

The first form of CREATE TYPE creates a composite type. The composite type is specified by a list of attribute names and data types. An attribute's collation can be specified too, if its data type is collatable. A composite type is essentially the same as the row type of a table, but using CREATE TYPE avoids the need to create an actual table when all that is wanted is to define a type. A stand-alone composite type is useful, for example, as the argument or return type of a function.

To be able to create a composite type, you must have USAGE privilege on all attribute types.

Enumerated Types

The second form of CREATE TYPE creates an enumerated (ENUM) type, as described in Enumerated Types in the PostgreSQL documentation. ENUM types take a list of quoted labels, each of which must be less than NAMEDATALEN bytes long (64 in a standard build).

It is possible to create an enumerated type with zero labels, but such a type cannot be used to hold values before at least one label is added using ALTER TYPE.

Range Types

The third form of CREATE TYPE creates a new range type, as described in Range Types.

The range type's subtype can be any type with an associated b-tree operator class (to determine the ordering of values for the range type). Normally the subtype's default b-tree operator class is used to determine ordering; to use a non-default operator class, specify its name with subtype_opclass. If the subtype is collatable, and you want to use a non-default collation in the range's ordering, specify the desired collation with the collation option.

The optional canonical function must take one argument of the range type being defined, and return a value of the same type. This is used to convert range values to a canonical form, when applicable. See Section Defining New Range Types for more information. Creating a canonical function is a bit tricky, since it must be defined before the range type can be declared. To do this, you must first create a shell type,
which is a placeholder type that has no properties except a name and an owner. This is done by issuing
the command CREATE TYPE name, with no additional parameters. Then the function can be declared
using the shell type as argument and result, and finally the range type can be declared using the same
name. This automatically replaces the shell type entry with a valid range type.

The optional subtype_diff function must take two values of the subtype type as argument, and return a
double precision value representing the difference between the two given values. While this is optional,
providing it allows much greater efficiency of GiST indexes on columns of the range type. See Defining
New Range Types for more information.

Base Types

The fourth form of CREATE TYPE creates a new base type (scalar type). You must be a superuser to
create a new base type. The parameters may appear in any order, not only that shown in the syntax, and
most are optional. You must register two or more functions (using CREATE FUNCTION) before defining
the type. The support functions input_function and output_function are required, while the functions
receive_function, send_function, type_modifier_input_function, type_modifier_output_function, and
analyze_function are optional. Generally these functions have to be coded in C or another low-level
language. In Greenplum Database, any function used to implement a data type must be defined as
IMMUTABLE.

The input_function converts the type’s external textual representation to the internal representation used by
the operators and functions defined for the type. output_function performs the reverse transformation. The
input function may be declared as taking one argument of type cstring, or as taking three arguments of
types cstring, oid, integer. The first argument is the input text as a C string, the second argument
is the type’s own OID (except for array types, which instead receive their element type’s OID), and the
third is the typmod of the destination column, if known (−1 will be passed if not). The input function must
return a value of the data type itself. Usually, an input function should be declared STRICT; if it is not, it
will be called with a NULL first parameter when reading a NULL input value. The function must still return
NULL in this case, unless it raises an error. (This case is mainly meant to support domain input functions,
which may need to reject NULL inputs.) The output function must be declared as taking one argument of
the new data type. The output function must return type cstring. Output functions are not invoked for
NULL values.

The optional receive_function converts the type’s external binary representation to the internal
representation. If this function is not supplied, the type cannot participate in binary input. The binary
representation should be chosen to be cheap to convert to internal form, while being reasonably
portable. (For example, the standard integer data types use network byte order as the external binary
representation, while the internal representation is in the machine’s native byte order.) The receive function
should perform adequate checking to ensure that the value is valid. The receive function may be declared
as taking one argument of type internal, or as taking three arguments of types internal, oid,
integer. The first argument is a pointer to a StringInfo buffer holding the received byte string; the
optional arguments are the same as for the text input function. The receive function must return a value of
the data type itself. Usually, a receive function should be declared STRICT; if it is not, it will be called with
a NULL first parameter when reading a NULL input value. The function must still return NULL in this case,
unless it raises an error. (This case is mainly meant to support domain receive functions, which may need
to reject NULL inputs.) Similarly, the optional send_function converts from the internal representation to the
external binary representation. If this function is not supplied, the type cannot participate in binary output.
The send function must be declared as taking one argument of the new data type. The send function must return
type bytea. Send functions are not invoked for NULL values.

The optional type_modifier_input_function and type_modifier_output_function are required if the type
supports modifiers. Modifiers are optional constraints attached to a type declaration, such as char(5)
or numeric(30,2). While Greenplum Database allows user-defined types to take one or more
simple constants or identifiers as modifiers, this information must fit into a single non-negative integer
value for storage in the system catalogs. Greenplum Database passes the declared modifier(s) to the
type_modifier_input_function in the form of a cstring array. The modifier input function must check
the values for validity, throwing an error if they are incorrect. If the values are correct, the modifier input
function returns a single non-negative integer value that Greenplum Database stores as the column
Typmod. Type modifiers are rejected if the type was not defined with a type_modifier_input_function. The type_modifier_output_function converts the internal integer typmod value back to the correct form for user display. The modifier output function must return a cstring value that is the exact string to append to the type name. For example, numeric's function might return ("(30,2)"). The type_modifier_output_function is optional. When not specified, the default display format is the stored typmod integer value enclosed in parentheses.

You should at this point be wondering how the input and output functions can be declared to have results or arguments of the new type, when they have to be created before the new type can be created. The answer is that the type should first be defined as a shell type, which is a placeholder type that has no properties except a name and an owner. This is done by issuing the command CREATE TYPE name, with no additional parameters. Then the I/O functions can be defined referencing the shell type. Finally, CREATE TYPE with a full definition replaces the shell entry with a complete, valid type definition, after which the new type can be used normally.

The like_type parameter provides an alternative method for specifying the basic representation properties of a data type: copy them from some existing type. The values internallength, passedbyvalue, alignment, and storage are copied from the named type. (It is possible, though usually undesirable, to override some of these values by specifying them along with the LIKE clause.) Specifying representation this way is especially useful when the low-level implementation of the new type "piggybacks" on an existing type in some fashion.

While the details of the new type's internal representation are only known to the I/O functions and other functions you create to work with the type, there are several properties of the internal representation that must be declared to Greenplum Database. Foremost of these is internallength. Base data types can be fixed-length, in which case internallength is a positive integer, or variable length, indicated by setting internallength to VARIABLE. (Internally, this is represented by setting typlen to -1.) The internal representation of all variable-length types must start with a 4-byte integer giving the total length of this value of the type.

The optional flag PASSEDBYVALUE indicates that values of this data type are passed by value, rather than by reference. You may not pass by value types whose internal representation is larger than the size of the Datum type (4 bytes on most machines, 8 bytes on a few).

The alignment parameter specifies the storage alignment required for the data type. The allowed values equate to alignment on 1, 2, 4, or 8 byte boundaries. Note that variable-length types must have an alignment of at least 4, since they necessarily contain an int4 as their first component.

The storage parameter allows selection of storage strategies for variable-length data types. (Only plain is allowed for fixed-length types.) plain specifies that data of the type will always be stored in-line and not compressed. extended specifies that the system will first try to compress a long data value, and will move the value out of the main table row if it's still too long. external allows the value to be moved out of the main table, but the system will not try to compress it. main allows compression, but discourages moving the value out of the main table. (Data items with this storage strategy may still be moved out of the main table if there is no other way to make a row fit, but they will be kept in the main table preferentially over extended and external items.)

A default value may be specified, in case a user wants columns of the data type to default to something other than the null value. Specify the default with the DEFAULT key word. (Such a default may be overridden by an explicit DEFAULT clause attached to a particular column.)

To indicate that a type is an array, specify the type of the array elements using the ELEMENT key word. For example, to define an array of 4-byte integers (int4), specify ELEMENT = int4. More details about array types appear below.

The category and preferred parameters can be used to help control which implicit cast Greenplum Database applies in ambiguous situations. Each data type belongs to a category named by a single ASCII character, and each type is either "preferred" or not within its category. The parser will prefer casting to preferred types (but only from other types within the same category) when this rule helps resolve overloaded functions or operators. For types that have no implicit casts to or from any other types, it is sufficient to retain the default settings. However, for a group of related types that have implicit casts, it is
often helpful to mark them all as belonging to a category and select one or two of the "most general" types as being preferred within the category. The category parameter is especially useful when you add a user-defined type to an existing built-in category, such as the numeric or string types. It is also possible to create new entirely-user-defined type categories. Select any ASCII character other than an upper-case letter to name such a category.

To indicate the delimiter to be used between values in the external representation of arrays of this type, delimiter can be set to a specific character. The default delimiter is the comma (,). Note that the delimiter is associated with the array element type, not the array type itself.

If the optional Boolean parameter collatable is true, column definitions and expressions of the type may carry collation information through use of the COLLATE clause. It is up to the implementations of the functions operating on the type to actually make use of the collation information; this does not happen automatically merely by marking the type collatable.

### Array Types

Whenever a user-defined type is created, Greenplum Database automatically creates an associated array type, whose name consists of the element type's name prepended with an underscore, and truncated if necessary to keep it less than NAMEDATALEN bytes long. (If the name so generated collides with an existing type name, the process is repeated until a non-colliding name is found.) This implicitly-created array type is variable length and uses the built-in input and output functions array_in and array_out. The array type tracks any changes in its element type's owner or schema, and is dropped if the element type is.

You might reasonably ask why there is an ELEMENT option, if the system makes the correct array type automatically. The only case where it's useful to use ELEMENT is when you are making a fixed-length type that happens to be internally an array of a number of identical things, and you want to allow these things to be accessed directly by subscripting, in addition to whatever operations you plan to provide for the type as a whole. For example, type point is represented as just two floating-point numbers, each can be accessed using point[0] and point[1]. Note that this facility only works for fixed-length types whose internal form is exactly a sequence of identical fixed-length fields. A subscriptable variable-length type must have the generalized internal representation used by array_in and array_out. For historical reasons (i.e., this is clearly wrong but it's far too late to change it), subscripting of fixed-length array types starts from zero, rather than from one as for variable-length arrays.

### Parameters

- **name**
  The name (optionally schema-qualified) of a type to be created.

- **attribute_name**
  The name of an attribute (column) for the composite type.

- **data_type**
  The name of an existing data type to become a column of the composite type.

- **collation**
  The name of an existing collation to be associated with a column of a composite type, or with a range type.

- **label**
  A string literal representing the textual label associated with one value of an enum type.

- **subtype**
  The name of the element type that the range type will represent ranges of.

- **subtype_operator_class**
  The name of a b-tree operator class for the subtype.

- **canonical_function**
The name of the canonicalization function for the range type.

`subtype_diff_function`
The name of a difference function for the subtype.

`input_function`
The name of a function that converts data from the type's external textual form to its internal form.

`output_function`
The name of a function that converts data from the type's internal form to its external textual form.

`receive_function`
The name of a function that converts data from the type's external binary form to its internal form.

`send_function`
The name of a function that converts data from the type's internal form to its external binary form.

`type_modifier_input_function`
The name of a function that converts an array of modifier(s) for the type to internal form.

`type_modifier_output_function`
The name of a function that converts the internal form of the type's modifier(s) to external textual form.

`internallength`
A numeric constant that specifies the length in bytes of the new type's internal representation. The default assumption is that it is variable-length.

`alignment`
The storage alignment requirement of the data type. Must be one of `char`, `int2`, `int4`, or `double`. The default is `int4`.

`storage`
The storage strategy for the data type. Must be one of `plain`, `external`, `extended`, or `main`. The default is `plain`.

`like_type`
The name of an existing data type that the new type will have the same representation as. The values `internallength`, `passedbyvalue`, `alignment`, and `storage`, are copied from that type, unless overridden by explicit specification elsewhere in this `CREATE TYPE` command.

`category`
The category code (a single ASCII character) for this type. The default is 'u', signifying a user-defined type. You can find the other standard category codes in `pg_type Category Codes`. You may also assign unused ASCII characters to custom categories that you create.

`preferred`
`true` if this type is a preferred type within its type category, else `false`. The default value is `false`. Be careful when you create a new preferred type within an existing type category; this could cause surprising behaviour changes.

`default`
The default value for the data type. If this is omitted, the default is null.

`element`
The type being created is an array; this specifies the type of the array elements.

**delimiter**

The delimiter character to be used between values in arrays made of this type.

**collatable**

True if this type's operations can use collation information. The default is false.

**compression_type**

Set to **ZLIB** (the default), **ZSTD**, **RLE_TYPE**, or **QUICKLZ**\(^1\) to specify the type of compression used in columns of this type.

**Note:** \(^1\)QuickLZ compression is available only in the commercial release of Pivotal Greenplum Database.

**compression_level**

For Zstd compression, set to an integer value from 1 (fastest compression) to 19 (highest compression ratio). For zlib compression, the valid range is from 1 to 9. The QuickLZ compression level can only be set to 1. For **RLE_TYPE**, the compression level can be set to an integer value from 1 (fastest compression) to 4 (highest compression ratio). The default compression level is 1.

**blocksize**

Set to the size, in bytes, for each block in the column. The **BLOCKSIZE** must be between 8192 and 2097152 bytes, and be a multiple of 8192. The default block size is 32768.

**Notes**

User-defined type names cannot begin with the underscore character (_) and can only be 62 characters long (or in general **NAMEDATALEN** – 2, rather than the **NAMEDATALEN** – 1 characters allowed for other names). Type names beginning with underscore are reserved for internally-created array type names.

Greenplum Database does not support adding storage options for row or composite types.

Storage options defined at the table- and column-level override the default storage options defined for a scalar type.

Because there are no restrictions on use of a data type once it's been created, creating a base type or range type is tantamount to granting public execute permission on the functions mentioned in the type definition. (The creator of the type is therefore required to own these functions.) This is usually not an issue for the sorts of functions that are useful in a type definition. But you might want to think twice before designing a type in a way that would require 'secret' information to be used while converting it to or from external form.

**Examples**

This example creates a composite type and uses it in a function definition:

```sql
CREATE TYPE compfoo AS (f1 int, f2 text);

CREATE FUNCTION getfoo() RETURNS SETOF compfoo AS $$
SELECT fooid, fooname FROM foo
$$ LANGUAGE SQL;
```

This example creates the enumerated type **mood** and uses it in a table definition:

```sql
CREATE TYPE mood AS ENUM ('sad', 'ok', 'happy');
CREATE TABLE person ( 
    name text, 
    current_mood mood
);
```
This example creates a range type:

```sql
CREATE TYPE float8_range AS RANGE (subtype = float8, subtype_diff = float8mi);
```

This example creates the base data type `box` and then uses the type in a table definition:

```sql
CREATE TYPE box;
CREATE FUNCTION my_box_in_function(cstring) RETURNS box AS ...
CREATE FUNCTION my_box_out_function(box) RETURNS cstring AS ...
CREATE TYPE box (INTERNALLENGTH = 16, INPUT = my_box_in_function, OUTPUT = my_box_out_function);
CREATE TABLE myboxes (id integer, description box);
```

If the internal structure of `box` were an array of four `float4` elements, we might instead use:

```sql
CREATE TYPE box (INTERNALLENGTH = 16, INPUT = my_box_in_function, OUTPUT = my_box_out_function, ELEMENT = float4);
```

which would allow a `box` value's component numbers to be accessed by subscripting. Otherwise the type behaves the same as before.

This example creates a large object type and uses it in a table definition:

```sql
CREATE TYPE bigobj (INPUT = lo_filein, OUTPUT = lo_fileout, INTERNALLENGTH = VARIABLE);
CREATE TABLE big_objs (id integer, obj bigobj);
```
Compatibility
The first form of the `CREATE TYPE` command, which creates a composite type, conforms to the SQL standard. The other forms are Greenplum Database extensions. The `CREATE TYPE` statement in the SQL standard also defines other forms that are not implemented in Greenplum Database.

The ability to create a composite type with zero attributes is a Greenplum Database-specific deviation from the standard (analogous to the same case in `CREATE TABLE`).

See Also
`ALTER TYPE`, `CREATE DOMAIN`, `CREATE FUNCTION`, `DROP TYPE`

CREATE USER

Defines a new database role with the `LOGIN` privilege by default.

Synopsis

```plaintext
CREATE USER name [[WITH] option [ ... ]]
```

where `option` can be:

- `SUPERUSER | NOSUPERUSER`
- `CREATEDB | NOCREATEDB`
- `CREATEROLE | NOCREATEROLE`
- `CREATEUSER | NOCREATEUSER`
- `CREATEEXTABLE | NOCREATEEXTABLE`
  
  ```plaintext
  [ ( attribute='value'[, ...] ) ]
  where attributes and value are:
  type='readable'|'writable'
  protocol='gpfdist'|'http'
  ```
- `INHERIT | NOINHERIT`
- `LOGIN | NOLOGIN`
- `REPLICATION | NOREPLICATION`
- `CONNECTION LIMIT connlimit`
  
  ```plaintext
  [ ENCRYPTED | UNENCRYPTED ] PASSWORD 'password'
  ```
- `VALID UNTIL 'timestamp'`

  ```plaintext
  IN ROLE role_name [, ...]
  IN GROUP role_name
  ROLE role_name [, ...]
  ADMIN role_name [, ...]
  USER role_name [, ...]
  SYSID uid
  RESOURCE QUEUE queue_name
  RESOURCE GROUP group_name
  [ DENY deny_point ]
  [ DENY BETWEEN deny_point AND deny_point]
  ```

Description

`CREATE USER` is an alias for `CREATE ROLE`.

The only difference between `CREATE ROLE` and `CREATE USER` is that `LOGIN` is assumed by default with `CREATE USER`, whereas `NOLOGIN` is assumed by default with `CREATE ROLE`.

Compatibility

There is no `CREATE USER` statement in the SQL standard.
**CREATE USER MAPPING**

Defines a new mapping of a user to a foreign server.

**Synopsis**

```
CREATE USER MAPPING FOR { username | USER | CURRENT_USER | PUBLIC }
  SERVER servername
  [ OPTIONS ( option 'value' [, ... ] ) ]
```

**Description**

`CREATE USER MAPPING` defines a mapping of a user to a foreign server. You must be the owner of the server to define user mappings for it.

**Parameters**

- `username`
  
The name of an existing user that is mapped to the foreign server. `CURRENT_USER` and `USER` match the name of the current user. `PUBLIC` is used to match all present and future user names in the system.

- `servername`
  
The name of an existing server for which Greenplum Database is to create the user mapping.

- `OPTIONS ( option 'value' [, ... ] )`
  
The options for the new user mapping. The options typically define the actual user name and password of the mapping. Option names must be unique. The option names and values are specific to the server's foreign-data wrapper.

**Examples**

Create a user mapping for user `bob`, server `foo`:

```
CREATE USER MAPPING FOR bob SERVER foo OPTIONS (user 'bob', password 'secret');
```

**Compatibility**

`CREATE USER MAPPING` conforms to ISO/IEC 9075-9 (SQL/MED).

**See Also**

`ALTER USER MAPPING`, `DROP USER MAPPING`, `CREATE FOREIGN DATA WRAPPER`, `CREATE SERVER`
Synopsis

CREATE [OR REPLACE] [TEMP | TEMPORARY] [RECURSIVE] VIEW name [ ( column_name [, ...] ) ]
  [ WITH { view_option_name [= view_option_value] [, ... ] } ]
AS query
  [ WITH [ CASCADED | LOCAL ] CHECK OPTION ]

Description

CREATE VIEW defines a view of a query. The view is not physically materialized. Instead, the query is run every time the view is referenced in a query.

CREATE OR REPLACE VIEW is similar, but if a view of the same name already exists, it is replaced. The new query must generate the same columns that were generated by the existing view query (that is, the same column names in the same order, and with the same data types), but it may add additional columns to the end of the list. The calculations giving rise to the output columns may be completely different.

If a schema name is given then the view is created in the specified schema. Otherwise it is created in the current schema. Temporary views exist in a special schema, so a schema name may not be given when creating a temporary view. The name of the view must be distinct from the name of any other view, table, sequence, index or foreign table in the same schema.

Parameters

TEMPORARY | TEMP

If specified, the view is created as a temporary view. Temporary views are automatically dropped at the end of the current session. Existing permanent relations with the same name are not visible to the current session while the temporary view exists, unless they are referenced with schema-qualified names. If any of the tables referenced by the view are temporary, the view is created as a temporary view (whether TEMPORARY is specified or not).

RECURSIVE

Creates a recursive view. The syntax

CREATE RECURSIVE VIEW [ schema . ] view_name (column_names) AS
SELECT ...;

is equivalent to

CREATE VIEW [ schema . ] view_name AS WITH RECURSIVE view_name (column_names) AS (SELECT ...) SELECT column_names
FROM view_name;

A view column name list must be specified for a recursive view.

name

The name (optionally schema-qualified) of a view to be created.

column_name

An optional list of names to be used for columns of the view. If not given, the column names are deduced from the query.

WITH ( view_option_name [= view_option_value] [, ... ] )

This clause specifies optional parameters for a view; the following parameters are supported:

check_option (string)
This parameter may be either local or cascaded, and is equivalent to specifying WITH [ CASCADED | LOCAL ] CHECK OPTION (see below). This option can be changed on existing views using ALTER VIEW.

security_barrier (boolean)
This should be used if the view is intended to provide row-level security.

query
A SELECT or VALUES command which will provide the columns and rows of the view.

Notes
Views in Greenplum Database are read only. The system will not allow an insert, update, or delete on a view. You can get the effect of an updatable view by creating rewrite rules on the view into appropriate actions on other tables. For more information see CREATE RULE.

Be careful that the names and data types of the view's columns will be assigned the way you want. For example:

CREATE VIEW vista AS SELECT 'Hello World';

is bad form in two ways: the column name defaults to ?column?, and the column data type defaults to unknown. If you want a string literal in a view's result, use something like:

CREATE VIEW vista AS SELECT text 'Hello World' AS hello;

Access to tables referenced in the view is determined by permissions of the view owner not the current user (even if the current user is a superuser). This can be confusing in the case of superusers, since superusers typically have access to all objects. In the case of a view, even superusers must be explicitly granted access to tables referenced in the view if they are not the owner of the view.

However, functions called in the view are treated the same as if they had been called directly from the query using the view. Therefore the user of a view must have permissions to call any functions used by the view.

If you create a view with an ORDER BY clause, the ORDER BY clause is ignored when you do a SELECT from the view.

When CREATE OR REPLACE VIEW is used on an existing view, only the view's defining SELECT rule is changed. Other view properties, including ownership, permissions, and non-SELECT rules, remain unchanged. You must own the view to replace it (this includes being a member of the owning role).

Examples
Create a view consisting of all comedy films:

CREATE VIEW comedies AS SELECT * FROM films WHERE kind = 'comedy';

This will create a view containing the columns that are in the film table at the time of view creation. Though * was used to create the view, columns added later to the table will not be part of the view.

Create a view that gets the top ten ranked baby names:

CREATE VIEW topten AS SELECT name, rank, gender, year FROM names, rank WHERE rank < '11' AND names.id=rank.id;

Create a recursive view consisting of the numbers from 1 to 100:

CREATE RECURSIVE VIEW public.nums_1_100 (n) AS VALUES (1)
UNION ALL
  SELECT n+1 FROM nums_1_100 WHERE n < 100;

Notice that although the recursive view's name is schema-qualified in this `CREATE VIEW` command, its internal self-reference is not schema-qualified. This is because the implicitly-created CTE’s name cannot be schema-qualified.

**Compatibility**

The SQL standard specifies some additional capabilities for the `CREATE VIEW` statement that are not in Greenplum Database. The optional clauses for the full SQL command in the standard are:

- **CHECK OPTION** — This option has to do with updatable views. All `INSERT` and `UPDATE` commands on the view will be checked to ensure data satisfy the view-defining condition (that is, the new data would be visible through the view). If they do not, the update will be rejected.
- **LOCAL** — Check for integrity on this view.
- **CASCADED** — Check for integrity on this view and on any dependent view. `CASCADED` is assumed if neither `CASCADED` nor `LOCAL` is specified.

`CREATE OR REPLACE VIEW` is a Greenplum Database language extension. So is the concept of a temporary view.

**See Also**

`SELECT`, `DROP VIEW`
DECLARE

Defines a cursor.

Synopsis

```sql
DECLARE name [BINARY] [INSENSITIVE] [NO SCROLL] CURSOR
[WITH | WITHOUT] HOLD
FOR query [FOR READ ONLY]
```

Description

 DECLARE allows a user to create cursors, which can be used to retrieve a small number of rows at a time out of a larger query. Cursors can return data either in text or in binary format using FETCH.

**Note:** This page describes usage of cursors at the SQL command level. If you are trying to use cursors inside a PL/pgSQL function, the rules are different. See PL/pgSQL Language.

Normal cursors return data in text format, the same as a SELECT would produce. Since data is stored natively in binary format, the system must do a conversion to produce the text format. Once the information comes back in text form, the client application may need to convert it to a binary format to manipulate it. In addition, data in the text format is often larger in size than in the binary format. Binary cursors return the data in a binary representation that may be more easily manipulated. Nevertheless, if you intend to display the data as text anyway, retrieving it in text form will save you some effort on the client side.

As an example, if a query returns a value of one from an integer column, you would get a string of 1 with a default cursor whereas with a binary cursor you would get a 4-byte field containing the internal representation of the value (in big-endian byte order).

Binary cursors should be used carefully. Many applications, including psql, are not prepared to handle binary cursors and expect data to come back in the text format.

**Note:**

When the client application uses the 'extended query' protocol to issue a FETCH command, the Bind protocol message specifies whether data is to be retrieved in text or binary format. This choice overrides the way that the cursor is defined. The concept of a binary cursor as such is thus obsolete when using extended query protocol — any cursor can be treated as either text or binary.

A cursor can be specified in the WHERE CURRENT OF clause of the UPDATE or DELETE statement to update or delete table data. The UPDATE or DELETE statement can only be executed on the server, for example in an interactive psql session or a script. Language extensions such as PL/pgSQL do not have support for updatable cursors.

Parameters

**name**

The name of the cursor to be created.

**BINARY**

Causes the cursor to return data in binary rather than in text format.

**INSENSITIVE**

Indicates that data retrieved from the cursor should be unaffected by updates to the tables underlying the cursor while the cursor exists. In Greenplum Database, all cursors are insensitive. This key word currently has no effect and is present for compatibility with the SQL standard.
A cursor cannot be used to retrieve rows in a nonsequential fashion. This is the default behavior in Greenplum Database, since scrollable cursors (SCROLL) are not supported.

**WITH HOLD**

**WITHOUT HOLD**

WITH HOLD specifies that the cursor may continue to be used after the transaction that created it successfully commits. WITHOUT HOLD specifies that the cursor cannot be used outside of the transaction that created it. WITHOUT HOLD is the default.

WITH HOLD cannot not be specified when the query includes a FOR UPDATE or FOR SHARE clause.

**query**

A SELECT or VALUES command which will provide the rows to be returned by the cursor.

If the cursor is used in the WHERE CURRENT OF clause of the UPDATE or DELETE command, the SELECT command must satisfy the following conditions:

- Cannot reference a view or external table.
- References only one table.
- The table must be updatable. For example, the following are not updatable: table functions, set-returning functions, append-only tables, columnar tables.
- Cannot contain any of the following:
  - A grouping clause
  - A set operation such as UNION ALL or UNION DISTINCT
  - A sorting clause
  - A windowing clause
  - A join or a self-join

Specifying the FOR UPDATE clause in the SELECT command prevents other sessions from changing the rows between the time they are fetched and the time they are updated. Without the FOR UPDATE clause, a subsequent use of the UPDATE or DELETE command with the WHERE CURRENT OF clause has no effect if the row was changed since the cursor was created.

**Note:** Specifying the FOR UPDATE clause in the SELECT command locks the entire table, not just the selected rows.

**FOR READ ONLY**

**FOR READ ONLY** indicates that the cursor is used in a read-only mode.

**Notes**

Unless WITH HOLD is specified, the cursor created by this command can only be used within the current transaction. Thus, DECLARE without WITH HOLD is useless outside a transaction block: the cursor would survive only to the completion of the statement. Therefore Greenplum Database reports an error if this command is used outside a transaction block. Use BEGIN and COMMIT (or ROLLBACK) to define a transaction block.

If WITH HOLD is specified and the transaction that created the cursor successfully commits, the cursor can continue to be accessed by subsequent transactions in the same session. (But if the creating transaction is aborted, the cursor is removed.) A cursor created with WITH HOLD is closed when an explicit CLOSE command is issued on it, or the session ends. In the current implementation, the rows represented by a held cursor are copied into a temporary file or memory area so that they remain available for subsequent transactions.

If you create a cursor with the DECLARE command in a transaction, you cannot use the SET command in the transaction until you close the cursor with the CLOSE command.
Scrollable cursors are not currently supported in Greenplum Database. You can only use FETCH to move the cursor position forward, not backwards.

DECLARE...FOR UPDATE is not supported with append-optimized tables.

You can see all available cursors by querying the `pg_cursors` system view.

**Examples**

Declare a cursor:

```
DECLARE mycursor CURSOR FOR SELECT * FROM mytable;
```

**Compatibility**

SQL standard allows cursors only in embedded SQL and in modules. Greenplum Database permits cursors to be used interactively.

Greenplum Database does not implement an OPEN statement for cursors. A cursor is considered to be open when it is declared.

The SQL standard allows cursors to move both forward and backward. All Greenplum Database cursors are forward moving only (not scrollable).

Binary cursors are a Greenplum Database extension.

`CLOSE, DELETE, FETCH, MOVE, SELECT, UPDATE`

### DELETE

Deletes rows from a table.

**Synopsis**

```
[ WITH [ RECURSIVE ] with_query [, ...] ]
DELETE FROM [ONLY] table [[AS] alias]
[USING usinglist]
[WHERE condition | WHERE CURRENT OF cursor_name]
[RETURNING * | output_expression [[AS] output_name] [, ...]]
```

**Description**

`DELETE` deletes rows that satisfy the `WHERE` clause from the specified table. If the `WHERE` clause is absent, the effect is to delete all rows in the table. The result is a valid, but empty table.

By default, `DELETE` will delete rows in the specified table and all its child tables. If you wish to delete only from the specific table mentioned, you must use the `ONLY` clause.

There are two ways to delete rows in a table using information contained in other tables in the database: using sub-selects, or specifying additional tables in the `USING` clause. Which technique is more appropriate depends on the specific circumstances.

If the `WHERE CURRENT OF` clause is specified, the row that is deleted is the one most recently fetched from the specified cursor.

The `WHERE CURRENT OF` clause is not supported with replicated tables.
The optional `RETURNING` clause causes `DELETE` to compute and return value(s) based on each row actually deleted. Any expression using the table’s columns, and/or columns of other tables mentioned in `USING`, can be computed. The syntax of the `RETURNING` list is identical to that of the output list of `SELECT`.

**Note:** The `RETURNING` clause is not supported when deleting from append-optimized tables.

You must have the `DELETE` privilege on the table to delete from it.

**Note:** As the default, Greenplum Database acquires an `EXCLUSIVE` lock on tables for `DELETE` operations on heap tables. When the Global Deadlock Detector is enabled, the lock mode for `DELETE` operations on heap tables is `ROW EXCLUSIVE`. See `Global Deadlock Detector`.

**Outputs**

On successful completion, a `DELETE` command returns a command tag of the form

```
DELETE count
```

The `count` is the number of rows deleted. If `count` is 0, no rows were deleted by the query (this is not considered an error).

If the `DELETE` command contains a `RETURNING` clause, the result will be similar to that of a `SELECT` statement containing the columns and values defined in the `RETURNING` list, computed over the row(s) deleted by the command.

**Parameters**

- **with_query**
  - The `WITH` clause allows you to specify one or more subqueries that can be referenced by name in the `DELETE` query.
  - For a `DELETE` command that includes a `WITH` clause, the clause can only contain `SELECT` statements, the `WITH` clause cannot contain a data-modifying command (`INSERT`, `UPDATE`, or `DELETE`).
  - See `WITH Queries (Common Table Expressions)` and `SELECT` for details.

- **ONLY**
  - If specified, delete rows from the named table only. When not specified, any tables inheriting from the named table are also processed.

- **table**
  - The name (optionally schema-qualified) of an existing table.

- **alias**
  - A substitute name for the target table. When an alias is provided, it completely hides the actual name of the table. For example, given `DELETE FROM foo AS f`, the remainder of the `DELETE` statement must refer to this table as `f` not `foo`.

- **usinglist**
  - A list of table expressions, allowing columns from other tables to appear in the `WHERE` condition. This is similar to the list of tables that can be specified in the `FROM` Clause of a `SELECT` statement; for example, an alias for the table name can be specified. Do not repeat the target table in the `usinglist`, unless you wish to set up a self-join.

- **condition**
  - An expression returning a value of type `boolean`, which determines the rows that are to be deleted.

- **cursor_name**
  - The name of the cursor to use in a `WHERE CURRENT OF` condition. The row to be deleted is the one most recently fetched from this cursor. The cursor must be a simple non-grouping query on the `DELETE` target table.
WHERE CURRENT OF cannot be specified together with a Boolean condition.

The DELETE...WHERE CURRENT OF cursor statement can only be executed on the server, for example in an interactive psql session or a script. Language extensions such as PL/pgSQL do not have support for updatable cursors.

See DECLARE for more information about creating cursors.

**output_expression**

An expression to be computed and returned by the DELETE command after each row is deleted. The expression can use any column names of the table or table(s) listed in USING. Write * to return all columns.

**output_name**

A name to use for a returned column.

**Notes**

Greenplum Database lets you reference columns of other tables in the WHERE condition by specifying the other tables in the USING clause. For example, to the name Hannah from the rank table, one might do:

```sql
DELETE FROM rank USING names WHERE names.id = rank.id AND name = 'Hannah';
```

What is essentially happening here is a join between rank and names, with all successfully joined rows being marked for deletion. This syntax is not standard. However, this join style is usually easier to write and faster to execute than a more standard sub-select style, such as:

```sql
DELETE FROM rank WHERE id IN (SELECT id FROM names WHERE name = 'Hannah');
```

When using DELETE to remove all the rows of a table (for example: DELETE * FROM table;), Greenplum Database adds an implicit TRUNCATE command (when user permissions allow). The added TRUNCATE command frees the disk space occupied by the deleted rows without requiring a VACUUM of the table. This improves scan performance of subsequent queries, and benefits ELT workloads that frequently insert and delete from temporary tables.

Execution of UPDATE and DELETE commands directly on a specific partition (child table) of a partitioned table is not supported. Instead, these commands must be executed on the root partitioned table, the table created with the CREATE TABLE command.

For a partitioned table, all the child tables are locked during the DELETE operation when the Global Deadlock Detector is not enabled (the default). Only some of the leaf child tables are locked when the Global Deadlock Detector is enabled. For information about the Global Deadlock Detector, see Global Deadlock Detector.

**Examples**

Delete all films but musicals:

```sql
DELETE FROM films WHERE kind <> 'Musical';
```

Clear the table films:

```sql
DELETE FROM films;
```

Delete completed tasks, returning full details of the deleted rows:

```sql
DELETE FROM tasks WHERE status = 'DONE' RETURNING *;
```
Delete using a join:

```
DELETE FROM rank USING names WHERE names.id = rank.id AND name = 'Hannah';
```

**Compatibility**
This command conforms to the SQL standard, except that the **USING** and **RETURNING** clauses are Greenplum Database extensions, as is the ability to use **WITH** with **DELETE**.

**See Also**

`DECLARE, TRUNCATE`

---

**DISCARD**

Discards the session state.

**Synopsis**

```
DISCARD { ALL | PLANS | TEMPORARY | TEMP }
```

**Description**

**DISCARD** releases internal resources associated with a database session. This command is useful for partially or fully resetting the session's state. There are several subcommands to release different types of resources; the **DISCARD ALL** variant subsumes all the others, and also resets additional state.

**Parameters**

**PLANS**

Releases all cached query plans, forcing re-planning to occur the next time the associated prepared statement is used.

**SEQUENCES**

Discards all cached sequence-related state, including any preallocated sequence values that have not yet been returned by `nextval()`. (See **CREATE SEQUENCE** for a description of preallocated sequence values.)

**TEMPORARY/TEMP**

Drops all temporary tables created in the current session.

**ALL**

Releases all temporary resources associated with the current session and resets the session to its initial state. Currently, this has the same effect as executing the following sequence of statements:

```
SET SESSION AUTHORIZATION DEFAULT;
RESET ALL;
DEALLOCATE ALL;
CLOSE ALL;
UNLISTEN *;
SELECT pg_advisory_unlock_all();
DISCARD PLANS;
DISCARD SEQUENCES;
DISCARD TEMP;
```
Notes
DISCARD ALL cannot be executed inside a transaction block.

Compatibility
DISCARD is a Greenplum Database extension.

**DO**

Executes an anonymous code block as a transient anonymous function.

**Synopsis**

```
DO [ LANGUAGE lang_name ] code
```

**Description**

**DO** executes an anonymous code block, or in other words a transient anonymous function in a procedural language.

The code block is treated as though it were the body of a function with no parameters, returning void. It is parsed and executed a single time.

The optional `LANGUAGE` clause can appear either before or after the code block.

Anonymous blocks are procedural language structures that provide the capability to create and execute procedural code on the fly without persistently storing the code as database objects in the system catalogs. The concept of anonymous blocks is similar to UNIX shell scripts, which enable several manually entered commands to be grouped and executed as one step. As the name implies, anonymous blocks do not have a name, and for this reason they cannot be referenced from other objects. Although built dynamically, anonymous blocks can be easily stored as scripts in the operating system files for repetitive execution.

Anonymous blocks are standard procedural language blocks. They carry the syntax and obey the rules that apply to the procedural language, including declaration and scope of variables, execution, exception handling, and language usage.

The compilation and execution of anonymous blocks are combined in one step, while a user-defined function needs to be re-defined before use each time its definition changes.

**Parameters**

- **code**
  The procedural language code to be executed. This must be specified as a string literal, just as with the `CREATE FUNCTION` command. Use of a dollar-quoted literal is recommended. Optional keywords have no effect. These procedural languages are supported: PL/pgSQL (plpgsql), PL/Python (plpythonu), and PL/Perl (plperl and plperlu).

- **lang_name**
  The name of the procedural language that the code is written in. The default is `plpgsql`. The language must be installed on the Greenplum Database system and registered in the database.

**Notes**

The PL/pgSQL language is installed on the Greenplum Database system and is registered in a user created database. The PL/Python and PL/Perl languages are installed by default, but not registered. Other languages are not installed or registered. The system catalog `pg_language` contains information about the registered languages in a database.
The user must have `USAGE` privilege for the procedural language, or must be a superuser if the language is untrusted. This is the same privilege requirement as for creating a function in the language.

Anonymous blocks do not support function volatility or `EXECUTE ON` attributes.

**Examples**

This PL/pgSQL example grants all privileges on all views in schema `public` to role `webuser`:

```sql
DO $$
DECLARE r record;
BEGIN
    FOR r IN SELECT table_schema, table_name FROM information_schema.tables
        WHERE table_type = 'VIEW' AND table_schema = 'public'
    LOOP
        EXECUTE 'GRANT ALL ON ' || quote_ident(r.table_schema) || '.' || quote_ident(r.table_name) || ' TO webuser';
    END LOOP;
END$$;
```

This PL/pgSQL example determines if a Greenplum Database user is a superuser. In the example, the anonymous block retrieves the input value from a temporary table.

```sql
CREATE TEMP TABLE list AS VALUES ('gpadmin') DISTRIBUTED RANDOMLY;
DO $$
DECLARE
    name TEXT := 'gpadmin';
    superuser TEXT := '';
    t1_row pg_authid%ROWTYPE;
BEGIN
    SELECT * INTO t1_row FROM pg_authid, list
        WHERE pg_authid.rolname = name;
    IF t1_row.rolsuper = 'f' THEN
        superuser := 'not ';
    END IF;
    RAISE NOTICE 'user % is %a superuser', t1_row.rolname, superuser;
END $$ LANGUAGE plpgsql;
```

**Note:** The example PL/pgSQL uses `SELECT` with the `INTO` clause. It is different from the SQL command `SELECT INTO`.

**Compatibility**

There is no `DO` statement in the SQL standard.

**See Also**

`CREATE LANGUAGE `PL/pgSQL Language`

**DROP AGGREGATE**

Removes an aggregate function.

**Synopsis**

```
DROP AGGREGATE [IF EXISTS] name ( aggregate_signature ) [CASCADE | RESTRICT]
```

where `aggregate_signature` is:

```
* | 
```
Description

DROP AGGREGATE will delete an existing aggregate function. To execute this command the current user must be the owner of the aggregate function.

Parameters

IF EXISTS
Do not throw an error if the aggregate does not exist. A notice is issued in this case.

name
The name (optionally schema-qualified) of an existing aggregate function.

argmode
The mode of an argument: IN or VARIADIC. If omitted, the default is IN.

argname
The name of an argument. Note that DROP AGGREGATE does not actually pay any attention to argument names, since only the argument data types are needed to determine the aggregate function’s identity.

argtype
An input data type on which the aggregate function operates. To reference a zero-argument aggregate function, write * in place of the list of input data types. To reference an ordered-set aggregate function, write ORDER BY between the direct and aggregated argument specifications.

CASCADE
Automatically drop objects that depend on the aggregate function.

RESTRICT
Refuse to drop the aggregate function if any objects depend on it. This is the default.

Notes

Alternative syntaxes for referencing ordered-set aggregates are described under ALTER AGGREGATE.

Examples

To remove the aggregate function myavg for type integer:

```
DROP AGGREGATE myavg(integer);
```

To remove the hypothetical-set aggregate function myrank, which takes an arbitrary list of ordering columns and a matching list of direct arguments:

```
DROP AGGREGATE myrank(VARIADIC "any" ORDER BY VARIADIC "any");
```

Compatibility

There is no DROP AGGREGATE statement in the SQL standard.

See Also

ALTER AGGREGATE, CREATE AGGREGATE
**DROP CAST**

Removes a cast.

**Synopsis**

```
DROP CAST [IF EXISTS] (sourcetype AS targettype) [CASCADE | RESTRICT]
```

**Description**

`DROP CAST` will delete a previously defined cast. To be able to drop a cast, you must own the source or the target data type. These are the same privileges that are required to create a cast.

**Parameters**

- **IF EXISTS**
  
  Do not throw an error if the cast does not exist. A notice is issued in this case.

- **sourcetype**
  
  The name of the source data type of the cast.

- **targettype**
  
  The name of the target data type of the cast.

- **CASCADE**
  
  **RESTRICT**

  These keywords have no effect since there are no dependencies on casts.

**Examples**

To drop the cast from type `text` to type `int`:

```
DROP CAST (text AS int);
```

**Compatibility**

There `DROP CAST` command conforms to the SQL standard.

**See Also**

`CREATE CAST`

**DROP COLLATION**

Removes a previously defined collation.

**Synopsis**

```
DROP COLLATION [ IF EXISTS ] name [ CASCADE | RESTRICT ]
```

**Parameters**

- **IF EXISTS**

  Do not throw an error if the collation does not exist. A notice is issued in this case.

- **name**

  The name of the collation. The collation name can be schema-qualified.
CASCADE
   Automatically drop objects that depend on the collation.

RESTRICT
   Refuse to drop the collation if any objects depend on it. This is the default.

Notes
DROP COLLATION removes a previously defined collation. To be able to drop a collation, you must own the collation.

Examples
To drop the collation named german:

```
DROP COLLATION german;
```

Compatibility
The DROP COLLATION command conforms to the SQL standard, apart from the IF EXISTS option, which is a Greenplum Database extension.

See Also
ALTER COLLATION, CREATE COLLATION

**DROP CONVERSION**

Removes a conversion.

Synopsis

```
DROP CONVERSION [IF EXISTS] name [CASCADE | RESTRICT]
```

Description

DROP CONVERSION removes a previously defined conversion. To be able to drop a conversion, you must own the conversion.

Parameters

**IF EXISTS**
   Do not throw an error if the conversion does not exist. A notice is issued in this case.

**name**
   The name of the conversion. The conversion name may be schema-qualified.

**CASCADE**
   **RESTRICT**
   These keywords have no effect since there are no dependencies on conversions.

Examples

Drop the conversion named myname:

```
DROP CONVERSION myname;
```
Compatibility

There is no DROP CONVERSION statement in the SQL standard. The standard has CREATE TRANSLATION and DROP TRANSLATION statements that are similar to the Greenplum Database CREATE CONVERSION and DROP CONVERSION statements.

See Also

ALTER CONVERSION, CREATE CONVERSION

**DROP DATABASE**

Removes a database.

**Synopsis**

```
DROP DATABASE [IF EXISTS] name
```

**Description**

DROP DATABASE drops a database. It removes the catalog entries for the database and deletes the directory containing the data. It can only be executed by the database owner. Also, it cannot be executed while you or anyone else are connected to the target database. (Connect to postgres or any other database to issue this command.)

*Warning:* DROP DATABASE cannot be undone. Use it with care!

**Parameters**

*IF EXISTS*

Do not throw an error if the database does not exist. A notice is issued in this case.

*name*

The name of the database to remove.

**Notes**

DROP DATABASE cannot be executed inside a transaction block.

This command cannot be executed while connected to the target database. Thus, it might be more convenient to use the program dropdb instead, which is a wrapper around this command.

**Examples**

Drop the database named testdb:

```
DROP DATABASE testdb;
```

**Compatibility**

There is no DROP DATABASE statement in the SQL standard.

**See Also**

ALTER DATABASE, CREATE DATABASE

**DROP DOMAIN**

Removes a domain.
Synopsis

```
DROP DOMAIN [IF EXISTS] name [, ...] [CASCADE | RESTRICT]
```

Description

DROP DOMAIN removes a previously defined domain. You must be the owner of a domain to drop it.

Parameters

**IF EXISTS**
Do not throw an error if the domain does not exist. A notice is issued in this case.

**name**
The name (optionally schema-qualified) of an existing domain.

**CASCADE**
Automatically drop objects that depend on the domain (such as table columns).

**RESTRICT**
Refuse to drop the domain if any objects depend on it. This is the default.

Examples

Drop the domain named `zipcode`:

```
DROP DOMAIN zipcode;
```

Compatibility

This command conforms to the SQL standard, except for the **IF EXISTS** option, which is a Greenplum Database extension.

See Also

ALTER DOMAIN, CREATE DOMAIN

**DROP EXTENSION**

Removes an extension from a Greenplum database.

Synopsis

```
DROP EXTENSION [ IF EXISTS ] name [, ...] [ CASCADE | RESTRICT ]
```

Description

DROP EXTENSION removes extensions from the database. Dropping an extension causes its component objects to be dropped as well.

**Note:** The required supporting extension files what were installed to create the extension are not deleted. The files must be manually removed from the Greenplum Database hosts.

You must own the extension to use **DROP EXTENSION**.

This command fails if any of the extension objects are in use in the database. For example, if a table is defined with columns of the extension type. Add the **CASCADE** option to forcibly remove those dependent objects.
Important: Before issuing a DROP EXTENSION with the CASCADE keyword, you should be aware of all object that depend on the extension to avoid unintended consequences.

Parameters

**IF EXISTS**

Do not throw an error if the extension does not exist. A notice is issued.

**name**

The name of an installed extension.

**CASCADE**

Automatically drop objects that depend on the extension, and in turn all objects that depend on those objects. See the PostgreSQL information about *Dependency Tracking*.

**RESTRICT**

Refuse to drop an extension if any objects depend on it, other than the extension member objects. This is the default.

Compatibility

DROP EXTENSION is a Greenplum Database extension.

See Also

CREATE EXTENSION, ALTER EXTENSION

**DROP EXTERNAL TABLE**

Removes an external table definition.

Synopsis

```
DROP EXTERNAL [WEB] TABLE [IF EXISTS] name [CASCADE | RESTRICT]
```

Description

DROP EXTERNAL TABLE drops an existing external table definition from the database system. The external data sources or files are not deleted. To execute this command you must be the owner of the external table.

Parameters

**WEB**

Optional keyword for dropping external web tables.

**IF EXISTS**

Do not throw an error if the external table does not exist. A notice is issued in this case.

**name**

The name (optionally schema-qualified) of an existing external table.

**CASCADE**

Automatically drop objects that depend on the external table (such as views).

**RESTRICT**

Refuse to drop the external table if any objects depend on it. This is the default.
Examples
Remove the external table named staging if it exists:

```sql
DROP EXTERNAL TABLE IF EXISTS staging;
```

Compatibility
There is no DROP EXTERNAL TABLE statement in the SQL standard.

See Also
CREATE EXTERNAL TABLE

**DROP FOREIGN DATA WRAPPER**
Removes a foreign-data wrapper.

Synopsis

```
DROP FOREIGN DATA WRAPPER [ IF EXISTS ] name [ CASCADE | RESTRICT ]
```

Description

DROP FOREIGN DATA WRAPPER removes an existing foreign-data wrapper from the current database. A foreign-data wrapper may be removed only by its owner.

Parameters

**IF EXISTS**
Do not throw an error if the foreign-data wrapper does not exist. Greenplum Database issues a notice in this case.

**name**
The name of an existing foreign-data wrapper.

**CASCADE**
Automatically drop objects that depend on the foreign-data wrapper (such as servers).

**RESTRICT**
Refuse to drop the foreign-data wrapper if any object depends on it. This is the default.

Examples

Drop the foreign-data wrapper named dbi:

```sql
DROP FOREIGN DATA WRAPPER dbi;
```

Compatibility

DROP FOREIGN DATA WRAPPER conforms to ISO/IEC 9075-9 (SQL/MED). The IF EXISTS clause is a Greenplum Database extension.

See Also

CREATE FOREIGN DATA WRAPPER, ALTER FOREIGN DATA WRAPPER
**DROP FOREIGN TABLE**

Removes a foreign table.

**Synopsis**

```
DROP FOREIGN TABLE [ IF EXISTS ] name [, ...] [ CASCADE | RESTRICT ]
```

**Description**

DROP FOREIGN TABLE removes an existing foreign table. Only the owner of a foreign table can remove it.

**Parameters**

- **IF EXISTS**
  
  Do not throw an error if the foreign table does not exist. Greenplum Database issues a notice in this case.

- **name**
  
  The name (optionally schema-qualified) of the foreign table to drop.

- **CASCADE**
  
  Automatically drop objects that depend on the foreign table (such as views).

- **REstrict**
  
  Refuse to drop the foreign table if any objects depend on it. This is the default.

**Examples**

Drop the foreign tables named *films* and *distributors*:

```
DROP FOREIGN TABLE films, distributors;
```

**Compatibility**

DROP FOREIGN TABLE conforms to ISO/IEC 9075-9 (SQL/MED), except that the standard only allows one foreign table to be dropped per command. The IF EXISTS clause is a Greenplum Database extension.

**See Also**

| ALTER FOREIGN TABLE | CREATE FOREIGN TABLE |

---

**DROP FUNCTION**

Removes a function.

**Synopsis**

```
DROP FUNCTION [IF EXISTS] name ( [ [argmode] [argname] argtype [, ...] ] ) [CASCADE | RESTRICT]
```
Description

DROP FUNCTION removes the definition of an existing function. To execute this command the user must be the owner of the function. The argument types to the function must be specified, since several different functions may exist with the same name and different argument lists.

Parameters

IF EXISTS

Do not throw an error if the function does not exist. A notice is issued in this case.

name

The name (optionally schema-qualified) of an existing function.

argmode

The mode of an argument: either IN, OUT, INOUT, or VARIADIC. If omitted, the default is IN. Note that DROP FUNCTION does not actually pay any attention to OUT arguments, since only the input arguments are needed to determine the function's identity. So it is sufficient to list the IN, INOUT, and VARIADIC arguments.

argname

The name of an argument. Note that DROP FUNCTION does not actually pay any attention to argument names, since only the argument data types are needed to determine the function's identity.

argtype

The data type(s) of the function's arguments (optionally schema-qualified), if any.

CASCADE

Automatically drop objects that depend on the function such as operators.

RESTRICT

Refuse to drop the function if any objects depend on it. This is the default.

Examples

Drop the square root function:

```sql
DROP FUNCTION sqrt(integer);
```

Compatibility

A DROP FUNCTION statement is defined in the SQL standard, but it is not compatible with this command.

See Also

CREATE FUNCTION, ALTER FUNCTION

DROP GROUP

Removes a database role.

Synopsis

```sql
DROP GROUP [IF EXISTS] name [, ...]
```

Description

DROP GROUP is an alias for DROP ROLE. See DROP ROLE for more information.
**Compatibility**

There is no `DROP GROUP` statement in the SQL standard.

**See Also**

`DROP ROLE`

---

**DROP INDEX**

Removes an index.

**Synopsis**

```
DROP INDEX [ CONCURRENTLY ] [ IF EXISTS ] name [, ...] [ CASCADE | RESTRICT ]
```

**Description**

`DROP INDEX` drops an existing index from the database system. To execute this command you must be the owner of the index.

**Parameters**

**CONCURRENTLY**

Drop the index without locking out concurrent selects, inserts, updates, and deletes on the index's table. A normal `DROP INDEX` acquires an exclusive lock on the table, blocking other accesses until the index drop can be completed. With this option, the command instead waits until conflicting transactions have completed.

There are several caveats to be aware of when using this option. Only one index name can be specified, and the `CASCADE` option is not supported. (Thus, an index that supports a `UNIQUE` or `PRIMARY KEY` constraint cannot be dropped this way.) Also, regular `DROP INDEX` commands can be performed within a transaction block, but `DROP INDEX CONCURRENTLY` cannot.

**IF EXISTS**

Do not throw an error if the index does not exist. A notice is issued in this case.

**name**

The name (optionally schema-qualified) of an existing index.

**CASCADE**

Automatically drop objects that depend on the index.

**RESTRICT**

Refuse to drop the index if any objects depend on it. This is the default.

**Examples**

Remove the index `title_idx`:

```
DROP INDEX title_idx;
```

**Compatibility**

`DROP INDEX` is a Greenplum Database language extension. There are no provisions for indexes in the SQL standard.
See Also

ALTER INDEX, CREATE INDEX, REINDEX

**DROP LANGUAGE**

Removes a procedural language.

**Synopsis**

```
DROP [PROCEDURAL] LANGUAGE [IF EXISTS] name [CASCADE | RESTRICT]
```

**Description**

`DROP LANGUAGE` will remove the definition of the previously registered procedural language. You must be a superuser or owner of the language to drop a language.

**Parameters**

- **PROCEDURAL**
  
  Optional keyword - has no effect.

- **IF EXISTS**
  
  Do not throw an error if the language does not exist. A notice is issued in this case.

- **name**

  The name of an existing procedural language. For backward compatibility, the name may be enclosed by single quotes.

- **CASCADE**

  Automatically drop objects that depend on the language (such as functions written in that language).

- **RESTRICT**

  Refuse to drop the language if any objects depend on it. This is the default.

**Examples**

Remove the procedural language `plsample`:

```
DROP LANGUAGE plsample;
```

**Compatibility**

There is no `DROP LANGUAGE` statement in the SQL standard.

**See Also**

ALTER LANGUAGE, CREATE LANGUAGE

**DROP OPERATOR**

Removes an operator.

**Synopsis**

```
DROP OPERATOR [IF EXISTS] name ( {lefttype | NONE} ,
{righttype | NONE} ) [CASCADE | RESTRICT]
```
Description
DROP OPERATOR drops an existing operator from the database system. To execute this command you must be the owner of the operator.

Parameters
IF EXISTS
Do not throw an error if the operator does not exist. A notice is issued in this case.

name
The name (optionally schema-qualified) of an existing operator.

lefttype
The data type of the operator's left operand; write NONE if the operator has no left operand.

righttype
The data type of the operator's right operand; write NONE if the operator has no right operand.

CASCADE
Automatically drop objects that depend on the operator.

RESTRICT
Refuse to drop the operator if any objects depend on it. This is the default.

Examples
Remove the power operator \(a^b\) for type integer:

```
DROP OPERATOR ^ (integer, integer);
```

Remove the left unary bitwise complement operator \(~b\) for type bit:

```
DROP OPERATOR ~ (none, bit);
```

Remove the right unary factorial operator \(x!\) for type bigint:

```
DROP OPERATOR ! (bigint, none);
```

Compatibility
There is no DROP OPERATOR statement in the SQL standard.

See Also
ALTER OPERATOR, CREATE OPERATOR

DROP OPERATOR CLASS
Removes an operator class.

Synopsis

```
DROP OPERATOR CLASS [IF EXISTS] name USING index_method [CASCADE | RESTRICT]
```
**Description**

DROP OPERATOR drops an existing operator class. To execute this command you must be the owner of the operator class.

**Parameters**

**IF EXISTS**

Do not throw an error if the operator class does not exist. A notice is issued in this case.

**name**

The name (optionally schema-qualified) of an existing operator class.

**index_method**

The name of the index access method the operator class is for.

**CASCADE**

Automatically drop objects that depend on the operator class.

**RESTRICT**

Refuse to drop the operator class if any objects depend on it. This is the default.

**Examples**

Remove the B-tree operator class widget_ops:

```
DROP OPERATOR CLASS widget_ops USING btree;
```

This command will not succeed if there are any existing indexes that use the operator class. Add **CASCADE** to drop such indexes along with the operator class.

**Compatibility**

There is no **DROP OPERATOR CLASS** statement in the SQL standard.

**See Also**

**ALTER OPERATOR CLASS**, **CREATE OPERATOR CLASS**

---

**DROP OPERATOR FAMILY**

Removes an operator family.

**Synopsis**

```
DROP OPERATOR FAMILY [IF EXISTS] name USING index_method [CASCADE | RESTRICT]
```

**Description**

DROP OPERATOR FAMILY drops an existing operator family. To execute this command you must be the owner of the operator family.

DROP OPERATOR FAMILY includes dropping any operator classes contained in the family, but it does not drop any of the operators or functions referenced by the family. If there are any indexes depending on operator classes within the family, you will need to specify **CASCADE** for the drop to complete.

**Parameters**

**IF EXISTS**
Do not throw an error if the operator family does not exist. A notice is issued in this case.

**name**
The name (optionally schema-qualified) of an existing operator family.

**index_method**
The name of the index access method the operator family is for.

**CASCADE**
Automatically drop objects that depend on the operator family.

**RESTRICT**
Refuse to drop the operator family if any objects depend on it. This is the default.

### Examples
Remove the B-tree operator family `float_ops`:

```
DROP OPERATOR FAMILY float_ops USING btree;
```

This command will not succeed if there are any existing indexes that use the operator family. Add **CASCADE** to drop such indexes along with the operator family.

### Compatibility
There is no *DROP OPERATOR FAMILY* statement in the SQL standard.

### See Also
- [ALTER OPERATOR FAMILY](#)
- [CREATE OPERATOR FAMILY](#)
- [ALTER OPERATOR CLASS](#)
- [CREATE OPERATOR CLASS](#)
- [DROP OPERATOR CLASS](#)

---

**DROP OWNED**

Removes database objects owned by a database role.

### Synopsis

```
DROP OWNED BY name [, ...] [CASCADE | RESTRICT]
```

### Description

*DROP OWNED* drops all the objects in the current database that are owned by one of the specified roles. Any privileges granted to the given roles on objects in the current database or on shared objects (databases, tablespaces) will also be revoked.

### Parameters

**name**
The name of a role whose objects will be dropped, and whose privileges will be revoked.

**CASCADE**
Automatically drop objects that depend on the affected objects.

**RESTRICT**
Refuse to drop the objects owned by a role if any other database objects depend on one of the affected objects. This is the default.
Notes

DROP OWNED is often used to prepare for the removal of one or more roles. Because DROP OWNED only affects the objects in the current database, it is usually necessary to execute this command in each database that contains objects owned by a role that is to be removed.

Using the CASCADE option may make the command recurse to objects owned by other users.

The REASSIGN OWNED command is an alternative that reassigns the ownership of all the database objects owned by one or more roles. However, REASSIGN OWNED does not deal with privileges for other objects.

Examples

Remove any database objects owned by the role named sally:

```
DROP OWNED BY sally;
```

Compatibility

The DROP OWNED command is a Greenplum Database extension.

See Also

REASSIGN OWNED, DROP ROLE

DROP PROTOCOL

Removes a external table data access protocol from a database.

Synopsis

```
DROP PROTOCOL [IF EXISTS] name
```

Description

DROP PROTOCOL removes the specified protocol from a database. A protocol name can be specified in the CREATE EXTERNAL TABLE command to read data from or write data to an external data source.

You must be a superuser or the protocol owner to drop a protocol.

Warning: If you drop a data access protocol, external tables that have been defined with the protocol will no longer be able to access the external data source.

Parameters

IF EXISTS

Do not throw an error if the protocol does not exist. A notice is issued in this case.

name

The name of an existing data access protocol.

Notes

If you drop a data access protocol, the call handlers that defined in the database that are associated with the protocol are not dropped. You must drop the functions manually.

Shared libraries that were used by the protocol should also be removed from the Greenplum Database hosts.
Compatibility
DROP PROTOCOL is a Greenplum Database extension.

See Also
CREATE EXTERNAL TABLE, CREATE PROTOCOL

DROP RESOURCE GROUP
Removes a resource group.

Synopsis

```
DROP RESOURCE GROUP group_name
```

Description
This command removes a resource group from Greenplum Database. Only a superuser can drop a resource group. When you drop a resource group, the memory and CPU resources reserved by the group are returned to Greenplum Database.

To drop a role resource group, the group cannot be assigned to any roles, nor can it have any statements pending or running in the group. If you drop a resource group that you created for an external component, the behavior is determined by the external component. For example, dropping a resource group that you assigned to a PL/Container runtime kills running containers in the group.

You cannot drop the pre-defined admin_group and default_group resource groups.

Parameters

`group_name`
The name of the resource group to remove.

Notes

You cannot submit a DROP RESOURCE GROUP command in an explicit transaction or sub-transaction.

Use `ALTER ROLE` to remove a resource group assigned to a specific user/role.

Perform the following query to view all of the currently active queries for all resource groups:

```
SELECT usename, query, waiting, pid, rsgid, rsgname, rsgqueueduration FROM pg_stat_activity;
```

To view the resource group assignments, perform the following query on the pg_roles and pg_resgroup system catalog tables:

```
SELECT rolname, rsgname FROM pg_roles, pg_resgroup WHERE pg_roles.rolresgroup=pg_resgroup.oid;
```

Examples

Remove the resource group assigned to a role. This operation then assigns the default resource group `default_group` to the role:

```
ALTER ROLE bob RESOURCE GROUP NONE;
```
Remove the resource group named `adhoc`:

```
DROP RESOURCE GROUP adhoc;
```

**Compatibility**

The `DROP RESOURCE GROUP` statement is a Greenplum Database extension.

**See Also**

`ALTER RESOURCE GROUP`, `CREATE RESOURCE GROUP`, `ALTER ROLE`

---

**DROP RESOURCE QUEUE**

Removes a resource queue.

**Synopsis**

```
DROP RESOURCE QUEUE queue_name
```

**Description**

This command removes a resource queue from Greenplum Database. To drop a resource queue, the queue cannot have any roles assigned to it, nor can it have any statements waiting in the queue. Only a superuser can drop a resource queue.

**Parameters**

`queue_name`

The name of a resource queue to remove.

**Notes**

Use `ALTER ROLE` to remove a user from a resource queue.

To see all the currently active queries for all resource queues, perform the following query of the `pg_locks` table joined with the `pg_roles` and `pg_resqueue` tables:

```
SELECT rolname, rsqname, locktype, objid, pid,
mode, granted FROM pg_roles, pg_resqueue, pg_locks WHERE
pg_roles.rolresqueue=pg_locks.objid AND
pg_locks.objid=pg_resqueue.oid;
```

To see the roles assigned to a resource queue, perform the following query of the `pg_roles` and `pg_resqueue` system catalog tables:

```
SELECT rolname, rsqname FROM pg_roles, pg_resqueue WHERE
pg_roles.rolresqueue=pg_resqueue.oid;
```

**Examples**

Remove a role from a resource queue (and move the role to the default resource queue, `pg_default`):

```
ALTER ROLE bob RESOURCE QUEUE NONE;
```
Remove the resource queue named *adhoc*:

```sql
DROP RESOURCE QUEUE adhoc;
```  

**Compatibility**

The `DROP RESOURCE QUEUE` statement is a Greenplum Database extension.

**See Also**

`ALTER RESOURCE QUEUE`, `CREATE RESOURCE QUEUE`, `ALTER ROLE`

---

## DROP ROLE

Removes a database role.

### Synopsis

```sql
DROP ROLE [IF EXISTS] name [, ...]
```  

### Description

`DROP ROLE` removes the specified role(s). To drop a superuser role, you must be a superuser yourself. To drop non-superuser roles, you must have `CREATEROLE` privilege.

A role cannot be removed if it is still referenced in any database; an error will be raised if so. Before dropping the role, you must drop all the objects it owns (or reassign their ownership) and revoke any privileges the role has been granted on other objects. The `REASSIGN OWNED` and `DROP OWNED` commands can be useful for this purpose.

However, it is not necessary to remove role memberships involving the role: `DROP ROLE` automatically revokes any memberships of the target role in other roles, and of other roles in the target role. The other roles are not dropped nor otherwise affected.

### Parameters

**IF EXISTS**

Do not throw an error if the role does not exist. A notice is issued in this case.

**name**

The name of the role to remove.

### Examples

Remove the roles named *sally* and *bob*:

```sql
DROP ROLE sally, bob;
```  

### Compatibility

The SQL standard defines `DROP ROLE`, but it allows only one role to be dropped at a time, and it specifies different privilege requirements than Greenplum Database uses.

### See Also

`REASSIGN OWNED`, `DROP OWNED`, `CREATE ROLE`, `ALTER ROLE`, `SET ROLE`
**DROP RULE**

Removes a rewrite rule.

**Synopsis**

```
DROP RULE [IF EXISTS] name ON table_name [CASCADE | RESTRICT]
```

**Description**

DROP RULE drops a rewrite rule from a table or view.

**Parameters**

**IF EXISTS**

Do not throw an error if the rule does not exist. A notice is issued in this case.

**name**

The name of the rule to remove.

**table_name**

The name (optionally schema-qualified) of the table or view that the rule applies to.

**CASCADE**

Automatically drop objects that depend on the rule.

**RESTRICT**

Refuse to drop the rule if any objects depend on it. This is the default.

**Examples**

Remove the rewrite rule `sales_2006` on the table `sales`:

```
DROP RULE sales_2006 ON sales;
```

**Compatibility**

DROP RULE is a Greenplum Database language extension, as is the entire query rewrite system.

**See Also**

ALTER RULE, CREATE RULE

**DROP SCHEMA**

Removes a schema.

**Synopsis**

```
DROP SCHEMA [IF EXISTS] name [, ...] [CASCADE | RESTRICT]
```

**Description**

DROP SCHEMA removes schemas from the database. A schema can only be dropped by its owner or a superuser. Note that the owner can drop the schema (and thereby all contained objects) even if he does not own some of the objects within the schema.
**Parameters**

**IF EXISTS**
Do not throw an error if the schema does not exist. A notice is issued in this case.

**name**
The name of the schema to remove.

**CASCADE**
Automatically drops any objects contained in the schema (tables, functions, etc.).

**RESTRICT**
Refuse to drop the schema if it contains any objects. This is the default.

**Examples**
Remove the schema *mystuff* from the database, along with everything it contains:

```
DROP SCHEMA mystuff CASCADE;
```

**Compatibility**

`DROP SCHEMA` is fully conforming with the SQL standard, except that the standard only allows one schema to be dropped per command. Also, the `IF EXISTS` option is a Greenplum Database extension.

**See Also**

`CREATE SCHEMA`, `ALTER SCHEMA`

---

**DROP SEQUENCE**

Removes a sequence.

**Synopsis**

```
DROP SEQUENCE [IF EXISTS] name [, ...] [CASCADE | RESTRICT]
```

**Description**

`DROP SEQUENCE` removes a sequence generator table. You must own the sequence to drop it (or be a superuser).

**Parameters**

**IF EXISTS**
Do not throw an error if the sequence does not exist. A notice is issued in this case.

**name**
The name (optionally schema-qualified) of the sequence to remove.

**CASCADE**
Automatically drop objects that depend on the sequence.

**RESTRICT**
Refuse to drop the sequence if any objects depend on it. This is the default.
Examples
Remove the sequence myserial:

```
DROP SEQUENCE myserial;
```

Compatibility
DROP SEQUENCE is fully conforming with the SQL standard, except that the standard only allows one sequence to be dropped per command. Also, the IF EXISTS option is a Greenplum Database extension.

See Also
ALTER SEQUENCE, CREATE SEQUENCE

**DROP SERVER**

Removes a foreign server descriptor.

Synopsis

```
DROP SERVER [ IF EXISTS ] servername [ CASCADE | RESTRICT ]
```

Description

DROP SERVER removes an existing foreign server descriptor. The user executing this command must be the owner of the server.

Parameters

**IF EXISTS**

Do not throw an error if the server does not exist. Greenplum Database issues a notice in this case.

**servername**

The name of an existing server.

**CASCADE**

Automatically drop objects that depend on the server (such as user mappings).

**RESTRICT**

Refuse to drop the server if any object depends on it. This is the default.

Examples

Drop the server named foo if it exists:

```
DROP SERVER IF EXISTS foo;
```

Compatibility

DROP SERVER conforms to ISO/IEC 9075-9 (SQL/MED). The IF EXISTS clause is a Greenplum Database extension.

See Also

CREATE SERVER, ALTER SERVER
**DROP TABLE**

Removes a table.

**Synopsis**

```
DROP TABLE [IF EXISTS] name [, ...] [CASCADE | RESTRICT]
```

**Description**

`DROP TABLE` removes tables from the database. Only the table owner, the schema owner, and superuser can drop a table. To empty a table of rows without removing the table definition, use `DELETE` or `TRUNCATE`.

`DROP TABLE` always removes any indexes, rules, triggers, and constraints that exist for the target table. However, to drop a table that is referenced by a view, `CASCADE` must be specified. `CASCADE` will remove a dependent view entirely.

**Parameters**

**IF EXISTS**

Do not throw an error if the table does not exist. A notice is issued in this case.

**name**

The name (optionally schema-qualified) of the table to remove.

**CASCADE**

Automatically drop objects that depend on the table (such as views).

**RESTRICT**

Refuse to drop the table if any objects depend on it. This is the default.

**Examples**

Remove the table `mytable`:

```
DROP TABLE mytable;
```

**Compatibility**

`DROP TABLE` is fully conforming with the SQL standard, except that the standard only allows one table to be dropped per command. Also, the `IF EXISTS` option is a Greenplum Database extension.

**See Also**

`CREATE TABLE`, `ALTER TABLE`, `TRUNCATE`

**DROP TABLESPACE**

Removes a tablespace.

**Synopsis**

```
DROP TABLESPACE [IF EXISTS].tablespacename
```
### Description

DROP TABLESPACE removes a tablespace from the system.

A tablespace can only be dropped by its owner or a superuser. The tablespace must be empty of all database objects before it can be dropped. It is possible that objects in other databases may still reside in the tablespace even if no objects in the current database are using the tablespace. Also, if the tablespace is listed in the `temp_tablespaces` setting of any active session, the `DROP` might fail due to temporary files residing in the tablespace.

### Parameters

- **IF EXISTS**
  
  Do not throw an error if the tablespace does not exist. A notice is issued in this case.

- **tablespacename**
  
  The name of the tablespace to remove.

### Examples

Remove the tablespace `mystuff`:

```sql
DROP TABLESPACE mystuff;
```

### Compatibility

DROP TABLESPACE is a Greenplum Database extension.

### See Also

CREATE TABLESPACE, ALTER TABLESPACE

---

### DROP TEXT SEARCH CONFIGURATION

Removes a text search configuration.

#### Synopsis

```sql
DROP TEXT SEARCH CONFIGURATION [ IF EXISTS ] name [ CASCADE | RESTRICT ]
```

#### Description

DROP TEXT SEARCH CONFIGURATION drops an existing text search configuration. To execute this command you must be the owner of the configuration.

#### Parameters

- **IF EXISTS**
  
  Do not throw an error if the text search configuration does not exist. A notice is issued in this case.

- **name**
  
  The name (optionally schema-qualified) of an existing text search configuration.

- **CASCADE**
  
  Automatically drop objects that depend on the text search configuration.

- **RESTRICT**
  
  Refuse to drop the text search configuration if any objects depend on it. This is the default.
Examples
Remove the text search configuration my_english:

```
DROP TEXT SEARCH CONFIGURATION my_english;
```

This command will not succeed if there are any existing indexes that reference the configuration in `to_tsvector` calls. Add `CASCADE` to drop such indexes along with the text search configuration.

Compatibility
There is no `DROP TEXT SEARCH CONFIGURATION` statement in the SQL standard.

See Also
`ALTER TEXT SEARCH CONFIGURATION`, `CREATE TEXT SEARCH CONFIGURATION`

**DROP TEXT SEARCH DICTIONARY**

Removes a text search dictionary.

Synopsis

```
DROP TEXT SEARCH DICTIONARY [ IF EXISTS ] name [ CASCADE | RESTRICT ]
```

Description

`DROP TEXT SEARCH DICTIONARY` drops an existing text search dictionary. To execute this command you must be the owner of the dictionary.

Parameters

- **IF EXISTS**
  Do not throw an error if the text search dictionary does not exist. A notice is issued in this case.

- **name**
  The name (optionally schema-qualified) of an existing text search dictionary.

- **CASCADE**
  Automatically drop objects that depend on the text search dictionary.

- **RESTRICT**
  Refuse to drop the text search dictionary if any objects depend on it. This is the default.

Examples

Remove the text search dictionary `english`:

```
DROP TEXT SEARCH DICTIONARY english;
```

This command will not succeed if there are any existing text search configurations that use the dictionary. Add `CASCADE` to drop such configurations along with the dictionary.

Compatibility

There is no `CREATE TEXT SEARCH DICTIONARY` statement in the SQL standard.
DROP TEXT SEARCH PARSER

Description
Remove a text search parser.

Synopsis
DROP TEXT SEARCH PARSER [ IF EXISTS ] name [ CASCADE | RESTRICT ]

Description
DROP TEXT SEARCH PARSER drops an existing text search parser. You must be a superuser to use this command.

Parameters
IF EXISTS
Do not throw an error if the text search parser does not exist. A notice is issued in this case.

name
The name (optionally schema-qualified) of an existing text search parser.

CASCADE
Automatically drop objects that depend on the text search parser.

RESTRICT
Refuse to drop the text search parser if any objects depend on it. This is the default.

Examples
Remove the text search parser my_parser:

DROP TEXT SEARCH PARSER my_parser;

This command will not succeed if there are any existing text search configurations that use the parser. Add CASCADE to drop such configurations along with the parser.

Compatibility
There is no DROP TEXT SEARCH PARSER statement in the SQL standard.

See Also
ALTER TEXT SEARCH PARSER, CREATE TEXT SEARCH PARSER

DROP TEXT SEARCH TEMPLATE

Description
Removes a text search template.
Synopsis

```
DROP TEXT SEARCH TEMPLATE [ IF EXISTS ] name [ CASCADE | RESTRICT ]
```

Description

DROP TEXT SEARCH TEMPLATE drops an existing text search template. You must be a superuser to use this command.

You must be a superuser to use ALTER TEXT SEARCH TEMPLATE.

Parameters

IF EXISTS

Do not throw an error if the text search template does not exist. A notice is issued in this case.

name

The name (optionally schema-qualified) of an existing text search template.

CASCADE

Automatically drop objects that depend on the text search template.

RESTRICT

Refuse to drop the text search template if any objects depend on it. This is the default.

Compatibility

There is no DROP TEXT SEARCH TEMPLATE statement in the SQL standard.

See Also

ALTER TEXT SEARCH TEMPLATE, CREATE TEXT SEARCH TEMPLATE

DROP TYPE

Removes a data type.

Synopsis

```
DROP TYPE [IF EXISTS] name [, ...] [CASCADE | RESTRICT]
```

Description

DROP TYPE will remove a user-defined data type. Only the owner of a type can remove it.

Parameters

IF EXISTS

Do not throw an error if the type does not exist. A notice is issued in this case.

name

The name (optionally schema-qualified) of the data type to remove.

CASCADE

Automatically drop objects that depend on the type (such as table columns, functions, operators).

RESTRICT
Refuse to drop the type if any objects depend on it. This is the default.

**Examples**

Remove the data type `box`;

```
DROP TYPE box;
```

**Compatibility**

This command is similar to the corresponding command in the SQL standard, apart from the `IF EXISTS` option, which is a Greenplum Database extension. But note that much of the `CREATE TYPE` command and the data type extension mechanisms in Greenplum Database differ from the SQL standard.

**See Also**

`ALTER TYPE, CREATE TYPE`

**DROP USER**

Removes a database role.

**Synopsis**

```
DROP USER [IF EXISTS] name [, ...]
```

**Description**

`DROP USER` is an alias for `DROP ROLE`. See `DROP ROLE` for more information.

**Compatibility**

There is no `DROP USER` statement in the SQL standard. The SQL standard leaves the definition of users to the implementation.

**See Also**

`DROP ROLE`

**DROP USER MAPPING**

Removes a user mapping for a foreign server.

**Synopsis**

```
DROP USER MAPPING [ IF EXISTS ] { username | USER | CURRENT_USER | PUBLIC } SERVER servername
```

**Description**

`DROP USER MAPPING` removes an existing user mapping from a foreign server. To execute this command, the current user must be the owner of the server containing the mapping.

**Parameters**

`IF EXISTS`
Do not throw an error if the user mapping does not exist. Greenplum Database issues a notice in this case.

**username**

User name of the mapping. CURRENT_USER and USER match the name of the current user. PUBLIC is used to match all present and future user names in the system.

**servername**

Server name of the user mapping.

**Examples**

Drop the user mapping named bob, server foo if it exists:

```
DROP USER MAPPING IF EXISTS FOR bob SERVER foo;
```

**Compatibility**

DROP SERVER conforms to ISO/IEC 9075-9 (SQL/MED). The IF EXISTS clause is a Greenplum Database extension.

**See Also**

CREATE USER MAPPING, ALTER USER MAPPING

---

**DROP VIEW**

Removes a view.

**Synopsis**

```
DROP VIEW [IF EXISTS] name [, ...] [CASCADE | RESTRICT]
```

**Description**

DROP VIEW will remove an existing view. Only the owner of a view can remove it.

**Parameters**

**IF EXISTS**

Do not throw an error if the view does not exist. A notice is issued in this case.

**name**

The name (optionally schema-qualified) of the view to remove.

**CASCADE**

Automatically drop objects that depend on the view (such as other views).

**RESTRICT**

Refuse to drop the view if any objects depend on it. This is the default.

**Examples**

Remove the view topten;

```
DROP VIEW topten;
```
Compatibility
DROP VIEW is fully conforming with the SQL standard, except that the standard only allows one view to be dropped per command. Also, the IF EXISTS option is a Greenplum Database extension.

See Also
CREATE VIEW

END
Commits the current transaction.

Synopsis
```
END [WORK | TRANSACTION]
```

Description
END commits the current transaction. All changes made by the transaction become visible to others and are guaranteed to be durable if a crash occurs. This command is a Greenplum Database extension that is equivalent to COMMIT.

Parameters
```
WORK
TRANSACTION
```
Optional keywords. They have no effect.

Examples
Commit the current transaction:
```
END;
```

Compatibility
END is a Greenplum Database extension that provides functionality equivalent to COMMIT, which is specified in the SQL standard.

See Also
BEGIN, ROLLBACK, COMMIT

EXECUTE
Executes a prepared SQL statement.

Synopsis
```
EXECUTE name [ (parameter [, ...] ) ]
```

Description
EXECUTE is used to execute a previously prepared statement. Since prepared statements only exist for the duration of a session, the prepared statement must have been created by a PREPARE statement executed earlier in the current session.
If the `PREPARE` statement that created the statement specified some parameters, a compatible set of parameters must be passed to the `EXECUTE` statement, or else an error is raised. Note that (unlike functions) prepared statements are not overloaded based on the type or number of their parameters; the name of a prepared statement must be unique within a database session.

For more information on the creation and usage of prepared statements, see `PREPARE`.

### Parameters

- **name**: The name of the prepared statement to execute.
- **parameter**: The actual value of a parameter to the prepared statement. This must be an expression yielding a value that is compatible with the data type of this parameter, as was determined when the prepared statement was created.

### Examples

Create a prepared statement for an `INSERT` statement, and then execute it:

```
PREPARE fooplan (int, text, bool, numeric) AS INSERT INTO foo VALUES($1, $2, $3, $4);
EXECUTE fooplan(1, 'Hunter Valley', 't', 200.00);
```

### Compatibility

The SQL standard includes an `EXECUTE` statement, but it is only for use in embedded SQL. This version of the `EXECUTE` statement also uses a somewhat different syntax.

### See Also

`DEALLOCATE`, `PREPARE`

---

**EXPLAIN**

Shows the query plan of a statement.

### Synopsis

```
EXPLAIN [ ( option [, ...] ) ] statement
EXPLAIN [ANALYZE] [VERBOSE] statement
```

where `option` can be one of:

```
ANALYZE [ boolean ]
VERBOSE [ boolean ]
COSTS [ boolean ]
BUFFERS [ boolean ]
TIMING [ boolean ]
FORMAT { TEXT | XML | JSON | YAML }
```

### Description

`EXPLAIN` displays the query plan that the Greenplum or Postgres Planner generates for the supplied statement. Query plans are a tree plan of nodes. Each node in the plan represents a single operation, such as table scan, join, aggregation or a sort.
Plans should be read from the bottom up as each node feeds rows into the node directly above it. The bottom nodes of a plan are usually table scan operations (sequential, index or bitmap index scans). If the query requires joins, aggregations, or sorts (or other operations on the raw rows) then there will be additional nodes above the scan nodes to perform these operations. The topmost plan nodes are usually the Greenplum Database motion nodes (redistribute, explicit redistribute, broadcast, or gather motions). These are the operations responsible for moving rows between the segment instances during query processing.

The output of `EXPLAIN` has one line for each node in the plan tree, showing the basic node type plus the following cost estimates that the planner made for the execution of that plan node:

- **cost** — the planner's guess at how long it will take to run the statement (measured in cost units that are arbitrary, but conventionally mean disk page fetches). Two cost numbers are shown: the start-up cost before the first row can be returned, and the total cost to return all the rows. Note that the total cost assumes that all rows will be retrieved, which may not always be the case (if using `LIMIT` for example).

- **rows** — the total number of rows output by this plan node. This is usually less than the actual number of rows processed or scanned by the plan node, reflecting the estimated selectivity of any `WHERE` clause conditions. Ideally the top-level nodes estimate will approximate the number of rows actually returned, updated, or deleted by the query.

- **width** — total bytes of all the rows output by this plan node.

It is important to note that the cost of an upper-level node includes the cost of all its child nodes. The topmost node of the plan has the estimated total execution cost for the plan. This is this number that the planner seeks to minimize. It is also important to realize that the cost only reflects things that the query optimizer cares about. In particular, the cost does not consider the time spent transmitting result rows to the client.

`EXPLAIN ANALYZE` causes the statement to be actually executed, not only planned. The `EXPLAIN ANALYZE` plan shows the actual results along with the planner's estimates. This is useful for seeing whether the planner's estimates are close to reality. In addition to the information shown in the `EXPLAIN` plan, `EXPLAIN ANALYZE` will show the following additional information:

- The total elapsed time (in milliseconds) that it took to run the query.
- The number of workers (segments) involved in a plan node operation. Only segments that return rows are counted.
- The maximum number of rows returned by the segment that produced the most rows for an operation. If multiple segments produce an equal number of rows, the one with the longest `time to end` is the one chosen.
- The segment id number of the segment that produced the most rows for an operation.
- For relevant operations, the `work_mem` used by the operation. If `work_mem` was not sufficient to perform the operation in memory, the plan will show how much data was spilled to disk and how many passes over the data were required for the lowest performing segment. For example:

  Work_mem used: 64K bytes avg, 64K bytes max (seg0).
  Work_mem wanted: 90K bytes avg, 90K bytes max (seg0) to abate workfile I/O affecting 2 workers.
  [seg0] pass 0: 488 groups made from 488 rows; 263 rows written to workfile
  [seg0] pass 1: 263 groups made from 263 rows

- The time (in milliseconds) it took to retrieve the first row from the segment that produced the most rows, and the total time taken to retrieve all rows from that segment. The `<time> to first row` may be omitted if it is the same as the `<time> to end`.

  **Important:** Keep in mind that the statement is actually executed when `ANALYZE` is used. Although `EXPLAIN` `ANALYZE` will discard any output that a `SELECT` would return, other side effects of the
statement will happen as usual. If you wish to use `EXPLAIN ANALYZE` on a DML statement without letting the command affect your data, use this approach:

```sql
BEGIN;
EXPLAIN ANALYZE ...;
ROLLBACK;
```

Only the `ANALYZE` and `VERBOSE` options can be specified, and only in that order, without surrounding the option list in parentheses.

**Parameters**

**ANALYZE**

Carry out the command and show the actual run times and other statistics. This parameter defaults to `FALSE` if you omit it; specify `ANALYZE true` to enable it.

**VERBOSE**

Display additional information regarding the plan. Specifically, include the output column list for each node in the plan tree, schema-qualify table and function names, always label variables in expressions with their range table alias, and always print the name of each trigger for which statistics are displayed. This parameter defaults to `FALSE` if you omit it; specify `VERBOSE true` to enable it.

**COSTS**

Include information on the estimated startup and total cost of each plan node, as well as the estimated number of rows and the estimated width of each row. This parameter defaults to `TRUE` if you omit it; specify `COSTS false` to disable it.

**BUFFERS**

Include information on buffer usage. Specifically, include the number of shared blocks hit, read, dirtied, and written, the number of local blocks hit, read, dirtied, and written, and the number of temp blocks read and written. A *hit* means that a read was avoided because the block was found already in cache when needed. Shared blocks contain data from regular tables and indexes; local blocks contain data from temporary tables and indexes; while temp blocks contain short-term working data used in sorts, hashes, Materialize plan nodes, and similar cases. The number of blocks *dirtied* indicates the number of previously unmodified blocks that were changed by this query; while the number of blocks *written* indicates the number of previously-dirtied blocks evicted from cache by this backend during query processing. The number of blocks shown for an upper-level node includes those used by all its child nodes. In text format, only non-zero values are printed. This parameter may only be used when `ANALYZE` is also enabled. This parameter defaults to `FALSE` if you omit it; specify `BUFFERS true` to enable it.

**TIMING**

Include actual startup time and time spent in each node in the output. The overhead of repeatedly reading the system clock can slow down the query significantly on some systems, so it may be useful to set this parameter to `FALSE` when only actual row counts, and not exact times, are needed. Run time of the entire statement is always measured, even when node-level timing is turned off with this option. This parameter may only be used when `ANALYZE` is also enabled. It defaults to `TRUE`.

**FORMAT**

Specify the output format, which can be `TEXT`, `XML`, `JSON`, or `YAML`. Non-text output contains the same information as the text output format, but is easier for programs to parse. This parameter defaults to `TEXT`.

```
boolean
```
Specifies whether the selected option should be turned on or off. You can write `TRUE`, `ON`, or `1` to enable the option, and `FALSE`, `OFF`, or `0` to disable it. The boolean value can also be omitted, in which case `TRUE` is assumed.

**Statement**

Any `SELECT`, `INSERT`, `UPDATE`, `DELETE`, `VALUES`, `EXECUTE`, `DECLARE`, or `CREATE TABLE AS` statement, whose execution plan you wish to see.

**Notes**

In order to allow the query optimizer to make reasonably informed decisions when optimizing queries, the `ANALYZE` statement should be run to record statistics about the distribution of data within the table. If you have not done this (or if the statistical distribution of the data in the table has changed significantly since the last time `ANALYZE` was run), the estimated costs are unlikely to conform to the real properties of the query, and consequently an inferior query plan may be chosen.

An SQL statement that is run during the execution of an `EXPLAIN ANALYZE` command is excluded from Greenplum Database resource queues.

For more information about query profiling, see "Query Profiling" in the *Greenplum Database Administrator Guide*. For more information about resource queues, see "Resource Management with Resource Queues" in the *Greenplum Database Administrator Guide*.

**Examples**

To illustrate how to read an `EXPLAIN` query plan, consider the following example for a very simple query:

```sql
EXPLAIN SELECT * FROM names WHERE name = 'Joelle';

<table>
<thead>
<tr>
<th>QUERY PLAN</th>
</tr>
</thead>
<tbody>
<tr>
<td>Gather Motion 3:1 (slice1; segments: 3) (cost=0.00..431.27 rows=1 width=58)</td>
</tr>
<tr>
<td>-&gt; Seq Scan on names (cost=0.00..431.27 rows=1 width=58) Filter: (name = 'Joelle'::text)</td>
</tr>
<tr>
<td>Optimizer: Pivotal Optimizer (GPORCA) version 3.23.0</td>
</tr>
<tr>
<td>(4 rows)</td>
</tr>
</tbody>
</table>
```

If we read the plan from the bottom up, the query optimizer starts by doing a sequential scan of the `names` table. Notice that the `WHERE` clause is being applied as a `filter` condition. This means that the scan operation checks the condition for each row it scans, and outputs only the ones that pass the condition.

The results of the scan operation are passed up to a `gather motion` operation. In Greenplum Database, a gather motion is when segments send rows up to the master. In this case we have 3 segment instances sending to 1 master instance (3:1). This operation is working on `slice1` of the parallel query execution plan. In Greenplum Database a query plan is divided into `slices` so that portions of the query plan can be worked on in parallel by the segments.

The estimated startup cost for this plan is 00.00 (no cost) and a total cost of 431.27. The planner is estimating that this query will return one row.

Here is the same query, with cost estimates suppressed:

```sql
EXPLAIN (COSTS FALSE) SELECT * FROM names WHERE name = 'Joelle';

<table>
<thead>
<tr>
<th>QUERY PLAN</th>
</tr>
</thead>
<tbody>
<tr>
<td>Gather Motion 3:1 (slice1; segments: 3)</td>
</tr>
<tr>
<td>-&gt; Seq Scan on names Filter: (name = 'Joelle'::text)</td>
</tr>
<tr>
<td>Optimizer: Pivotal Optimizer (GPORCA) version 3.23.0</td>
</tr>
<tr>
<td>(4 rows)</td>
</tr>
</tbody>
</table>
```
Here is the same query, with JSON formatting:

```
EXPLAIN (FORMAT JSON) SELECT * FROM names WHERE name = 'Joelle';
```

```json
[  ...  
  {    
    "Plan": {      
      "Node Type": "Gather Motion",    
      "Senders": 3,    
      "Receivers": 1,    
      "Slice": 1,    
      "Segments": 3,    
      "Gang Type": "primary reader",    
      "Startup Cost": 0.00,    
      "Total Cost": 431.27,    
      "Plan Rows": 1,    
      "Plan Width": 58,    
      "Plans": [        
      {        
        "Node Type": "Seq Scan",        
        "Parent Relationship": "Outer",        
        "Slice": 1,        
        "Segments": 3,        
        "Gang Type": "primary reader",        
        "Relation Name": "names",        
        "Alias": "names",        
        "Startup Cost": 0.00,        
        "Total Cost": 431.27,        
        "Plan Rows": 1,        
        "Plan Width": 58,        
        "Filter": "(name = 'Joelle'::text)"      
      }        
      ]      
    }      
  },      
  "Settings": {        
    "Optimizer": "Pivotal Optimizer (GPORCA) version 3.23.0"      
  }  
]
```

If there is an index and we use a query with an indexable `WHERE` condition, `EXPLAIN` might show a different plan. This query generates a plan with an index scan, with YAML formatting:

```
EXPLAIN (FORMAT YAML) SELECT * FROM NAMES WHERE LOCATION='Sydney, Australia';
```

```yaml
- Plan:  
  Node Type: "Gather Motion"  
  Senders: 3  
  Receivers: 1  
  Slice: 1  
  Segments: 3  
  Gang Type: "primary reader"  
  Startup Cost: 0.00  
  Total Cost: 10.81  
  Plan Rows: 10000  
  Plan Width: 70  
  Plans:  
    - Node Type: "Index Scan"  
      Parent Relationship: "Outer"
```

(1 row)
Compatibility

There is no EXPLAIN statement defined in the SQL standard.

See Also

ANALYZE

**FETCH**

Retrieves rows from a query using a cursor.

**Synopsis**

```sql
FETCH [ forward_direction { FROM | IN } ] cursor_name
```

where `forward_direction` can be empty or one of:

- NEXT
- FIRST
- LAST
- ABSOLUTE `count`
- RELATIVE `count`
- `count`
- ALL
- FORWARD
- FORWARD `count`
- FORWARD ALL

**Description**

`FETCH` retrieves rows using a previously-created cursor.

*Note:* This page describes usage of cursors at the SQL command level. If you are trying to use cursors inside a PL/pgSQL function, the rules are different. See [PL/pgSQL Language](#).

A cursor has an associated position, which is used by `FETCH`. The cursor position can be before the first row of the query result, on any particular row of the result, or after the last row of the result. When created, a cursor is positioned before the first row. After fetching some rows, the cursor is positioned on the row most recently retrieved. If `FETCH` runs off the end of the available rows then the cursor is left positioned after the last row. `FETCH ALL` will always leave the cursor positioned after the last row.
The forms NEXT, FIRST, LAST, ABSOLUTE, RELATIVE fetch a single row after moving the cursor appropriately. If there is no such row, an empty result is returned, and the cursor is left positioned before the first row or after the last row as appropriate.

The forms using FORWARD retrieve the indicated number of rows moving in the forward direction, leaving the cursor positioned on the last-returned row (or after all rows, if the count exceeds the number of rows available). Note that it is not possible to move a cursor position backwards in Greenplum Database, since scrollable cursors are not supported. You can only move a cursor forward in position using FETCH.

RELATIVE 0 and FORWARD 0 request fetching the current row without moving the cursor, that is, re-fetching the most recently fetched row. This will succeed unless the cursor is positioned before the first row or after the last row, in which case no row is returned.

Outputs

On successful completion, a FETCH command returns a command tag of the form

```
FETCH count
```

The count is the number of rows fetched (possibly zero). Note that in psql, the command tag will not actually be displayed, since psql displays the fetched rows instead.

Parameters

**forward_direction**

Defines the fetch direction and number of rows to fetch. Only forward fetches are allowed in Greenplum Database. It can be one of the following:

**NEXT**

Fetch the next row. This is the default if direction is omitted.

**FIRST**

Fetch the first row of the query (same as ABSOLUTE 1). Only allowed if it is the first FETCH operation using this cursor.

**LAST**

Fetch the last row of the query (same as ABSOLUTE -1).

**ABSOLUTE count**

Fetch the specified row of the query. Position after last row if count is out of range. Only allowed if the row specified by count moves the cursor position forward.

**RELATIVE count**

Fetch the specified row of the query count rows ahead of the current cursor position. RELATIVE 0 re-fetches the current row, if any. Only allowed if count moves the cursor position forward.

**count**

Fetch the next count number of rows (same as FORWARD count).

**ALL**

Fetch all remaining rows (same as FORWARD ALL).

**FORWARD**

Fetch the next row (same as NEXT).

**FORWARD count**

Fetch the next count number of rows. FORWARD 0 re-fetches the current row.

**FORWARD ALL**

Fetch all remaining rows.
The name of an open cursor.

Notes

Greenplum Database does not support scrollable cursors, so you can only use `FETCH` to move the cursor position forward.

`ABSOLUTE` fetches are not any faster than navigating to the desired row with a relative move: the underlying implementation must traverse all the intermediate rows anyway.

`DECLARE` is used to define a cursor. Use `MOVE` to change cursor position without retrieving data.

Examples

-- Start the transaction:

```
BEGIN;
```

-- Set up a cursor:

```
DECLARE mycursor CURSOR FOR SELECT * FROM films;
```

-- Fetch the first 5 rows in the cursor `mycursor`:

```
FETCH FORWARD 5 FROM mycursor;
```

<table>
<thead>
<tr>
<th>code</th>
<th>title</th>
<th>did</th>
<th>date_prod</th>
<th>kind</th>
<th>len</th>
</tr>
</thead>
<tbody>
<tr>
<td>BL101</td>
<td>The Third Man</td>
<td>101</td>
<td>1949-12-23</td>
<td>Drama</td>
<td>01:44</td>
</tr>
<tr>
<td>BL102</td>
<td>The African Queen</td>
<td>101</td>
<td>1951-08-11</td>
<td>Romantic</td>
<td>01:43</td>
</tr>
<tr>
<td>JL201</td>
<td>Une Femme est une Femme</td>
<td>102</td>
<td>1961-03-12</td>
<td>Romantic</td>
<td>01:25</td>
</tr>
<tr>
<td>P_301</td>
<td>Vertigo</td>
<td>103</td>
<td>1958-11-14</td>
<td>Action</td>
<td>02:08</td>
</tr>
<tr>
<td>P_302</td>
<td>Becket</td>
<td>103</td>
<td>1964-02-03</td>
<td>Drama</td>
<td>02:28</td>
</tr>
</tbody>
</table>

-- Close the cursor and end the transaction:

```
CLOSE mycursor;
COMMIT;
```

Change the `kind` column of the table `films` in the row at the `c_films` cursor's current position:

```
UPDATE films SET kind = 'Dramatic' WHERE CURRENT OF c_films;
```

Compatibility

SQL standard allows cursors only in embedded SQL and in modules. Greenplum Database permits cursors to be used interactively.

The variant of `FETCH` described here returns the data as if it were a `SELECT` result rather than placing it in host variables. Other than this point, `FETCH` is fully upward-compatible with the SQL standard.

The `FETCH` forms involving `FORWARD`, as well as the forms `FETCH count` and `FETCHALL`, in which `FORWARD` is implicit, are Greenplum Database extensions. `BACKWARD` is not supported.

The SQL standard allows only `FROM` preceding the cursor name; the option to use `IN`, or to leave them out altogether, is an extension.

Description

Greenplum Database unifies the concepts of users and groups into a single kind of entity called a role. It is therefore not necessary to use the keyword GROUP to identify whether a grantee is a user or a group. GROUP is still allowed in the command, but it is a noise word.

The GRANT command has two basic variants: one that grants privileges on a database object (table, column, view, foreign table, sequence, database, foreign-data wrapper, foreign server, function, procedural language, schema, or tablespace), and one that grants membership in a role.

GRANT on Database Objects

This variant of the GRANT command gives specific privileges on a database object to one or more roles. These privileges are added to those already granted, if any.

There is also an option to grant privileges on all objects of the same type within one or more schemas. This functionality is currently supported only for tables, sequences, and functions (but note that ALL TABLES is considered to include views and foreign tables).

The keyword PUBLIC indicates that the privileges are to be granted to all roles, including those that may be created later. PUBLIC may be thought of as an implicitly defined group-level role that always includes all roles. Any particular role will have the sum of privileges granted directly to it, privileges granted to any role it is presently a member of, and privileges granted to PUBLIC.

If WITH GRANT OPTION is specified, the recipient of the privilege may in turn grant it to others. Without a grant option, the recipient cannot do that. Grant options cannot be granted to PUBLIC.

There is no need to grant privileges to the owner of an object (usually the role that created it), as the owner has all privileges by default. (The owner could, however, choose to revoke some of their own privileges for safety.)

The right to drop an object, or to alter its definition in any way is not treated as a grantable privilege; it is inherent in the owner, and cannot be granted or revoked. (However, a similar effect can be obtained by granting or revoking membership in the role that owns the object; see below.) The owner implicitly has all grant options for the object, too.

Greenplum Database grants default privileges on some types of objects to PUBLIC. No privileges are granted to PUBLIC by default on tables, table columns, sequences, foreign data wrappers, foreign servers, large objects, schemas, or tablespaces. For other types of objects, the default privileges granted to PUBLIC are as follows:

- CONNECT and TEMPORARY (create temporary tables) privileges for databases,
- EXECUTE privilege for functions, and
- USAGE privilege for languages and data types (including domains).

The object owner can, of course, REVOKE both default and expressly granted privileges. (For maximum security, issue the REVOKE in the same transaction that creates the object; then there is no window in which another user can use the object.)

> GRANT on Roles

This variant of the GRANT command grants membership in a role to one or more other roles. Membership in a role is significant because it conveys the privileges granted to a role to each of its members.
If `WITH ADMIN OPTION` is specified, the member may in turn grant membership in the role to others, and revoke membership in the role as well. Without the admin option, ordinary users cannot do that. A role is not considered to hold `WITH ADMIN OPTION` on itself, but it may grant or revoke membership in itself from a database session where the session user matches the role. Database superusers can grant or revoke membership in any role to anyone. Roles having `CREATEROLE` privilege can grant or revoke membership in any role that is not a superuser.

Unlike the case with privileges, membership in a role cannot be granted to `PUBLIC`.

**GRANT on Protocols**

You can also use the `GRANT` command to specify which users can access a trusted protocol. (If the protocol is not trusted, you cannot give any other user permission to use it to read or write data.)

- To allow a user to create a readable external table with a trusted protocol:

  ```sql
  GRANT SELECT ON PROTOCOL protocolname TO username
  ```

- To allow a user to create a writable external table with a trusted protocol:

  ```sql
  GRANT INSERT ON PROTOCOL protocolname TO username
  ```

- To allow a user to create both readable and writable external table with a trusted protocol:

  ```sql
  GRANT ALL ON PROTOCOL protocolname TO username
  ```

You can also use this command to grant users permissions to create and use `s3` and `pxf` external tables. However, external tables of type `http`, `https`, `gpfdist`, and `gpfdists`, are implemented internally in Greenplum Database instead of as custom protocols. For these types, use the `CREATE ROLE` or `ALTER ROLE` command to set the `CREATEEXTTABLE` or `NOCREATEEXTTABLE` attribute for each user. See `CREATE ROLE` for syntax and examples.

**Parameters**

**SELECT**

- Allows `SELECT` from any column, or the specific columns listed, of the specified table, view, or sequence. Also allows the use of `COPY TO`. This privilege is also needed to reference existing column values in `UPDATE` or `DELETE`.

**INSERT**

- Allows `INSERT` of a new row into the specified table. If specific columns are listed, only those columns may be assigned to in the `INSERT` command (other columns will receive default values). Also allows `COPY FROM`.

**UPDATE**

- Allows `UPDATE` of any column, or the specific columns listed, of the specified table. `SELECT ... FOR UPDATE` and `SELECT ... FOR SHARE` also require this privilege on at least one column, (as well as the `SELECT` privilege). For sequences, this privilege allows the use of the `nextval()` and `setval()` functions.

**DELETE**

- Allows `DELETE` of a row from the specified table.

**REFERENCES**

This keyword is accepted, although foreign key constraints are currently not supported in Greenplum Database. To create a foreign key constraint, it is necessary to have this privilege on both the referencing and referenced columns. The privilege may be granted for all columns of a table, or just specific columns.

**TRIGGER**

- Allows the creation of a trigger on the specified table.
**Note:** Greenplum Database does not support triggers.

**TRUNCATE**

Allows TRUNCATE of all rows from the specified table.

**CREATE**

For databases, allows new schemas to be created within the database.

For schemas, allows new objects to be created within the schema. To rename an existing object, you must own the object and have this privilege for the containing schema.

For tablespaces, allows tables and indexes to be created within the tablespace, and allows databases to be created that have the tablespace as their default tablespace. (Note that revoking this privilege will not alter the placement of existing objects.)

**CONNECT**

Allows the user to connect to the specified database. This privilege is checked at connection startup (in addition to checking any restrictions imposed by pg_hba.conf).

**TEMPORARY**

**TEMP**

Allows temporary tables to be created while using the database.

**EXECUTE**

Allows the use of the specified function and the use of any operators that are implemented on top of the function. This is the only type of privilege that is applicable to functions. (This syntax works for aggregate functions, as well.)

**USAGE**

For procedural languages, allows the use of the specified language for the creation of functions in that language. This is the only type of privilege that is applicable to procedural languages.

For schemas, allows access to objects contained in the specified schema (assuming that the objects' own privilege requirements are also met). Essentially this allows the grantee to look up objects within the schema.

For sequences, this privilege allows the use of the currval() and nextval() function.

For types and domains, this privilege allows the use of the type or domain in the creation of tables, functions, and other schema objects. (Note that it does not control general "usage" of the type, such as values of the type appearing in queries. It only prevents objects from being created that depend on the type. The main purpose of the privilege is controlling which users create dependencies on a type, which could prevent the owner from changing the type later.)

For foreign-data wrappers, this privilege enables the grantee to create new servers using that foreign-data wrapper.

For servers, this privilege enables the grantee to create foreign tables using the server, and also to create, alter, or drop their own user's user mappings associated with that server.

**ALL PRIVILEGES**

Grant all of the available privileges at once. The PRIVILEGES key word is optional in Greenplum Database, though it is required by strict SQL.

**PUBLIC**

A special group-level role that denotes that the privileges are to be granted to all roles, including those that may be created later.

**WITH GRANT OPTION**

The recipient of the privilege may in turn grant it to others.
**WITH ADMIN OPTION**

The member of a role may in turn grant membership in the role to others.

**Notes**

A user may perform `SELECT`, `INSERT`, and so forth, on a column if they hold that privilege for either the specific column or the whole table. Granting the privilege at the table level and then revoking it for one column does not do what you might wish: the table-level grant is unaffected by a column-level operation.

Database superusers can access all objects regardless of object privilege settings. One exception to this rule is view objects. Access to tables referenced in the view is determined by permissions of the view owner not the current user (even if the current user is a superuser).

If a superuser chooses to issue a `GRANT` or `REVOKE` command, the command is performed as though it were issued by the owner of the affected object. In particular, privileges granted via such a command will appear to have been granted by the object owner. For role membership, the membership appears to have been granted by the containing role itself.

`GRANT` and `REVOKE` can also be done by a role that is not the owner of the affected object, but is a member of the role that owns the object, or is a member of a role that holds privileges `WITH GRANT OPTION` on the object. In this case the privileges will be recorded as having been granted by the role that actually owns the object or holds the privileges `WITH GRANT OPTION`.

Granting permission on a table does not automatically extend permissions to any sequences used by the table, including sequences tied to `SERIAL` columns. Permissions on a sequence must be set separately.

The `GRANT` command cannot be used to set privileges for the protocols `file`, `gpfdist`, or `gpfdists`. These protocols are implemented internally in Greenplum Database. Instead, use the `CREATE ROLE` or `ALTER ROLE` command to set the `CREATEEXTTABLE` attribute for the role.

Use `psql`'s `\dp` meta-command to obtain information about existing privileges for tables and columns. There are other `\d` meta-commands that you can use to display the privileges of non-table objects.

**Examples**

Grant insert privilege to all roles on table `mytable`:

```
GRANT INSERT ON mytable TO PUBLIC;
```  

Grant all available privileges to role `sally` on the view `topten`. Note that while the above will indeed grant all privileges if executed by a superuser or the owner of `topten`, when executed by someone else it will only grant those permissions for which the granting role has grant options.

```
GRANT ALL PRIVILEGES ON topten TO sally;
```  

Grant membership in role `admins` to user `joe`:

```
GRANT admins TO joe;
```  

**Compatibility**

The `PRIVILEGES` key word is required in the SQL standard, but optional in Greenplum Database. The SQL standard does not support setting the privileges on more than one object per command.

Greenplum Database allows an object owner to revoke their own ordinary privileges: for example, a table owner can make the table read-only to themselves by revoking their own `INSERT`, `UPDATE`, `DELETE`, and `TRUNCATE` privileges. This is not possible according to the SQL standard. Greenplum Database treats the owner's privileges as having been granted by the owner to the owner; therefore they can revoke them too. In the SQL standard, the owner's privileges are granted by an assumed `system` entity.
The SQL standard provides for a usage privilege on other kinds of objects: character sets, collations, translations.

In the SQL standard, sequences only have a usage privilege, which controls the use of the next value for expression, which is equivalent to the function nextval in Greenplum Database. The sequence privileges select and update are Greenplum Database extensions. The application of the sequence usage privilege to the currval function is also a Greenplum Database extension (as is the function itself).

Privileges on databases, tablespaces, schemas, and languages are Greenplum Database extensions.

revoke, create role, alter role

**INSERT**

Creates new rows in a table.

**Synopsis**

```
[ WITH [ RECURSIVE ] with_query [ , ... ] ]
INSERT INTO table [( column [ , ... ] )]
  { DEFAULT VALUES | VALUES ( { expression | DEFAULT } [ , ... ] ) [ , ... ]
  | query)
  [ RETURNING * | output_expression [[AS] output_name] [ , ... ]]
```

**Description**

`insert` inserts new rows into a table. One can insert one or more rows specified by value expressions, or zero or more rows resulting from a query.

The target column names may be listed in any order. If no list of column names is given at all, the default is the columns of the table in their declared order. The values supplied by the `VALUES` clause or query are associated with the explicit or implicit column list left-to-right.

Each column not present in the explicit or implicit column list will be filled with a default value, either its declared default value or null if there is no default.

If the expression for any column is not of the correct data type, automatic type conversion will be attempted.

The optional `RETURNING` clause causes `insert` to compute and return value(s) based on each row actually inserted. This is primarily useful for obtaining values that were supplied by defaults, such as a serial sequence number. However, any expression using the table's columns is allowed. The syntax of the `RETURNING` list is identical to that of the output list of `select`.

You must have `insert` privilege on a table in order to insert into it. When a column list is specified, you need `insert` privilege only on the listed columns. Use of the `RETURNING` clause requires `select` privilege on all columns mentioned in `RETURNING`. If you provide a `query` to insert rows from a query, you must have `select` privilege on any table or column referenced in the query.

**Outputs**

On successful completion, an `insert` command returns a command tag of the form:

```
insert oid count
```

The `count` is the number of rows inserted. If count is exactly one, and the target table has OIDs, then `oid` is the OID assigned to the inserted row. Otherwise `oid` is zero.
Parameters

**with_query**

The **WITH** clause allows you to specify one or more subqueries that can be referenced by name in the **INSERT** query.

For an **INSERT** command that includes a **WITH** clause, the clause can only contain **SELECT** statements, the **WITH** clause cannot contain a data-modifying command (**INSERT**, **UPDATE**, or **DELETE**).

It is possible for the query (**SELECT** statement) to also contain a **WITH** clause. In such a case both sets of **with_query** can be referenced within the **INSERT** query, but the second one takes precedence since it is more closely nested.

See **WITH Queries (Common Table Expressions)** and **SELECT** for details.

**table**

The name (optionally schema-qualified) of an existing table.

**column**

The name of a column in table. The column name can be qualified with a subfield name or array subscript, if needed. (Inserting into only some fields of a composite column leaves the other fields null.)

**DEFAULT VALUES**

All columns will be filled with their default values.

**expression**

An expression or value to assign to the corresponding column.

**DEFAULT**

The corresponding column will be filled with its default value.

**query**

A query (**SELECT** statement) that supplies the rows to be inserted. Refer to the **SELECT** statement for a description of the syntax.

**output_expression**

An expression to be computed and returned by the **INSERT** command after each row is inserted. The expression can use any column names of the table. Write * to return all columns of the inserted row(s).

**output_name**

A name to use for a returned column.

Notes

To insert data into a partitioned table, you specify the root partitioned table, the table created with the **CREATE TABLE** command. You also can specify a leaf child table of the partitioned table in an **INSERT** command. An error is returned if the data is not valid for the specified leaf child table. Specifying a child table that is not a leaf child table in the **INSERT** command is not supported. Execution of other DML commands such as **UPDATE** and **DELETE** on any child table of a partitioned table is not supported. These commands must be executed on the root partitioned table, the table created with the **CREATE TABLE** command.

For a partitioned table, all the child tables are locked during the **INSERT** operation when the Global Deadlock Detector is not enabled (the default). Only some of the leaf child tables are locked when the Global Deadlock Detector is enabled. For information about the Global Deadlock Detector, see **Global Deadlock Detector**.

For append-optimized tables, Greenplum Database supports a maximum of 127 concurrent **INSERT** transactions into a single append-optimized table.
For writable S3 external tables, the `INSERT` operation uploads to one or more files in the configured S3 bucket, as described in `s3:// Protocol`. Pressing `Ctrl-c` cancels the `INSERT` and stops uploading to S3.

**Examples**

Insert a single row into table `films`:

```
INSERT INTO films VALUES ('UA502', 'Bananas', 105, '1971-07-13', 'Comedy', '82 minutes');
```

In this example, the `length` column is omitted and therefore it will have the default value:

```
INSERT INTO films (code, title, did, date_prod, kind) VALUES ('T_601', 'Yojimbo', 106, '1961-06-16', 'Drama');
```

This example uses the `DEFAULT` clause for the `date_prod` column rather than specifying a value:

```
INSERT INTO films VALUES ('UA502', 'Bananas', 105, DEFAULT, 'Comedy', '82 minutes');
```

To insert a row consisting entirely of default values:

```
INSERT INTO films DEFAULT VALUES;
```

To insert multiple rows using the `VALUES` syntax:

```
INSERT INTO films (code, title, did, date_prod, kind) VALUES ('T6717', 'Tampopo', 110, '1985-02-10', 'Comedy'), ('HG120', 'The Dinner Game', 140, DEFAULT, 'Comedy');
```

This example inserts some rows into table `films` from a table `tmp_films` with the same column layout as `films`:

```
INSERT INTO films SELECT * FROM tmp_films WHERE date_prod < '2004-05-07';
```

Insert a single row into table `distributors`, returning the sequence number generated by the `DEFAULT` clause:

```
INSERT INTO distributors (did, dname) VALUES (DEFAULT, 'XYZ Widgets') RETURNING did;
```

**Compatibility**

`INSERT` conforms to the SQL standard. The case in which a column name list is omitted, but not all the columns are filled from the `VALUES` clause or query, is disallowed by the standard.

Possible limitations of the `query` clause are documented under `SELECT`.

**See Also**

`COPY, SELECT, CREATE EXTERNAL TABLE, s3:// Protocol`

**LOAD**

Loads or reloads a shared library file.
Synopsis

LOAD 'filename'

Description

This command loads a shared library file into the Greenplum Database server address space. If the file had been loaded previously, it is first unloaded. This command is primarily useful to unload and reload a shared library file that has been changed since the server first loaded it. To make use of the shared library, function(s) in it need to be declared using the CREATE FUNCTION command.

The file name is specified in the same way as for shared library names in CREATE FUNCTION; in particular, one may rely on a search path and automatic addition of the system's standard shared library file name extension.

Note that in Greenplum Database the shared library file (.so file) must reside in the same path location on every host in the Greenplum Database array (masters, segments, and mirrors).

Only database superusers can load shared library files.

Parameters

filename

The path and file name of a shared library file. This file must exist in the same location on all hosts in your Greenplum Database array.

Examples

Load a shared library file:

LOAD '/usr/local/greenplum-db/lib/myfuncs.so';

Compatibility

LOAD is a Greenplum Database extension.

CREATE FUNCTION

LOCK

Locks a table.

Synopsis

LOCK [TABLE] [ONLY] name [ * ] [, ...] [IN lockmode MODE] [NOWAIT]

where lockmode is one of:

| ACCESS SHARE | ROW SHARE | ROW EXCLUSIVE | SHARE UPDATE EXCLUSIVE |
| SHARE | SHARE ROW EXCLUSIVE | EXCLUSIVE | ACCESS EXCLUSIVE |

Description

LOCK TABLE obtains a table-level lock, waiting if necessary for any conflicting locks to be released. If NOWAIT is specified, LOCK TABLE does not wait to acquire the desired lock: if it cannot be acquired immediately, the command is aborted and an error is emitted. Once obtained, the lock is held for the
remainder of the current transaction. There is no UNLOCK TABLE command; locks are always released at transaction end.

When acquiring locks automatically for commands that reference tables, Greenplum Database always uses the least restrictive lock mode possible. LOCK TABLE provides for cases when you might need more restrictive locking. For example, suppose an application runs a transaction at the Read Committed isolation level and needs to ensure that data in a table remains stable for the duration of the transaction. To achieve this you could obtain SHARE lock mode over the table before querying. This will prevent concurrent data changes and ensure subsequent reads of the table see a stable view of committed data, because SHARE lock mode conflicts with the ROW EXCLUSIVE lock acquired by writers, and your LOCK TABLE name IN SHARE MODE statement will wait until any concurrent holders of ROW EXCLUSIVE mode locks commit or roll back. Thus, once you obtain the lock, there are no uncommitted writes outstanding; furthermore none can begin until you release the lock.

To achieve a similar effect when running a transaction at the REPEATABLE READ or SERIALIZABLE isolation level, you have to execute the LOCK TABLE statement before executing any SELECT or data modification statement. A REPEATABLE READ or SERIALIZABLE transaction's view of data will be frozen when its first SELECT or data modification statement begins. A LOCK TABLE later in the transaction will still prevent concurrent writes — but it won't ensure that what the transaction reads corresponds to the latest committed values.

If a transaction of this sort is going to change the data in the table, then it should use SHARE ROW EXCLUSIVE lock mode instead of SHARE mode. This ensures that only one transaction of this type runs at a time. Without this, a deadlock is possible: two transactions might both acquire SHARE mode, and then be unable to also acquire ROW EXCLUSIVE mode to actually perform their updates. Note that a transaction's own locks never conflict, so a transaction can acquire ROW EXCLUSIVE mode when it holds SHARE mode — but not if anyone else holds SHARE mode. To avoid deadlocks, make sure all transactions acquire locks on the same objects in the same order, and if multiple lock modes are involved for a single object, then transactions should always acquire the most restrictive mode first.

### Parameters

**name**

The name (optionally schema-qualified) of an existing table to lock. If ONLY is specified, only that table is locked. If ONLY is not specified, the table and all its descendant tables (if any) are locked. Optionally, * can be specified after the table name to explicitly indicate that descendant tables are included.

If multiple tables are given, tables are locked one-by-one in the order specified in the LOCK TABLE command.

**lockmode**

The lock mode specifies which locks this lock conflicts with. If no lock mode is specified, then ACCESS EXCLUSIVE, the most restrictive mode, is used. Lock modes are as follows:

- **ACCESS SHARE** — Conflicts with the ACCESS EXCLUSIVE lock mode only. The SELECT command acquires a lock of this mode on referenced tables. In general, any query that only reads a table and does not modify it will acquire this lock mode.

- **ROW SHARE** — Conflicts with the EXCLUSIVE and ACCESS EXCLUSIVE lock modes. The SELECT FOR SHARE command automatically acquires a lock of this mode on the target table(s) (in addition to ACCESS SHARE locks on any other tables that are referenced but not selected FOR SHARE).

- **ROW EXCLUSIVE** — Conflicts with the SHARE, SHARE ROW EXCLUSIVE, EXCLUSIVE, and ACCESS EXCLUSIVE lock modes. The commands INSERT and COPY automatically acquire this lock mode on the target table (in addition to ACCESS SHARE locks on any other referenced tables) See Note.

- **SHARE UPDATE EXCLUSIVE** — Conflicts with the SHARE UPDATE EXCLUSIVE, SHARE, SHARE ROW EXCLUSIVE, EXCLUSIVE, and ACCESS EXCLUSIVE lock modes.
This mode protects a table against concurrent schema changes and VACUUM runs. Acquired by VACUUM (without FULL) on heap tables and ANALYZE.

- **SHARE** — Conflicts with the ROW EXCLUSIVE, SHARE UPDATE EXCLUSIVE, SHARE ROW EXCLUSIVE, EXCLUSIVE, and ACCESS EXCLUSIVE lock modes. This mode protects a table against concurrent data changes. Acquired automatically by CREATE INDEX.

- **SHARE ROW EXCLUSIVE** — Conflicts with the ROW EXCLUSIVE, SHARE UPDATE EXCLUSIVE, SHARE, SHARE ROW EXCLUSIVE, EXCLUSIVE, and ACCESS EXCLUSIVE lock modes. This lock mode is not automatically acquired by any Greenplum Database command.

- **EXCLUSIVE** — Conflicts with the ROW SHARE, ROW EXCLUSIVE, SHARE UPDATE EXCLUSIVE, SHARE, SHARE ROW EXCLUSIVE, EXCLUSIVE, and ACCESS EXCLUSIVE lock modes. This mode allows only concurrent ACCESS SHARE locks, i.e., only reads from the table can proceed in parallel with a transaction holding this lock mode. This lock mode is automatically acquired for UPDATE, SELECT FOR UPDATE, and DELETE in Greenplum Database (which is more restrictive locking than in regular PostgreSQL). See Note.

- **ACCESS EXCLUSIVE** — Conflicts with locks of all modes (ACCESS SHARE, ROW SHARE, row EXCLUSIVE, SHARE UPDATE EXCLUSIVE, SHARE, SHARE ROW EXCLUSIVE, EXCLUSIVE, and ACCESS EXCLUSIVE). This mode guarantees that the holder is the only transaction accessing the table in any way. Acquired automatically by the ALTER TABLE, DROP TABLE, TRUNCATE, REINDEX, CLUSTER, and VACUUM FULL commands. This is the default lock mode for LOCK TABLE statements that do not specify a mode explicitly. This lock is also briefly acquired by VACUUM (without FULL) on append-optimized tables during processing.

  **Note:** As the default, Greenplum Database acquires an EXCLUSIVE lock on tables for DELETE, UPDATE, and SELECT FOR UPDATE operations on heap tables. When the Global Deadlock Detector is enabled, the lock mode for the operations on heap tables is ROW EXCLUSIVE. See Global Deadlock Detector.

**NOWAIT**

Specifies that LOCK TABLE should not wait for any conflicting locks to be released: if the specified lock(s) cannot be acquired immediately without waiting, the transaction is aborted.

**Notes**

LOCK TABLE ... IN ACCESS SHARE MODE requires SELECT privileges on the target table. All other forms of LOCK require table-level UPDATE, DELETE, or TRUNCATE privileges.

LOCK TABLE is useless outside of a transaction block: the lock would be held only to the completion of the LOCK statement. Therefore, Greenplum Database reports an error if LOCK is used outside of a transaction block. Use BEGIN and END to define a transaction block.

LOCK TABLE only deals with table-level locks, and so the mode names involving ROW are all misnomers. These mode names should generally be read as indicating the intention of the user to acquire row-level locks within the locked table. Also, ROW EXCLUSIVE mode is a shareable table lock. Keep in mind that all the lock modes have identical semantics so far as LOCK TABLE is concerned, differing only in the rules about which modes conflict with which. For information on how to acquire an actual row-level lock, see the FOR UPDATE/FOR SHARE clause in the SELECT reference documentation.
Examples

Obtain a SHARE lock on the films table when going to perform inserts into the films_user_comments table:

```sql
BEGIN WORK;
LOCK TABLE films IN SHARE MODE;
SELECT id FROM films
  WHERE name = 'Star Wars: Episode I - The Phantom Menace';
-- Do ROLLBACK if record was not returned
INSERT INTO films_user_comments VALUES
  (_id_, 'GREAT! I was waiting for it for so long!');
COMMIT WORK;
```

Take a SHARE ROW EXCLUSIVE lock on a table when performing a delete operation:

```sql
BEGIN WORK;
LOCK TABLE films IN SHARE ROW EXCLUSIVE MODE;
DELETE FROM films_user_comments WHERE id IN
  (SELECT id FROM films WHERE rating < 5);
DELETE FROM films WHERE rating < 5;
COMMIT WORK;
```

Compatibility

There is no LOCK TABLE in the SQL standard, which instead uses SET TRANSACTION to specify concurrency levels on transactions. Greenplum Database supports that too.

Except for ACCESS SHARE, ACCESS EXCLUSIVE, and SHARE UPDATE EXCLUSIVE lock modes, the Greenplum Database lock modes and the LOCK TABLE syntax are compatible with those present in Oracle.

See Also

`BEGIN`, `SET TRANSACTION`, `SELECT`

MOVE

Positions a cursor.

Synopsis

```sql
MOVE [ forward_direction [ FROM | IN ] ] cursor_name
```

where `forward_direction` can be empty or one of:

- NEXT
- FIRST
- LAST
- ABSOLUTE `count`
- RELATIVE `count`
- `count`
- ALL
- FORWARD
- FORWARD `count`
- FORWARD ALL
Description

`MOVE` repositions a cursor without retrieving any data. `MOVE` works exactly like the `FETCH` command, except it only positions the cursor and does not return rows.

Note that it is not possible to move a cursor position backwards in Greenplum Database, since scrollable cursors are not supported. You can only move a cursor forward in position using `MOVE`.

Outputs

On successful completion, a `MOVE` command returns a command tag of the form

```
MOVE count
```

The count is the number of rows that a `FETCH` command with the same parameters would have returned (possibly zero).

Parameters

`forward_direction`

The parameters for the `MOVE` command are identical to those of the `FETCH` command; refer to `FETCH` for details on syntax and usage.

`cursor_name`

The name of an open cursor.

Examples

-- Start the transaction:

```
BEGIN;
```

-- Set up a cursor:

```
DECLARE mycursor CURSOR FOR SELECT * FROM films;
```

-- Move forward 5 rows in the cursor `mycursor`:

```
MOVE FORWARD 5 IN mycursor;
MOVE 5
```

-- Fetch the next row after that (row 6):

```
FETCH 1 FROM mycursor;
```

```
<table>
<thead>
<tr>
<th>code</th>
<th>title</th>
<th>did</th>
<th>date_prod</th>
<th>kind</th>
<th>len</th>
</tr>
</thead>
<tbody>
<tr>
<td>P_303</td>
<td>48 Hrs</td>
<td>103</td>
<td>1982-10-22</td>
<td>Action</td>
<td>01:37</td>
</tr>
</tbody>
</table>
```

-- Close the cursor and end the transaction:

```
CLOSE mycursor;
COMMIT;
```

Compatibility

There is no `MOVE` statement in the SQL standard.

See Also

`DECLARE`, `FETCH`, `CLOSE`
**PREPARE**

Prepare a statement for execution.

**Synopsis**

```
PREPARE name [ (datatype [, ...] ) ] AS statement
```

**Description**

PREPARE creates a prepared statement. A prepared statement is a server-side object that can be used to optimize performance. When the `PREPARE` statement is executed, the specified statement is parsed, analyzed, and rewritten. When an `EXECUTE` command is subsequently issued, the prepared statement is planned and executed. This division of labor avoids repetitive parse analysis work, while allowing the execution plan to depend on the specific parameter values supplied.

Prepared statements can take parameters: values that are substituted into the statement when it is executed. When creating the prepared statement, refer to parameters by position, using $1, $2, etc. A corresponding list of parameter data types can optionally be specified. When a parameter's data type is not specified or is declared as unknown, the type is inferred from the context in which the parameter is first used (if possible). When executing the statement, specify the actual values for these parameters in the `EXECUTE` statement.

Prepared statements only last for the duration of the current database session. When the session ends, the prepared statement is forgotten, so it must be recreated before being used again. This also means that a single prepared statement cannot be used by multiple simultaneous database clients; however, each client can create their own prepared statement to use. Prepared statements can be manually cleaned up using the `DEALLOCATE` command.

Prepared statements have the largest performance advantage when a single session is being used to execute a large number of similar statements. The performance difference will be particularly significant if the statements are complex to plan or rewrite, for example, if the query involves a join of many tables or requires the application of several rules. If the statement is relatively simple to plan and rewrite but relatively expensive to execute, the performance advantage of prepared statements will be less noticeable.

**Parameters**

- **name**
  
  An arbitrary name given to this particular prepared statement. It must be unique within a single session and is subsequently used to execute or deallocate a previously prepared statement.

- **datatype**
  
  The data type of a parameter to the prepared statement. If the data type of a particular parameter is unspecified or is specified as unknown, it will be inferred from the context in which the parameter is first used. To refer to the parameters in the prepared statement itself, use $1, $2, etc.

- **statement**
  
  Any `SELECT`, `INSERT`, `UPDATE`, `DELETE`, or `VALUES` statement.

**Notes**

If a prepared statement is executed enough times, the server may eventually decide to save and re-use a generic plan rather than re-planning each time. This will occur immediately if the prepared statement has no parameters; otherwise it occurs only if the generic plan appears to be not much more expensive than a
plan that depends on specific parameter values. Typically, a generic plan will be selected only if the query's performance is estimated to be fairly insensitive to the specific parameter values supplied.

To examine the query plan Greenplum Database is using for a prepared statement, use `EXPLAIN`. If a generic plan is in use, it will contain parameter symbols $n$, while a custom plan will have the current actual parameter values substituted into it.

For more information on query planning and the statistics collected by Greenplum Database for that purpose, see the `ANALYZE` documentation.

Although the main point of a prepared statement is to avoid repeated parse analysis and planning of the statement, Greenplum will force re-analysis and re-planning of the statement before using it whenever database objects used in the statement have undergone definitional (DDL) changes since the previous use of the prepared statement. Also, if the value of `search_path` changes from one use to the next, the statement will be re-parsed using the new `search_path`. (This latter behavior is new as of Greenplum 6.)

These rules make use of a prepared statement semantically almost equivalent to re-submitting the same query text over and over, but with a performance benefit if no object definitions are changed, especially if the best plan remains the same across uses. An example of a case where the semantic equivalence is not perfect is that if the statement refers to a table by an unqualified name, and then a new table of the same name is created in a schema appearing earlier in the `search_path`, no automatic re-parse will occur since no object used in the statement changed. However, if some other change forces a re-parse, the new table will be referenced in subsequent uses.

You can see all prepared statements available in the session by querying the `pg_prepared_statements` system view.

### Examples

Create a prepared statement for an `INSERT` statement, and then execute it:

```sql
PREPARE fooplan (int, text, bool, numeric) AS INSERT INTO foo VALUES($1, $2, $3, $4);
EXECUTE fooplan(1, 'Hunter Valley', 't', 200.00);
```

Create a prepared statement for a `SELECT` statement, and then execute it. Note that the data type of the second parameter is not specified, so it is inferred from the context in which $2 is used:

```sql
PREPARE usrrptplan (int) AS SELECT * FROM users u, logs l
WHERE u.usrid=$1 AND u.usrid=l.usrid AND l.date = $2;
EXECUTE usrrptplan(1, current_date);
```

### Compatibility

The SQL standard includes a `PREPARE` statement, but it is only for use in embedded SQL. This version of the `PREPARE` statement also uses a somewhat different syntax.

`EXECUTE`, `DEALLOCATE`

---

**REASSIGN OWNED**

Changes the ownership of database objects owned by a database role.

### Synopsis

```
REASSIGN OWNED BY old_role [, ...] TO new_role
```
**Description**

`REASSIGN OWNED` changes the ownership of database objects owned by any of the `old_roles` to `new_role`.

**Parameters**

`old_role`

The name of a role. The ownership of all the objects in the current database, and of all shared objects (databases, tablespaces), owned by this role will be reassigned to `new_role`.

`new_role`

The name of the role that will be made the new owner of the affected objects.

**Notes**

`REASSIGN OWNED` is often used to prepare for the removal of one or more roles. Because `REASSIGN OWNED` does not affect objects in other databases, it is usually necessary to execute this command in each database that contains objects owned by a role that is to be removed.

`REASSIGN OWNED` requires privileges on both the source role(s) and the target role.

The `DROP OWNED` command is an alternative that simply drops all of the database objects owned by one or more roles. `DROP OWNED` requires privileges only on the source role(s).

The `REASSIGN OWNED` command does not affect any privileges granted to the `old_roles` on objects that are not owned by them. Likewise, it does not affect default privileges created with `ALTER DEFAULT PRIVILEGES`. Use `DROP OWNED` to revoke such privileges.

**Examples**

Reassign any database objects owned by the role named `sally` and `bob` to `admin`;

```sql
REASSIGN OWNED BY sally, bob TO admin;
```

**Compatibility**

The `REASSIGN OWNED` command is a Greenplum Database extension.

**See Also**

`DROP OWNED`, `DROP ROLE`, `ALTER DATABASE`

---

**REINDEX**

Rebuilds indexes.

**Synopsis**

```sql
REINDEX {INDEX | TABLE | DATABASE | SYSTEM} name
```

**Description**

`REINDEX` rebuilds an index using the data stored in the index's table, replacing the old copy of the index. There are several scenarios in which to use `REINDEX`:

- An index has become bloated, that is, it contains many empty or nearly-empty pages. This can occur with B-tree indexes in Greenplum Database under certain uncommon access patterns. `REINDEX` provides a way to reduce the space consumption of the index by writing a new version of the index without the dead pages.
• You have altered the \texttt{FILLFACTOR} storage parameter for an index, and wish to ensure that the change has taken full effect.

**Parameters**

**INDEX**

Recreate the specified index.

**TABLE**

Recreate all indexes of the specified table. If the table has a secondary TOAST table, that is reindexed as well.

**DATABASE**

Recreate all indexes within the current database. Indexes on shared system catalogs are also processed. This form of \texttt{REINDEX} cannot be executed inside a transaction block.

**SYSTEM**

Recreate all indexes on system catalogs within the current database. Indexes on shared system catalogs are included. Indexes on user tables are not processed. This form of \texttt{REINDEX} cannot be executed inside a transaction block.

**name**

The name of the specific index, table, or database to be reindexed. Index and table names may be schema-qualified. Presently, \texttt{REINDEX DATABASE} and \texttt{REINDEX SYSTEM} can only reindex the current database, so their parameter must match the current database's name.

**Notes**

\texttt{REINDEX} is similar to a drop and recreate of the index in that the index contents are rebuilt from scratch. However, the locking considerations are rather different. \texttt{REINDEX} locks out writes but not reads of the index's parent table. It also takes an exclusive lock on the specific index being processed, which will block reads that attempt to use that index. In contrast, \texttt{DROP INDEX} momentarily takes an exclusive lock on the parent table, blocking both writes and reads. The subsequent \texttt{CREATE INDEX} locks out writes but not reads; since the index is not there, no read will attempt to use it, meaning that there will be no blocking but reads may be forced into expensive sequential scans.

Reindexing a single index or table requires being the owner of that index or table. Reindexing a database requires being the owner of the database (note that the owner can therefore rebuild indexes of tables owned by other users). Of course, superusers can always reindex anything.

\texttt{REINDEX} does not update the \texttt{reltuples} and \texttt{relpages} statistics for the index. To update those statistics, run \texttt{ANALYZE} on the table after reindexing.

If you suspect that shared global system catalog indexes are corrupted, they can only be reindexed in Greenplum utility mode. The typical symptom of a corrupt shared index is "index is not a btree" errors, or else the server crashes immediately at startup due to reliance on the corrupted indexes. Contact Greenplum Customer Support for assistance in this situation.

**Examples**

Rebuild a single index:

\begin{verbatim}
REINDEX INDEX my_index;
\end{verbatim}

Rebuild all the indexes on the table \texttt{my_table}:

\begin{verbatim}
REINDEX TABLE my_table;
\end{verbatim}
Compatibility
There is no REINDEX command in the SQL standard.

See Also
CREATE INDEX, DROP INDEX, VACUUM

**RELEASE SAVEPOINT**
Destroys a previously defined savepoint.

**Synopsis**
```
RELEASE [SAVEPOINT] savepoint_name
```

**Description**
RELEASE SAVEPOINT destroys a savepoint previously defined in the current transaction.

Destroying a savepoint makes it unavailable as a rollback point, but it has no other user visible behavior. It does not undo the effects of commands executed after the savepoint was established. (To do that, see ROLLBACK TO SAVEPOINT.) Destroying a savepoint when it is no longer needed may allow the system to reclaim some resources earlier than transaction end.

RELEASE SAVEPOINT also destroys all savepoints that were established after the named savepoint was established.

**Parameters**
- `savepoint_name`
The name of the savepoint to destroy.

**Examples**
To establish and later destroy a savepoint:
```
BEGIN;
  INSERT INTO table1 VALUES (3);
  SAVEPOINT my_savepoint;
  INSERT INTO table1 VALUES (4);
  RELEASE SAVEPOINT my_savepoint;
COMMIT;
```

The above transaction will insert both 3 and 4.

**Compatibility**
This command conforms to the SQL standard. The standard specifies that the key word SAVEPOINT is mandatory, but Greenplum Database allows it to be omitted.

**See Also**
BEGIN, SAVEPOINT, ROLLBACK TO SAVEPOINT, COMMIT

**RESET**
Restores the value of a system configuration parameter to the default value.
Synopsis

<table>
<thead>
<tr>
<th>RESET configuration_parameter</th>
</tr>
</thead>
<tbody>
<tr>
<td>RESET ALL</td>
</tr>
</tbody>
</table>

Description

RESET restores system configuration parameters to their default values. RESET is an alternative spelling for SET configuration_parameter TO DEFAULT.

The default value is defined as the value that the parameter would have had, had no SET ever been issued for it in the current session. The actual source of this value might be a compiled-in default, the master postgresql.conf configuration file, command-line options, or per-database or per-user default settings. See Server Configuration Parameters for more information.

Parameters

configuration_parameter
  The name of a system configuration parameter. See Server Configuration Parameters for details.

ALL
  Resets all settable configuration parameters to their default values.

Examples

Set the statement_mem configuration parameter to its default value:

```
RESET statement_mem;
```

Compatibility

RESET is a Greenplum Database extension.

FROM { [ GROUP ] role_name | PUBLIC } [, ...]
    [CASCADE | RESTRICT]

REVOKE [ADMIN OPTION FOR] parent_role [, ...]
FROM [ GROUP ] member_role [, ...]
Description

REVOKE command revokes previously granted privileges from one or more roles. The key word PUBLIC refers to the implicitly defined group of all roles.

See the description of the GRANT command for the meaning of the privilege types.

Note that any particular role will have the sum of privileges granted directly to it, privileges granted to any role it is presently a member of, and privileges granted to PUBLIC. Thus, for example, revoking SELECT privilege from PUBLIC does not necessarily mean that all roles have lost SELECT privilege on the object: those who have it granted directly or via another role will still have it. Similarly, revoking SELECT from a user might not prevent that user from using SELECT if PUBLIC or another membership role still has SELECT rights.

If GRANT OPTION FOR is specified, only the grant option for the privilege is revoked, not the privilege itself. Otherwise, both the privilege and the grant option are revoked.

If a role holds a privilege with grant option and has granted it to other roles then the privileges held by those other roles are called dependent privileges. If the privilege or the grant option held by the first role is being revoked and dependent privileges exist, those dependent privileges are also revoked if CASCADE is specified, else the revoke action will fail. This recursive revocation only affects privileges that were granted through a chain of roles that is traceable to the role that is the subject of this REVOKE command. Thus, the affected roles may effectively keep the privilege if it was also granted through other roles.

When you revoke privileges on a table, Greenplum Database revokes the corresponding column privileges (if any) on each column of the table, as well. On the other hand, if a role has been granted privileges on a table, then revoking the same privileges from individual columns will have no effect.

When revoking membership in a role, GRANT OPTION is instead called ADMIN OPTION, but the behavior is similar.

Parameters

See GRANT.

Notes

A user may revoke only those privileges directly granted by that user. If, for example, user A grants a privilege with grant option to user B, and user B has in turn granted it to user C, then user A cannot revoke the privilege directly from C. Instead, user A could revoke the grant option from user B and use the CASCADE option so that the privilege is in turn revoked from user C. For another example, if both A and B grant the same privilege to C, A can revoke his own grant but not B's grant, so C effectively still has the privilege.

When a non-owner of an object attempts to REVOKE privileges on the object, the command fails outright if the user has no privileges whatsoever on the object. As long as some privilege is available, the command proceeds, but it will revoke only those privileges for which the user has grant options. The REVOKE ALL PRIVILEGES forms issue a warning message if no grant options are held, while the other forms issue a warning if grant options for any of the privileges specifically named in the command are not held. (In principle these statements apply to the object owner as well, but since Greenplum Database always treats the owner as holding all grant options, the cases can never occur.)

If a superuser chooses to issue a GRANT or REVOKE command, Greenplum Database performs the command as though it were issued by the owner of the affected object. Since all privileges ultimately come from the object owner (possibly indirectly via chains of grant options), it is possible for a superuser to revoke all privileges, but this might require use of CASCADE as stated above.

REVOKE may also be invoked by a role that is not the owner of the affected object, but is a member of the role that owns the object, or is a member of a role that holds privileges WITH GRANT OPTION on
the object. In this case, Greenplum Database performs the command as though it were issued by the
containing role that actually owns the object or holds the privileges WITH GRANT OPTION. For example, if
table t1 is owned by role g1, of which role u1 is a member, then u1 can revoke privileges on t1 that are
recorded as being granted by g1. This includes grants made by u1 as well as by other members of role g1.

If the role that executes REVOKE holds privileges indirectly via more than one role membership path, it is
unspecified which containing role will be used to perform the command. In such cases it is best practice to
use SET ROLE to become the specific role as which you want to do the REVOKE. Failure to do so may lead
to revoking privileges other than the ones you intended, or not revoking any privileges at all.

Use psql's \dp meta-command to obtain information about existing privileges for tables and columns.
There are other \d meta-commands that you can use to display the privileges of non-table objects.

Examples

Revoke insert privilege for the public on table films:

```
REVOKE INSERT ON films FROM PUBLIC;
```

Revoke all privileges from role sally on view topten. Note that this actually means revoke all privileges
that the current role granted (if not a superuser).

```
REVOKE ALL PRIVILEGES ON topten FROM sally;
```

Revoke membership in role admins from user joe:

```
REVOKE admins FROM joe;
```

Compatibility

The compatibility notes of the GRANT command also apply to REVOKE.

Either RESTRICt or CASCADe is required according to the standard, but Greenplum Database assumes
RESTRICt by default.

See Also

GRANT

**ROLLBACK**

Aborts the current transaction.

Synopsis

```
ROLLBACK [WORK | TRANSACTION]
```

Description

ROLLBACK rolls back the current transaction and causes all the updates made by the transaction to be
discarded.

Parameters

WORK

TRANSACTION

Optional key words. They have no effect.
Notes
Use COMMIT to successfully end the current transaction.
Issuing ROLLBACK when not inside a transaction does no harm, but it will provoke a warning message.

Examples
To discard all changes made in the current transaction:

```
ROLLBACK;
```

Compatibility
The SQL standard only specifies the two forms ROLLBACK and ROLLBACK WORK. Otherwise, this command is fully conforming.

See Also
BEGIN, COMMIT, SAVEPOINT, ROLLBACK TO SAVEPOINT

**ROLLBACK TO SAVEPOINT**

Rolls back the current transaction to a savepoint.

Synopsis

```
ROLLBACK [WORK | TRANSACTION] TO [SAVEPOINT] savepoint_name
```

Description
This command will roll back all commands that were executed after the savepoint was established. The savepoint remains valid and can be rolled back to again later, if needed.

```
ROLLBACK TO SAVEPOINT implicitly destroys all savepoints that were established after the named savepoint.
```

Parameters

```
WORK
TRANSACTION
```

Optional key words. They have no effect.

```
savepoint_name
```

The name of a savepoint to roll back to.

Notes
Use RELEASE SAVEPOINT to destroy a savepoint without discarding the effects of commands executed after it was established.

Specifying a savepoint name that has not been established is an error.

Cursors have somewhat non-transactional behavior with respect to savepoints. Any cursor that is opened inside a savepoint will be closed when the savepoint is rolled back. If a previously opened cursor is affected by a FETCH command inside a savepoint that is later rolled back, the cursor remains at the position that FETCH left it pointing to (that is, cursor motion caused by FETCH is not rolled back). Closing a cursor is not undone by rolling back, either. However, other side-effects caused by the cursor's query (such as side-effects of volatile functions called by the query) are rolled back if they occur during a savepoint that is later rolled back. A cursor whose execution causes a transaction to abort is put in a cannot-execute
state, so while the transaction can be restored using `ROLLBACK TO SAVEPOINT`, the cursor can no longer be used.

**Examples**

To undo the effects of the commands executed after `my_savepoint` was established:

```sql
ROLLBACK TO SAVEPOINT my_savepoint;
```

Cursor positions are not affected by a savepoint rollback:

```sql
BEGIN;
  DECLARE foo CURSOR FOR SELECT 1 UNION SELECT 2;
  SAVEPOINT foo;
  FETCH 1 FROM foo;
  column  ----------
  1
  ROLLBACK TO SAVEPOINT foo;
  FETCH 1 FROM foo;
  column  ----------
  2
COMMIT;
```

**Compatibility**

The SQL standard specifies that the key word `SAVEPOINT` is mandatory, but Greenplum Database (and Oracle) allow it to be omitted. SQL allows only `WORK`, not `TRANSACTION`, as a noise word after `ROLLBACK`. Also, SQL has an optional clause `AND [NO] CHAIN` which is not currently supported by Greenplum Database. Otherwise, this command conforms to the SQL standard.

**See Also**

`BEGIN`, `COMMIT`, `SAVEPOINT`, `RELEASE SAVEPOINT`, `ROLLBACK`

**SAVEPOINT**

Defines a new savepoint within the current transaction.

**Synopsis**

```
SAVEPOINT savepoint_name
```

**Description**

`SAVEPOINT` establishes a new savepoint within the current transaction.

A savepoint is a special mark inside a transaction that allows all commands that are executed after it was established to be rolled back, restoring the transaction state to what it was at the time of the savepoint.

**Parameters**

`savepoint_name`

The name of the new savepoint.
**Notes**

Use `ROLLBACK TO SAVEPOINT` to rollback to a savepoint. Use `RELEASE SAVEPOINT` to destroy a savepoint, keeping the effects of commands executed after it was established.

Savepoints can only be established when inside a transaction block. There can be multiple savepoints defined within a transaction.

**Examples**

To establish a savepoint and later undo the effects of all commands executed after it was established:

```sql
BEGIN;
    INSERT INTO table1 VALUES (1);
    SAVEPOINT my_savepoint;
    INSERT INTO table1 VALUES (2);
    ROLLBACK TO SAVEPOINT my_savepoint;
    INSERT INTO table1 VALUES (3);
COMMIT;
```

The above transaction will insert the values 1 and 3, but not 2.

To establish and later destroy a savepoint:

```sql
BEGIN;
    INSERT INTO table1 VALUES (3);
    SAVEPOINT my_savepoint;
    INSERT INTO table1 VALUES (4);
    RELEASE SAVEPOINT my_savepoint;
COMMIT;
```

The above transaction will insert both 3 and 4.

**Compatibility**

SQL requires a savepoint to be destroyed automatically when another savepoint with the same name is established. In Greenplum Database, the old savepoint is kept, though only the more recent one will be used when rolling back or releasing. (Releasing the newer savepoint will cause the older one to again become accessible to `ROLLBACK TO SAVEPOINT` and `RELEASE SAVEPOINT`.) Otherwise, `SAVEPOINT` is fully SQL conforming.

**See Also**

`BEGIN`, `COMMIT`, `ROLLBACK`, `RELEASE SAVEPOINT`, `ROLLBACK TO SAVEPOINT`

**SELECT**

Retrieves rows from a table or view.

**Synopsis**

```sql
[ WITH [ RECURSIVE ] with_query [, ...] ]
SELECT [ALL | DISTINCT [ON (expression [, ...])]]
    * | expression [AS output_name] [, ...]
    [FROM from_item [, ...]]
    [WHERE condition]
    [GROUP BY grouping_element [, ...]]
    [HAVING condition [, ...]]
    [WINDOW window_name AS (window_definition) [, ...] ]
    [{UNION | INTERSECT | EXCEPT} [ALL | DISTINCT] select]
```
[ORDER BY expression [ASC | DESC | USING operator] [NULLS {FIRST | LAST}] [, ...]]
[LIMIT {count | ALL}]
[OFFSET start [ ROW | ROWS ]]
[FETCH { FIRST | NEXT } [ count ] [ ROW | ROWS ] ONLY]
[FOR {UPDATE | NO KEY UPDATE | SHARE | KEY SHARE} [OF table_name [, ...]]
[NOWAIT] [ ...]]

TABLE { [ ONLY ] table_name [ * ] | with_query_name }

where with_query is:

with_query_name [( column_name [, ...] )] AS ( select | values | insert | update | delete )

where from_item can be one of:

[ONLY] table_name [ * ] [ [ AS ] alias [( column_alias [, ...] )] ]
( select ) [ AS ] alias [( column_alias [, ...] )] with_query_name [ [ AS ] alias [( column_alias [, ...] )] ]

[NULLS {FIRST | LAST}] [, ...]]
[{ RANGE | ROWS} frame_start
| (RANGE | ROWS) BETWEEN frame_start AND frame_end]

where frame_start and frame_end can be one of:

UNBOUNDED PRECEDING
value PRECEDING
CURRENT ROW
value FOLLOWING
UNBOUNDED FOLLOWING

Note: The RECURSIVE keyword is a Beta feature.
Description

**SELECT** retrieves rows from zero or more tables. The general processing of **SELECT** is as follows:

1. All queries in the **WITH** clause are computed. These effectively serve as temporary tables that can be referenced in the **FROM** list.
2. All elements in the **FROM** list are computed. (Each element in the **FROM** list is a real or virtual table.) If more than one element is specified in the **FROM** list, they are cross-joined together.
3. If the **WHERE** clause is specified, all rows that do not satisfy the condition are eliminated from the output.
4. If the **GROUP BY** clause is specified, or if there are aggregate function calls, the output is combined into groups of rows that match on one or more values, and the results of aggregate functions are computed. If the **HAVING** clause is present, it eliminates groups that do not satisfy the given condition.
5. The actual output rows are computed using the **SELECT** output expressions for each selected row or row group.
6. **SELECT DISTINCT** eliminates duplicate rows from the result. **SELECT DISTINCT ON** eliminates rows that match on all the specified expressions. **SELECT ALL** (the default) will return all candidate rows, including duplicates.
7. If a window expression is specified (and optional **WINDOW** clause), the output is organized according to the positional (row) or value-based (range) window frame.
8. The actual output rows are computed using the **SELECT** output expressions for each selected row.
9. Using the operators **UNION**, **INTERSECT**, and **EXCEPT**, the output of more than one **SELECT** statement can be combined to form a single result set. The **UNION** operator returns all rows that are in one or both of the result sets. The **INTERSECT** operator returns all rows that are strictly in both result sets. The **EXCEPT** operator returns the rows that are in the first result set but not in the second. In all three cases, duplicate rows are eliminated unless **ALL** is specified. The noise word **DISTINCT** can be added to explicitly specify eliminating duplicate rows. Notice that **DISTINCT** is the default behavior here, even though **ALL** is the default for **SELECT** itself.
10. If the **ORDER BY** clause is specified, the returned rows are sorted in the specified order. If **ORDER BY** is not given, the rows are returned in whatever order the system finds fastest to produce.
11. If the **LIMIT** (or **FETCH FIRST**) or **OFFSET** clause is specified, the **SELECT** statement only returns a subset of the result rows.
12. If **FOR UPDATE**, **FOR NO KEY UPDATE**, **FOR SHARE**, or **FOR KEY SHARE** is specified, the **SELECT** statement locks the entire table against concurrent updates.

You must have **SELECT** privilege on each column used in a **SELECT** command. The use of **FOR NO KEY UPDATE**, **FOR UPDATE**, **FOR SHARE**, or **FOR KEY SHARE** requires **UPDATE** privilege as well (for at least one column of each table so selected).

Parameters

**The WITH Clause**

The optional **WITH** clause allows you to specify one or more subqueries that can be referenced by name in the primary query. The subqueries effectively act as temporary tables or views for the duration of the primary query. Each subquery can be a **SELECT**, **INSERT**, **UPDATE**, or **DELETE** statement. When writing a data-modifying statement (**INSERT**, **UPDATE**, or **DELETE**) in **WITH**, it is usual to include a **RETURNING** clause. It is the output of **RETURNING**, not the underlying table that the statement modifies, that forms the temporary table that is read by the primary query. If **RETURNING** is omitted, the statement is still executed, but it produces no output so it cannot be referenced as a table by the primary query.

For a **SELECT** command that includes a **WITH** clause, the clause can contain at most a single clause that modifies table data (**INSERT**, **UPDATE** or **DELETE command**).

A **with_query_name** without schema qualification must be specified for each query in the **WITH** clause. Optionally, a list of column names can be specified; if the list of column names is omitted, the names are inferred from the subquery. The primary query and the **WITH** queries are all (notionally) executed at the same time.
If `RECURSIVE` is specified, it allows a `SELECT` subquery to reference itself by name. Such a subquery has the general form

```
non_recursive_term UNION [ALL | DISTINCT] recursive_term
```

where the recursive self-reference appears on the right-hand side of the `UNION`. Only one recursive self-reference is permitted per query. Recursive data-modifying statements are not supported, but you can use the results of a recursive `SELECT` query in a data-modifying statement.

If the `RECURSIVE` keyword is specified, the `WITH` queries need not be ordered: a query can reference another query that is later in the list. However, circular references, or mutual recursion, are not supported.

Without the `RECURSIVE` keyword, `WITH` queries can only reference sibling `WITH` queries that are earlier in the `WITH` list.

**WITH RECURSIVE limitations.** These items are not supported:

- A recursive `WITH` clause that contains the following in the `recursive_term`.
  - Subqueries with a self-reference
  - `DISTINCT` clause
  - `GROUP BY` clause
  - A window function
- A recursive `WITH` clause where the `with_query_name` is a part of a set operation.

Following is an example of the set operation limitation. This query returns an error because the set operation `UNION` contains a reference to the table `foo`.

```
WITH RECURSIVE foo(i) AS (
    SELECT 1
    UNION ALL
    SELECT i+1 FROM (SELECT * FROM foo UNION SELECT 0) bar
)
SELECT * FROM foo LIMIT 5;
```

This recursive CTE is allowed because the set operation `UNION` does not have a reference to the CTE `foo`.

```
WITH RECURSIVE foo(i) AS (
    SELECT 1
    UNION ALL
    SELECT i+1 FROM (SELECT * FROM bar UNION SELECT 0) bar, foo
    WHERE foo.i = bar.a
)
SELECT * FROM foo LIMIT 5;
```

A key property of `WITH` queries is that they are evaluated only once per execution of the primary query, even if the primary query refers to them more than once. In particular, data-modifying statements are guaranteed to be executed once and only once, regardless of whether the primary query reads all or any of their output.

The primary query and the `WITH` queries are all (notionally) executed at the same time. This implies that the effects of a data-modifying statement in `WITH` cannot be seen from other parts of the query, other than by reading its `RETURNING` output. If two such data-modifying statements attempt to modify the same row, the results are unspecified.

See `WITH Queries (Common Table Expressions)` in the *Greenplum Database Administrator Guide* for additional information.

**The SELECT List**
The **select** list (between the key words **select** and **from**) specifies expressions that form the output rows of the **select** statement. The expressions can (and usually do) refer to columns computed in the **from** clause.

An **expression** in the **select** list can be a constant value, a column reference, an operator invocation, a function call, an aggregate expression, a window expression, a scalar subquery, and so on. A number of constructs can be classified as an expression but do not follow any general syntax rules. These generally have the semantics of a function or operator. For information about SQL value expressions and function calls, see “Querying Data” in the Greenplum Database Administrator Guide.

Just as in a table, every output column of a **select** has a name. In a simple **select** this name is just used to label the column for display, but when the **select** is a sub-query of a larger query, the name is seen by the larger query as the column name of the virtual table produced by the sub-query. To specify the name to use for an output column, write `as output_name` after the column's expression. (You can omit `as`, but only if the desired output name does not match any SQL keyword. For protection against possible future keyword additions, you can always either write `as` or double-quote the output name.) If you do not specify a column name, Greenplum Database chooses a name automatically. If the column's expression is a simple column reference then the chosen name is the same as that column's name. In more complex cases, a function or type name may be used, or the system may fall back on a generated name such as ?column? or `columnN`.

An output column's name can be used to refer to the column's value in **order by** and **group by** clauses, but not in the **where** or **having** clauses; there you must write out the expression instead.

Instead of an expression, `*` can be written in the output list as a shorthand for all the columns of the selected rows. Also, you can write `table_name.*` as a shorthand for the columns coming from just that table. In these cases it is not possible to specify new names with `as`; the output column names will be the same as the table columns’ names.

**The DISTINCT Clause**

If **select distinct** is specified, all duplicate rows are removed from the result set (one row is kept from each group of duplicates). **select all** specifies the opposite: all rows are kept; that is the default.

**select distinct on ( expression [, ...] )** keeps only the first row of each set of rows where the given expressions evaluate to equal. The **distinct on** expressions are interpreted using the same rules as for **order by** (see above). Note that the “first row” of each set is unpredictable unless **order by** is used to ensure that the desired row appears first. For example:

```sql
SELECT DISTINCT ON (location) location, time, report
FROM weather_reports
ORDER BY location, time DESC;
```

retrieves the most recent weather report for each location. But if we had not used **order by** to force descending order of time values for each location, we’d have gotten a report from an unpredictable time for each location.

The **distinct on** expression(s) must match the leftmost **order by** expression(s). The **order by** clause will normally contain additional expression(s) that determine the desired precedence of rows within each **distinct on** group.

**The FROM Clause**

The **from** clause specifies one or more source tables for the **select**. If multiple sources are specified, the result is the Cartesian product (cross join) of all the sources. But usually qualification conditions are added (via **where**) to restrict the returned rows to a small subset of the Cartesian product. The **from** clause can contain the following elements:

`table_name`
The name (optionally schema-qualified) of an existing table or view. If **ONLY** is specified, only that table is scanned. If **ONLY** is not specified, the table and all its descendant tables (if any) are scanned.

**alias**

A substitute name for the `FROM` item containing the alias. An alias is used for brevity or to eliminate ambiguity for self-joins (where the same table is scanned multiple times). When an alias is provided, it completely hides the actual name of the table or function; for example given `FROM foo AS f`, the remainder of the `SELECT` must refer to this `FROM` item as `f` not `foo`. If an alias is written, a column alias list can also be written to provide substitute names for one or more columns of the table.

**select**

A sub-`SELECT` can appear in the `FROM` clause. This acts as though its output were created as a temporary table for the duration of this single `SELECT` command. Note that the sub-`SELECT` must be surrounded by parentheses, and an alias must be provided for it. A `VALUES` command can also be used here. See "Non-standard Clauses" in the `Compatibility` section for limitations of using correlated sub-selects in Greenplum Database.

**with_query_name**

A `with` query is referenced in the `FROM` clause by specifying its `with_query_name`, just as though the name were a table name. The `with_query_name` cannot contain a schema qualifier. An alias can be provided in the same way as for a table.

The `with` query hides a table of the same name for the purposes of the primary query. If necessary, you can refer to a table of the same name by qualifying the table name with the schema.

**function_name**

Function calls can appear in the `FROM` clause. (This is especially useful for functions that return result sets, but any function can be used.) This acts as though its output were created as a temporary table for the duration of this single `SELECT` command. An alias may also be used. If an alias is written, a column alias list can also be written to provide substitute names for one or more attributes of the function's composite return type. If the function has been defined as returning the record data type, then an alias or the key word `AS` must be present, followed by a column definition list in the form `( column_name data_type [, ... ] )`. The column definition list must match the actual number and types of columns returned by the function.

**join_type**

One of:

- `[INNER] JOIN`
- `LEFT [OUTER] JOIN`
- `RIGHT [OUTER] JOIN`
- `FULL [OUTER] JOIN`
- `CROSS JOIN`

For the **INNER** and **OUTER** join types, a join condition must be specified, namely exactly one of `NATURAL`, `ON join_condition`, or `USING ( join_column [, ... ] )`. See below for the meaning. For `CROSS JOIN`, none of these clauses may appear.

A `JOIN` clause combines two `FROM` items, which for convenience we will refer to as "tables", though in reality they can be any type of `FROM` item. Use parentheses if necessary to determine the order of nesting. In the absence of parentheses, `JOINS` nest left-to-right. In any case `JOIN` binds more tightly than the commas separating `FROM-list` items.

`CROSS JOIN` and `INNER JOIN` produce a simple Cartesian product, the same result as you get from listing the two tables at the top level of `FROM`, but restricted by the join
condition (if any). **CROSS JOIN** is equivalent to **INNER JOIN ON** (TRUE), that is, no rows are removed by qualification. These join types are just a notational convenience, since they do nothing you could not do with plain FROM and WHERE.

**LEFT OUTER JOIN** returns all rows in the qualified Cartesian product (i.e., all combined rows that pass its join condition), plus one copy of each row in the left-hand table for which there was no right-hand row that passed the join condition. This left-hand row is extended to the full width of the joined table by inserting null values for the right-hand columns. Note that only the **JOIN** clause's own condition is considered while deciding which rows have matches. Outer conditions are applied afterwards.

Conversely, **RIGHT OUTER JOIN** returns all the joined rows, plus one row for each unmatched right-hand row (extended with nulls on the left). This is just a notational convenience, since you could convert it to a **LEFT OUTER JOIN** by switching the left and right tables.

**FULL OUTER JOIN** returns all the joined rows, plus one row for each unmatched left-hand row (extended with nulls on the right), plus one row for each unmatched right-hand row (extended with nulls on the left).

**ON** _join_condition_

_join_condition_ is an expression resulting in a value of type boolean (similar to a WHERE clause) that specifies which rows in a join are considered to match.

**USING** ( _join_column_ [, ...])

A clause of the form **USING** (a, b, ...) is shorthand for ON left_table.a = right_table.a AND left_table.b = right_table.b .... Also, USING implies that only one of each pair of equivalent columns will be included in the join output, not both.

**NATURAL**

**NATURAL** is shorthand for a USING list that mentions all columns in the two tables that have the same names. If there are no common column names, **NATURAL** is equivalent to ON TRUE.

**The WHERE Clause**

The optional WHERE clause has the general form:

```
WHERE condition
```

where _condition_ is any expression that evaluates to a result of type boolean. Any row that does not satisfy this condition will be eliminated from the output. A row satisfies the condition if it returns true when the actual row values are substituted for any variable references.

**The GROUP BY Clause**

The optional GROUP BY clause has the general form:

```
GROUP BY grouping_element [, ...]
```

where _grouping_element_ can be one of:

- ()
- expression
- ROLLUP ( _expression_ [, ...])
- CUBE ( _expression_ [, ...])
- GROUPING SETS ( ( _grouping_element_ [, ...]) )

**GROUP BY** will condense into a single row all selected rows that share the same values for the grouped expressions. _expression_ can be an input column name, or the name or ordinal number of an output column.
(SELECT list item), or an arbitrary expression formed from input-column values. In case of ambiguity, a GROUP BY name will be interpreted as an input-column name rather than an output column name.

Aggregate functions, if any are used, are computed across all rows making up each group, producing a separate value for each group. (If there are aggregate functions but no GROUP BY clause, the query is treated as having a single group comprising all the selected rows.) The set of rows fed to each aggregate function can be further filtered by attaching a FILTER clause to the aggregate function call. When a FILTER clause is present, only those rows matching it are included in the input to that aggregate function. See Aggregate Expressions.

When GROUP BY is present, or any aggregate functions are present, it is not valid for the SELECT list expressions to refer to ungrouped columns except within aggregate functions or when the ungrouped column is functionally dependent on the grouped columns, since there would otherwise be more than one possible value to return for an ungrouped column. A functional dependency exists if the grouped columns (or a subset thereof) are the primary key of the table containing the ungrouped column.

Keep in mind that all aggregate functions are evaluated before evaluating any “scalar” expressions in the HAVING clause or SELECT list. This means that, for example, a CASE expression cannot be used to skip evaluation of an aggregate function; see Expression Evaluation Rules.

Greenplum Database has the following additional OLAP grouping extensions (often referred to as supergroups):

ROLLUP

A ROLLUP grouping is an extension to the GROUP BY clause that creates aggregate subtotals that roll up from the most detailed level to a grand total, following a list of grouping columns (or expressions). ROLLUP takes an ordered list of grouping columns, calculates the standard aggregate values specified in the GROUP BY clause, then creates progressively higher-level subtotals, moving from right to left through the list. Finally, it creates a grand total. A ROLLUP grouping can be thought of as a series of grouping sets. For example:

```
GROUP BY ROLLUP (a,b,c)
```

is equivalent to:

```
GROUP BY GROUPING SETS( (a,b,c), (a,b), (a), () )
```

Notice that the \(n\) elements of a ROLLUP translate to \(n+1\) grouping sets. Also, the order in which the grouping expressions are specified is significant in a ROLLUP.

CUBE

A CUBE grouping is an extension to the GROUP BY clause that creates subtotals for all of the possible combinations of the given list of grouping columns (or expressions). In terms of multidimensional analysis, CUBE generates all the subtotals that could be calculated for a data cube with the specified dimensions. For example:

```
GROUP BY CUBE (a,b,c)
```

is equivalent to:

```
GROUP BY GROUPING SETS( (a,b,c), (a,b), (a,c), (b,c), (a),
(b), (c), () )
```

Notice that \(n\) elements of a CUBE translate to \(2n\) grouping sets. Consider using CUBE in any situation requiring cross-tabular reports. CUBE is typically most suitable in queries that use columns from multiple dimensions rather than columns representing different levels of a single dimension. For instance, a commonly requested cross-tabulation might need subtotals for all the combinations of month, state, and product.
GROUPING SETS

You can selectively specify the set of groups that you want to create using a GROUPING SETS expression within a GROUP BY clause. This allows precise specification across multiple dimensions without computing a whole ROLLUP or CUBE. For example:

GROUP BY GROUPING SETS( (a,c), (a,b) )

If using the grouping extension clauses ROLLUP, CUBE, or GROUPING SETS, two challenges arise. First, how do you determine which result rows are subtotals, and then the exact level of aggregation for a given subtotal. Or, how do you differentiate between result rows that contain both stored NULL values and "NULL" values created by the ROLLUP or CUBE. Secondly, when duplicate grouping sets are specified in the GROUP BY clause, how do you determine which result rows are duplicates? There are two additional grouping functions you can use in the SELECT list to help with this:

- grouping(column [, ...]) — The grouping function can be applied to one or more grouping attributes to distinguish super-aggregated rows from regular grouped rows. This can be helpful in distinguishing a "NULL" representing the set of all values in a super-aggregated row from a NULL value in a regular row. Each argument in this function produces a bit — either 1 or 0, where 1 means the result row is super-aggregated, and 0 means the result row is from a regular grouping. The grouping function returns an integer by treating these bits as a binary number and then converting it to a base-10 integer.

- group_id() — For grouping extension queries that contain duplicate grouping sets, the group_id function is used to identify duplicate rows in the output. All unique grouping set output rows will have a group_id value of 0. For each duplicate grouping set detected, the group_id function assigns a group_id number greater than 0. All output rows in a particular duplicate grouping set are identified by the same group_id number.

The WINDOW Clause

The optional WINDOW clause specifies the behavior of window functions appearing in the query’s SELECT list or ORDER BY clause. These functions can reference the WINDOW clause entries by name in their OVER clauses. A WINDOW clause entry does not have to be referenced anywhere, however; if it is not used in the query it is simply ignored. It is possible to use window functions without any WINDOW clause at all, since a window function call can specify its window definition directly in its OVER clause. However, the WINDOW clause saves typing when the same window definition is needed for more than one window function.

For example:

```
SELECT vendor, rank() OVER (mywindow) FROM sale
GROUP BY vendor
WINDOW mywindow AS (ORDER BY sum(prc*qty));
```

A WINDOW clause has this general form:

```
WINDOW window_name AS (window_definition)
```

where window_name is a name that can be referenced from OVER clauses or subsequent window definitions, and window_definition is:

```
[existing_window_name]
[PARTITION BY expression [, ...]]
[ORDER BY expression [ASC | DESC | USING operator] [NULLS {FIRST | LAST}] [, ...] ]
[frame_clause]
```

existing_window_name
If an `existing_window_name` is specified it must refer to an earlier entry in the `WINDOW` list; the new window copies its partitioning clause from that entry, as well as its ordering clause if any. The new window cannot specify its own `PARTITION BY` clause, and it can specify `ORDER BY` only if the copied window does not have one. The new window always uses its own frame clause; the copied window must not specify a frame clause.

**PARTITION BY**

The `PARTITION BY` clause organizes the result set into logical groups based on the unique values of the specified expression. The elements of the `PARTITION BY` clause are interpreted in much the same fashion as elements of a `GROUP BY` clause, except that they are always simple expressions and never the name or number of an output column. Another difference is that these expressions can contain aggregate function calls, which are not allowed in a regular `GROUP BY` clause. They are allowed here because windowing occurs after grouping and aggregation. When used with window functions, the functions are applied to each partition independently. For example, if you follow `PARTITION BY` with a column name, the result set is partitioned by the distinct values of that column. If omitted, the entire result set is considered one partition.

Similarly, the elements of the `ORDER BY` list are interpreted in much the same fashion as elements of an `ORDER BY` clause, except that the expressions are always taken as simple expressions and never the name or number of an output column.

**ORDER BY**

The elements of the `ORDER BY` clause define how to sort the rows in each partition of the result set. If omitted, rows are returned in whatever order is most efficient and may vary. **Note:** Columns of data types that lack a coherent ordering, such as `time`, are not good candidates for use in the `ORDER BY` clause of a window specification. Time, with or without time zone, lacks a coherent ordering because addition and subtraction do not have the expected effects. For example, the following is not generally true: \( x::time < x::time + '2 hour'::interval \)

**frame_clause**

The optional `frame_clause` defines the window frame for window functions that depend on the frame (not all do). The window frame is a set of related rows for each row of the query (called the current row). The `frame_clause` can be one of

\[
\begin{align*}
\{ & \text{RANGE} \mid \text{ROWS} \} \text{ frame_start} \\
\{ & \text{RANGE} \mid \text{ROWS} \} \text{ BETWEEN frame_start AND frame_end}
\end{align*}
\]

where `frame_start` and `frame_end` can be one of

- UNBOUNDED PRECEDING
- value PRECEDING
- CURRENT ROW
- value FOLLOWING
- UNBOUNDED FOLLOWING

If `frame_end` is omitted it defaults to `CURRENT ROW`. Restrictions are that `frame_start` cannot be `UNBOUNDED FOLLOWING`, `frame_end` cannot be `UNBOUNDED PRECEDING`, and the `frame_end` choice cannot appear earlier in the above list than the `frame_start` choice — for example `RANGE BETWEEN CURRENT ROW AND value PRECEDING` is not allowed.

The default framing option is `RANGE UNBOUNDED PRECEDING`, which is the same as `RANGE BETWEEN UNBOUNDED PRECEDING AND CURRENT ROW`; it sets the frame to be all rows from the partition start up through the current row's last peer (a row that `ORDER BY` considers equivalent to the current row, or all rows if there is no `ORDER BY`). In general, `UNBOUNDED PRECEDING` means that the frame starts with the first row of the partition, and similarly `UNBOUNDED FOLLOWING` means that the frame ends with the last row of
the partition (regardless of \texttt{RANGE} or \texttt{ROWS} mode). In \texttt{ROWS} mode, \texttt{CURRENT \ ROW} means that the frame starts or ends with the current row; but in \texttt{RANGE} mode it means that the frame starts or ends with the current row's first or last peer in the \texttt{ORDER \ BY} ordering. The \texttt{value \ PRECEDING} and \texttt{value \ FOLLOWING} cases are currently only allowed in \texttt{ROWS} mode. They indicate that the frame starts or ends with the row that many rows before or after the current row. \texttt{value} must be an integer expression not containing any variables, aggregate functions, or window functions. The value must not be null or negative; but it can be zero, which selects the current row itself.

Beware that the \texttt{ROWS} options can produce unpredictable results if the \texttt{ORDER \ BY} ordering does not order the rows uniquely. The \texttt{RANGE} options are designed to ensure that rows that are peers in the \texttt{ORDER \ BY} ordering are treated alike; all peer rows will be in the same frame.

Use either a \texttt{ROWS} or \texttt{RANGE} clause to express the bounds of the window. The window bound can be one, many, or all rows of a partition. You can express the bound of the window either in terms of a range of data values offset from the value in the current row (\texttt{RANGE}), or in terms of the number of rows offset from the current row (\texttt{ROWS}). When using the \texttt{RANGE} clause, you must also use an \texttt{ORDER \ BY} clause. This is because the calculation performed to produce the window requires that the values be sorted. Additionally, the \texttt{ORDER \ BY} clause cannot contain more than one expression, and the expression must result in either a date or a numeric value. When using the \texttt{ROWS} or \texttt{RANGE} clauses, if you specify only a starting row, the current row is used as the last row in the window.

**PRECEDING** — The \texttt{PRECEDING} clause defines the first row of the window using the current row as a reference point. The starting row is expressed in terms of the number of rows preceding the current row. For example, in the case of \texttt{ROWS} framing, \texttt{5 \ PRECEDING} sets the window to start with the fifth row preceding the current row. In the case of \texttt{RANGE} framing, it sets the window to start with the first row whose ordering column value precedes that of the current row by 5 in the given order. If the specified order is ascending by date, this will be the first row within 5 days before the current row. \texttt{UNBOUNDED \ PRECEDING} sets the first row in the window to be the first row in the partition.

**BETWEEN** — The \texttt{BETWEEN} clause defines the first and last row of the window, using the current row as a reference point. First and last rows are expressed in terms of the number of rows preceding and following the current row, respectively. For example, \texttt{BETWEEN \ 3 \ PRECEDING \ AND \ 5 \ FOLLOWING} sets the window to start with the third row preceding the current row, and end with the fifth row following the current row. Use \texttt{BETWEEN \ UNBOUNDED \ PRECEDING \ AND \ UNBOUNDED \ FOLLOWING} to set the first and last rows in the window to be the first and last row in the partition, respectively. This is equivalent to the default behavior if no \texttt{ROW} or \texttt{RANGE} clause is specified.

**FOLLOWING** — The \texttt{FOLLOWING} clause defines the last row of the window using the current row as a reference point. The last row is expressed in terms of the number of rows following the current row. For example, in the case of \texttt{ROWS} framing, \texttt{5 \ FOLLOWING} sets the window to end with the fifth row following the current row. In the case of \texttt{RANGE} framing, it sets the window to end with the last row whose ordering column value follows that of the current row by 5 in the given order. If the specified order is ascending by date, this will be the last row within 5 days after the current row. Use \texttt{UNBOUNDED \ FOLLOWING} to set the last row in the window to be the last row in the partition.

If you do not specify a \texttt{ROW} or a \texttt{RANGE} clause, the window bound starts with the first row in the partition (\texttt{UNBOUNDED \ PRECEDING}) and ends with the current row (\texttt{CURRENT \ ROW}) if \texttt{ORDER \ BY} is used. If an \texttt{ORDER \ BY} is not specified, the window starts with the first row in the partition (\texttt{UNBOUNDED \ PRECEDING}) and ends with last row in the partition (\texttt{UNBOUNDED \ FOLLOWING}).

**The HAVING Clause**
The optional **HAVING** clause has the general form:

```
HAVING condition
```

where *condition* is the same as specified for the **WHERE** clause. **HAVING** eliminates group rows that do not satisfy the condition. **HAVING** is different from **WHERE**: **WHERE** filters individual rows before the application of **GROUP BY**, while **HAVING** filters group rows created by **GROUP BY**. Each column referenced in *condition* must unambiguously reference a grouping column, unless the reference appears within an aggregate function or the ungrouped column is functionally dependent on the grouping columns.

The presence of **HAVING** turns a query into a grouped query even if there is no **GROUP BY** clause. This is the same as what happens when the query contains aggregate functions but no **GROUP BY** clause. All the selected rows are considered to form a single group, and the **SELECT** list and **HAVING** clause can only reference table columns from within aggregate functions. Such a query will emit a single row if the **HAVING** condition is true, zero rows if it is not true.

**The UNION Clause**

The **UNION** clause has this general form:

```
select_statement UNION [ALL | DISTINCT] select_statement
```

where *select_statement* is any **SELECT** statement without an **ORDER BY**, **LIMIT**, **FOR NO KEY UPDATE**, **FOR UPDATE**, **FOR SHARE**, or **FOR KEY SHARE** clause. (**ORDER BY** and **LIMIT** can be attached to a subquery expression if it is enclosed in parentheses. Without parentheses, these clauses will be taken to apply to the result of the **UNION**, not to its right-hand input expression.)

The **UNION** operator computes the set union of the rows returned by the involved **SELECT** statements. A row is in the set union of two result sets if it appears in at least one of the result sets. The two **SELECT** statements that represent the direct operands of the **UNION** must produce the same number of columns, and corresponding columns must be of compatible data types.

The result of **UNION** does not contain any duplicate rows unless the **ALL** option is specified. **ALL** prevents elimination of duplicates. (Therefore, **UNION ALL** is usually significantly quicker than **UNION**; use **ALL** when you can.) **DISTINCT** can be written to explicitly specify the default behavior of eliminating duplicate rows.

Multiple **UNION** operators in the same **SELECT** statement are evaluated left to right, unless otherwise indicated by parentheses.

Currently, **FOR NO KEY UPDATE**, **FOR UPDATE**, **FOR SHARE**, and **FOR KEY SHARE** cannot be specified either for a **UNION** result or for any input of a **UNION**.

**The INTERSECT Clause**

The **INTERSECT** clause has this general form:

```
select_statement INTERSECT [ALL | DISTINCT] select_statement
```

where *select_statement* is any **SELECT** statement without an **ORDER BY**, **LIMIT**, **FOR NO KEY UPDATE**, **FOR UPDATE**, **FOR SHARE**, or **FOR KEY SHARE** clause.

The **INTERSECT** operator computes the set intersection of the rows returned by the involved **SELECT** statements. A row is in the intersection of two result sets if it appears in both result sets.

The result of **INTERSECT** does not contain any duplicate rows unless the **ALL** option is specified. With **ALL**, a row that has *m* duplicates in the left table and *n* duplicates in the right table will appear \( \min(m, n) \) times in the result set. **DISTINCT** can be written to explicitly specify the default behavior of eliminating duplicate rows.
Multiple `INTERSECT` operators in the same `SELECT` statement are evaluated left to right, unless parentheses dictate otherwise. `INTERSECT` binds more tightly than `UNION`. That is, `A UNION B INTERSECT C` will be read as `A UNION (B INTERSECT C)`.

Currently, `FOR NO KEY UPDATE`, `FOR UPDATE`, `FOR SHARE`, and `FOR KEY SHARE` cannot be specified either for an `INTERSECT` result or for any input of an `INTERSECT`.

The `EXCEPT` Clause

The `EXCEPT` clause has this general form:

```
select_statement EXCEPT [ALL | DISTINCT] select_statement
```

where `select_statement` is any `SELECT` statement without an `ORDER BY`, `LIMIT`, `FOR NO KEY UPDATE`, `FOR UPDATE`, `FOR SHARE`, or `FOR KEY SHARE` clause.

The `EXCEPT` operator computes the set of rows that are in the result of the left `SELECT` statement but not in the result of the right one.

The result of `EXCEPT` does not contain any duplicate rows unless the `ALL` option is specified. With `ALL`, a row that has `m` duplicates in the left table and `n` duplicates in the right table will appear `max(m-n,0)` times in the result set. `DISTINCT` can be written to explicitly specify the default behavior of eliminating duplicate rows.

Multiple `EXCEPT` operators in the same `SELECT` statement are evaluated left to right, unless parentheses dictate otherwise. `EXCEPT` binds at the same level as `UNION`.

Currently, `FOR NO KEY UPDATE`, `FOR UPDATE`, `FOR SHARE`, and `FOR KEY SHARE` cannot be specified either for an `EXCEPT` result or for any input of an `EXCEPT`.

The `ORDER BY` Clause

The optional `ORDER BY` clause has this general form:

```
ORDER BY expression [ASC | DESC | USING operator] [NULLS {FIRST | LAST}] [,...]
```

where `expression` can be the name or ordinal number of an output column (`SELECT` list item), or it can be an arbitrary expression formed from input-column values.

The `ORDER BY` clause causes the result rows to be sorted according to the specified expressions. If two rows are equal according to the left-most expression, they are compared according to the next expression and so on. If they are equal according to all specified expressions, they are returned in an implementation-dependent order.

The ordinal number refers to the ordinal (left-to-right) position of the output column. This feature makes it possible to define an ordering on the basis of a column that does not have a unique name. This is never absolutely necessary because it is always possible to assign a name to an output column using the `AS` clause.

It is also possible to use arbitrary expressions in the `ORDER BY` clause, including columns that do not appear in the `SELECT` output list. Thus the following statement is valid:

```
SELECT name FROM distributors ORDER BY code;
```

A limitation of this feature is that an `ORDER BY` clause applying to the result of a `UNION`, `INTERSECT`, or `EXCEPT` clause may only specify an output column name or number, not an expression.

If an `ORDER BY` expression is a simple name that matches both an output column name and an input column name, `ORDER BY` will interpret it as the output column name. This is the opposite of the choice that `GROUP BY` will make in the same situation. This inconsistency is made to be compatible with the SQL standard.
Optionally one may add the key word **ASC** (ascending) or **DESC** (descending) after any expression in the **ORDER BY** clause. If not specified, **ASC** is assumed by default. Alternatively, a specific ordering operator name may be specified in the **USING** clause. **ASC** is usually equivalent to **USING <** and **DESC** is usually equivalent to **USING >**. (But the creator of a user-defined data type can define exactly what the default sort ordering is, and it might correspond to operators with other names.)

If **NULLS LAST** is specified, null values sort after all non-null values; if **NULLS FIRST** is specified, null values sort before all non-null values. If neither is specified, the default behavior is **NULLS LAST** when **ASC** is specified or implied, and **NULLS FIRST** when **DESC** is specified (thus, the default is to act as though nulls are larger than non-nulls). When **USING** is specified, the default nulls ordering depends upon whether the operator is a less-than or greater-than operator.

Note that ordering options apply only to the expression they follow; for example **ORDER BY x, y DESC** does not mean the same thing as **ORDER BY x DESC, y DESC**.

Character-string data is sorted according to the locale-specific collation order that was established when the database was created.

Character-string data is sorted according to the collation that applies to the column being sorted. That can be overridden as needed by including a **COLLATE** clause in the expression, for example **ORDER BY mycolumn COLLATE "en_US"**. For information about defining collations, see **CREATE COLLATION**.

### The LIMIT Clause

The **LIMIT** clause consists of two independent sub-clauses:

```
LIMIT { count | ALL }
OFFSET start
```

where **count** specifies the maximum number of rows to return, while **start** specifies the number of rows to skip before starting to return rows. When both are specified, start rows are skipped before starting to count the **count** rows to be returned.

If the **count** expression evaluates to **NULL**, it is treated as **LIMIT ALL**, that is, no limit. If **start** evaluates to **NULL**, it is treated the same as **OFFSET 0**.

SQL:2008 introduced a different syntax to achieve the same result, which Greenplum Database also supports. It is:

```
OFFSET start [ ROW | ROWS ]
FETCH { FIRST | NEXT } [ { count } | { ROW | ROWS } ONLY
```

In this syntax, the **start** or **count** value is required by the standard to be a literal constant, a parameter, or a variable name; as a Greenplum Database extension, other expressions are allowed, but will generally need to be enclosed in parentheses to avoid ambiguity. If **count** is omitted in a **FETCH** clause, it defaults to 1. **ROW** and **ROWS** as well as **FIRST** and **NEXT** are noise words that don't influence the effects of these clauses. According to the standard, the **OFFSET** clause must come before the **FETCH** clause if both are present; but Greenplum Database allows either order.

When using **LIMIT**, it is a good idea to use an **ORDER BY** clause that constrains the result rows into a unique order. Otherwise you will get an unpredictable subset of the query's rows — you may be asking for the tenth through twentieth rows, but tenth through twentieth in what ordering? You don't know what ordering unless you specify **ORDER BY**.

The query optimizer takes **LIMIT** into account when generating a query plan, so you are very likely to get different plans (yielding different row orders) depending on what you use for **LIMIT** and **OFFSET**. Thus, using different **LIMIT/OFFSET** values to select different subsets of a query result will give inconsistent results unless you enforce a predictable result ordering with **ORDER BY**. This is not a defect; it is an inherent consequence of the fact that SQL does not promise to deliver the results of a query in any particular order unless **ORDER BY** is used to constrain the order.

### The Locking Clause
FOR UPDATE, FOR NO KEY UPDATE, FOR SHARE and FOR KEY SHARE are locking clauses; they affect how SELECT locks rows as they are obtained from the table.

The locking clause has the general form

```
FOR lock_strength [OF table_name [ , ... ] ] [ NOWAIT ]
```

where `lock_strength` can be one of

- FOR UPDATE - Locks the table with an EXCLUSIVE lock.
- FOR NO KEY UPDATE - Locks the table with an EXCLUSIVE lock.
- FOR SHARE - Locks the table with a ROW SHARE lock.
- FOR KEY SHARE - Locks the table with a ROW SHARE lock.

**Note:** By default, Greenplum Database acquires an EXCLUSIVE lock on tables for DELETE and UPDATE operations on heap tables. When the Global Deadlock Detector is enabled the lock mode for DELETE and UPDATE operations on heap tables is ROW EXCLUSIVE. The Global Deadlock Detector is enabled by setting the `gp_enable_global_deadlock_detector` configuration parameter to true. See Global Deadlock Detector in the Greenplum Database Administrator Guide for information about the Global Deadlock Detector.

For more information on each row-level lock mode, refer to Explicit Locking in the PostgreSQL documentation.

To prevent the operation from waiting for other transactions to commit, use the NOWAIT option. With NOWAIT, the statement reports an error, rather than waiting, if a selected row cannot be locked immediately. Note that NOWAIT applies only to the row-level lock(s) — the required ROW SHARE table-level lock is still taken in the ordinary way. You can use LOCK with the NOWAIT option first, if you need to acquire the table-level lock without waiting.

If specific tables are named in a locking clause, then only rows coming from those tables are locked; any other tables used in the SELECT are simply read as usual. A locking clause without a table list affects all tables used in the statement. If a locking clause is applied to a view or sub-query, it affects all tables used in the view or sub-query. However, these clauses do not apply to WITH queries referenced by the primary query. If you want row locking to occur within a WITH query, specify a locking clause within the WITH query.

Multiple locking clauses can be written if it is necessary to specify different locking behavior for different tables. If the same table is mentioned (or implicitly affected) by both more than one locking clause, then it is processed as if it was only specified by the strongest one. Similarly, a table is processed as NOWAIT if that is specified in any of the clauses affecting it.

The locking clauses cannot be used in contexts where returned rows cannot be clearly identified with individual table rows; for example they cannot be used with aggregation.

When a locking clause appears at the top level of a SELECT query, the rows that are locked are exactly those that are returned by the query; in the case of a join query, the rows locked are those that contribute to returned join rows. In addition, rows that satisfied the query conditions as of the query snapshot will be locked, although they will not be returned if they were updated after the snapshot and no longer satisfy the query conditions. If a LIMIT is used, locking stops once enough rows have been returned to satisfy the limit (but note that rows skipped over by OFFSET will get locked). Similarly, if a locking clause is used in a cursor's query, only rows actually fetched or stepped past by the cursor will be locked.

When locking clause appears in a sub-SELECT, the rows locked are those returned to the outer query by the sub-query. This might involve fewer rows than inspection of the sub-query alone would suggest, since conditions from the outer query might be used to optimize execution of the sub-query. For example,

```
SELECT * FROM (SELECT * FROM mytable FOR UPDATE) ss WHERE coll = 5;
```

will lock only rows having `coll` = 5, even though that condition is not textually within the sub-query.
It is possible for a `SELECT` command running at the `READ COMMITTED` transaction isolation level and using `ORDER BY` and a locking clause to return rows out of order. This is because `ORDER BY` is applied first. The command sorts the result, but might then block trying to obtain a lock on one or more of the rows. Once the `SELECT` unblocks, some of the ordering column values might have been modified, leading to those rows appearing to be out of order (though they are in order in terms of the original column values). This can be worked around at need by placing the `FOR UPDATE/SHARE` clause in a sub-query, for example

```sql
SELECT * FROM (SELECT * FROM mytable FOR UPDATE) ss ORDER BY column1;
```

Note that this will result in locking all rows of `mytable`, whereas `FOR UPDATE` at the top level would lock only the actually returned rows. This can make for a significant performance difference, particularly if the `ORDER BY` is combined with `LIMIT` or other restrictions. So this technique is recommended only if concurrent updates of the ordering columns are expected and a strictly sorted result is required.

At the `REPEATABLE READ` or `SERIALIZABLE` transaction isolation level this would cause a serialization failure (with a `SQLSTATE` of `40001`), so there is no possibility of receiving rows out of order under these isolation levels.

### The TABLE Command

The command

```
TABLE name
```

is completely equivalent to

```
SELECT * FROM name
```

It can be used as a top-level command or as a space-saving syntax variant in parts of complex queries.

### Examples

To join the table `films` with the table `distributors`:

```sql
SELECT f.title, f.did, d.name, f.date_prod, f.kind FROM distributors d, films f WHERE f.did = d.did
```

To sum the column `length` of all films and group the results by `kind`:

```sql
SELECT kind, sum(length) AS total FROM films GROUP BY kind;
```

To sum the column `length` of all films, group the results by `kind` and show those group totals that are less than 5 hours:

```sql
SELECT kind, sum(length) AS total FROM films GROUP BY kind HAVING sum(length) < interval '5 hours';
```

Calculate the subtotals and grand totals of all sales for movie `kind` and `distributor`.

```sql
SELECT kind, distributor, sum(prc*qty) FROM sales GROUP BY ROLLUP(kind, distributor) ORDER BY 1,2,3;
```

Calculate the rank of movie distributors based on total sales:

```sql
SELECT distributor, sum(prc*qty),
       rank() OVER (ORDER BY sum(prc*qty) DESC)
FROM sale
```
GROUP BY distributor ORDER BY 2 DESC;

The following two examples are identical ways of sorting the individual results according to the contents of the second column (name):

SELECT * FROM distributors ORDER BY name;
SELECT * FROM distributors ORDER BY 2;

The next example shows how to obtain the union of the tables distributors and actors, restricting the results to those that begin with the letter w in each table. Only distinct rows are wanted, so the key word ALL is omitted:

SELECT distributors.name FROM distributors WHERE distributors.name LIKE 'W%' UNION SELECT actors.name FROM actors WHERE actors.name LIKE 'W%';

This example shows how to use a function in the FROM clause, both with and without a column definition list:

CREATE FUNCTION distributors(int) RETURNS SETOF distributors AS $$ SELECT * FROM distributors WHERE did = $1; $$ LANGUAGE SQL;
SELECT * FROM distributors(111);

CREATE FUNCTION distributors_2(int) RETURNS SETOF record AS $$ SELECT * FROM distributors WHERE did = $1; $$ LANGUAGE SQL;
SELECT * FROM distributors_2(111) AS (dist_id int, dist_name text);

This example uses a simple WITH clause:

WITH test AS (  SELECT random() as x FROM generate_series(1, 3)  )  SELECT * FROM test UNION ALL SELECT * FROM test;

This example uses the WITH clause to display per-product sales totals in only the top sales regions.

WITH regional_sales AS  SELECT region, SUM(amount) AS total_sales FROM orders GROUP BY region ), top_regions AS (  SELECT region FROM regional_sales WHERE total_sales > (SELECT SUM(total_sales) FROM regional_sales)  )  SELECT region, product, SUM(quantity) AS product_units,  SUM(amount) AS product_sales FROM orders WHERE region IN (SELECT region FROM top_regions) GROUP BY region, product;

The example could have been written without the WITH clause but would have required two levels of nested sub-SELECT statements.
This example uses the `WITH RECURSIVE` clause to find all subordinates (direct or indirect) of the employee Mary, and their level of indirectness, from a table that shows only direct subordinates:

```sql
WITH RECURSIVE employee_recursive(distance, employee_name, manager_name) AS
  (SELECT 1, employee_name, manager_name
   FROM employee
   WHERE manager_name = 'Mary'
   UNION ALL
   SELECT er.distance + 1, e.employee_name, e.manager_name
   FROM employee_recursive er, employee e
   WHERE er.employee_name = e.manager_name
  )
SELECT distance, employee_name FROM employee_recursive;
```

The typical form of recursive queries: an initial condition, followed by `UNION [ALL]`, followed by the recursive part of the query. Be sure that the recursive part of the query will eventually return no tuples, or else the query will loop indefinitely. See `WITH Queries (Common Table Expressions)` in the Greenplum Database Administrator Guide for more examples.

**Compatibility**

The `SELECT` statement is compatible with the SQL standard, but there are some extensions and some missing features.

**Omitted FROM Clauses**

Greenplum Database allows one to omit the `FROM` clause. It has a straightforward use to compute the results of simple expressions. For example:

```sql
SELECT 2+2;
```

Some other SQL databases cannot do this except by introducing a dummy one-row table from which to do the `SELECT`.

Note that if a `FROM` clause is not specified, the query cannot reference any database tables. For example, the following query is invalid:

```sql
SELECT distributors.* WHERE distributors.name = 'Westward';
```

In earlier releases, setting a server configuration parameter, `add_missing_from`, to true allowed Greenplum Database to add an implicit entry to the query's `FROM` clause for each table referenced by the query. This is no longer allowed.

**Omitting the AS Key Word**

In the SQL standard, the optional key word `AS` can be omitted before an output column name whenever the new column name is a valid column name (that is, not the same as any reserved keyword). Greenplum Database is slightly more restrictive: `AS` is required if the new column name matches any keyword at all, reserved or not. Recommended practice is to use `AS` or double-quote output column names, to prevent any possible conflict against future keyword additions.

In `FROM` items, both the standard and Greenplum Database allow `AS` to be omitted before an alias that is an unreserved keyword. But this is impractical for output column names, because of syntactic ambiguities.

**ONLY and Inheritance**

The SQL standard requires parentheses around the table name when writing `ONLY`, for example:

```sql
SELECT * FROM ONLY (tab1), ONLY (tab2) WHERE ...;
```

Greenplum Database considers these parentheses to be optional.
Greenplum Database allows a trailing * to be written to explicitly specify the non-ONLY behavior of including child tables. The standard does not allow this.

(These points apply equally to all SQL commands supporting the ONLY option.)

Namespace Available to GROUP BY and ORDER BY

In the SQL-92 standard, an ORDER BY clause may only use output column names or numbers, while a GROUP BY clause may only use expressions based on input column names. Greenplum Database extends each of these clauses to allow the other choice as well (but it uses the standard's interpretation if there is ambiguity). Greenplum Database also allows both clauses to specify arbitrary expressions. Note that names appearing in an expression are always taken as input-column names, not as output column names.

SQL:1999 and later use a slightly different definition which is not entirely upward compatible with SQL-92. In most cases, however, Greenplum Database interprets an ORDER BY or GROUP BY expression the same way SQL:1999 does.

Functional Dependencies

Greenplum Database recognizes functional dependency (allowing columns to be omitted from GROUP BY) only when a table's primary key is included in the GROUP BY list. The SQL standard specifies additional conditions that should be recognized.

LIMIT and OFFSET

The clauses LIMIT and OFFSET are Greenplum Database-specific syntax, also used by MySQL. The SQL:2008 standard has introduced the clauses OFFSET .. FETCH {FIRST|NEXT} ... for the same functionality, as shown above. This syntax is also used by IBM DB2. (Applications for Oracle frequently use a workaround involving the automatically generated rownum column, which is not available in Greenplum Database, to implement the effects of these clauses.)

FOR NO KEY UPDATE, FOR UPDATE, FOR SHARE, and FOR KEY SHARE

Although FOR UPDATE appears in the SQL standard, the standard allows it only as an option of DECLARE CURSOR. Greenplum Database allows it in any SELECT query as well as in sub-SELECTs, but this is an extension. The FOR NO KEY UPDATE, FOR SHARE, and FOR KEY SHARE variants, as well as the NOWAIT option, do not appear in the standard.

Data-Modifying Statements in WITH

Greenplum Database allows INSERT, UPDATE, and DELETE to be used as WITH queries. This is not found in the SQL standard.

Nonstandard Clauses

The clause DISTINCT ON is not defined in the SQL standard.

Limited Use of STABLE and VOLATILE Functions

To prevent data from becoming out-of-sync across the segments in Greenplum Database, any function classified as STABLE or VOLATILE cannot be executed at the segment database level if it contains SQL or modifies the database in any way. See CREATE FUNCTION for more information.

EXPLAIN

SELECT INTO

Defines a new table from the results of a query.

Synopsis

[ WITH [ RECURSIVE ] with_query [, ... ] ]
**Description**

`SELECT INTO` creates a new table and fills it with data computed by a query. The data is not returned to the client, as it is with a normal `SELECT`. The new table’s columns have the names and data types associated with the output columns of the `SELECT`.

**Parameters**

The majority of parameters for `SELECT INTO` are the same as `SELECT`.

- **TEMPORARY**
- **TEMP**
  - If specified, the table is created as a temporary table.

- **UNLOGGED**
  - If specified, the table is created as an unlogged table. Data written to unlogged tables is not written to the write-ahead (WAL) log, which makes them considerably faster than ordinary tables. However, the contents of an unlogged table are not replicated to mirror segment instances. Also an unlogged table is not crash-safe. After a segment instance crash or unclean shutdown, the data for the unlogged table on that segment is truncated. Any indexes created on an unlogged table are automatically unlogged as well.

- **new_table**
  - The name (optionally schema-qualified) of the table to be created.

**Examples**

Create a new table `films_recent` consisting of only recent entries from the table `films`:

```sql
SELECT * INTO films_recent FROM films WHERE date_prod >= '2016-01-01';
```

**Compatibility**

The SQL standard uses `SELECT INTO` to represent selecting values into scalar variables of a host program, rather than creating a new table. The Greenplum Database usage of `SELECT INTO` to represent table creation is historical. It is best to use `CREATE TABLE AS` for this purpose in new applications.

**See Also**

`SELECT, CREATE TABLE AS`
**SET**

Changes the value of a Greenplum Database configuration parameter.

**Synopsis**

```
SET [SESSION | LOCAL] configuration_parameter {TO | =} value |
'value' | DEFAULT)

SET [SESSION | LOCAL] TIME_ZONE {timezone | LOCAL | DEFAULT}
```

**Description**

The `SET` command changes server configuration parameters. Any configuration parameter classified as a `session` parameter can be changed on-the-fly with `SET`. `SET` affects only the value used by the current session.

If `SET` or `SET SESSION` is issued within a transaction that is later aborted, the effects of the `SET` command disappear when the transaction is rolled back. Once the surrounding transaction is committed, the effects will persist until the end of the session, unless overridden by another `SET`.

The effects of `SET LOCAL` last only till the end of the current transaction, whether committed or not. A special case is `SET` followed by `SET LOCAL` within a single transaction: the `SET LOCAL` value will be seen until the end of the transaction, but afterwards (if the transaction is committed) the `SET` value will take effect.

If `SET LOCAL` is used within a function that includes a `SET` option for the same configuration parameter (see `CREATE FUNCTION`), the effects of the `SET LOCAL` command disappear at function exit; the value in effect when the function was called is restored anyway. This allows `SET LOCAL` to be used for dynamic or repeated changes of a parameter within a function, while retaining the convenience of using the `SET` option to save and restore the caller’s value. Note that a regular `SET` command overrides any surrounding function's `SET` option; its effects persist unless rolled back.

If you create a cursor with the `DECLARE` command in a transaction, you cannot use the `SET` command in the transaction until you close the cursor with the `CLOSE` command.

See `Server Configuration Parameters` for information about server parameters.

**Parameters**

- **SESSION**

  Specifies that the command takes effect for the current session. This is the default.

- **LOCAL**

  Specifies that the command takes effect for only the current transaction. After `COMMIT` or `ROLLBACK`, the session-level setting takes effect again. Note that `SET LOCAL` will appear to have no effect if it is executed outside of a transaction.

- **configuration_parameter**

  The name of a Greenplum Database configuration parameter. Only parameters classified as `session` can be changed with `SET`. See `Server Configuration Parameters` for details.

- **value**

  New value of parameter. Values can be specified as string constants, identifiers, numbers, or comma-separated lists of these. `DEFAULT` can be used to specify resetting the parameter to its default value. If specifying memory sizing or time units, enclose the value in single quotes.

- **TIME_ZONE**

  The effects of `SET LOCAL` last only till the end of the current transaction, whether committed or not. A special case is `SET` followed by `SET LOCAL` within a single transaction: the `SET LOCAL` value will be seen until the end of the transaction, but afterwards (if the transaction is committed) the `SET` value will take effect.
SET TIME ZONE value is an alias for SET timezone TO value. The syntax SET TIME ZONE allows special syntax for the time zone specification. Here are examples of valid values:

'PST8PDT'
'Europe/Rome'

-7 (time zone 7 hours west from UTC)
INTERVAL '-08:00' HOUR TO MINUTE (time zone 8 hours west from UTC).

LOCAL DEFAULT

Set the time zone to your local time zone (that is, server's default value of timezone). See the Time zone section of the PostgreSQL documentation for more information about time zones in Greenplum Database.

Examples

Set the schema search path:

```
SET search_path TO my_schema, public;
```

Increase the segment host memory per query to 200 MB:

```
SET statement_mem TO '200MB';
```

Set the style of date to traditional POSTGRES with "day before month" input convention:

```
SET datestyle TO postgres, dmy;
```

Set the time zone for San Mateo, California (Pacific Time):

```
SET TIME ZONE 'PST8PDT';
```

Set the time zone for Italy:

```
SET TIME ZONE 'Europe/Rome';
```

Compatibility

SET TIME ZONE extends syntax defined in the SQL standard. The standard allows only numeric time zone offsets while Greenplum Database allows more flexible time-zone specifications. All other SET features are Greenplum Database extensions.

RESET, SHOW

SET CONSTRAINTS

Sets constraint check timing for the current transaction.

**Note:** Referential integrity syntax (foreign key constraints) is accepted but not enforced.

Synopsis

```
SET CONSTRAINTS { ALL | name [, ...] } { DEFERRED | IMMEDIATE }
```
Description

SET CONSTRAINTS sets the behavior of constraint checking within the current transaction. IMMEDIATE constraints are checked at the end of each statement. DEFERRED constraints are not checked until transaction commit. Each constraint has its own IMMEDIATE or DEFERRED mode.

Upon creation, a constraint is given one of three characteristics: DEFERRABLE INITIALLY DEFERRED, DEFERRABLE INITIALLY IMMEDIATE, or NOT DEFERRABLE. The third class is always IMMEDIATE and is not affected by the SET CONSTRAINTS command. The first two classes start every transaction in the indicated mode, but their behavior can be changed within a transaction by SET CONSTRAINTS.

SET CONSTRAINTS with a list of constraint names changes the mode of just those constraints (which must all be deferrable). Each constraint name can be schema-qualified. The current schema search path is used to find the first matching name if no schema name is specified. SET CONSTRAINTS ALL changes the mode of all deferrable constraints.

When SET CONSTRAINTS changes the mode of a constraint from DEFERRED to IMMEDIATE, the new mode takes effect retroactively: any outstanding data modifications that would have been checked at the end of the transaction are instead checked during the execution of the SET CONSTRAINTS command. If any such constraint is violated, the SET CONSTRAINTS fails (and does not change the constraint mode). Thus, SET CONSTRAINTS can be used to force checking of constraints to occur at a specific point in a transaction.

Currently, only UNIQUE, PRIMARY KEY, REFERENCES (foreign key), and EXCLUDE constraints are affected by this setting. NOT NULL and CHECK constraints are always checked immediately when a row is inserted or modified (not at the end of the statement). Uniqueness and exclusion constraints that have not been declared DEFERRABLE are also checked immediately.

The firing of triggers that are declared as "constraint triggers" is also controlled by this setting — they fire at the same time that the associated constraint should be checked.

Notes

Because Greenplum Database does not require constraint names to be unique within a schema (but only per-table), it is possible that there is more than one match for a specified constraint name. In this case SET CONSTRAINTS will act on all matches. For a non-schema-qualified name, once a match or matches have been found in some schema in the search path, schemas appearing later in the path are not searched.

This command only alters the behavior of constraints within the current transaction. Issuing this outside of a transaction block emits a warning and otherwise has no effect.

Compatibility

This command complies with the behavior defined in the SQL standard, except for the limitation that, in Greenplum Database, it does not apply to NOT NULL and CHECK constraints. Also, Greenplum Database checks non-deferrable uniqueness constraints immediately, not at end of statement as the standard would suggest.

SET ROLE

Sets the current role identifier of the current session.

Synopsis

<table>
<thead>
<tr>

</table>
Description
This command sets the current role identifier of the current SQL-session context to be `rolename`. The role name may be written as either an identifier or a string literal. After `SET ROLE`, permissions checking for SQL commands is carried out as though the named role were the one that had logged in originally.

The specified `rolename` must be a role that the current session user is a member of. If the session user is a superuser, any role can be selected.

The `NONE` and `RESET` forms reset the current role identifier to be the current session role identifier. These forms may be executed by any user.

Parameters

```
SESSION
```

Specifies that the command takes effect for the current session. This is the default.

```
LOCAL
```

Specifies that the command takes effect for only the current transaction. After `COMMIT` or `ROLLBACK`, the session-level setting takes effect again. Note that `SET LOCAL` will appear to have no effect if it is executed outside of a transaction.

```
rolename
```

The name of a role to use for permissions checking in this session.

```
NONE
```

Reset the current role identifier to be the current session role identifier (that of the role used to log in).

```
RESET
```

Reset the current role identifier to be the current session role identifier (that of the role used to log in).

Notes

Using this command, it is possible to either add privileges or restrict privileges. If the session user role has the `INHERITS` attribute, then it automatically has all the privileges of every role that it could `SET ROLE` to; in this case `SET ROLE` effectively drops all the privileges assigned directly to the session user and to the other roles it is a member of, leaving only the privileges available to the named role. On the other hand, if the session user role has the `NOINHERITS` attribute, `SET ROLE` drops the privileges assigned directly to the session user and instead acquires the privileges available to the named role.

In particular, when a superuser chooses to `SET ROLE` to a non-superuser role, she loses her superuser privileges.

`SET ROLE` has effects comparable to `SET SESSION AUTHORIZATION`, but the privilege checks involved are quite different. Also, `SET SESSION AUTHORIZATION` determines which roles are allowable for later `SET ROLE` commands, whereas changing roles with `SET ROLE` does not change the set of roles allowed to a later `SET ROLE`.

`SET ROLE` does not process session variables specified by the role's `ALTER ROLE` settings; the session variables are only processed during login.

Examples

```
SELECT SESSION_USER, CURRENT_USER;
session_user | current_user
--------------+--------------
peter        | peter

SET ROLE 'paul';

SELECT SESSION_USER, CURRENT_USER;
session_user | current_user
--------------+--------------
```
Compatibility
Greenplum Database allows identifier syntax (*rolename*), while the SQL standard requires the role name to be written as a string literal. SQL does not allow this command during a transaction; Greenplum Database does not make this restriction. The `SESSION` and `LOCAL` modifiers are a Greenplum Database extension, as is the `RESET` syntax.

See Also

*SET SESSION AUTHORIZATION*

**SET SESSION AUTHORIZATION**
Sets the session role identifier and the current role identifier of the current session.

Synopsis

```
SET [SESSION | LOCAL] SESSION AUTHORIZATION *rolename*
SET [SESSION | LOCAL] SESSION AUTHORIZATION DEFAULT
RESET SESSION AUTHORIZATION
```

Description

This command sets the session role identifier and the current role identifier of the current SQL-session context to be *rolename*. The role name may be written as either an identifier or a string literal. Using this command, it is possible, for example, to temporarily become an unprivileged user and later switch back to being a superuser.

The session role identifier is initially set to be the (possibly authenticated) role name provided by the client. The current role identifier is normally equal to the session user identifier, but may change temporarily in the context of `setuid` functions and similar mechanisms; it can also be changed by `SET ROLE`. The current user identifier is relevant for permission checking.

The session user identifier may be changed only if the initial session user (the authenticated user) had the superuser privilege. Otherwise, the command is accepted only if it specifies the authenticated user name.

The `DEFAULT` and `RESET` forms reset the session and current user identifiers to be the originally authenticated user name. These forms may be executed by any user.

Parameters

**SESSION**

- Specifies that the command takes effect for the current session. This is the default.

**LOCAL**

- Specifies that the command takes effect for only the current transaction. After `COMMIT` or `ROLLBACK`, the session-level setting takes effect again. Note that `SET LOCAL` will appear to have no effect if it is executed outside of a transaction.

*rolename*

- The name of the role to assume.

**NONE**

- Reset the session and current role identifiers to be that of the role used to log in.
Examples

```
SELECT SESSION_USER, CURRENT_USER;
+---------+---------+
| session_user | current_user |
|---------+---------|
| peter   | peter   |

SET SESSION AUTHORIZATION 'paul';

SELECT SESSION_USER, CURRENT_USER;
+---------+---------+
| session_user | current_user |
|---------+---------|
| paul   | paul   |
```

Compatibility

The SQL standard allows some other expressions to appear in place of the literal `rolename`, but these options are not important in practice. Greenplum Database allows identifier syntax (`rolename`), which SQL does not. SQL does not allow this command during a transaction; Greenplum Database does not make this restriction. The `SESSION` and `LOCAL` modifiers are a Greenplum Database extension, as is the `RESET` syntax.

- `SET ROLE`
- `SET TRANSACTION`

**SET TRANSACTION**

Sets the characteristics of the current transaction.

**Synopsis**

```
SET TRANSACTION [transaction_mode] [READ ONLY | READ WRITE]
SET TRANSACTION SNAPSHOT snapshot_id
SET SESSION CHARACTERISTICS AS TRANSACTION transaction_mode
[READ ONLY | READ WRITE]
[NOT] DEFERRABLE
```

where `transaction_mode` is one of:

```
ISOLATION LEVEL (SERIALIZABLE | REPEATABLE READ | READ COMMITTED | READ UNCOMMITTED)
```

**Description**

The `SET TRANSACTION` command sets the characteristics of the current transaction. It has no effect on any subsequent transactions.

The available transaction characteristics are the transaction isolation level, the transaction access mode (read/write or read-only), and the deferrable mode.

**Note:** Deferrable transactions require the transaction to be serializable. Greenplum Database does not support serializable transactions, so including the `DEFERRABLE` clause has no effect.

Greenplum Database does not support the `SET TRANSACTION SNAPSHOT` command.

The isolation level of a transaction determines what data the transaction can see when other transactions are running concurrently.
- **READ COMMITTED** — A statement can only see rows committed before it began. This is the default.
- **REPEATABLE READ** — All statements in the current transaction can only see rows committed before the first query or data-modification statement executed in the transaction.

The SQL standard defines two additional levels, **READ UNCOMMITTED** and **SERIALIZABLE**. In Greenplum Database **READ UNCOMMITTED** is treated as **READ COMMITTED**. If you specify **SERIALIZABLE**, Greenplum Database falls back to **REPEATABLE READ**.

The transaction isolation level cannot be changed after the first query or data-modification statement (SELECT, INSERT, DELETE, UPDATE, FETCH, or COPY) of a transaction has been executed.

The transaction access mode determines whether the transaction is read/write or read-only. Read/write is the default. When a transaction is read-only, the following SQL commands are disallowed: INSERT, UPDATE, DELETE, and COPY FROM if the table they would write to is not a temporary table; all CREATE, ALTER, and DROP commands; GRANT, REVOKE, TRUNCATE; and EXPLAIN ANALYZE and EXECUTE if the command they would execute is among those listed. This is a high-level notion of read-only that does not prevent all writes to disk.

The **DEFERRABLE** transaction property has no effect unless the transaction is also **SERIALIZABLE** and **READ ONLY**. When all of these properties are set on a transaction, the transaction may block when first acquiring its snapshot, after which it is able to run without the normal overhead of a **SERIALIZABLE** transaction and without any risk of contributing to or being cancelled by a serialization failure. Because Greenplum Database does not support serializable transactions, the **DEFERRABLE** transaction property has no effect in Greenplum Database.

**Parameters**

**SESSION CHARACTERISTICS**

Sets the default transaction characteristics for subsequent transactions of a session.

- **READ UNCOMMITTED**
- **READ COMMITTED**
- **REPEATABLE READ**
- **SERIALIZABLE**

The SQL standard defines four transaction isolation levels: **READ UNCOMMITTED**, **READ COMMITTED**, **REPEATABLE READ**, and **SERIALIZABLE**.

**READ UNCOMMITTED** allows transactions to see changes made by uncommitted concurrent transactions. This is not possible in Greenplum Database, so **READ UNCOMMITTED** is treated the same as **READ COMMITTED**.

**READ COMMITTED**, the default isolation level in Greenplum Database, guarantees that a statement can only see rows committed before it began. The same statement executed twice in a transaction can produce different results if another concurrent transaction commits after the statement is executed the first time.

The **REPEATABLE READ** isolation level guarantees that a transaction can only see rows committed before it began. **REPEATABLE READ** is the strictest transaction isolation level Greenplum Database supports. Applications that use the **REPEATABLE READ** isolation level must be prepared to retry transactions due to serialization failures.

The **SERIALIZABLE** transaction isolation level guarantees that all statements of the current transaction can only see rows committed before the first query or data-modification statement was executed in this transaction. If a pattern of reads and writes among concurrent serializable transactions would create a situation which could not have occurred for any serial (one-at-a-time) execution of those transactions, one of the transactions will be rolled back with a **serialization_failure** error. Greenplum Database does not fully support **SERIALIZABLE** as defined by the standard, so if you specify **SERIALIZABLE**, Greenplum Database falls back to **REPEATABLE READ**. See **Compatibility** for more information about transaction serializability in Greenplum Database.

**READ WRITE**
**READ ONLY**

Determines whether the transaction is read/write or read-only. Read/write is the default. When a transaction is read-only, the following SQL commands are disallowed: `INSERT`, `UPDATE`, `DELETE`, and `COPY FROM` if the table they would write to is not a temporary table; all `CREATE`, `ALTER`, and `DROP` commands; `GRANT`, `REVOKE`, `TRUNCATE`; and `EXPLAIN`, `ANALYZE`, and `EXECUTE` if the command they would execute is among those listed.

**[NOT] DEFERRABLE**

The `DEFERRABLE` transaction property has no effect in Greenplum Database because `SERIALIZABLE` transactions are not supported. If `DEFERRABLE` is specified and the transaction is also `SERIALIZABLE` and `READ ONLY`, the transaction may block when first acquiring its snapshot, after which it is able to run without the normal overhead of a `SERIALIZABLE` transaction and without any risk of contributing to or being cancelled by a serialization failure. This mode is well suited for long-running reports or backups.

**Notes**

If `SET TRANSACTION` is executed without a prior `START TRANSACTION` or `BEGIN`, a warning is issued and the command has no effect.

It is possible to dispense with `SET TRANSACTION` by instead specifying the desired transaction modes in `BEGIN` or `START TRANSACTION`.

The session default transaction modes can also be set by setting the configuration parameters `default_transaction_isolation`, `default_transaction_read_only`, and `default_transaction_deferrable`.

**Examples**

Set the transaction isolation level for the current transaction:

```
BEGIN;
SET TRANSACTION ISOLATION LEVEL REPEATABLE READ;
```

**Compatibility**

Both commands are defined in the SQL standard. `SERIALIZABLE` is the default transaction isolation level in the standard. In Greenplum Database the default is `READ COMMITTED`. Due to lack of predicate locking, Greenplum Database does not fully support the `SERIALIZABLE` level, so it falls back to the `REPEATABLE READ` level when `SERIAL` is specified. Essentially, a predicate-locking system prevents phantom reads by restricting what is written, whereas a multi-version concurrency control model (MVCC) as used in Greenplum Database prevents them by restricting what is read.

PostgreSQL provides a true serializable isolation level, called serializable snapshot isolation (SSI), which monitors concurrent transactions and rolls back transactions that could introduce serialization anomalies. Greenplum Database does not implement this isolation mode.

In the SQL standard, there is one other transaction characteristic that can be set with these commands: the size of the diagnostics area. This concept is specific to embedded SQL, and therefore is not implemented in the Greenplum Database server.

The `DEFERRABLE` transaction mode is a Greenplum Database language extension.

The SQL standard requires commas between successive `transaction_modes`, but for historical reasons Greenplum Database allows the commas to be omitted.

`BEGIN`, `LOCK`
**SHOW**

Shows the value of a system configuration parameter.

**Synopsis**

```
SHOW configuration_parameter
SHOW ALL
```

**Description**

`SHOW` displays the current settings of Greenplum Database system configuration parameters. You can set these parameters with the `SET` statement, or by editing the `postgresql.conf` configuration file of the Greenplum Database master. Note that some parameters viewable by `SHOW` are read-only — their values can be viewed but not set. See the Greenplum Database Reference Guide for details.

**Parameters**

- `configuration_parameter`
  The name of a system configuration parameter.
- `ALL`
  Shows the current value of all configuration parameters.

**Examples**

Show the current setting of the parameter `DateStyle`:

```
SHOW DateStyle;
 DateStyle
 -----------
 ISO, MDY
 (1 row)
```

Show the current setting of the parameter `geqo`:

```
SHOW geqo;
geqo
 ------
 off
 (1 row)
```

Show the current setting of all parameters:

```
SHOW ALL;
 name     | setting | description
------------------------
 application_name | psql     | Sets the application name to be reported in sta...
 .
 .
 xmlbinary        | base64   | Sets how binary values are to be encoded in XML.
 xmloption        | content  | Sets whether XML data in implicit parsing and...
```
Compatibility
SHOW is a Greenplum Database extension.

See Also
SET, RESET

START TRANSACTION
Starts a transaction block.

Synopsis
START TRANSACTION [transaction_mode] [READ WRITE | READ ONLY]

where transaction_mode is:

ISOLATION LEVEL {SERIALIZABLE | READ COMMITTED | READ UNCOMMITTED}

Description
START TRANSACTION begins a new transaction block. If the isolation level or read/write mode is specified, the new transaction has those characteristics, as if SET TRANSACTION was executed. This is the same as the BEGIN command.

Parameters
READ UNCOMMITTED
READ COMMITTED
REPEATABLE READ
SERIALIZABLE

The SQL standard defines four transaction isolation levels: READ UNCOMMITTED, READ COMMITTED, REPEATABLE READ, and SERIALIZABLE.

READ UNCOMMITTED allows transactions to see changes made by uncommitted concurrent transactions. This is not possible in Greenplum Database, so READ UNCOMMITTED is treated the same as READ COMMITTED.

READ COMMITTED, the default isolation level in Greenplum Database, guarantees that a statement can only see rows committed before it began. The same statement executed twice in a transaction can produce different results if another concurrent transaction commits after the statement is executed the first time.

The REPEATABLE READ isolation level guarantees that a transaction can only see rows committed before it began. REPEATABLE READ is the strictest transaction isolation level Greenplum Database supports. Applications that use the REPEATABLE READ isolation level must be prepared to retry transactions due to serialization failures.

The SERIALIZABLE transaction isolation level guarantees that executing multiple concurrent transactions produces the same effects as running the same transactions one at a time. If you specify SERIALIZABLE, Greenplum Database falls back to REPEATABLE READ.

READ WRITE
READ ONLY
Determines whether the transaction is read/write or read-only. Read/write is the default. When a transaction is read-only, the following SQL commands are disallowed: INSERT, UPDATE, DELETE, and COPY FROM if the table they would write to is not a temporary table; all CREATE, ALTER, and DROP commands; GRANT, REVOKE, TRUNCATE; and EXPLAIN ANALYZE and EXECUTE if the command they would execute is among those listed.

Examples
To begin a transaction block:

    START TRANSACTION;

Compatibility
In the standard, it is not necessary to issue START TRANSACTION to start a transaction block: any SQL command implicitly begins a block. Greenplum Database behavior can be seen as implicitly issuing a COMMIT after each command that does not follow START TRANSACTION (or BEGIN), and it is therefore often called 'autocommit'. Other relational database systems may offer an autocommit feature as a convenience.

The SQL standard requires commas between successive transaction_modes, but for historical reasons Greenplum Database allows the commas to be omitted.

See also the compatibility section of SET TRANSACTION.

See Also
BEGIN, SET TRANSACTION

**TRUNCATE**

Empties a table of all rows.

Synopsis

```
TRUNCATE [TABLE] [ONLY] name [ * ] [, ...]
[ RESTART IDENTITY | CONTINUE IDENTITY ] [CASCADE | RESTRICT]
```

Description

TRUNCATE quickly removes all rows from a table or set of tables. It has the same effect as an unqualified DELETE on each table, but since it does not actually scan the tables it is faster. This is most useful on large tables.

You must have the TRUNCATE privilege on the table to truncate table rows.

TRUNCATE acquires an access exclusive lock on the tables it operates on, which blocks all other concurrent operations on the table. When RESTART IDENTITY is specified, any sequences that are to be restarted are likewise locked exclusively. If concurrent access to a table is required, then the DELETE command should be used instead.

Parameters

name

The name (optionally schema-qualified) of a table to truncate. If ONLY is specified before the table name, only that table is truncated. If ONLY is not specified, the table and all its descendant tables (if any) are truncated. Optionally, * can be specified after the table name to explicitly indicate that descendant tables are included.
CASCADE
Because this key word applies to foreign key references (which are not supported in Greenplum Database) it has no effect.

RESTART IDENTITY
Automatically restart sequences owned by columns of the truncated table(s).

CONTINUE IDENTITY
Do not change the values of sequences. This is the default.

RESTRICT
Because this key word applies to foreign key references (which are not supported in Greenplum Database) it has no effect.

Notes
TRUNCATE will not run any user-defined ON DELETE triggers that might exist for the tables.
TRUNCATE will not truncate any tables that inherit from the named table. Only the named table is truncated, not its child tables.
TRUNCATE will not truncate any sub-tables of a partitioned table. If you specify a sub-table of a partitioned table, TRUNCATE will not remove rows from the sub-table and its child tables.
TRUNCATE is not MVCC-safe. After truncation, the table will appear empty to concurrent transactions, if they are using a snapshot taken before the truncation occurred.
TRUNCATE is transaction-safe with respect to the data in the tables: the truncation will be safely rolled back if the surrounding transaction does not commit.
TRUNCATE acquires an ACCESS EXCLUSIVE lock on each table it operates on, which blocks all other concurrent operations on the table. If concurrent access to a table is required, then the DELETE command should be used instead.

When RESTART IDENTITY is specified, the implied ALTER SEQUENCE RESTART operations are also done transactionally; that is, they will be rolled back if the surrounding transaction does not commit. This is unlike the normal behavior of ALTER SEQUENCE RESTART. Be aware that if any additional sequence operations are done on the restarted sequences before the transaction rolls back, the effects of these operations on the sequences will be rolled back, but not their effects on currval(); that is, after the transaction currval() will continue to reflect the last sequence value obtained inside the failed transaction, even though the sequence itself may no longer be consistent with that. This is similar to the usual behavior of currval() after a failed transaction.

Examples
Empty the tables films and distributors:

```
TRUNCATE films, distributors;
```

The same, and also reset any associated sequence generators:

```
TRUNCATE films, distributors RESTART IDENTITY;
```

Compatibility
The SQL:2008 standard includes a TRUNCATE command with the syntax TRUNCATE TABLE tablename. The clauses CONTINUE IDENTITY/RESTART IDENTITY also appear in that standard, but have slightly different though related meanings. Some of the concurrency behavior of this command is left implementation-defined by the standard, so the above notes should be considered and compared with other implementations if necessary.

DELETE, DROP TABLE

UPDATE

Updates rows of a table.

Synopsis

[ WITH [ RECURSIVE ] with_query [, ...] ]
UPDATE [ONLY] table [[AS] alias]
  SET {column = {expression | DEFAULT} |
     (column [, ...]) = (expression | DEFAULT) [, ...]) }
  [FROM fromlist]
  [WHERE condition | WHERE CURRENT OF cursor_name ]

Description

UPDATE changes the values of the specified columns in all rows that satisfy the condition. Only the columns to be modified need be mentioned in the SET clause; columns not explicitly modified retain their previous values.

By default, UPDATE will update rows in the specified table and all its subtables. If you wish to only update the specific table mentioned, you must use the ONLY clause.

There are two ways to modify a table using information contained in other tables in the database: using sub-selects, or specifying additional tables in the FROM clause. Which technique is more appropriate depends on the specific circumstances.

If the WHERE CURRENT OF clause is specified, the row that is updated is the one most recently fetched from the specified cursor.

The WHERE CURRENT OF clause is not supported with replicated tables.

You must have the UPDATE privilege on the table, or at least on the column(s) that are listed to be updated. You must also have the SELECT privilege on any column whose values are read in the expressions or condition.

Note: As the default, Greenplum Database acquires an EXCLUSIVE lock on tables for UPDATE operations on heap tables. When the Global Deadlock Detector is enabled, the lock mode for UPDATE operations on heap tables is ROW EXCLUSIVE. See Global Deadlock Detector.

Outputs

On successful completion, an UPDATE command returns a command tag of the form:

```
UPDATE count
```

where count is the number of rows updated. If count is 0, no rows matched the condition (this is not considered an error).

Parameters

with_query

The WITH clause allows you to specify one or more subqueries that can be referenced by name in the UPDATE query.

For an UPDATE command that includes a WITH clause, the clause can only contain SELECT commands, the WITH clause cannot contain a data-modifying command (INSERT, UPDATE, or DELETE).
It is possible for the query (SELECT statement) to also contain a WITH clause. In such a case both sets of WITH_query can be referenced within the UPDATE query, but the second one takes precedence since it is more closely nested.

See WITH Queries (Common Table Expressions) and SELECT for details.

**ONLY**

If specified, update rows from the named table only. When not specified, any tables inheriting from the named table are also processed.

**table**

The name (optionally schema-qualified) of an existing table.

**alias**

A substitute name for the target table. When an alias is provided, it completely hides the actual name of the table. For example, given `UPDATE foo AS f`, the remainder of the UPDATE statement must refer to this table as f not foo.

**column**

The name of a column in table. The column name can be qualified with a subfield name or array subscript, if needed. Do not include the table's name in the specification of a target column.

**expression**

An expression to assign to the column. The expression may use the old values of this and other columns in the table.

**DEFAULT**

Set the column to its default value (which will be NULL if no specific default expression has been assigned to it).

**fromlist**

A list of table expressions, allowing columns from other tables to appear in the WHERE condition and the update expressions. This is similar to the list of tables that can be specified in the FROM clause of a SELECT statement. Note that the target table must not appear in the fromlist, unless you intend a self-join (in which case it must appear with an alias in the fromlist).

**condition**

An expression that returns a value of type boolean. Only rows for which this expression returns true will be updated.

**cursor_name**

The name of the cursor to use in a WHERE CURRENT OF condition. The row to be updated is the one most recently fetched from the cursor. The cursor must be a non-grouping query on the UPDATE command target table. See DECLARE for more information about creating cursors.

WHERE CURRENT OF cannot be specified together with a Boolean condition.

Note that WHERE CURRENT OF cannot be specified together with a Boolean condition. The UPDATE...WHERE CURRENT OF statement can only be executed on the server, for example in an interactive psql session or a script. Language extensions such as PL/pgSQL do not have support for updatable cursors.

See DECLARE for more information about creating cursors.

**output_expression**

An expression to be computed and returned by the UPDATE command after each row is updated. The expression may use any column names of the table or table(s) listed in FROM. Write * to return all columns.
**output_name**

A name to use for a returned column.

**Notes**

*SET* is not allowed on the Greenplum distribution key columns of a table.

When a *FROM* clause is present, what essentially happens is that the target table is joined to the tables mentioned in the from list, and each output row of the join represents an update operation for the target table. When using *FROM* you should ensure that the join produces at most one output row for each row to be modified. In other words, a target row should not join to more than one row from the other table(s). If it does, then only one of the join rows will be used to update the target row, but which one will be used is not readily predictable.

Because of this indeterminacy, referencing other tables only within sub-selects is safer, though often harder to read and slower than using a join.

Executing *UPDATE* and *DELETE* commands directly on a specific partition (child table) of a partitioned table is not supported. Instead, execute these commands on the root partitioned table, the table created with the *CREATE TABLE* command.

For a partitioned table, all the child tables are locked during the *UPDATE* operation when the Global Deadlock Detector is not enabled (the default). Only some of the leaf child tables are locked when the Global Deadlock Detector is enabled. For information about the Global Deadlock Detector, see *Global Deadlock Detector*.

**Examples**

Change the word *Drama* to *Dramatic* in the column *kind* of the table *films*:

```sql
UPDATE films SET kind = 'Dramatic' WHERE kind = 'Drama';
```

Adjust temperature entries and reset precipitation to its default value in one row of the table *weather*:

```sql
UPDATE weather SET temp_lo = temp_lo+1, temp_hi = temp_lo+15, prcp = DEFAULT
WHERE city = 'San Francisco' AND date = '2016-07-03';
```

Use the alternative column-list syntax to do the same update:

```sql
UPDATE weather SET (temp_lo, temp_hi, prcp) = (temp_lo+1, temp_lo+15, DEFAULT)
WHERE city = 'San Francisco' AND date = '2016-07-03';
```

Increment the sales count of the salesperson who manages the account for Acme Corporation, using the *FROM* clause syntax (assuming both tables being joined are distributed in Greenplum Database on the *id* column):

```sql
UPDATE employees SET sales_count = sales_count + 1 FROM accounts
WHERE accounts.name = 'Acme Corporation'
AND employees.id = accounts.id;
```

Perform the same operation, using a sub-select in the *WHERE* clause:

```sql
UPDATE employees SET sales_count = sales_count + 1 WHERE id =
(SELECT id FROM accounts WHERE name = 'Acme Corporation');
```
Attempt to insert a new stock item along with the quantity of stock. If the item already exists, instead update the stock count of the existing item. To do this without failing the entire transaction, use savepoints.

BEGIN;
-- other operations
SAVEPOINT sp1;
INSERT INTO wines VALUES('Chateau Lafite 2003', '24');
-- Assume the above fails because of a unique key violation,
-- so now we issue these commands:
ROLLBACK TO sp1;
UPDATE wines SET stock = stock + 24 WHERE winename = 'Chateau Lafite 2003';
-- continue with other operations, and eventually
COMMIT;

Compatibility

This command conforms to the SQL standard, except that the FROM clause is a Greenplum Database extension.

According to the standard, the column-list syntax should allow a list of columns to be assigned from a single row-valued expression, such as a sub-select:

UPDATE accounts SET (contact_last_name, contact_first_name) =
(SELECT last_name, first_name FROM salesmen
WHERE salesmen.id = accounts.sales_id);

This is not currently implemented — the source must be a list of independent expressions.

Some other database systems offer a FROM option in which the target table is supposed to be listed again within FROM. That is not how Greenplum Database interprets FROM. Be careful when porting applications that use this extension.

DECLARE, DELETE, SELECT, INSERT

VACUUM

Garbage-collects and optionally analyzes a database.

Synopsis

VACUUM [(( FULL | FREEZE | VERBOSE | ANALYZE ) [, ...]) [table [((column [, ... ] )]]]
VACUUM [FULL] [FREEZE] [VERBOSE] [table]
VACUUM [FULL] [FREEZE] [VERBOSE] ANALYZE [table [((column [, ... ] )]]]

Description

VACUUM reclaims storage occupied by deleted tuples. In normal Greenplum Database operation, tuples that are deleted or obsoleted by an update are not physically removed from their table; they remain present on disk until a VACUUM is done. Therefore it is necessary to do VACUUM periodically, especially on frequently-updated tables.
With no parameter, `VACUUM` processes every table in the current database. With a parameter, `VACUUM` processes only that table.

`VACUUM ANALYZE` performs a `VACUUM` and then an `ANALYZE` for each selected table. This is a handy combination form for routine maintenance scripts. See `ANALYZE` for more details about its processing.

`VACUUM` (without `FULL`) marks deleted and obsoleted data in tables and indexes for future reuse and reclaims space for re-use only if the space is at the end of the table and an exclusive table lock can be easily obtained. Unused space at the start or middle of a table remains as is. With heap tables, this form of the command can operate in parallel with normal reading and writing of the table, as an exclusive lock is not obtained. However, extra space is not returned to the operating system (in most cases); it's just kept available for re-use within the same table. `VACUUM FULL` rewrites the entire contents of the table into a new disk file with no extra space, allowing unused space to be returned to the operating system. This form is much slower and requires an exclusive lock on each table while it is being processed.

With append-optimized tables, `VACUUM` compacts a table by first vacuuming the indexes, then compacting each segment file in turn, and finally vacuuming auxiliary relations and updating statistics. On each segment, visible rows are copied from the current segment file to a new segment file, and then the current segment file is scheduled to be dropped and the new segment file is made available. Plain `VACUUM` of an append-optimized table allows scans, inserts, deletes, and updates of the table while a segment file is compacted. However, an Access Exclusive lock is taken briefly to drop the current segment file and activate the new segment file.

`VACUUM FULL` does more extensive processing, including moving of tuples across blocks to try to compact the table to the minimum number of disk blocks. This form is much slower and requires an Access Exclusive lock on each table while it is being processed. The Access Exclusive lock guarantees that the holder is the only transaction accessing the table in any way.

When the option list is surrounded by parentheses, the options can be written in any order. Without parentheses, options must be specified in exactly the order shown above. The parenthesized syntax was added in Greenplum Database 6.0; the unparenthesized syntax is deprecated.

**Important:** For information on the use of `VACUUM`, `VACUUM FULL`, and `VACUUM ANALYZE`, see `Notes`.

**Outputs**

When `VERBOSE` is specified, `VACUUM` emits progress messages to indicate which table is currently being processed. Various statistics about the tables are printed as well.

**Parameters**

`FULL`

Selects a full vacuum, which may reclaim more space, but takes much longer and exclusively locks the table. This method also requires extra disk space, since it writes a new copy of the table and doesn't release the old copy until the operation is complete. Usually this should only be used when a significant amount of space needs to be reclaimed from within the table.

`FREEZE`

Specifying `FREEZE` is equivalent to performing `VACUUM` with the `vacuum_freeze_min_age` server configuration parameter set to zero. See `Server Configuration Parameters` for information about `vacuum_freeze_min_age`.

`VERBOSE`

Prints a detailed vacuum activity report for each table.

`ANALYZE`

Updates statistics used by the planner to determine the most efficient way to execute a query.

`table`
The name (optionally schema-qualified) of a specific table to vacuum. Defaults to all tables in the current database.

`column`

The name of a specific column to analyze. Defaults to all columns. If a column list is specified, `ANALYZE` is implied.

**Notes**

`VACUUM` cannot be executed inside a transaction block.

Vacuum active databases frequently (at least nightly), in order to remove expired rows. After adding or deleting a large number of rows, running the `VACUUM` command with `ANALYZE` for the affected table might be useful. This updates the system catalogs with the results of all recent changes, and allows the Greenplum Database query optimizer to make better choices in planning queries.

**Important:** PostgreSQL has a separate optional server process called the *autovacuum daemon*, whose purpose is to automate the execution of `VACUUM` and `ANALYZE` commands. Greenplum Database enables the autovacuum daemon to perform `VACUUM` operations only on the Greenplum Database template database `template0`. Autovacuum is enabled for `template0` because connections are not allowed to `template0`. The autovacuum daemon performs `VACUUM` operations on `template0` to manage transaction IDs (XIDs) and help avoid transaction ID wraparound issues in `template0`.

Manual `VACUUM` operations must be performed in user-defined databases to manage transaction IDs (XIDs) in those databases.

`VACUUM` causes a substantial increase in I/O traffic, which can cause poor performance for other active sessions. Therefore, it is advisable to vacuum the database at low usage times.

`VACUUM` commands skip external and foreign tables.

`VACUUM FULL` reclaims all expired row space, however it requires an exclusive lock on each table being processed, is a very expensive operation, and might take a long time to complete on large, distributed Greenplum Database tables. Perform `VACUUM FULL` operations during database maintenance periods.

The `FULL` option is not recommended for routine use, but might be useful in special cases. An example is when you have deleted or updated most of the rows in a table and would like the table to physically shrink to occupy less disk space and allow faster table scans. `VACUUM FULL` will usually shrink the table more than a plain `VACUUM` would.

As an alternative to `VACUUM FULL`, you can re-create the table with a `CREATE TABLE AS` statement and drop the old table.

For append-optimized tables, `VACUUM` requires enough available disk space to accommodate the new segment file during the `VACUUM` process. If the ratio of hidden rows to total rows in a segment file is less than a threshold value (10, by default), the segment file is not compacted. The threshold value can be configured with the `gp_appendonly_compaction_threshold` server configuration parameter. `VACUUM FULL` ignores the threshold and rewrites the segment file regardless of the ratio. `VACUUM` can be disabled for append-optimized tables using the `gp_appendonly_compaction` server configuration parameter. See [Server Configuration Parameters](#) for information about the server configuration parameters.

If a concurrent serializable transaction is detected when an append-optimized table is being vacuumed, the current and subsequent segment files are not compacted. If a segment file has been compacted but a concurrent serializable transaction is detected in the transaction that drops the original segment file, the drop is skipped. This could leave one or two segment files in an "awaiting drop" state after the vacuum has completed.

For more information about concurrency control in Greenplum Database, see “Routine System Maintenance Tasks” in *Greenplum Database Administrator Guide*. 
**Examples**

To clean a single table `onek`, analyze it for the optimizer and print a detailed vacuum activity report:

```
VACUUM (VERBOSE, ANALYZE) onek;
```

Vacuum all tables in the current database:

```
VACUUM;
```

Vacuum a specific table only:

```
VACUUM (VERBOSE, ANALYZE) mytable;
```

Vacuum all tables in the current database and collect statistics for the query optimizer:

```
VACUUM ANALYZE;
```

**Compatibility**

There is no `VACUUM` statement in the SQL standard.

**See Also**

`ANALYZE`

**VALUES**

Computes a set of rows.

**Synopsis**

```
VALUES ( expression [, ...] ) [, ...] 
  [ORDER BY sort_expression [ ASC | DESC | USING operator ] [, ...] ] 
  [LIMIT { count | ALL } ] 
  [OFFSET start [ ROW | ROWS ] ] 
  [FETCH { FIRST | NEXT } [count ] { ROW | ROWS } ONLY ]
```

**Description**

`VALUES` computes a row value or set of row values specified by value expressions. It is most commonly used to generate a "constant table" within a larger command, but it can be used on its own.

When more than one row is specified, all the rows must have the same number of elements. The data types of the resulting table’s columns are determined by combining the explicit or inferred types of the expressions appearing in that column, using the same rules as for `UNION`.

Within larger commands, `VALUES` is syntactically allowed anywhere that `SELECT` is. Because it is treated like a `SELECT` by the grammar, it is possible to use the `ORDER BY`, `LIMIT` (or equivalent `FETCH FIRST`), and `OFFSET` clauses with a `VALUES` command.

**Parameters**

`expression`

A constant or expression to compute and insert at the indicated place in the resulting table (set of rows). In a `VALUES` list appearing at the top level of an `INSERT`, an expression can be replaced by `DEFAULT` to indicate that the destination column’s default value should be inserted. `DEFAULT` cannot be used when `VALUES` appears in other contexts.
**sort_expression**

An expression or integer constant indicating how to sort the result rows. This expression may refer to the columns of the VALUES result as `column1`, `column2`, etc. For more details, see "The ORDER BY Clause" in the parameters for `SELECT`.

**operator**

A sorting operator. For more details, see "The ORDER BY Clause" in the parameters for `SELECT`.

**LIMIT count**

**OFFSET start**

The maximum number of rows to return. For more details, see “The LIMIT Clause” in the parameters for `SELECT`.

**Notes**

VALUES lists with very large numbers of rows should be avoided, as you may encounter out-of-memory failures or poor performance. VALUES appearing within INSERT is a special case (because the desired column types are known from the INSERT's target table, and need not be inferred by scanning the VALUES list), so it can handle larger lists than are practical in other contexts.

**Examples**

A bare VALUES command:

```sql
VALUES (1, 'one'), (2, 'two'), (3, 'three');
```

This will return a table of two columns and three rows. It is effectively equivalent to:

```sql
SELECT 1 AS column1, 'one' AS column2
UNION ALL
SELECT 2, 'two'
UNION ALL
SELECT 3, 'three';
```

More usually, VALUES is used within a larger SQL command. The most common use is in INSERT:

```sql
INSERT INTO films (code, title, did, date_prod, kind)
VALUES ('T_601', 'Yojimbo', 106, '1961-06-16', 'Drama');
```

In the context of INSERT, entries of a VALUES list can be `DEFAULT` to indicate that the column default should be used here instead of specifying a value:

```sql
INSERT INTO films VALUES
('UA502', 'Bananas', 105, DEFAULT, 'Comedy', '82 minutes'),
('T_601', 'Yojimbo', 106, DEFAULT, 'Drama', DEFAULT);
```

VALUES can also be used where a sub-SELECT might be written, for example in a FROM clause:

```sql
SELECT f.* FROM films f, (VALUES('MGM', 'Horror'), ('UA', 'Sci-Fi')) AS t (studio, kind) WHERE f.studio = t.studio AND f.kind = t.kind;
UPDATE employees SET salary = salary * v.increase FROM (VALUES(1, 200000, 1.2), (2, 400000, 1.4)) AS v (depno, target, increase) WHERE employees.depno = v.depno AND employees.sales >= v.target;
```
Note that an `AS` clause is required when `VALUES` is used in a `FROM` clause, just as is true for `SELECT`. It is not required that the `AS` clause specify names for all the columns, but it is good practice to do so. The default column names for `VALUES` are `column1`, `column2`, etc. in Greenplum Database, but these names might be different in other database systems.

When `VALUES` is used in `INSERT`, the values are all automatically coerced to the data type of the corresponding destination column. When it is used in other contexts, it may be necessary to specify the correct data type. If the entries are all quoted literal constants, coercing the first is sufficient to determine the assumed type for all:

```sql
SELECT * FROM machines WHERE ip_address IN
  (VALUES('192.168.0.1'::inet), ('192.168.0.10'),
   ('192.0.2.43'));
```

**Note:** For simple `IN` tests, it is better to rely on the list-of-scalars form of `IN` than to write a `VALUES` query as shown above. The list of scalars method requires less writing and is often more efficient.

**Compatibility**

`VALUES` conforms to the SQL standard. `LIMIT` and `OFFSET` are Greenplum Database extensions; see also under `SELECT`.

`INSERT`, `SELECT`
Data Types

Greenplum Database has a rich set of native data types available to users. Users may also define new data types using the `CREATE TYPE` command. This reference shows all of the built-in data types. In addition to the types listed here, there are also some internally used data types, such as `oid` (object identifier), but those are not documented in this guide.

Additional modules that you register may also install new data types. The `hstore` module, for example, introduces a new data type and associated functions for working with key-value pairs. See `hstore`. The `citext` module adds a case-insensitive text data type. See `citext`.

The following data types are specified by SQL: `bit`, `bit varying`, `boolean`, `character varying`, `varchar`, `character`, `char`, `date`, `double precision`, `integer`, `interval`, `numeric`, `decimal`, `real`, `smallint`, `time` (with or without time zone), and `timestamp` (with or without time zone).

Each data type has an external representation determined by its input and output functions. Many of the built-in types have obvious external formats. However, several types are either unique to PostgreSQL (and Greenplum Database), such as geometric paths, or have several possibilities for formats, such as the date and time types. Some of the input and output functions are not invertible. That is, the result of an output function may lose accuracy when compared to the original input.

### Table 84: Greenplum Database Built-in Data Types

<table>
<thead>
<tr>
<th>Name</th>
<th>Alias</th>
<th>Size</th>
<th>Range</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>bigint</td>

</table>

**Date/Time Types**

Greenplum supports the full set of SQL date and time types, shown in Table 85: Date/Time Types. The operations available on these data types are described in Date/Time Functions and Operators in the PostgreSQL documentation. Dates are counted according to the Gregorian calendar, even in years before that calendar was introduced (see History of Units in the PostgreSQL documentation for more information).

**Table 85: Date/Time Types**

<table>
<thead>

<td>time interval</td>
<td>-178000000 years</td>
<td>178000000 years</td>
<td>1 microsecond / 14 digits</td>
</tr>
</tbody>
</table>

**Note:** The SQL standard requires that writing just `timestamp` be equivalent to `timestamp` without time zone, and Greenplum honors that behavior. `timestamptz` is accepted as an abbreviation for `timestamp` with time zone; this is a PostgreSQL extension.

`time`, `timestamp`, and `interval` accept an optional precision value `p` which specifies the number of fractional digits retained in the seconds field. By default, there is no explicit bound on precision. The allowed range of `p` is from 0 to 6 for the `timestamp` and `interval` types.

**Note:** When `timestamp` values are stored as eight-byte integers (currently the default), microsecond precision is available over the full range of values. When `timestamp` values are stored as double precision floating-point numbers instead (a deprecated compile-time option), the effective limit of precision might be less than 6. `timestamp` values are stored as seconds before or after midnight 2000-01-01. When `timestamp` values are implemented using floating-point numbers, microsecond precision is achieved for dates within a few years of 2000-01-01, but the precision degrades for dates further away. Note that using floating-point datetimes allows a larger range of `timestamp` values to be represented than shown above: from 4713 BC up to 5874897 AD.

The same compile-time option also determines whether `time` and `interval` values are stored as floating-point numbers or eight-byte integers. In the floating-point case, large `interval` values degrade in precision as the size of the interval increases.

For the `time` types, the allowed range of `p` is from 0 to 6 when eight-byte integer storage is used, or from 0 to 10 when floating-point storage is used.

The `interval` type has an additional option, which is to restrict the set of stored fields by writing one of these phrases:

YEAR
MONTH
DAY
HOUR
MINUTE
SECOND
YEAR TO MONTH
DAY TO HOUR
DAY TO MINUTE
DAY TO SECOND
HOUR TO MINUTE
HOUR TO SECOND
MINUTE TO SECOND

Note that if both fields and \( p \) are specified, the fields must include SECOND, since the precision applies only to the seconds.

The type time with time zone is defined by the SQL standard, but the definition exhibits properties which lead to questionable usefulness. In most cases, a combination of date, time, timestamp without time zone, and timestamp with time zone should provide a complete range of date/time functionality required by any application.

The types abstime and reltime are lower precision types which are used internally. You are discouraged from using these types in applications; these internal types might disappear in a future release.

Greenplum Database 6 and later releases do not automatically cast text from the deprecated timestamp format YYYYMMDDHH24MISS. The format could not be parsed unambiguously in previous Greenplum Database releases.

For example, this command returns an error in Greenplum Database 6. In previous releases, a timestamp is returned.

```sql
# select to_timestamp('20190905140000');
```

In Greenplum Database 6, this command returns a timestamp.

```sql
# select to_timestamp('20190905140000','YYYYMMDDHH24MISS');
```

Date/Time Input

Date and time input is accepted in almost any reasonable format, including ISO 8601, SQL-compatible, traditional POSTGRES, and others. For some formats, ordering of day, month, and year in date input is ambiguous and there is support for specifying the expected ordering of these fields. Set the DateStyle parameter to MDY to select month-day-year interpretation, DMY to select day-month-year interpretation, or YMD to select year-month-day interpretation.

Greenplum is more flexible in handling date/time input than the SQL standard requires. See Appendix B. Date/Time Support in the PostgreSQL documentation for the exact parsing rules of date/time input and for the recognized text fields including months, days of the week, and time zones.

Remember that any date or time literal input needs to be enclosed in single quotes, like text strings. SQL requires the following syntax

```
type [ (p) ] 'value'
```

where \( p \) is an optional precision specification giving the number of fractional digits in the seconds field. Precision can be specified for time, timestamp, and interval types. The allowed values are mentioned above. If no precision is specified in a constant specification, it defaults to the precision of the literal value.

Dates

Table 86: Date Input shows some possible inputs for the date type.

### Table 86: Date Input

<table>
<thead>
<tr>
<th>Example</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1999-01-08</td>
<td>ISO 8601; January 8 in any mode (recommended format)</td>
</tr>
</tbody>
</table>
Times

The time-of-day types are `time [ (p) ] without time zone` and `time [ (p) ] with time zone`. `time` alone is equivalent to `time` without time zone.

Valid input for these types consists of a time of day followed by an optional time zone. (See Table 87: Time Input and Table 88: Time Zone Input.) If a time zone is specified in the input for `time` without time zone, it is silently ignored. You can also specify a date but it will be ignored, except when you use a time zone name that involves a daylight-savings rule, such as `America/New_York`. In this case specifying the date is required in order to determine whether standard or daylight-savings time applies. The appropriate time zone offset is recorded in the `time` with time zone value.

Table 87: Time Input

<table>
<thead>
<tr>
<th>Example</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>04:05:06.789</td>
<td>ISO 8601</td>

<td>Military abbreviation for UTC</td>
</tr>
<tr>
<td>z</td>
<td>Short form of zulu</td>
</tr>
</tbody>
</table>

Refer to Time Zones for more information on how to specify time zones.

Time Stamps

Valid input for the time stamp types consists of the concatenation of a date and a time, followed by an optional time zone, followed by an optional AD or BC. (Alternatively, AD/BC can appear before the time zone, but this is not the preferred ordering.) Thus: 1999-01-08 04:05:06 and: 1999-01-08 04:05:06 -8:00 are valid values, which follow the ISO 8601 standard. In addition, the common format: January 8 04:05:06 1999 PST is supported.

The SQL standard differentiates `timestamp without time zone` and `timestamp with time zone` literals by the presence of a + or – symbol and time zone offset after the time. Hence, according to the standard, `TIMESTAMP '2004-10-19 10:23:54'` is a timestamp without time zone, while `TIMESTAMP '2004-10-19 10:23:54+02'` is a timestamp with time zone. Greenplum never examines the content of a literal string before determining its type, and therefore will treat both of the above as timestamp without time zone. To ensure that a literal is treated as timestamp with time zone, give it the correct explicit type: `TIMESTAMP WITH TIME ZONE '2004-10-19 10:23:54+02'`.

In a literal that has been determined to be timestamp with time zone, Greenplum will silently ignore any time zone indication. That is, the resulting value is derived from the date/time fields in the input value, and is not adjusted for time zone.

For `timestamp with time zone`, the internally stored value is always in UTC (Universal Coordinated Time, traditionally known as Greenwich Mean Time, GMT). An input value that has an explicit time zone specified is converted to UTC using the appropriate offset for that time zone. If no time zone is stated in the input string, then it is assumed to be in the time zone indicated by the system's `TimeZone` parameter, and is converted to UTC using the offset for the `timezone` zone.

When a `timestamp with time zone` value is output, it is always converted from UTC to the current `timezone` zone, and displayed as local time in that zone. To see the time in another time zone, either change `timezone` or use the `AT TIME ZONE` construct (see `AT TIME ZONE` in the PostgreSQL documentation).
Conversions between `timestamp without time zone` and `timestamp with time zone` normally assume that the `timestamp without time zone` value should be taken or given as `timezone` local time. A different time zone can be specified for the conversion using `AT TIME ZONE`.

**Special Values**

Greenplum supports several special date/time input values for convenience, as shown in Table 89: Special Date/Time Inputs. The values `infinity` and `-infinity` are specially represented inside the system and will be displayed unchanged; but the others are simply notational shorthands that will be converted to ordinary date/time values when read. (In particular, `now` and related strings are converted to a specific time value as soon as they are read.) All of these values need to be enclosed in single quotes when used as constants in SQL commands.

### Table 89: Special Date/Time Inputs

<table>
<thead>
<tr>
<th>Input String</th>
<th>Valid Types</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>epoch</td>
<td>date, timestamp</td>
<td>1970-01-01 00:00:00+00 (Unix system time zero)</td>
</tr>
<tr>
<td>infinity</td>
<td>date, timestamp</td>
<td>later than all other time stamps</td>
</tr>
<tr>
<td>-infinity</td>
<td>date, timestamp</td>
<td>earlier than all other time stamps</td>
</tr>
<tr>
<td>now</td>
<td>date, time, timestamp</td>
<td>current transaction’s start time</td>
</tr>
<tr>
<td>today</td>
<td>date, timestamp</td>
<td>midnight today</td>
</tr>
<tr>
<td>tomorrow</td>
<td>date, timestamp</td>
<td>midnight tomorrow</td>
</tr>
<tr>
<td>yesterday</td>
<td>date, timestamp</td>
<td>midnight yesterday</td>
</tr>
<tr>
<td>allballs</td>
<td>time</td>
<td>00:00:00.00.00 UTC</td>
</tr>
</tbody>
</table>

The following SQL-compatible functions can also be used to obtain the current time value for the corresponding data type: `CURRENT_DATE`, `CURRENT_TIME`, `CURRENT_TIMESTAMP`, `LOCALTIME`, `LOCALTIMESTAMP`. The latter four accept an optional subsecond precision specification. (See Current Date/Time in the PostgreSQL documentation.) Note that these are SQL functions and are *not* recognized in data input strings.

**Date/Time Output**

The output format of the date/time types can be set to one of the four styles ISO 8601, SQL (Ingres), traditional POSTGRES (Unix `date` format), or German. The default is the ISO format. (The SQL standard requires the use of the ISO 8601 format. The name of the SQL output format is a historical accident.) Table 90: Date/Time Output Styles shows examples of each output style. The output of the `date` and `time` types is generally only the date or time part in accordance with the given examples. However, the POSTGRES style outputs date-only values in ISO format.

### Table 90: Date/Time Output Styles

<table>
<thead>
<tr>
<th>Style Specification</th>
<th>Description</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>ISO</td>
<td>ISO 8601, SQL standard</td>
<td>1997-12-17 07:37:16-08</td>
</tr>
<tr>
<td>SQL</td>
<td>traditional style</td>
<td>12/17/1997 07:37:16.00 PST</td>
</tr>
<tr>
<td>Postgres</td>
<td>original style</td>
<td>Wed Dec 17 07:37:16 1997 PST</td>
</tr>
</tbody>
</table>
ISO 8601 specifies the use of uppercase letter T to separate the date and time. Greenplum accepts that format on input, but on output it uses a space rather than T, as shown above. This is for readability and for consistency with RFC 3339 as well as some other database systems.

In the SQL and POSTGRES styles, day appears before month if DMY field ordering has been specified, otherwise month appears before day. (See Table 86: Date Input for how this setting also affects interpretation of input values.) Table 91: Date Order Conventions shows examples.

Table 91: Date Order Conventions

<table>
<thead>
<tr>
<th>datestyle Setting</th>
<th>Input Ordering</th>
<th>Example Output</th>
</tr>
</thead>
<tbody>
<tr>
<td>SQL, DMY</td>
<td>day/month/year</td>
<td>17/12/1997 15:37:16.00 CET</td>
</tr>
<tr>
<td>SQL, MDY</td>
<td>month/day/year</td>
<td>12/17/1997 07:37:16.00 PST</td>
</tr>
<tr>
<td>Postgres, DMY</td>
<td>day/month/year</td>
<td>Wed 17 Dec 07:37:16 1997 PST</td>
</tr>
</tbody>
</table>

The date/time style can be selected by the user using the SET datestyle command, the DateStyle parameter in the postgresql.conf configuration file, or the PGDATESTYLE environment variable on the server or client.

The formatting function to_char (see Data Type Formatting Functions) is also available as a more flexible way to format date/time output.

### Time Zones

Time zones, and time-zone conventions, are influenced by political decisions, not just earth geometry. Time zones around the world became somewhat standardized during the 1900s, but continue to be prone to arbitrary changes, particularly with respect to daylight-savings rules. Greenplum uses the widely-used IANA (Olson) time zone database for information about historical time zone rules. For times in the future, the assumption is that the latest known rules for a given time zone will continue to be observed indefinitely far into the future.

Greenplum endeavors to be compatible with the SQL standard definitions for typical usage. However, the SQL standard has an odd mix of date and time types and capabilities. Two obvious problems are:

1. Although the date type cannot have an associated time zone, the time type can. Time zones in the real world have little meaning unless associated with a date as well as a time, since the offset can vary through the year with daylight-saving time boundaries.
2. The default time zone is specified as a constant numeric offset from UTC. It is therefore impossible to adapt to daylight-saving time when doing date/time arithmetic across DST boundaries.

To address these difficulties, we recommend using date/time types that contain both date and time when using time zones. We do not recommend using the type time with time zone (though it is supported by Greenplum for legacy applications and for compliance with the SQL standard). Greenplum assumes your local time zone for any type containing only date or time.

All timezone-aware dates and times are stored internally in UTC. They are converted to local time in the zone specified by the TimeZone configuration parameter before being displayed to the client.

Greenplum allows you to specify time zones in three different forms:
1. A full time zone name, for example America/New_York. The recognized time zone names are listed in the pg_timezone_names view. Greenplum uses the widely-used IANA time zone data for this purpose, so the same time zone names are also recognized by other software.

2. A time zone abbreviation, for example PST. Such a specification merely defines a particular offset from UTC, in contrast to full time zone names which can imply a set of daylight savings transition-date rules as well. The recognized abbreviations are listed in the pg_timezone_abbrevs view. You cannot set the configuration parameters TimeZone or log_timezone to a time zone abbreviation, but you can use abbreviations in date/time input values and with the AT Time ZONE operator.

3. In addition to the timezone names and abbreviations, Greenplum will accept POSIX-style time zone specifications of the form STD offset or STD offset DST, where STD is a zone abbreviation, offset is a numeric offset in hours west from UTC, and DST is an optional daylight-savings zone abbreviation, assumed to stand for one hour ahead of the given offset. For example, if EST5EDT were not already a recognized zone name, it would be accepted and would be functionally equivalent to United States East Coast time. In this syntax, a zone abbreviation can be a string of letters, or an arbitrary string surrounded by angle brackets (<>). When a daylight-savings zone abbreviation is present, it is assumed to be used according to the same daylight-savings transition rules used in the IANA time zone database’s entry. In a standard Greenplum installation, is the same as US/Eastern, so that POSIX-style time zone specifications follow USA daylight-savings rules. If needed, you can adjust this behavior by replacing the file.

In short, this is the difference between abbreviations and full names: abbreviations represent a specific offset from UTC, whereas many of the full names imply a local daylight-savings time rule, and so have two possible UTC offsets. As an example, 2014-06-04 12:00 America/New_York represents noon local time in New York, which for this particular date was Eastern Daylight Time (UTC-4). So 2014-06-04 12:00 EDT specifies that same time instant. But 2014-06-04 12:00 EST specifies noon Eastern Standard Time (UTC-5), regardless of whether daylight savings was nominally in effect on that date.

To complicate matters, some jurisdictions have used the same timezone abbreviation to mean different UTC offsets at different times; for example, in Moscow MSK has meant UTC+3 in some years and UTC+4 in others. Greenplum interprets such abbreviations according to whatever they meant (or had most recently meant) on the specified date; but, as with the EST example above, this is not necessarily the same as local civil time on that date.

One should be wary that the POSIX-style time zone feature can lead to silently accepting bogus input, since there is no check on the reasonableness of the zone abbreviations. For example, SET TIME ZONE TO FOOBAR0 will work, leaving the system effectively using a rather peculiar abbreviation for UTC. Another issue to keep in mind is that in POSIX time zone names, positive offsets are used for locations of Greenwich. Everywhere else, Greenplum follows the ISO-8601 convention that positive timezone offsets are of Greenwich.

In all cases, timezone names and abbreviations are recognized case-insensitively.

Neither timezone names nor abbreviations are hard-wired into the server; they are obtained from configuration files (see Configuring Localization Settings).

The TimeZone configuration parameter can be set in the file, or in any of the other standard ways for setting configuration parameters. There are also some special ways to set it:

1. The SQL command SET TIME ZONE sets the time zone for the session. This is an alternative spelling of SET TIMEZONE TO with a more SQL-spec-compatible syntax.
2. The PGTZ environment variable is used by libpq clients to send a SET TIME ZONE command to the server upon connection.

Interval Input

interval values can be written using the following verbose syntax:

@ quantity unit quantity unit... direction
where quantity is a number (possibly signed); unit is microsecond, millisecond, second, minute, hour, day, week, month, year, decade, century, millennium, or abbreviations or plurals of these units; direction can be ago or empty. The at sign (@) is optional noise. The amounts of the different units are implicitly added with appropriate sign accounting. ago negates all the fields. This syntax is also used for interval output, if intervalStyle is set to postgres_verbose.

Quantities of days, hours, minutes, and seconds can be specified without explicit unit markings. For example, '1 12:59:10' is read the same as '1 day 12 hours 59 min 10 sec'. Also, a combination of years and months can be specified with a dash; for example '200-10' is read the same as '200 years 10 months'. (These shorter forms are in fact the only ones allowed by the SQL standard, and are used for output when intervalStyle is set to sql_standard.)

Interval values can also be written as ISO 8601 time intervals, using either the format with designators of the standard's section 4.4.3.2 or the alternative format of section 4.4.3.3. The format with designators looks like this:

\[ P \text{ quantity unit quantity unit ... } T \text{ quantity unit ...} \]

The string must start with a P, and may include a T that introduces the time-of-day units. The available unit abbreviations are given in Table 92: ISO 8601 Interval Unit Abbreviations. Units may be omitted, and may be specified in any order, but units smaller than a day must appear after T. In particular, the meaning of M depends on whether it is before or after T.

Table 92: ISO 8601 Interval Unit Abbreviations

<table>
<thead>
<tr>
<th>Abbreviation</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>Y</td>
<td>Years</td>
</tr>
<tr>
<td>M</td>
<td>Months (in the date part)</td>
</tr>
<tr>
<td>W</td>
<td>Weeks</td>
</tr>
<tr>
<td>D</td>
<td>Days</td>
</tr>
<tr>
<td>H</td>
<td>Hours</td>
</tr>
<tr>
<td>M</td>
<td>Minutes (in the time part)</td>
</tr>
<tr>
<td>S</td>
<td>Seconds</td>
</tr>
</tbody>
</table>

In the alternative format:

\[ P \text{ years-months-days } T \text{ hours:minutes:seconds} \]

the string must begin with P, and a T separates the date and time parts of the interval. The values are given as numbers similar to ISO 8601 dates.

When writing an interval constant with a fields specification, or when assigning a string to an interval column that was defined with a fields specification, the interpretation of unmarked quantities depends on the fields. For example INTERVAL '1' YEAR is read as 1 year, whereas INTERVAL '1' means 1 second. Also, field values to the right of the least significant field allowed by the fields specification are silently discarded. For example, writing INTERVAL '1 day 2:03:04' HOUR TO MINUTE results in dropping the seconds field, but not the day field.

According to the SQL standard all fields of an interval value must have the same sign, so a leading negative sign applies to all fields; for example the negative sign in the interval literal '-1 2:03:04' applies to both the days and hour/minute/second parts. Greenplum allows the fields to have different signs, and traditionally treats each field in the textual representation as independently signed, so that the hour/
minute/second part is considered positive in this example. If *IntervalStyle* is set to *sql_standard* then a leading sign is considered to apply to all fields (but only if no additional signs appear). Otherwise the traditional Greenplum interpretation is used. To avoid ambiguity, it's recommended to attach an explicit sign to each field if any field is negative.

In the verbose input format, and in some fields of the more compact input formats, field values can have fractional parts; for example '1.5 week' or '01:02:03.45'. Such input is converted to the appropriate number of months, days, and seconds for storage. When this would result in a fractional number of months or days, the fraction is added to the lower-order fields using the conversion factors 1 month = 30 days and 1 day = 24 hours. For example, '1.5 month' becomes 1 month and 15 days. Only seconds will ever be shown as fractional on output.

*Table 93: Interval Input* shows some examples of valid interval input.

<table>
<thead>
<tr>
<th>Example</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1-2</td>
<td>SQL standard format: 1 year 2 months</td>
</tr>
<tr>
<td>3 4:05:06</td>
<td>SQL standard format: 3 days 4 hours 5 minutes 6 seconds</td>
</tr>
<tr>
<td>1 year 2 months 3 days 4 hours 5 minutes 6 seconds</td>
<td>Traditional Postgres format: 1 year 2 months 3 days 4 hours 5 minutes 6 seconds</td>
</tr>
<tr>
<td>P1Y2M3DT4H5M6S</td>
<td>ISO 801 format with designators: same meaning as above</td>
</tr>
<tr>
<td>P0001-02-03T04:05:06</td>
<td>ISO 801 alternative format: same meaning as above</td>
</tr>
</tbody>
</table>

Internally interval values are stored as months, days, and seconds. This is done because the number of days in a month varies, and a day can have 23 or 25 hours if a daylight savings time adjustment is involved. The months and days fields are integers while the seconds field can store fractions. Because intervals are usually created from constant strings or timestamp subtraction, this storage method works well in most cases, but can cause unexpected results:

```
SELECT EXTRACT(hours from '80 minutes'::interval); date_part ----------- 1
SELECT EXTRACT(days from '80 hours'::interval); date_part ----------- 0
```

Functions *justify_days* and *justify_hours* are available for adjusting days and hours that overflow their normal ranges.

### Interval Output

The output format of the interval type can be set to one of the four styles *sql_standard*, *postgres*, *postgres_verbose*, or *iso_8601*, using the command *SET intervalstyle*. The default is the *postgres* format. *Table 94: Interval Output Style Examples* shows examples of each output style.

The *sql_standard* style produces output that conforms to the SQL standard's specification for interval literal strings, if the interval value meets the standard's restrictions (either year-month only or day-time only, with no mixing of positive and negative components). Otherwise the output looks like a standard year-month literal string followed by a day-time literal string, with explicit signs added to disambiguate mixed-sign intervals.

The output of the *postgres* style matches the output of PostgreSQL releases prior to 8.4 when the *DateStyle* parameter was set to *ISO*.

The output of the *postgres_verbose* style matches the output of PostgreSQL releases prior to 8.4 when the *DateStyle* parameter was set to non-*ISO* output.

The output of the *iso_8601* style matches the format with designators described in section 4.4.3.2 of the ISO 8601 standard.
Table 94: Interval Output Style Examples

<table>

</table>

**Pseudo-Types**

Greenplum Database supports special-purpose data type entries that are collectively called *pseudo-types*. A pseudo-type cannot be used as a column data type, but it can be used to declare a function's argument or result type. Each of the available pseudo-types is useful in situations where a function's behavior does not correspond to simply taking or returning a value of a specific SQL data type.

Functions coded in procedural languages can use pseudo-types only as allowed by their implementation languages. The procedural languages all forbid use of a pseudo-type as an argument type, and allow only `void` and `record` as a result type.

A function with the pseudo-type `record` as a return data type returns an unspecified row type. The `record` represents an array of possibly-anonymous composite types. Since composite datums carry their own type identification, no extra knowledge is needed at the array level.

The pseudo-type `void` indicates that a function returns no value.

**Note:** Greenplum Database does not support triggers and the pseudo-type `trigger`.

The types `anyelement`, `anyarray`, `anynonarray`, and `anyenum` are pseudo-types called polymorphic types. Some procedural languages also support polymorphic functions using the types `anyarray`, `anyelement`, `anyenum`, and `anynonarray`.

The pseudo-type `anytable` is a Greenplum Database type that specifies a table expression—an expression that computes a table. Greenplum Database allows this type only as an argument to a user-defined function. See Table Value Expressions for more about the `anytable` pseudo-type.

For more information about pseudo-types, see the PostgreSQL documentation about Pseudo-Types.

**Polymorphic Types**

Four pseudo-types of special interest are `anyelement`, `anyarray`, `anynonarray`, and `anyenum`, which are collectively called polymorphic types. Any function declared using these types is said to be a polymorphic function. A polymorphic function can operate on many different data types, with the specific data types being determined by the data types actually passed to it at runtime.

Polymorphic arguments and results are tied to each other and are resolved to a specific data type when a query calling a polymorphic function is parsed. Each position (either argument or return value) declared as `anyelement` is allowed to have any specific actual data type, but in any given call they must all be the same actual type. Each position declared as `anyarray` can have any array data type, but similarly they must all be the same type. If there are positions declared `anyarray` and others declared `anyelement`, the actual array type in the `anyarray` positions must be an array whose elements are the same type appearing in the `anyelement` positions. `anynonarray` is treated exactly the same as `anyelement`, but adds the additional constraint that the actual type must not be an array type. `anyenum` is treated exactly the same as `anyelement`, but adds the additional constraint that the actual type must be an `enum` type.
When more than one argument position is declared with a polymorphic type, the net effect is that only certain combinations of actual argument types are allowed. For example, a function declared as 
\[ \text{equal}(\text{anylelement}, \text{anylelement}) \] takes any two input values, so long as they are of the same data type.

When the return value of a function is declared as a polymorphic type, there must be at least one argument position that is also polymorphic, and the actual data type supplied as the argument determines the actual result type for that call. For example, if there were not already an array subscripting mechanism, one could define a function that implements subscripting as 
\[ \text{subscript}(\text{anyarray}, \text{integer}) \] returns 
\[ \text{anylelement} \]. This declaration constrains the actual first argument to be an array type, and allows the parser to infer the correct result type from the actual first argument's type. Another example is that a function declared as 
\[ \text{myfunc}(\text{anyarray}) \] returns 
\[ \text{anyenum} \] will only accept arrays of 
\[ \text{enum} \] types.

Note that 
\[ \text{anynonarray} \] and 
\[ \text{anyarray} \] do not represent separate type variables; they are the same type as 
\[ \text{anylelement} \], just with an additional constraint. For example, declaring a function as 
\[ \text{myfunc}(\text{anylelement}, \text{anynonarray}) \] is equivalent to declaring it as 
\[ \text{myfunc}(\text{anynonarray}, \text{anynonarray}) \]: both actual arguments must be the same 
\[ \text{enum} \] type.

A variadic function (one taking a variable number of arguments) is polymorphic when its last parameter is declared as 
\[ \text{VARIADIC anyarray} \]. For purposes of argument matching and determining the actual result type, such a function behaves the same as if you had declared the appropriate number of 
\[ \text{anynonarray} \] parameters.

For more information about polymorphic types, see the PostgreSQL documentation about Polymorphic Arguments and Return Types.

### Table Value Expressions

The 
\[ \text{anynonarray} \] pseudo-type declares a function argument that is a table value expression. The notation for a table value expression is a 
\[ \text{SELECT} \] statement enclosed in a 
\[ \text{TABLE()} \] function. You can specify a distribution policy for the table by adding 
\[ \text{SCATTER RANDOMLY} \], or a 
\[ \text{SCATTER BY} \] clause with a column list to specify the distribution key.

The 
\[ \text{SELECT} \] statement is executed when the function is called and the result rows are distributed to segments so that each segment executes the function with a subset of the result table.

For example, this table expression selects three columns from a table named 
\[ \text{customer} \] and sets the distribution key to the first column:

```sql
TABLE(SELECT cust_key, name, address FROM customer SCATTER BY 1)
```

The 
\[ \text{SELECT} \] statement may include joins on multiple base tables, 
\[ \text{WHERE} \] clauses, aggregates, and any other valid query syntax.

The 
\[ \text{anynonarray} \] type is only permitted in functions implemented in the C or C++ languages. The body of the function can access the table using the Greenplum Database Server Programming Interface (SPI) or the Greenplum Partner Connector (GPPC) API.

The 
\[ \text{anynonarray} \] type is used in some user-defined functions in the Pivotal GPText API. The following GPText example uses the 
\[ \text{TABLE} \] function with the 
\[ \text{SCATTER BY} \] clause in the GPText function 
\[ \text{gptext.index()} \] to populate the index 
\[ \text{mydb.mytest.articles} \] with data from the 
\[ \text{messages} \] table:

```sql
SELECT * FROM gptext.index(TABLE(SELECT * FROM mytest.messages SCATTER BY distrib_id), 'mydb.mytest.messages');
```

For information about the function 
\[ \text{gptext.index()} \], see the Pivotal GPText documentation.
Text Search Data Types

Greenplum Database provides two data types that are designed to support full text search, which is the activity of searching through a collection of natural-language documents to locate those that best match a query. The tsvector type represents a document in a form optimized for text search; the tsquery type similarly represents a text query. Using Full Text Search provides a detailed explanation of this facility, and Text Search Functions and Operators summarizes the related functions and operators.

The tsvector and tsquery types cannot be part of the distribution key of a Greenplum Database table.

tsvector

A tsvector value is a sorted list of distinct lexemes, which are words that have been normalized to merge different variants of the same word (see Using Full Text Search for details). Sorting and duplicate-elimination are done automatically during input, as shown in this example:

```
SELECT 'a fat cat sat on a mat and ate a fat rat'::tsvector;

  tsvector
  -----------------------------
    'a' 'and' 'ate' 'cat' 'fat' 'mat' 'on' 'rat' 'sat'
```

To represent lexemes containing whitespace or punctuation, surround them with quotes:

```
SELECT $$the lexeme '    ' contains spaces$$::tsvector;

  tsvector
  -------------------------------------------
    '    ' 'contains' 'lexeme' 'spaces' 'the'
```

(We use dollar-quoted string literals in this example and the next one to avoid the confusion of having to double quote marks within the literals.) Embedded quotes and backslashes must be doubled:

```
SELECT $$the lexeme 'Joe''s' contains a quote$$::tsvector;

  tsvector
  ------------------------------------------------
    'Joe''s' 'a' 'contains' 'lexeme' 'quote' 'the'
```

Optionally, integer positions can be attached to lexemes:

```
SELECT 'a:1 fat:2 cat:3 sat:4 on:5 a:6 mat:7 and:8 ate:9 a:10 fat:11 rat:12'::tsvector;

  tsvector
  -----------------------------------------------------------------------------
    'a':1,6,10 'and':8 'ate':9 'cat':3 'fat':2,11 'mat':7 'on':5 'rat':12 'sat':4
```

A position normally indicates the source word's location in the document. Positional information can be used for proximity ranking. Position values can range from 1 to 16383; larger numbers are silently set to 16383. Duplicate positions for the same lexeme are discarded.

Lexemes that have positions can further be labeled with a weight, which can be A, B, C, or D. D is the default and hence is not shown on output:

```
SELECT 'a:1A fat:2B,4C cat:5D'::tsvector;

  tsvector
  ---------------------
    'a':1A 'cat':5 'fat':2B,4C
```

Weights are typically used to reflect document structure, for example by marking title words differently from body words. Text search ranking functions can assign different priorities to the different weight markers.
It is important to understand that the tsvector type itself does not perform any normalization; it assumes the words it is given are normalized appropriately for the application. For example,

```sql
select 'The Fat Rats '::tsvector;
  tsvector
------------------
  'Fat' 'Rats' 'The'
```

For most English-text-searching applications the above words would be considered non-normalized, but tsvector doesn't care. Raw document text should usually be passed through to_tsvector to normalize the words appropriately for searching:

```sql
SELECT to_tsvector('english', 'The Fat Rats');
  to_tsvector
-----------------
  'fat':2 'rat':3
```

tsquery

A tsquery value stores lexemes that are to be searched for, and combines them honoring the Boolean operators & (AND), | (OR), and ! (NOT). Parentheses can be used to enforce grouping of the operators:

```sql
SELECT 'fat & rat '::tsquery;
  tsquery
-----------
  'fat' & 'rat'

SELECT 'fat & (rat | cat) '::tsquery;
  tsquery
------------------------
  'fat' & ( 'rat' | 'cat' )

SELECT 'fat & rat & ! cat '::tsquery;
  tsquery
------------------------
  'fat' & 'rat' & '!cat'
```

In the absence of parentheses, ! (NOT) binds most tightly, and & (AND) binds more tightly than | (OR).

Optionally, lexemes in a tsquery can be labeled with one or more weight letters, which restricts them to match only tsvector lexemes with matching weights:

```sql
SELECT 'fat:ab & cat '::tsquery;
  tsquery
-------------
  'fat':AB & 'cat'
```

Also, lexemes in a tsquery can be labeled with * to specify prefix matching:

```sql
SELECT 'super:* '::tsquery;
  tsquery
--------
  'super':*
```

This query will match any word in a tsvector that begins with "super". Note that prefixes are first processed by text search configurations, which means this comparison returns true:

```sql
SELECT to_tsvector( 'postgraduate' ) @@ to_tsquery( 'postgres:*' );
  ?column?
```

because `postgres` gets stemmed to `postgr`:

```
SELECT to_tsquery('postgres:*');
to_tsquery
------------
'postgr':*
(1 row)
```

which then matches `postgraduate`.

Quoting rules for lexemes are the same as described previously for lexemes in `tsvector`; and, as with `tsvector`, any required normalization of words must be done before converting to the `tsquery` type. The `to_tsquery` function is convenient for performing such normalization:

```
SELECT to_tsquery('Fat:ab & Cats');
to_tsquery
------------
'fat':AB & 'cat'
```

## Range Types

Range types are data types representing a range of values of some element type (called the range’s `subtype`). For instance, ranges of `timestamp` might be used to represent the ranges of time that a meeting room is reserved. In this case the data type is `tsrange` (short for “timestamp range”), and `timestamp` is the subtype. The subtype must have a total order so that it is well-defined whether element values are within, before, or after a range of values.

Range types are useful because they represent many element values in a single range value, and because concepts such as overlapping ranges can be expressed clearly. The use of time and date ranges for scheduling purposes is the clearest example; but price ranges, measurement ranges from an instrument, and so forth can also be useful.

### Built-in Range Types

Greenplum Database comes with the following built-in range types:

- `int4range` -- Range of `integer`
- `int8range` -- Range of `bigint`
- `numrange` -- Range of `numeric`
- `tsrange` -- Range of `timestamp without time zone`
- `tstzrange` -- Range of `timestamp with time zone`
- `daterange` -- Range of `date`

In addition, you can define your own range types; see `CREATE TYPE` for more information.

### Examples

```
CREATE TABLE reservation (room int, during tsrange);
INSERT INTO reservation VALUES
  (1108, '[2010-01-01 14:30, 2010-01-01 15:30]');

-- Containment
SELECT int4range(10, 20) @> 3;

-- Overlaps
```
### Inclusive and Exclusive Bounds

Every non-empty range has two bounds, the lower bound and the upper bound. All points between these values are included in the range. An inclusive bound means that the boundary point itself is included in the range as well, while an exclusive bound means that the boundary point is not included in the range.

In the text form of a range, an inclusive lower bound is represented by `[` while an exclusive lower bound is represented by `(`. Likewise, an inclusive upper bound is represented by `]`, while an exclusive upper bound is represented by `)` (See *Range Functions and Operators* for more details.)

The functions `lower_inc` and `upper_inc` test the inclusivity of the lower and upper bounds of a range value, respectively.

### Infinite (Unbounded) Ranges

The lower bound of a range can be omitted, meaning that all points less than the upper bound are included in the range. Likewise, if the upper bound of the range is omitted, then all points greater than the lower bound are included in the range. If both lower and upper bounds are omitted, all values of the element type are considered to be in the range.

This is equivalent to considering that the lower bound is “minus infinity”, or the upper bound is “plus infinity”, respectively. But note that these infinite values are never values of the range’s element type, and can never be part of the range. (So there is no such thing as an inclusive infinite bound -- if you try to write one, it will automatically be converted to an exclusive bound.)

Also, some element types have a notion of “infinity”, but that is just another value so far as the range type mechanisms are concerned. For example, in timestamp ranges, `[today,)` means the same thing as `[today,).` But `[today,infinity]` means something different from `[today,infinity)` -- the latter excludes the special `timestamp value infinity`.

The functions `lower_inf` and `upper_inf` test for infinite lower and upper bounds of a range, respectively.

### Range Input/Output

The input for a range value must follow one of the following patterns:

<table>
<thead>
<tr>
<th>Pattern</th>
</tr>
</thead>
<tbody>
<tr>
<td>(lower-bound, upper-bound)</td>
</tr>
<tr>
<td>(lower-bound, upper-bound]</td>
</tr>
<tr>
<td>[lower-bound, upper-bound)</td>
</tr>
<tr>
<td>[lower-bound, upper-bound]</td>
</tr>
<tr>
<td>empty</td>
</tr>
</tbody>
</table>

The parentheses or brackets indicate whether the lower and upper bounds are exclusive or inclusive, as described previously. Notice that the final pattern is `empty`, which represents an empty range (a range that contains no points).
The *lower-bound* may be either a string that is valid input for the subtype, or empty to indicate no lower bound. Likewise, *upper-bound* may be either a string that is valid input for the subtype, or empty to indicate no upper bound.

Each bound value can be quoted using " (double quote) characters. This is necessary if the bound value contains parentheses, brackets, commas, double quotes, or backslashes, since these characters would otherwise be taken as part of the range syntax. To put a double quote or backslash in a quoted bound value, precede it with a backslash. (Also, a pair of double quotes within a double-quoted bound value is taken to represent a double quote character, analogously to the rules for single quotes in SQL literal strings.) Alternatively, you can avoid quoting and use backslash-escaping to protect all data characters that would otherwise be taken as range syntax. Also, to write a bound value that is an empty string, write "", since writing nothing means an infinite bound.

Whitespace is allowed before and after the range value, but any whitespace between the parentheses or brackets is taken as part of the lower or upper bound value. (Depending on the element type, it might or might not be significant.)

Examples:

```
-- includes 3, does not include 7, and does include all points in between
SELECT '"3,7")::int4range;

-- does not include either 3 or 7, but includes all points in between
SELECT '3,7")::int4range;

-- includes only the single point 4
SELECT '"4,4")::int4range;

-- includes no points (and will be normalized to 'empty')
SELECT '"4,4")::int4range;
```

**Constructing Ranges**

Each range type has a constructor function with the same name as the range type. Using the constructor function is frequently more convenient than writing a range literal constant, since it avoids the need for extra quoting of the bound values. The constructor function accepts two or three arguments. The two-argument form constructs a range in standard form (lower bound inclusive, upper bound exclusive), while the three-argument form constructs a range with bounds of the form specified by the third argument. The third argument must be one of the strings ( ), ( [ ]), or [ ] . For example:

```
-- The full form is: lower bound, upper bound, and text argument indicating
-- inclusivity/exclusivity of bounds.
SELECT numrange(1.0, 14.0, '()');

-- If the third argument is omitted, '()' is assumed.
SELECT numrange(1.0, 14.0);

-- Although '()' is specified here, on display the value will be converted
to
-- canonical form, since int8range is a discrete range type (see below).
SELECT int8range(1, 14, '()');

-- Using NULL for either bound causes the range to be unbounded on that
side.
SELECT numrange(NULL, 2.2);
```
Discrete Range Types

A discrete range is one whose element type has a well-defined “step”, such as integer or date. In these types two elements can be said to be adjacent, when there are no valid values between them. This contrasts with continuous ranges, where it's always (or almost always) possible to identify other element values between two given values. For example, a range over the numeric type is continuous, as is a range over timestamp. (Even though timestamp has limited precision, and so could theoretically be treated as discrete, it's better to consider it continuous since the step size is normally not of interest.)

Another way to think about a discrete range type is that there is a clear idea of a “next” or “previous” value for each element value. Knowing that, it is possible to convert between inclusive and exclusive representations of a range’s bounds, by choosing the next or previous element value instead of the one originally given. For example, in an integer range type [4, 8] and (3, 9) denote the same set of values; but this would not be so for a range over numeric.

A discrete range type should have a canonicalization function that is aware of the desired step size for the element type. The canonicalization function is charged with converting equivalent values of the range type to have identical representations, in particular consistently inclusive or exclusive bounds. If a canonicalization function is not specified, then ranges with different formatting will always be treated as unequal, even though they might represent the same set of values in reality.

The built-in range types int4range, int8range, and daterange all use a canonical form that includes the lower bound and excludes the upper bound; that is, [). User-defined range types can use other conventions, however.

Defining New Range Types

Users can define their own range types. The most common reason to do this is to use ranges over subtypes not provided among the built-in range types. For example, to define a new range type of subtype float8:

```sql
CREATE TYPE floatrange AS RANGE (  subtype = float8,  subtype_diff = float8mi
);
SELECT '[-1.234, 5.678]'::floatrange;
```

Because float8 has no meaningful “step”, we do not define a canonicalization function in this example.

Defining your own range type also allows you to specify a different subtype B-tree operator class or collation to use, so as to change the sort ordering that determines which values fall into a given range.

If the subtype is considered to have discrete rather than continuous values, the CREATE TYPE command should specify a canonical function. The canonicalization function takes an input range value, and must return an equivalent range value that may have different bounds and formatting. The canonical output for two ranges that represent the same set of values, for example the integer ranges [1, 7] and [1, 8), must be identical. It doesn't matter which representation you choose to be the canonical one, so long as two equivalent values with different formattings are always mapped to the same value with the same formatting. In addition to adjusting the inclusive/exclusive bounds format, a canonicalization function might round off boundary values, in case the desired step size is larger than what the subtype is capable of storing. For instance, a range type over timestamp could be defined to have a step size of an hour, in which case the canonicalization function would need to round off bounds that weren't a multiple of an hour, or perhaps throw an error instead.

In addition, any range type that is meant to be used with GiST or SP-GiST indexes should define a subtype difference, or subtype_diff, function. (The index will still work without subtype_diff, but it is likely to be considerably less efficient than if a difference function is provided.) The subtype difference
function takes two input values of the subtype, and returns their difference (i.e., \( X \) minus \( Y \)) represented as a \texttt{float8} value. In our example above, the function \texttt{float8mi} that underlies the regular \texttt{float8} minus operator can be used; but for any other subtype, some type conversion would be necessary. Some creative thought about how to represent differences as numbers might be needed, too. To the greatest extent possible, the \texttt{subtype\_diff} function should agree with the sort ordering implied by the selected operator class and collation; that is, its result should be positive whenever its first argument is greater than its second according to the sort ordering.

A less-oversimplified example of a \texttt{subtype\_diff} function is:

```sql
CREATE FUNCTION time_subtype_diff(x time, y time) RETURNS float8 AS 'SELECT EXTRACT(EPOCH FROM (x - y))' LANGUAGE sql STRICT IMMUTABLE;

CREATE TYPE timerange AS RANGE (
    subtype = time,
    subtype_diff = time_subtype_diff
);

SELECT '([11:10, 23:00])'::timerange;
```

See \texttt{CREATE TYPE} for more information about creating range types.

**Indexing**

GiST and SP-GiST indexes can be created for table columns of range types. For instance, to create a GiST index:

```sql
CREATE INDEX reservation_idx ON reservation USING GIST (during);
```

A GiST or SP-GiST index can accelerate queries involving these range operators: 
\( = \), \( &= \), \( <@ \), \( @> \), 
\( -| - \), \( &= \), and \( &> \) (see \texttt{Range Functions and Operators} for more information).

In addition, B-tree and hash indexes can be created for table columns of range types. For these index types, basically the only useful range operation is equality. There is a B-tree sort ordering defined for range values, with corresponding \( < \) and \( > \) operators, but the ordering is rather arbitrary and not usually useful in the real world. Range types' B-tree and hash support is primarily meant to allow sorting and hashing internally in queries, rather than creation of actual indexes.
Summary of Built-in Functions

Greenplum Database supports built-in functions and operators including analytic functions and window functions that can be used in window expressions. For information about using built-in Greenplum Database functions see, "Using Functions and Operators" in the Greenplum Database Administrator Guide.

- Greenplum Database Function Types
- Built-in Functions and Operators

- Window Functions
- Advanced Aggregate Functions
- Text Search Functions and Operators
- Range Functions and Operators

Greenplum Database Function Types

Greenplum Database evaluates functions and operators used in SQL expressions. Some functions and operators are only allowed to execute on the master since they could lead to inconsistencies in Greenplum Database segment instances. This table describes the Greenplum Database Function Types.

Table 95: Functions in Greenplum Database

<table>
<thead>
<tr>
<th>Function Type</th>
<th>Greenplum Support</th>
<th>Description</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>IMMUTABLE</td>
<td>Yes</td>
<td>Relies only on information directly in its argument list. Given the same argument values, always returns the same result.</td>
<td></td>
</tr>
<tr>
<td>STABLE</td>
<td>Yes, in most cases</td>
<td>Within a single table scan, returns the same result for same argument values, but results change across SQL statements.</td>
<td>Results depend on database lookups or parameter values. current_timestamp family of functions is STABLE; values do not change within an execution.</td>
</tr>
<tr>
<td>VOLATILE</td>
<td>Restricted</td>
<td>Function values can change within a single table scan. For example: random(), timeofday().</td>
<td>Any function with side effects is volatile, even if its result is predictable. For example: setval().</td>
</tr>
</tbody>
</table>

In Greenplum Database, data is divided up across segments — each segment is a distinct PostgreSQL database. To prevent inconsistent or unexpected results, do not execute functions classified as VOLATILE at the segment level if they contain SQL commands or modify the database in any way. For example, functions such as setval() are not allowed to execute on distributed data in Greenplum Database because they can cause inconsistent data between segment instances.

To ensure data consistency, you can safely use VOLATILE and STABLE functions in statements that are evaluated on and run from the master. For example, the following statements run on the master (statements without a FROM clause):

```
SELECT setval('myseq', 201);
SELECT foo();
```
If a statement has a `FROM` clause containing a distributed table and the function in the `FROM` clause returns a set of rows, the statement can run on the segments:

```
SELECT * from foo();
```

Greenplum Database does not support functions that return a table reference (`rangeFuncs`) or functions that use the `refCursor` datatype.

## Built-in Functions and Operators

The following table lists the categories of built-in functions and operators supported by PostgreSQL. All functions and operators are supported in Greenplum Database as in PostgreSQL with the exception of `STABLE` and `VOLATILE` functions, which are subject to the restrictions noted in Greenplum Database Function Types. See the Functions and Operators section of the PostgreSQL documentation for more information about these built-in functions and operators.

### Table 96: Built-in functions and operators

</table>
### JSON Functions and Operators

Greenplum Database includes built-in functions and operators that create and manipulate JSON data.

- **JSON Operators**
- **JSON Creation Functions**
- **JSON Aggregate Functions**
- **JSON Processing Functions**
Note: For `json` data type values, all key/value pairs are kept even if a JSON object contains duplicate keys. For duplicate keys, JSON processing functions consider the last value as the operative one. For the `jsonb` data type, duplicate object keys are not kept. If the input includes duplicate keys, only the last value is kept. See About JSON Data in the Greenplum Database Administrator Guide.

### JSON Operators

This table describes the operators that are available for use with the `json` and `jsonb` data types.

#### Table 97: `json` and `jsonb` Operators

<table>
<thead>
<tr>
<th>Operator</th>
<th>Right Operand Type</th>
<th>Description</th>
<th>Example</th>
<th>Example Result</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>-&gt;</code></td>
<td><code>int</code></td>
<td>Get the JSON array element (indexed from zero).</td>
<td>'{&quot;a&quot;:&quot;foo&quot;},{&quot;b&quot;:&quot;bar&quot;},{&quot;c&quot;:&quot;baz&quot;}':json-&gt;2</td>
<td>&quot;c&quot;:&quot;baz&quot;</td>
</tr>
<tr>
<td><code>-&gt;</code></td>
<td><code>text</code></td>
<td>Get the JSON object field by key.</td>
<td>'{&quot;a&quot;:{&quot;b&quot;:&quot;foo&quot;}}':json-&gt;'a'</td>
<td>&quot;b&quot;:&quot;foo&quot;</td>
</tr>
<tr>
<td><code>-&gt;&gt;</code></td>
<td><code>int</code></td>
<td>Get the JSON array element as text.</td>
<td>'[1,2,3]':json-&gt;&gt;2</td>
<td>3</td>
</tr>
<tr>
<td><code>-&gt;&gt;</code></td>
<td><code>text</code></td>
<td>Get the JSON object field as text.</td>
<td>'{&quot;a&quot;:1,&quot;b&quot;:2}':json-&gt;&gt;'b'</td>
<td>2</td>
</tr>
<tr>
<td><code>#&gt;</code></td>
<td><code>text[]</code></td>
<td>Get the JSON object at specified path.</td>
<td>'{&quot;a&quot;:{&quot;b&quot;:{&quot;c&quot;:&quot;foo&quot;}}}':json#&gt;'{a,b}'</td>
<td>&quot;c&quot;: &quot;foo&quot;</td>
</tr>
<tr>
<td><code>#&gt;&gt;</code></td>
<td><code>text[]</code></td>
<td>Get the JSON object at specified path as text.</td>
<td>'{&quot;a&quot;:[1,2,3],&quot;b&quot;:[4,5,6]}':json#&gt;&gt;'{a,2}'</td>
<td>3</td>
</tr>
</tbody>
</table>

Note: There are parallel variants of these operators for both the `json` and `jsonb` data types. The field, element, and path extraction operators return the same data type as their left-hand input (either `json` or `jsonb`), except for those specified as returning `text`, which coerce the value to `text`. The field, element, and path extraction operators return `NULL`, rather than failing, if the JSON input does not have the right structure to match the request; for example if no such element exists.

Operators that require the `jsonb` data type as the left operand are described in the following table. Many of these operators can be indexed by `jsonb` operator classes. For a full description of `jsonb` containment and existence semantics, see `jsonb Containment and Existence` in the Greenplum Database Administrator Guide. For information about how these operators can be used to effectively index `jsonb` data, see `jsonb Indexing` in the Greenplum Database Administrator Guide.

#### Table 98: `jsonb` Operators

<table>
<thead>
<tr>
<th>Operator</th>
<th>Right Operand Type</th>
<th>Description</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>@&gt;</code></td>
<td><code>jsonb</code></td>
<td>Does the left JSON value contain within it the right value?</td>
<td>'{&quot;a&quot;:1, &quot;b&quot;:2}':jsonb @&gt; '{&quot;b&quot;:2}':jsonb</td>
</tr>
</tbody>
</table>
The standard comparison operators in the following table are available only for the `jsonb` data type, not for the `json` data type. They follow the ordering rules for B-tree operations described in `jsonb Indexing` in the Greenplum Database Administrator Guide.

Table 99: `jsonb` Comparison Operators

<table>
<thead>
<tr>
<th>Operator</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>&lt;</code></td>
<td>less than</td>
</tr>
<tr>
<td><code>&gt;</code></td>
<td>greater than</td>
</tr>
<tr>
<td><code>&lt;=</code></td>
<td>less than or equal to</td>
</tr>
<tr>
<td><code>&gt;=</code></td>
<td>greater than or equal to</td>
</tr>
<tr>
<td><code>=</code></td>
<td>equal</td>
</tr>
<tr>
<td><code>&lt;&gt;</code> or <code>!=</code></td>
<td>not equal</td>
</tr>
</tbody>
</table>

**Note:** The `!=` operator is converted to `<>` in the parser stage. It is not possible to implement `!=` and `<>` operators that do different things.

**JSON Creation Functions**

This table describes the functions that create `json` data type values. (Currently, there are no equivalent functions for `jsonb`, but you can cast the result of one of these functions to `jsonb`.)
# Table 100: JSON Creation Functions

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
<th>Example</th>
<th>Example Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>to_json(anyelement)</td>
<td>Returns the value as a JSON object. Arrays and composites are processed recursively and are converted to arrays and objects. If the input contains a cast from the type to json, the cast function is used to perform the conversion; otherwise, a JSON scalar value is produced. For any scalar type other than a number, a Boolean, or a null value, the text representation will be used, properly quoted and escaped so that it is a valid JSON string.</td>
<td>to_json('Fred said &quot;Hi.&quot;'::text)</td>
<td>&quot;Fred said &quot;Hi. &quot;&quot;</td>
</tr>
<tr>
<td>array_to_json(anyarray[, pretty_bool])</td>
<td>Returns the array as a JSON array. A multidimensional array becomes a JSON array of arrays. Line feeds will be added between dimension-1 elements if pretty_bool is true.</td>
<td>array_to_json('{{1,5}, {99,100}}'::int[])</td>
<td>[[1,5],[99,100]]</td>
</tr>
<tr>
<td>row_to_json(record[, pretty_bool])</td>
<td>Returns the row as a JSON object. Line feeds will be added between level-1 elements if pretty_bool is true.</td>
<td>row_to_json(row(1,'foo'))</td>
<td>{&quot;f1&quot;:1,&quot;f2&quot;:&quot;foo&quot;}</td>
</tr>
<tr>
<td>json_build_array(VARIADIC &quot;any&quot;)</td>
<td>Builds a possibly-heterogeneously-typed JSON array out of a VARIADIC argument list.</td>
<td>json_build_array(1,2,'3',4,5)</td>
<td>[1,2,&quot;3&quot;,4,5]</td>
</tr>
<tr>
<td>json_build_object(VARIADIC &quot;any&quot;)</td>
<td>Builds a JSON object out of a VARIADIC argument list. The argument list is taken in order and converted to a set of key/value pairs.</td>
<td>json_build_object('foo',1,&quot;bar&quot;:2)</td>
<td>{&quot;foo&quot;: 1, &quot;bar&quot;: 2}</td>
</tr>
<tr>
<td>Function</td>
<td>Description</td>
<td>Example</td>
<td>Example Result</td>
</tr>
<tr>
<td>----------</td>
<td>-------------</td>
<td>---------</td>
<td>----------------</td>
</tr>
<tr>
<td><code>json_object(text[])</code></td>
<td>Builds a JSON object out of a text array. The array must be either a one or a two dimensional array. The one dimensional array must have an even number of elements. The elements are taken as key/value pairs. For a two dimensional array, each inner array must have exactly two elements, which are taken as a key/value pair.</td>
<td><code>json_object('{a, 1, b, &quot;def&quot;, c, 3.5}')</code>&lt;br&gt;<code>json_object('{{a, 1},{b, &quot;def&quot;},{c, 3.5}}')</code></td>
<td><code>{&quot;a&quot;: &quot;1&quot;, &quot;b&quot;: &quot;def&quot;, &quot;c&quot;: &quot;3.5&quot;}</code>&lt;br&gt;<code>{&quot;a&quot;: &quot;1&quot;, &quot;b&quot;: &quot;def&quot;}</code></td>
</tr>
<tr>
<td><code>json_object(keys text[], values text[])</code></td>
<td>Builds a JSON object out of a text array. This form of <code>json_object</code> takes keys and values pairwise from two separate arrays. In all other respects it is identical to the one-argument form.</td>
<td><code>json_object('{a, b}', '{1,2}')</code></td>
<td><code>{&quot;a&quot;: &quot;1&quot;, &quot;b&quot;: &quot;2&quot;}</code></td>
</tr>
</tbody>
</table>

Note: `array_to_json` and `row_to_json` have the same behavior as `to_json` except for offering a pretty-printing option. The behavior described for `to_json` likewise applies to each individual value converted by the other JSON creation functions.

Note: The `hstore` extension has a cast from `hstore` to `json`, so that `hstore` values converted via the JSON creation functions will be represented as JSON objects, not as primitive string values.

### JSON Aggregate Functions

This table shows the functions aggregate records to an array of JSON objects and pairs of values to a JSON object.

**Table 101: JSON Aggregate Functions**

<table>
<thead>
<tr>
<th>Function</th>
<th>Argument Types</th>
<th>Return Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>json_agg(record)</code></td>
<td>record</td>
<td>json</td>
<td>Aggregates records as a JSON array of objects.</td>
</tr>
<tr>
<td><code>json_object_agg(name, value)</code></td>
<td>(&quot;any&quot;, &quot;any&quot;)</td>
<td>json</td>
<td>Aggregates name/value pairs as a JSON object.</td>
</tr>
</tbody>
</table>

### JSON Processing Functions

This table shows the functions that are available for processing `json` and `jsonb` values.

Many of these processing functions and operators convert Unicode escapes in JSON strings to the appropriate single character. This is not an issue if the input data type is `jsonb`, because the conversion...
was already done. However, for json data type input, this might result in an error being thrown. See About JSON Data in the Greenplum Database Administrator Guide.

### Table 102: JSON Processing Functions

<table>
<thead>
<tr>

Release Notes

Function

Return Type

Description

Example

json_object_
keys(json)

setof text

Returns set
of keys in the
outermost JSON
object.

json_object_
json_object_
keys('{"f1":"abc","f2":
keys
-----------------{"f3":"a",
f1
"f4":"b"}}')
f2

anyelement

Expands the
object in from_
json to a row
whose columns
match the record
type defined by
base. See Note 1.

select * from
a | b
json_populate_
---+--1 | 2
record(null::myrowtype,
'{"a":1,"b":2}')

setof
anyelement

Expands the
outermost array of
objects in from_
json to a set
of rows whose
columns match
the record type
defined by base.
See Note 1.

select * from
a | b
json_populate_
---+--1 | 2
recordset(null::myrowtype,
3 | 4
'[{"a":1,"b":2},
{"a":3,"b":4}]')

setof json

Expands a JSON
array to a set of
JSON values.

select * from
value
json_array_
----------elements('[1,true, 1
true
[2,false]]')
[2,false]

setof text

Expands a JSON
array to a set of
text values.

select * from
json_array_
elements_
text('["foo",
"bar"]')

text

Returns the type
json_
of the outermost
typeof('-123.4')
JSON value as
a text string.
Possible types are
object, array,
string, number,
boolean, and
null. See Note 2

Release Notes

Function

Return Type

Description

Example

json_to_
record(json)

record

Builds an arbitrary
record from a
JSON object. See
Note 1.

select *
a |
b
from json_to_
| d
record('{"a":1,"b":---+--------+--[1,2,3],"c":"bar"}')
1 | [1,2,3]
as x(a int, b
|
text, d text)

jsonb_to_
record(jsonb)

As with all
functions returning
record, the
caller must
explicitly define
the structure of
the record with an
AS clause.
json_to_
setof record
recordset(json)
jsonb_to_
recordset(jsonb)

Builds an arbitrary
set of records
from a JSON
array of objects
See Note 1.
As with all
functions returning
record, the
caller must
explicitly define
the structure of
the record with an
AS clause.

Example Result

select *
a | b
from json_to_
---+----1 | foo
recordset('[{"a":1,"b":"foo"},
2 |
{"a":"2","c":"bar"}]')
as x(a int, b
text);

Note:
1. The examples for the functions json_populate_record(),
json_populate_recordset(), json_to_record() and json_to_recordset() use
constants. However, the typical use would be to reference a table in the FROM clause and use
one of its json or jsonb columns as an argument to the function. The extracted key values
can then be referenced in other parts of the query. For example the value can be referenced in
WHERE clauses and target lists. Extracting multiple values in this way can improve performance
over extracting them separately with per-key operators.
JSON keys are matched to identical column names in the target row type. JSON type coercion
for these functions might not result in desired values for some types. JSON fields that do not
appear in the target row type will be omitted from the output, and target columns that do not
match any JSON field will be NULL.
2. The json_typeof function null return value of null should not be confused with a
SQL NULL. While calling json_typeof('null'::json) will return null, calling
json_typeof(NULL::json) will return a SQL NULL.

Window Functions
The following are Greenplum Database built-in window functions. All window functions are immutable.
For more information about window functions, see "Window Expressions" in the Greenplum Database
Administrator Guide.

1222


## Table 103: Window functions

<table>
<thead>
<tr>
<th>Function</th>
<th>Return Type</th>
<th>Full Syntax</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>cume_dist()</code></td>
<td>double precision</td>
<td><code>CUME_DIST() OVER ( [PARTITION BY expr ] ORDER BY expr )</code></td>
<td>Calculates the cumulative distribution of a value in a group of values. Rows with equal values always evaluate to the same cumulative distribution value.</td>
</tr>
<tr>
<td><code>dense_rank()</code></td>
<td>bigint</td>
<td><code>DENSE_RANK () OVER ( [PARTITION BY expr ] ORDER BY expr )</code></td>
<td>Computes the rank of a row in an ordered group of rows without skipping rank values. Rows with equal values are given the same rank value.</td>
</tr>
<tr>
<td><code>first_value(expr)</code></td>
<td>same as input expr type</td>
<td>`FIRST_VALUE( expr ) OVER ( [PARTITION BY expr ] ORDER BY expr [ROWS</td>
<td>RANGE frame_expr] )`</td>
</tr>
<tr>
<td><code>lag(expr [,offset] [,default])</code></td>
<td>same as input expr type</td>
<td><code>LAG( expr [, offset] [, default]) OVER ( [PARTITION BY expr ] ORDER BY expr )</code></td>
<td>Provides access to more than one row of the same table without doing a self join. Given a series of rows returned from a query and a position of the cursor, LAG provides access to a row at a given physical offset prior to that position. The default offset is 1. default sets the value that is returned if the offset goes beyond the scope of the window. If default is not specified, the default value is null.</td>
</tr>
<tr>
<td><code>last_value(expr)</code></td>
<td>same as input expr type</td>
<td>`LAST_VALUE(expr) OVER ( [PARTITION BY expr] ORDER BY expr [ROWS</td>
<td>RANGE frame_expr] )`</td>
</tr>
</tbody>
</table>
## Advanced Aggregate Functions

The following built-in advanced analytic functions are Greenplum extensions of the PostgreSQL database. Analytic functions are *immutable*.

<table>
<thead>
<tr>
<th>Function</th>
<th>Return Type</th>
<th>Full Syntax</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>lead(expr [,offset] [,default])</code></td>
<td>same as input <code>expr</code> type</td>
<td><code>LEAD(expr [,offset] [,expr default]) OVER ( [PARTITION BY expr] ORDER BY expr )</code></td>
<td>Provides access to more than one row of the same table without doing a self join. Given a series of rows returned from a query and a position of the cursor, <code>lead</code> provides access to a row at a given physical offset after that position. If <code>offset</code> is not specified, the default offset is 1. <code>default</code> sets the value that is returned if the offset goes beyond the scope of the window. If <code>default</code> is not specified, the default value is null.</td>
</tr>
<tr>
<td><code>ntile(expr)</code></td>
<td>bigint</td>
<td><code>NTILE(expr) OVER ( [PARTITION BY expr] ORDER BY expr )</code></td>
<td>Divides an ordered data set into a number of buckets (as defined by <code>expr</code>) and assigns a bucket number to each row.</td>
</tr>
<tr>
<td><code>percent_rank()</code></td>
<td>double precision</td>
<td><code>PERCENT_RANK () OVER ( [PARTITION BY expr] ORDER BY expr )</code></td>
<td>Calculates the rank of a hypothetical row <code>R</code> minus 1, divided by 1 less than the number of rows being evaluated (within a window partition).</td>
</tr>
<tr>
<td><code>rank()</code></td>
<td>bigint</td>
<td><code>RANK () OVER ( [PARTITION BY expr] ORDER BY expr )</code></td>
<td>Calculates the rank of a row in an ordered group of values. Rows with equal values for the ranking criteria receive the same rank. The number of tied rows are added to the rank number to calculate the next rank value. Ranks may not be consecutive numbers in this case.</td>
</tr>
<tr>
<td><code>row_number()</code></td>
<td>bigint</td>
<td><code>ROW_NUMBER () OVER ( [PARTITION BY expr] ORDER BY expr )</code></td>
<td>Assigns a unique number to each row to which it is applied (either each row in a window partition or each row of the query).</td>
</tr>
</tbody>
</table>
**Note:** The Greenplum MADlib Extension for Analytics provides additional advanced functions to perform statistical analysis and machine learning with Greenplum Database data. See [Greenplum MADlib Extension for Analytics](#).

### Table 104: Advanced Aggregate Functions

<table>
<thead>
<tr>
<th>Function</th>
<th>Return Type</th>
<th>Full Syntax</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>MEDIAN (expr)</td>
<td>timestamp, timestamptz, interval, float</td>
<td>MEDIAN (expression) Example: SELECT department_id, MEDIAN(salary) FROM employees GROUP BY department_id;</td>
<td>Can take a two-dimensional array as input. Treats such arrays as matrices.</td>
</tr>
<tr>
<td>PERCENTILE_CONT (expr) WITHIN GROUP (ORDER BY expr [DESC/ASC])</td>
<td>timestamp, timestamptz, interval, float</td>
<td>PERCENTILE_CONT(percentage) WITHIN GROUP (ORDER BY expression) Example: SELECT department_id, PERCENTILE_CONT (0.5) WITHIN GROUP (ORDER BY salary DESC) &quot;Median_cont&quot; FROM employees GROUP BY department_id;</td>
<td>Performs an inverse distribution function that assumes a continuous distribution model. It takes a percentile value and a sort specification and returns the same datatype as the numeric datatype of the argument. This returned value is a computed result after performing linear interpolation. Null are ignored in this calculation.</td>
</tr>
<tr>
<td>PERCENTILE_DISC (expr) WITHIN GROUP (ORDER BY expr [DESC/ASC])</td>
<td>timestamp, timestamptz, interval, float</td>
<td>PERCENTILE_DISC(percentage) WITHIN GROUP (ORDER BY expression) Example: SELECT department_id, PERCENTILE_DISC (0.5) WITHIN GROUP (ORDER BY salary DESC) &quot;Median_disc&quot; FROM employees GROUP BY department_id;</td>
<td>Performs an inverse distribution function that assumes a discrete distribution model. It takes a percentile value and a sort specification. This returned value is an element from the set. Null are ignored in this calculation.</td>
</tr>
<tr>
<td>Function</td>
<td>Return Type</td>
<td>Full Syntax</td>
<td>Description</td>
</tr>
<tr>
<td>----------</td>
<td>-------------</td>
<td>-------------</td>
<td>-------------</td>
</tr>
<tr>
<td>sum(array[])</td>
<td>smallint[], bigint[], float[]</td>
<td>sum([[1,2],[3,4]])</td>
<td>Performs matrix summation. Can take as input a two-dimensional array that is treated as a matrix.</td>
</tr>
<tr>
<td>pivot_sum (label[], label, expr)</td>
<td>int[], bigint[], float[]</td>
<td>pivot_sum( array['A1','A2'], attr, value)</td>
<td>A pivot aggregation using sum to resolve duplicate entries.</td>
</tr>
<tr>
<td>unnest (array[])</td>
<td>set of anyelement</td>
<td>unnest( array['one', 'row', 'per', 'item'])</td>
<td>Transforms a one dimensional array into rows. Returns a set of anyelement, a polymorphic pseudotype in PostgreSQL.</td>
</tr>
</tbody>
</table>

**Text Search Functions and Operators**

The following tables summarize the functions and operators that are provided for full text searching. See *Using Full Text Search* for a detailed explanation of Greenplum Database’s text search facility.

**Table 105: Text Search Operators**

<table>
<thead>
<tr>
<th>Operator</th>
<th>Description</th>
<th>Example</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>@@</td>
<td>tsvector matches tsquery?</td>
<td>to_tsvector('fat cats ate rats') @@ to_tsquery('cat &amp; rat')</td>
<td>t</td>
</tr>
<tr>
<td>@@@</td>
<td>deprecated synonym for @@</td>
<td>to_tsvector('fat cats ate rats') @@@ to_tsquery('cat &amp; rat')</td>
<td>t</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>concatenate tsvectors</td>
</tr>
<tr>
<td>&amp;&amp;</td>
<td>AND tsqueries together</td>
<td>'fat'</td>
<td>rat':tsquery &amp;&amp; 'cat':tsquery</td>
</tr>
<tr>
<td>Operator</td>
<td>Description</td>
<td>Example</td>
<td>Result</td>
</tr>
<tr>
<td>----------</td>
<td>-------------</td>
<td>---------</td>
<td>--------</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>OR tsquerys together</td>
</tr>
<tr>
<td>!!</td>
<td>negate a tsquery</td>
<td>!! 'cat'::tsquery</td>
<td>!!'cat'</td>
</tr>
<tr>
<td>@&gt;</td>
<td>tsquery contains another ?</td>
<td>'cat'::tsquery @&gt; 'cat &amp; rat'::tsquery</td>
<td>f</td>
</tr>
<tr>
<td>&lt;@</td>
<td>tsquery is contained in ?</td>
<td>'cat'::tsquery &lt;@ 'cat &amp; rat'::tsquery</td>
<td>t</td>
</tr>
</tbody>
</table>

**Note:** The tsquery containment operators consider only the lexemes listed in the two queries, ignoring the combining operators.

In addition to the operators shown in the table, the ordinary B-tree comparison operators (=, <, etc) are defined for types tsvector and tsquery. These are not very useful for text searching but allow, for example, unique indexes to be built on columns of these types.

**Table 106: Text Search Functions**

</tr>
<tr>
<td><code>tsvector_update_trigger_column()</code></td>
<td>trigger</td>
<td>trigger function for automatic tsvector column update</td>
<td>CREATE TRIGGER ... tsvector_update_trigger_column(tsvcol, configcol, title, body)</td>
<td></td>
</tr>
</tbody>
</table>
Note: All the text search functions that accept an optional regconfig argument will use the configuration specified by `default_text_search_config` when that argument is omitted.

The functions in the following table are listed separately because they are not usually used in everyday text searching operations. They are helpful for development and debugging of new text search configurations.

Table 107: Text Search Debugging Functions

</tbody>
</table>
Function | Return Type | Description | Example | Result  
---|---|---|---|---
`ts_token_type(parser_oid oid, OUT tokid integer, OUT alias text, OUT description text)` | `setof record` | get token types defined by parser | `ts_token_type(3722)` | `(1, asciiword, "Word, all ASCII")`  

`ts_stat(sqlquery text, [ weights text, ] OUT word text, OUT ndocinteger, OUT nentry integer)` | `setof record` | get statistics of a tsvectorcolumn | `ts_stat('SELECT vector from apod')` | `(foo, 10, 15)`  

**Range Functions and Operators**

See [Range Types](#) for an overview of range types.

The following table shows the operators available for range types.

**Table 108: Range Operators**

| Operator | Description | Example | Result  
---|---|---|---
<p>|=| equal| <code>int4range(1,5) = '1[4]':int4range</code>| t |
|&lt;&gt;| not equal| <code>numrange(1.1,2.2) &lt;&gt; numrange(1.1,2.3)</code>| t |
|&lt;| less than| <code>int4range(1,10) &lt; int4range(2,3)</code>| t |
|&gt;| greater than| <code>int4range(1,10) &gt; int4range(1,5)</code>| t |
|&lt;=| less than or equal| <code>numrange(1.1,2.2) &lt;= numrange(1.1,2.2)</code>| t |
|&gt;=| greater than or equal| <code>numrange(1.1,2.2) &gt;= numrange(1.1,2.2)</code>| t |
|@&gt;| contains range| <code>int4range(2,4) @&gt; int4range(2,3)</code>| t |
|@&gt;| contains element| <code>'[2011-01-01,2011-03-01)'::tsrange @&gt; '2011-01-10':tsamp</code>| t |</p>
<table>
<thead>
<tr>
<th>Operator</th>
<th>Description</th>
<th>Example</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt;@</td>
<td>range is contained by</td>
<td>int4range(2,4) &lt;@ int4range(1,7)</td>
<td>t</td>
</tr>
<tr>
<td>&lt;@</td>
<td>element is contained by</td>
<td>42 &lt;@ int4range(1,7)</td>
<td>f</td>
</tr>
<tr>
<td>&amp;&amp;</td>
<td>overlap (have points in common)</td>
<td>int8range(3,7) &amp;&amp; int8range(4,12)</td>
<td>t</td>
</tr>
<tr>
<td>&lt;&lt;</td>
<td>strictly left of</td>
<td>int8range(1,10) &lt;&lt; int8range(100,110)</td>
<td>t</td>
</tr>
<tr>
<td>&gt;&gt;</td>
<td>strictly right of</td>
<td>int8range(50,60) &gt;&gt; int8range(20,30)</td>
<td>t</td>
</tr>
<tr>
<td>&amp;&lt;</td>
<td>does not extend to the right of</td>
<td>int8range(1,20) &amp;&lt; int8range(18,20)</td>
<td>t</td>
</tr>
<tr>
<td>&amp;&gt;</td>
<td>does not extend to the left of</td>
<td>int8range(7,20) &amp;&gt; int8range(5,10)</td>
<td>t</td>
</tr>
<tr>
<td>-</td>
<td>-</td>
<td>is adjacent to</td>
<td>numrange(1.1,2.2) -</td>
</tr>
<tr>
<td>+</td>
<td>union</td>
<td>numrange(5,15) + numrange(10,20)</td>
<td>[5,20)</td>
</tr>
<tr>
<td>*</td>
<td>intersection</td>
<td>int8range(5,15) * int8range(10,20)</td>
<td>[10,15)</td>
</tr>
<tr>
<td>-</td>
<td>difference</td>
<td>int8range(5,15) - int8range(10,20)</td>
<td>[5,10)</td>
</tr>
</tbody>
</table>

The simple comparison operators <, >, <=, and >= compare the lower bounds first, and only if those are equal, compare the upper bounds. These comparisons are not usually very useful for ranges, but are provided to allow B-tree indexes to be constructed on ranges.

The left-of/right-of/adjacent operators always return false when an empty range is involved; that is, an empty range is not considered to be either before or after any other range.

The union and difference operators will fail if the resulting range would need to contain two disjoint sub-ranges, as such a range cannot be represented.

The following table shows the functions available for use with range types.

**Table 109: Range Functions**

<table>
<thead>
<tr>

<th>Description</th>
<th>Example</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>lower(anyrange)</td>
<td>range's element type</td>
<td>lower bound of range</td>
<td>lower(numrange(1.1,2.2))</td>
<td></td>
</tr>
<tr>
<td>upper(anyrange)</td>
<td>range's element type</td>
<td>upper bound of range</td>
<td>upper(numrange(1.2,2.2))</td>
<td></td>
</tr>
<tr>
<td>isempty(anyrange)</td>
<td>boolean</td>
<td>is the range empty?</td>
<td>isempty(numrange(1.2,2.2))</td>
<td>false</td>
</tr>
<tr>
<td>Function</td>
<td>Return Type</td>
<td>Description</td>
<td>Example</td>
<td>Result</td>
</tr>
<tr>
<td>-------------------</td>
<td>-------------</td>
<td>---------------------------------</td>
<td>------------------------------</td>
<td>--------</td>
</tr>
<tr>
<td>lower_inc(anyrange)</td>
<td>boolean</td>
<td>is the lower bound inclusive?</td>
<td>lower_inc(numrange(1.1,2.2))</td>
<td>true</td>
</tr>
<tr>
<td>upper_inc(anyrange)</td>
<td>boolean</td>
<td>is the upper bound inclusive?</td>
<td>upper_inc(numrange(1.1,2.2))</td>
<td>false</td>
</tr>
<tr>
<td>lower_inf(anyrange)</td>
<td>boolean</td>
<td>is the lower bound infinite?</td>
<td>lower_inf('(,)'::daterange)</td>
<td>true</td>
</tr>
<tr>
<td>upper_inf(anyrange)</td>
<td>boolean</td>
<td>is the upper bound infinite?</td>
<td>upper_inf('(,)'::daterange)</td>
<td>true</td>
</tr>
<tr>
<td>range_merge(anyrange, anyrange)</td>
<td>anyrange</td>
<td>the smallest range which includes both of the given ranges</td>
<td>range_merge('[1,2)'::int4range, '[3,4)'::int4range)</td>
<td>[1,4]</td>
</tr>
</tbody>
</table>

The `lower` and `upper` functions return null if the range is empty or the requested bound is infinite. The `lower_inc`, `upper_inc`, `lower_inf`, and `upper_inf` functions all return false for an empty range.
Procedural Languages and Analytics Extensions

This section describes the procedural languages and analytics extensions available with Greenplum Database.

The Greenplum Database distribution supports the following procedural languages; refer to the linked language documentation for installation and usage instructions:

- PL/Container
- PL/Java
- PL/Perl
- PL/pgSQL
- PL/Python
- PL/R

You can use the following analytics extensions with Greenplum Database; refer to the linked documentation for installation and usage instructions:

- MADlib
- PostGIS

PL/Container Language

This section includes the following information about PL/Container 1.1 and later:

- About the PL/Container Language Extension
- About PL/Container Resource Management
- PL/Container Docker Images
- Installing the PL/Container Language Extension
- Upgrading from PL/Container 1.0
- Upgrading from PL/Container 1.1
- Uninstalling PL/Container
- Using PL/Container Functions
- About PL/Container Running PL/Python
- About PL/Container Running PL/R
- Configuring PL/Container
- Installing Docker
- References

Note: The extension PL/Container 1.1 and later is installed by gppkg as a Greenplum Database extension, while the extension PL/Container 1.0 is installed as a Greenplum Database language. To upgrade to PL/Container 1.1 or later from PL/Container 1.0, you uninstall the old version and install the new version. See Upgrading from PL/Container 1.0.

Warning: PL/Container is compatible with Greenplum Database 5.2.0 and later. PL/Container has not been tested for compatibility with Greenplum Database 5.1.0 or 5.0.0.

About the PL/Container Language Extension

The Greenplum Database PL/Container language extension (PL/Container) is an interface that allows Greenplum Database to interact with a Docker container to execute a user-defined function (UDF) in the container. Docker containers ensure the user code cannot access the file system of the source host. Also, containers are started without network access or with limited network access and cannot connect back to Greenplum Database or open any other external connections. For information about available UDF languages, see PL/Container Docker Images.
Generally speaking, a Docker container is a Linux process that runs in a managed way by using Linux kernel features such as cgroups, namespaces and union file systems. A Docker image is the basis of a container. A Docker container is a running instance of a Docker image. When you start a Docker container you specify a Docker image. A Docker image is the collection of root filesystem changes and execution parameters that are used when you run a Docker container on the host system. An image does not have state and never changes. For information about Docker, see the Docker web site https://www.docker.com/.

Greenplum Database starts a container only on the first call to a function in that container. For example, consider a query that selects table data using all available segments, and applies a transformation to the data using a PL/Container function. In this case, Greenplum Database would start the Docker container only once on each segment, and then contact the running container to obtain the results.

After starting a full cycle of a query execution, the executor sends a call to the container. The container might respond with an SPI - SQL query executed by the container to get some data back from the database, returning the result to the query executor.

The container shuts down when the connection to it is closed. This occurs when you close the Greenplum Database session that started the container. A container running in standby mode has almost no consumption of CPU resources as it is waiting on the socket. PL/Container memory consumption depends on the amount of data you cache in global dictionaries.

**Warning:** PL/Container is not supported when Greenplum Database is run within a Docker container.

The PL/Container language extension is available as an open source module. For information about the module, see the README file in the GitHub repository at https://github.com/greenplum-db/plcontainer.

**About PL/Container Resource Management**

Greenplum Database runs PL/Container user-defined functions in Docker containers. The Docker containers and the Greenplum Database server share CPU and memory resources on the same hosts. In the default case, Greenplum Database is unaware of the resources consumed by running PL/Container instances. In PL/Container version 1.2 and later, you can use Greenplum Database resource groups to control overall CPU and memory resource usage for running PL/Container instances, as described in the following section.

PL/Container manages resource usage at two levels - the container level and the runtime level. You can control container-level CPU and memory resources with the `memory_mb` and `cpu_share` settings that you configure for the PL/Container runtime. `memory_mb` governs the memory resources available to each container instance. The `cpu_share` setting identifies the relative weighting of a container's CPU usage compared to other containers. Refer to PL/Container Configuration File for PL/Container configuration information.

You cannot by default restrict the number of executing PL/Container container instances, nor can you restrict the total amount of memory or CPU resources that they consume.

**Using Resource Groups to Manage PL/Container Resources**

In PL/Container version 1.2.0 and later, you can use Greenplum Database resource groups to manage and limit the total CPU and memory resources of containers in PL/Container runtimes. For more information about enabling, configuring, and using Greenplum Database resource groups, refer to Using Resource Groups in the Greenplum Database Administrator Guide.

**Note:** If you do not explicitly configure resource groups for a PL/Container runtime, its container instances are limited only by system resources. The containers may consume resources at the expense of the Greenplum Database server.

Resource groups for external components such as PL/Container use Linux control groups (cgroups) to manage component-level use of memory and CPU resources. When you manage PL/Container resources with resource groups, you configure both a memory limit and a CPU limit that Greenplum Database applies to all container instances that share the same PL/Container runtime configuration.
When you create a resource group to manage the resources of a PL/Container runtime, you must specify
MEMORY_AUDITOR=cgroup and CONCURRENCY=0 in addition to the required CPU and memory limits.
For example, the following command creates a resource group named plpy_run1_rg for a PL/Container
runtime:

```
CREATE RESOURCE GROUP plpy_run1_rg WITH (MEMORY_AUDITOR=cgroup,
CONCURRENCY=0,
  CPU_RATE_LIMIT=10, MEMORY_LIMIT=10);
```

PL/Container does not use the MEMORY_SHARED_QUOTA and MEMORY_SPILL_RATIO resource group
memory limits. Refer to the CREATE RESOURCE GROUP reference page for detailed information about this
SQL command.

You can create one or more resource groups to manage your running PL/Container instances. After you
create a resource group for PL/Container, you assign the resource group to one or more PL/Container
runtimes. You make this assignment using the groupid of the resource group. You can determine the
groupid for a given resource group name from the gp_resgroup_config gp_toolkit view. For
example, the following query displays the groupid of a resource group named plpy_run1_rg:

```
SELECT groupname, groupid FROM gp_toolkit.gp_resgroup_config
WHERE groupname='plpy_run1_rg';
```

<table>
<thead>
<tr>
<th>groupname</th>
<th>groupid</th>
</tr>
</thead>
<tbody>
<tr>
<td>plpy_run1_rg</td>
<td>16391</td>
</tr>
</tbody>
</table>

You assign a resource group to a PL/Container runtime configuration by specifying the -s
resource_group_id=rg_groupid option to the plcontainer runtime-add (new runtime)
or plcontainer runtime-replace (existing runtime) commands. For example, to assign the
plpy_run1_rg resource group to a new PL/Container runtime named python_run1:

```
plcontainer runtime-add -r python_run1 -i pivotaldata/plcontainer_python_shared:devel -l python -s resource_group_id=16391
```

You can also assign a resource group to a PL/Container runtime using the plcontainer runtime-
edit command. For information about the plcontainer command, see The plcontainer Utility.

After you assign a resource group to a PL/Container runtime, all container instances that share the same
runtime configuration are subject to the memory limit and the CPU limit that you configured for the group. If
you decrease the memory limit of a PL/Container resource group, queries executing in running containers
in the group may fail with an out of memory error. If you drop a PL/Container resource group while there
are running container instances, Greenplum Database kills the running containers.

**Configuring Resource Groups for PL/Container**

To use Greenplum Database resource groups to manage PL/Container resources, you must explicitly
configure both resource groups and PL/Container.

**Note:** PL/Container version 1.2 utilizes the new resource group capabilities introduced in
Greenplum Database version 5.8.0. If you downgrade to a Greenplum Database system that uses
PL/Container version 1.1. or earlier, you must use plcontainer runtime-edit to remove any
resource_group_id settings from your PL/Container runtime configuration.

**Procedure**

Perform the following procedure to configure PL/Container to use Greenplum Database resource groups
for CPU and memory resource management:
1. If you have not already configured and enabled resource groups in your Greenplum Database deployment, configure cgroups and enable Greenplum Database resource groups as described in *Using Resource Groups* in the *Greenplum Database Administrator Guide*.

   **Note:** If you have previously configured and enabled resource groups in your deployment, ensure that the Greenplum Database resource group gpdb.conf cgroups configuration file includes a `memory { }` block as described in the previous link.

2. Analyze the resource usage of your Greenplum Database deployment. Determine the percentage of resource group CPU and memory resources that you want to allocate to PL/Container Docker containers.

3. Determine how you want to distribute the total PL/Container CPU and memory resources that you identified in the step above among the PL/Container runtimes. Identify:
   - The number of PL/Container resource group(s) that you require.
   - The percentage of memory and CPU resources to allocate to each resource group.
   - The resource-group-to-PL/Container-runtime assignment(s).

4. Create the PL/Container resource groups that you identified in the step above. For example, suppose that you choose to allocate 25% of both memory and CPU Greenplum Database resources to PL/Container. If you further split these resources among 2 resource groups 60/40, the following SQL commands create the resource groups:

   ```sql
   CREATE RESOURCE GROUP plr_run1_rg WITH (MEMORY_AUDITOR=cgroup,
   CONCURRENCY=0,
   CPU_RATE_LIMIT=15, MEMORY_LIMIT=15);
   CREATE RESOURCE GROUP plpy_run1_rg WITH (MEMORY_AUDITOR=cgroup,
   CONCURRENCY=0,
   CPU_RATE_LIMIT=10, MEMORY_LIMIT=10);
   ```

5. Find and note the `groupid` associated with each resource group that you created. For example:

   ```sql
   SELECT groupname, groupid FROM gp_toolkit.gp_resgroup_config
   WHERE groupname IN ('plpy_run1_rg', 'plr_run1_rg');
   
<table>
<thead>
<tr>
<th>groupname</th>
<th>groupid</th>
</tr>
</thead>
<tbody>
<tr>
<td>plpy_run1_rg</td>
<td>16391</td>
</tr>
<tr>
<td>plr_run1_rg</td>
<td>16393</td>
</tr>
</tbody>
</table>
   (1 row)
   ```

6. Assign each resource group that you created to the desired PL/Container runtime configuration. If you have not yet created the runtime configuration, use the `plcontainer runtime-add` command. If the runtime already exists, use the `plcontainer runtime-replace` or `plcontainer runtime-edit` command to add the resource group assignment to the runtime configuration. For example:

   ```bash
   plcontainer runtime-add -r python_run1 -i pivotaldata/plcontainer_python_shared:devel -l python -s resource_group_id=16391
   plcontainer runtime-replace -r r_run1 -i pivotaldata/plcontainer_r_shared:devel -l r -s resource_group_id=16393
   ```

   For information about the `plcontainer` command, see *The plcontainer Utility*.

**PL/Container Docker Images**

A PL/Python image and a PL/R image are available from the Greenplum Database product download site of Pivotal Network at [https://network.pivotai.io/](https://network.pivotai.io/).

- **PL/Container for Python** - Docker image with Python 2.7.12 installed.

  The Python Data Science Module is also installed. The module contains a set python libraries related to data science. For information about the module, see *Python Data Science Module Package*. 

---

1236
• PL/Container for R - A Docker image with container with R-3.3.3 installed.

   The R Data Science package is also installed. The package contains a set of R libraries related to data science. For information about the module, see R Data Science Library Package.

The Docker image tag represents the PL/Container release version (for example, 1.0.0). For example, the full Docker image name for the PL/Container for Python Docker image is similar to pivotaldata/plc_python_shared:1.0.0. This is the name that is referred to in the default PL/Container configuration. Also, You can create custom Docker images, install the image and add the image to the PL/Container configuration.

Prerequisites

Ensure your Greenplum Database system meets the following prerequisites:

• PL/Container is supported on Pivotal Greenplum Database 5.2.x on Red Hat Enterprise Linux (RHEL) 7.x (or later) and CentOS 7.x (or later).

   Note: PL/Container is not supported on RHEL/CentOS 6.x systems, because those platforms do not officially support Docker.

• These are Docker host operating system prerequisites.

   RHEL or CentOS 7.x - Minimum supported Linux OS kernel version is 3.10. RHEL 7.x and CentOS 7.x use this kernel version.

   You can check your kernel version with the command `uname -r`

   Note: The Red Hat provided, maintained, and supported version of Docker is only available on RHEL 7. Docker feature developments are tied to RHEL7.x infrastructure components for kernel, devicemapper (thin provisioning, direct lvm), sVirt and systemd.

• Docker is installed on Greenplum Database hosts (master, primary and all standby hosts)

   • For RHEL or CentOS 7.x - Docker 17.05

   See Installing Docker.

• On each Greenplum Database host the `gpadmin` user should be part of the `docker` group for the user to be able to manage Docker images and containers.

Installing the PL/Container Language Extension

To use PL/Container, install the PL/Container language extension, install Docker images, and configure PL/Container to use the images.

1. Ensure the Greenplum Database hosts meet the prerequisites, see Prerequisites.
2. Install the PL/Container extension, see Installing the PL/Container Language Extension Package.

   If you are upgrading from PL/Container 1.0, see Upgrading from PL/Container 1.0.
3. Install Docker images and configure PL/Container, see Installing PL/Container Docker Images.

Installing the PL/Container Language Extension Package

Install the PL/Container language extension with the Greenplum Database `gppkg` utility.

1. Copy the PL/Container language extension package to the Greenplum Database master host as the `gpadmin` user.
2. Make sure Greenplum Database is up and running. If not, bring it up with this command.

   ```bash
gpstart -a
   ```

3. Run the package installation command.

   ```bash
gppkg -i plcontainer-1.1.0-rhel7-x86_64.gppkg
   ```
4. Source the file \$GPHOME/greenplum_path.sh.

source \$GPHOME/greenplum_path.sh

5. Restart Greenplum Database.

gpstop -ra

6. Enable PL/Container for specific databases by running this command.

a. For PL/Container 1.1 and later, log into the database as a Greenplum Database superuser (\$GPHOME/greenplum_path.sh) and run this command.

   create extension plcontainer;

   The command registers PL/Container and creates PL/Container-specific functions and views.

b. For PL/Container 1.0, run this command.

   psql -d your_database -f \$GPHOME/share/postgresql/plcontainer/plcontainer_install.sql

   The SQL script registers the language plcontainer in the database and creates PL/Container-specific functions and views.

After installing PL/Container, you can manage Docker images and manage the PL/Container configuration with the Greenplum Database plcontainer utility.

**Upgrading from PL/Container 1.0**

To upgrade to version 1.1 or higher, uninstall version 1.0 and install the new version. The gppkg utility installs PL/Container version 1.1 and later as a Greenplum Database extension, while PL/Container 1.0 is installed as a Greenplum Database language. The Docker images and the PL/Container configuration do not change when upgrading PL/Container, only the PL/Container extension installation changes.

As part of the upgrade process, you must drop PL/Container from all databases that are configured with PL/Container.

**Important:** Dropping PL/Container from a database drops all PL/Container UDFs from the database, including user-created PL/Container UDFs. If the UDFs are required, ensure you can re-create the UDFs before dropping PL/Container. This SELECT command lists the names of and body of PL/Container UDFs in a database.

   SELECT proname, prosrc FROM pg_proc WHERE prolang = (SELECT oid FROM pg_language WHERE lanname = 'plcontainer');

   For information about the catalog tables, pg_proc and pg_language, see **System Tables**.

These steps upgrade from PL/Container 1.0 to PL/Container 1.1 or later in a database. The steps save the PL/Container 1.0 configuration and restore the configuration for use with PL/Container 1.1 or later.

1. Save the PL/Container configuration. This example saves the configuration to plcontainer10-backup.xml in the local directory.

   plcontainer runtime-backup -f plcontainer10-backup.xml

2. Remove any setting elements that contain the use_container_network attribute from the configuration file. For example, this setting element must be removed from the configuration file.

   &lt;setting use_container_network="yes"&gt;
3. Run the `plcontainer_uninstall.sql` script as the `gpadmin` user for each database that is configured with PL/Container. For example, this command drops the `plcontainer` language in the `mytest` database.

```sql
psql -d mytest -f $GPHOME/share/postgresql/plcontainer/plcontainer_uninstall.sql
```

The script drops the `plcontainer` language with the `CASCADE` clause that drops PL/Container-specific functions and views in the database.

4. Use the Greenplum Database `gppkg` utility with the `-r` option to uninstall the PL/Container language extension. This example uninstalls the PL/Container language extension on a Linux system.

```
$ gppkg -r plcontainer-1.0.0
```

5. Run the package installation command. This example installs the PL/Container 1.1 language extension on a Linux system.

```
gppkg -i plcontainer-1.1.0-rhel7-x86_64.gppkg
```

6. Source the file `$GPHOME/greenplum_path.sh`.

```
source $GPHOME/greenplum_path.sh
```

7. Update the PL/Container configuration. This command restores the saved configuration.

```
plcontainer runtime-restore -f plcontainer10-backup.xml
```

8. Restart Greenplum Database.

```
gpstop -ra
```

9. Register the new PL/Container extension as an extension for each database that uses PL/Container UDFs. This `psql` command runs a `CREATE EXTENSION` command to register PL/Container in the database `mytest`.

```
psql -d mytest -c 'CREATE EXTENSION plcontainer;'
```

The command registers PL/Container as an extension and creates PL/Container-specific functions and views.

After upgrading PL/Container for a database, re-install any user-created PL/Container UDFs that are required.

**Upgrading from PL/Container 1.1**

To upgrade from PL/Container version 1.1 or higher, you save the current configuration, upgrade PL/Container, and then restore the configuration after upgrade. There is no need to update the Docker images when you upgrade PL/Container.

**Note:** Before you perform this upgrade procedure, ensure that you have migrated your PL/Container 1.1 package from your previous Greenplum Database installation to your new Greenplum Database installation. Refer to the `gppkg` command for package installation and migration information.

Perform the following procedure to upgrade from PL/Container 1.1 to PL/Container version 1.2 or later.

1. Save the PL/Container configuration. For example, to save the configuration to a file named `plcontainer110-backup.xml` in the local directory:

```
$ plcontainer runtime-backup -f plcontainer110-backup.xml
```
2. Use the Greenplum Database `gppkg` utility with the `-u` option to update the PL/Container language extension. For example, the following command updates the PL/Container language extension to version 1.2 on a Linux system:

```
$ gppkg -u plcontainer-1.2.0-rhel7-x86_64.gppkg
```

```
$ source $GPHOME/greenplum_path.sh
```

4. Restore the PL/Container configuration. For example, this command restores the PL/Container configuration that you saved in a previous step:

```
$ plcontainer runtime-restore -f plcontainer110-backup.xml
```

5. Restart Greenplum Database.

```
$ gpstop -ra
```

6. You do not need to re-register the PL/Container extension in the databases in which you previously created the extension. Do register the PL/Container extension in each new database that will run PL/Container UDFs. For example, the following command registers PL/Container in a database named `mytest`:

```
$ psql -d mytest -c 'CREATE EXTENSION plcontainer;'
```

The command also creates PL/Container-specific functions and views.

Note: PL/Container version 1.2 utilizes the new resource group capabilities introduced in Greenplum Database version 5.8.0. If you downgrade to a Greenplum Database system that uses PL/Container version 1.1. or earlier, you must use `plcontainer runtime-edit` to remove any `resource_group_id` settings from your PL/Container runtime configuration.

### Installing PL/Container Docker Images

The PL/Container language extension includes the `plcontainer` utility that installs Docker images on the Greenplum Database hosts and adds configuration information to the PL/Container configuration file. The configuration information allows PL/Container to create Docker containers with the Docker images. For information about `plcontainer`, see The `plcontainer` Utility.

Download the `tar.gz` file that contains the Docker images from Pivotal Network.

- `plcontainer-python-images-1.0.0.tar.gz`
- `plcontainer-r-images-1.0.0.tar.gz`

Install the Docker images on the Greenplum Database hosts. This example uses the `plcontainer` utility to install a Docker image for Python and to update the PL/Container configuration. The example assumes the Docker image to be installed is in a file in `/home/gpadmin`.

This `plcontainer` command installs the Docker image for PL/Python from a Docker image file.

```
plcontainer image-add -f /home/gpadmin/plcontainer-python-images-1.0.0.tar.gz
```

The utility displays progress information as it installs the Docker image on the Greenplum Database hosts. Use the `plcontainer image-list` command to display the installed Docker images on the local host.
This command adds information to the PL/Container configuration file so that PL/Container can access the Docker image to create a Docker container.

```
plcontainer runtime-add -r plc_py -i pivotaldata/plcontainer_python_shared:devel -l python
```

The utility displays progress information as it updates the PL/Container configuration file on the Greenplum Database instances.

You can view the PL/Container configuration information with the `plcontainer runtime-show -r plc_py` command. You can view the PL/Container configuration XML file with the `plcontainer runtime-edit` command.

**Uninstalling PL/Container**

To uninstall PL/Container, remove Docker containers and images, and then remove the PL/Container support from Greenplum Database.

When you remove support for PL/Container, the `plcontainer` user-defined functions that you created in the database will no longer work.

**Uninstall Docker Containers and Images**

On the Greenplum Database hosts, uninstall the Docker containers and images that are no longer required.

The `plcontainer image-list` command lists the Docker images that are installed on the local Greenplum Database host.

The `plcontainer image-delete` command deletes a specified Docker image from all Greenplum Database hosts.

Some Docker containers might exist on a host if the containers were not managed by PL/Container. You might need to remove the containers with Docker commands. These `docker` commands manage Docker containers and images on a local host.

- The command `docker ps -a` lists all containers on a host. The command `docker stop` stops a container.
- The command `docker images` lists the images on a host.
- The command `docker rmi` removes images.
- The command `docker rm` removes containers.

**Remove PL/Container Support for a Database**

For a database that no longer requires PL/Container, remove support for PL/Container.

**PL/Container 1.1 and Later**

For PL/Container 1.1 and later, drop the extension from the database. This `psql` command runs a `DROP EXTENSION` command to remove PL/Container in the database `mytest`.

```
psql -d mytest -c 'DROP EXTENSION plcontainer cascade;'
```

The command drops the `plcontainer` extension and drops PL/Container-specific functions and views from the database.
**PL/Container 1.0**

Run the `plcontainer_uninstall.sql` script as the `gpadmin` user. For example, this command removes the `plcontainer` language in the `mytest` database.

```sql
psql -d mytest -f $GPHOME/share/postgresql/plcontainer/plcontainer_uninstall.sql
```

The script drops the `plcontainer` language with `CASCADE` to drop PL/Container-specific functions and views from the database.

**Uninstalling PL/Container Language Extension**

If no databases have `plcontainer` as a registered language, uninstall the Greenplum Database PL/Container language extension with the `gppkg` utility.

1. Use the Greenplum Database `gppkg` utility with the `-r` option to uninstall the PL/Container language extension. This example uninstalls the PL/Container language extension on a Linux system:

   ```bash
   $ gppkg -r plcontainer-1.1.0
   ```

   You can run the `gppkg` utility with the options `-q --all` to list the installed extensions and their versions.

2. Reload `greenplum_path.sh`.

   ```bash
   $ source $GPHOME/greenplum_path.sh
   ```

3. Restart the database.

   ```bash
   $ gpstop -ra
   ```

**Using PL/Container Functions**

When you enable PL/Container in a database of a Greenplum Database system, the language `plcontainer` is registered in the database. You can create and run user-defined functions in the procedural languages supported by the PL/Container Docker images when you specify `plcontainer` as a language in a UDF definition.

A UDF definition that uses PL/Container must have these items.

- The first line of the UDF must be `# container: ID`
- The `LANGUAGE` attribute must be `plcontainer`

The `ID` is the name that PL/Container uses to identify a Docker image. When Greenplum Database executes a UDF on a host, the Docker image on the host is used to start a Docker container that runs the UDF. In the XML configuration file `plcontainer_configuration.xml`, there is a runtime XML element that contains a corresponding `id` XML element that specifies the Docker container startup information. See *Configuring PL/Container* for information about how PL/Container maps the `ID` to a Docker image. See *Examples* for example UDF definitions.

The PL/Container configuration file is read only on the first invocation of a PL/Container function in each Greenplum Database session that runs PL/Container functions. You can force the configuration file to be re-read by performing a `SELECT` command on the view `plcontainer_refresh_config` during the session. For example, this `SELECT` command forces the configuration file to be read.

```
SELECT * FROM plcontainer_refresh_config;
```
Running the command executes a PL/Container function that updates the configuration on the master and segment instances and returns the status of the refresh.

```
gp_segment_id | plcontainer_refresh_local_config
---------------+----------------------------------
   1          | ok
    0          | ok
   -1          | ok
(3 rows)
```

Also, you can show all the configurations in the session by performing a `SELECT` command on the view `plcontainer_show_config`. For example, this `SELECT` command returns the PL/Container configurations.

```
SELECT * FROM plcontainer_show_config;
```

Running the command executes a PL/Container function that displays configuration information from the master and segment instances. This is an example of the start and end of the view output.

```

    1          | ok
```

The PL/Container function `plcontainer_containers_summary()` displays information about the currently running Docker containers.

```
SELECT * FROM plcontainer_containers_summary();
```

If a normal (non-superuser) Greenplum Database user runs the function, the function displays information only for containers created by the user. If a Greenplum Database superuser runs the function, information
for all containers created by Greenplum Database users is displayed. This is sample output when 2 containers are running.

**Examples**

The values in the # container lines of the examples, plc_python_shared and plc_r_shared, are the id XML elements defined in the plcontainer_config.xml file. The id element is mapped to the image element that specifies the Docker image to be started. If you configured PL/Container with a different ID, change the value of the # container line. For information about configuring PL/Container and viewing the configuration settings, see Configuring PL/Container.

This is an example of PL/Python function that runs using the plc_python_shared container:

```python
CREATE OR REPLACE FUNCTION pylog100() RETURNS double precision AS $$
# container: plc_python_shared
import math
return math.log10(100)
$$ LANGUAGE plcontainer;
```

This is an example of a similar function using the plc_r_shared container:

```r
CREATE OR REPLACE FUNCTION rlog100() RETURNS text AS $$
# container: plc_r_shared
return(log10(100))
$$ LANGUAGE plcontainer;
```

If the # container line in a UDF specifies an ID that is not in the PL/Container configuration file, Greenplum Database returns an error when you try to execute the UDF.

**About PL/Container Running PL/Python**

In the Python language container, the module plpy is implemented. The module contains these methods:

- `plpy.execute(stmt)` - Executes the query string `stmt` and returns query result in a list of dictionary objects. To be able to access the result fields ensure your query returns named fields.
- `plpy.prepare(stmt[, argtypes])` - Prepares the execution plan for a query. It is called with a query string and a list of parameter types, if you have parameter references in the query.
- `plpy.execute(plan[, argtypes])` - Executes a prepared plan.
- `plpy.debug(msg)` - Sends a DEBUG2 message to the Greenplum Database log.
- `plpy.log(msg)` - Sends a LOG message to the Greenplum Database log.
- `plpy.info(msg)` - Sends an INFO message to the Greenplum Database log.
- `plpy.notice(msg)` - Sends a NOTICE message to the Greenplum Database log.
- `plpy.warning(msg)` - Sends a WARNING message to the Greenplum Database log.
• `plpy.error(msg)` - Sends an ERROR message to the Greenplum Database log. An ERROR message raised in Greenplum Database causes the query execution process to stop and the transaction to rollback.

• `plpy.fatal(msg)` - Sends a FATAL message to the Greenplum Database log. A FATAL message causes Greenplum Database session to be closed and transaction to be rolled back.

• `plpy.subtransaction()` - Manages `plpy.execute` calls in an explicit subtransaction. See Explicit Subtransactions in the PostgreSQL documentation for additional information about `plpy.subtransaction()`.

If an error of level ERROR or FATAL is raised in a nested Python function call, the message includes the list of enclosing functions.

The Python language container supports these string quoting functions that are useful when constructing ad-hoc queries.

• `plpy.quote_literal(string)` - Returns the string quoted to be used as a string literal in an SQL statement string. Embedded single-quotes and backslashes are properly doubled. `quote_literal()` returns null on null input (empty input). If the argument might be null, `quote_nullable()` might be more appropriate.

• `plpy.quote_nullable(string)` - Returns the string quoted to be used as a string literal in an SQL statement string. If the argument is null, returns `NULL`. Embedded single-quotes and backslashes are properly doubled.

• `plpy.quote_ident(string)` - Returns the string quoted to be used as an identifier in an SQL statement string. Quotes are added only if necessary (for example, if the string contains non-identifier characters or would be case-folded). Embedded quotes are properly doubled.

When returning text from a PL/Python function, PL/Container converts a Python unicode object to text in the database encoding. If the conversion cannot be performed, an error is returned.

PL/Container does not support this Greenplum Database PL/Python feature:

• Multi-dimensional arrays.

Also, the Python module has two global dictionary objects that retain the data between function calls. They are named GD and SD. GD is used to share the data between all the function running within the same container, while SD is used for sharing the data between multiple calls of each separate function. Be aware that accessing the data is possible only within the same session, when the container process lives on a segment or master. Be aware that for idle sessions Greenplum Database terminates segment processes, which means the related containers would be shut down and the data from GD and SD lost.

For information about PL/Python, see PL/Python Language.

### About PL/Container Running PL/R

In the R language container, the module `pg.spi` is implemented. The module contains these methods:

• `pg.spi.exec(stmt)` - Executes the query string `stmt` and returns query result in R data.frame. To be able to access the result fields make sure your query returns named fields.

• `pg.spi.prepare(stmt[, argtypes])` - Prepares the execution plan for a query. It is called with a query string and a list of parameter types if you have parameter references in the query.

• `pg.spi.execp(plan[, argtypes])` - Execute a prepared plan.

• `pg.spi.debug(msg)` - Sends a DEBUG2 message to the Greenplum Database log.

• `pg.spi.log(msg)` - Sends a LOG message to the Greenplum Database log.

• `pg.spi.info(msg)` - Sends an INFO message to the Greenplum Database log.

• `pg.spi.notice(msg)` - Sends a NOTICE message to the Greenplum Database log.

• `pg.spi.warning(msg)` - Sends a WARNING message to the Greenplum Database log.
• `pg.spi.error(msg)` - Sends an ERROR message to the Greenplum Database log. An ERROR message raised in Greenplum Database causes the query execution process to stop and the transaction to rollback.

• `pg.spi.fatal(msg)` - Sends a FATAL message to the Greenplum Database log. A FATAL message causes Greenplum Database session to be closed and transaction to be rolled back.

PL/Container does not support this PL/R feature:

• Multi-dimensional arrays.

For information about PL/R, see *PL/R Language*.

### Configuring PL/Container

The Greenplum Database utility `plcontainer` manages the PL/Container configuration files in a Greenplum Database system. The utility ensures that the configuration files are consistent across the Greenplum Database master and segment instances.

**Warning:** Modifying the configuration files on the segment instances without using the utility might create different, incompatible configurations on different Greenplum Database segments that could cause unexpected behavior.

Configuration changes that are made with the utility are applied to the XML files on all Greenplum Database segments. However, PL/Container configurations of currently running sessions use the configuration that existed during session start up. To update the PL/Container configuration in a running session, execute this command in the session.

```
SELECT * FROM plcontainer_refresh_config;
```

Running the command executes a PL/Container function that updates the session configuration on the master and segment instances.

### The plcontainer Utility

The `plcontainer` utility installs Docker images and manages the PL/Container configuration. The utility consists of two sets of commands.

• **image-** commands manage Docker images on the Greenplum Database system hosts.

• **runtime-** commands manage the PL/Container configuration file on the Greenplum Database instances. You can add Docker image information to the PL/Container configuration file including the image name, location, and shared folder information. You can also edit the configuration file.

To configure PL/Container to use a Docker image, you install the Docker image on all the Greenplum Database hosts and then add configuration information to the PL/Container configuration.

PL/Container configuration values, such as image names, runtime IDs, and parameter values and names are case sensitive.

### plcontainer Syntax

```
plcontainer [command] [-h | --help] [--verbose]
```

Where `command` is one of the following.

```
image-add {{-f | --file} image_file} | {{-u | --URL} image_URL}
image-delete {-i | --image} image_name
image-list
```
plcontainer Commands and Options

**image-add location**

Install a Docker image on the Greenplum Database hosts. Specify either the location of the Docker image file on the host or the URL to the Docker image. These are the supported location options.

- \{-f \|--file\} image_file Specify the tar archive file on the host that contains the Docker image. This example points to an image file in the gpadmin home directory `/home/gpadmin/test_image.tar.gz`
- \{-u \|--URL\} image_URL Specify the URL of the Docker repository and image. This example URL points to a local Docker repository `192.168.0.1:5000/images/mytest_plc_r:devel`

After installing the Docker image, use the `runtime-add` command to configure PL/Container to use the Docker image.

**image-delete \{-i \|--image\} image_name**

Remove an installed Docker image from all Greenplum Database hosts. Specify the full Docker image name including the tag for example `pivotaldata/plcontainer_python_shared:1.0.0`

**image-list**

List the Docker images installed on the host. The command list only the images on the local host, not remote hosts. The command lists all installed Docker images, including images installed with Docker commands.

**runtime-add options**

Add configuration information to the PL/Container configuration file on all Greenplum Database hosts. If the specified `runtime_id` exists, the utility returns an error and the configuration information is not added.

For information about PL/Container configuration, see [PL/Container Configuration File](#).

These are the supported options:

- \{-i \|--image\} docker-image
  - Required. Specify the full Docker image name, including the tag, that is installed on the Greenplum Database hosts. For example `pivotaldata/plcontainer_python:1.0.0`.
  - The utility returns a warning if the specified Docker image is not installed.
  - The `plcontainer image-list` command displays installed image information including the name and tag (the Repository and Tag columns).

- \{-l \|--language\} python \| r
Required. Specify the PL/Container language type, supported values are `python` (PL/Python) and `r` (PL/R). When adding configuration information for a new runtime, the utility adds a startup command to the configuration based on the language you specify.

Startup command for the Python language.

```
/clientdir/pyclient.sh
```

Startup command for the R language.

```
/clientdir/rclient.sh
```

```
{-r | --runtime} runtime_id
```

Required. Add the runtime ID. When adding a `runtime` element in the PL/Container configuration file, this is the value of the `id` element in the PL/Container configuration file. Maximum length is 63 Bytes.

You specify the name in the Greenplum Database UDF on the `# container` line. See Examples.

```
{-s | --setting} param=value
```

Optional. Specify a setting to add to the runtime configuration information. You can specify this option multiple times. The setting applies to the runtime configuration specified by the `runtime_id`. The parameter is the XML attribute of the `settings` element in the PL/Container configuration file. These are valid parameters.

- `cpu_share` - Set the CPU limit for each container in the runtime configuration. The default value is 1024. The value is a relative weighting of CPU usage compared to other containers.
- `memory_mb` - Set the memory limit for each container in the runtime configuration. The default value is 1024. The value is an integer that specifies the amount of memory in MB.
- `resource_group_id` - Assign the specified resource group to the runtime configuration. The resource group limits the total CPU and memory resource usage for all containers that share this runtime configuration. You must specify the `groupid` of the resource group. For information about managing PL/Container resources, see About PL/Container Resource Management.
- `roles` - Specify the Greenplum Database roles that are allowed to run a container for the runtime configuration. You can specify a single role name or comma separated lists of role names. The default is no restriction.
- `use_container_logging` - Enable or disable Docker logging for the container. The value is either `yes` (enable logging) or `no` (disable logging, the default).

The Greenplum Database server configuration parameter `log_min_messages` controls the log level. The default log level is `warning`. For information about PL/Container log information, see Notes.

```
{-v | --volume} shared-volume
```

Optional. Specify a Docker volume to bind mount. You can specify this option multiple times to define multiple volumes.

The format for a shared volume: `host-dir:container-dir:[rw|ro]`. The information is stored as attributes in the `shared_directory` element of the `runtime` element in the PL/Container configuration file.

- `host-dir` - absolute path to a directory on the host system. The Greenplum Database administrator user (gpadmin) must have appropriate access to the directory.
- `container-dir` - absolute path to a directory in the Docker container.
- `[rw|ro]` - read-write or read-only access to the host directory from the container.
When adding configuration information for a new runtime, the utility adds this read-only shared volume information.

```
greenplum-home/bin/plcontainer_clients:/clientdir:ro
```

If needed, you can specify other shared directories. The utility returns an error if the specified `container-dir` is the same as the one that is added by the utility, or if you specify multiple shared volumes with the same `container-dir`.

**Warning:** Allowing read-write access to a host directory requires special considerations.

- When specifying read-write access to host directory, ensure that the specified host directory has the correct permissions.
- When running PL/Container user-defined functions, multiple concurrent Docker containers that are running on a host could change data in the host directory. Ensure that the functions support multiple concurrent access to the data in the host directory.

**runtime-backup { -f | --file } config_file**

Copies the PL/Container configuration file to the specified file on the local host.

**runtime-delete { -r | --runtime } runtime_id**

Removes runtime configuration information in the PL/Container configuration file on all Greenplum Database instances. The utility returns a message if the specified `runtime_id` does not exist in the file.

**runtime-edit [{ -e | --editor } editor]**

Edit the XML file `plcontainer_configuration.xml` with the specified editor. The default editor is `vi`.

Saving the file updates the configuration file on all Greenplum Database hosts. If errors exist in the updated file, the utility returns an error and does not update the file.

**runtime-replace options**

Replaces runtime configuration information in the PL/Container configuration file on all Greenplum Database instances. If the `runtime_id` does not exist, the information is added to the configuration file. The utility adds a startup command and shared directory to the configuration.

See `runtime-add` for command options and information added to the configuration.

**runtime-restore { -f | --file } config_file**

Replaces information in the PL/Container configuration file `plcontainer_configuration.xml` on all Greenplum Database instances with the information from the specified file on the local host.

**runtime-show [{ -r | --runtime } runtime_id]**

Displays formatted PL/Container runtime configuration information. If a `runtime_id` is not specified, the configuration for all runtime IDs are displayed.

**runtime-verify**

Checks the PL/Container configuration information on the Greenplum Database instances with the configuration information on the master. If the utility finds inconsistencies, you are prompted to replace the remote copy with the local copy. The utility also performs XML validation.

```
-h | --help
```
Display help text. If specified without a command, displays help for all plcontainer commands. If specified with a command, displays help for the command.

**--verbose**

Enable verbose logging for the command.

**Examples**

These are examples of common commands to manage PL/Container:

- Install a Docker image on all Greenplum Database hosts. This example loads a Docker image from a file. The utility displays progress information on the command line as the utility installs the Docker image on all the hosts.

```bash
plcontainer image-add -f plc_newr.tar.gz
```

After installing the Docker image, you add or update a runtime entry in the PL/Container configuration file to give PL/Container access to the Docker image to start Docker containers.

- Add a container entry to the PL/Container configuration file. This example adds configuration information for a PL/R runtime, and specifies a shared volume and settings for memory and logging.

```bash
plcontainer runtime-add -r runtime2 -i test_image2:0.1 -l r \
   -v /host_dir2/shared2:/container_dir2/shared2:ro \
   -s memory_mb=512 -s use_container_logging=yes
```

The utility displays progress information on the command line as it adds the runtime configuration to the configuration file and distributes the updated configuration to all instances.

- Show specific runtime with given runtime id in configuration file

```bash
plcontainer runtime-show -r plc_python_shared
```

The utility displays the configuration information similar to this output.

```
PL/Container Runtime Configuration:
---------------------------------------------------------
Runtime ID: plc_python_shared
Linked Docker Image: test1:latest
Runtime Setting(s):
Shared Directory:
   ---- Shared Directory From HOST '/usr/local/greenplum-db/bin/plcontainer_clients' to Container '/clientdir', access mode is 'ro'
   ---- Shared Directory From HOST '/home/gpadmin/share/' to Container '/opt/share', access mode is 'rw'
---------------------------------------------------------
```

- Edit the configuration in an interactive editor of your choice. This example edits the configuration file with the vim editor.

```bash
plcontainer runtime-edit -e vim
```

When you save the file, the utility displays progress information on the command line as it distributes the file to the Greenplum Database hosts.

- Save the current PL/Container configuration to a file. This example saves the file to the local file /home/gpadmin/saved_plc_config.xml

```bash
plcontainer runtime-backup -f /home/gpadmin/saved_plc_config.xml
```
• Overwrite PL/Container configuration file with an XML file. This example replaces the information in the configuration file with the information from the file in the `/home/gpadmin` directory.

```
plcontainer runtime-restore -f /home/gpadmin/new_plcontainer_configuration.xml
```

The utility displays progress information on the command line as it distributes the updated file to the Greenplum Database instances.

**PL/Container Configuration File**

PL/Container maintains a configuration file `plcontainer_configuration.xml` in the data directory of all Greenplum Database segments. The PL/Container configuration file is an XML file. In the XML file, the root element `configuration` contains one or more `runtime` elements. You specify the `id` of the `runtime` element in the `# container:` line of a PL/Container function definition.

In an XML file, names, such as element and attribute names, and values are case sensitive.

This is an example file.

```xml
<?xml version="1.0" ?>
<configuration>
  <runtime>
    <id>plc_python_example1</id>
    <image>pivotaldata/plcontainer_python_with_clients:0.1</image>
    <command>./pyclient</command>
  </runtime>
  <runtime>
    <id>plc_python_example2</id>
    <image>pivotaldata/plcontainer_python_without_clients:0.1</image>
    <command>/clientdir/pyclient.sh</command>
    <shared_directory access="ro" container="/clientdir" host="/usr/local/greenplum-db/bin/plcontainer_clients"/>
    <setting memory_mb="512"/>
    <setting use_container_logging="yes"/>
    <setting cpu_share="1024"/>
    <setting resource_group_id="16391"/>
  </runtime>
  <runtime>
    <id>plc_r_example</id>
    <image>pivotaldata/plcontainer_r_without_clients:0.2</image>
    <command>/clientdir/rclient.sh</command>
    <shared_directory access="ro" container="/clientdir" host="/usr/local/greenplum-db/bin/plcontainer_clients"/>
    <setting use_container_logging="yes"/>
    <setting roles="gpadmin,user1"/>
  </runtime>
</configuration>
```

These are the XML elements and attributes in a PL/Container configuration file.

- **configuration**
  - Root element for the XML file.

- **runtime**
  - One element for each specific container available in the system. These are child elements of the `configuration` element.

  - **id**
    - Required. The value is used to reference a Docker container from a PL/Container user-defined function. The `id` value must be unique in the configuration. The `id` must start with
a character or digit (a-z, A-Z, or 0-9) and can contain characters, digits, or the characters underscore, period, or dash. Maximum length is 63 Bytes.

The **id** specifies which Docker image to use when PL/Container creates a Docker container to execute a user-defined function.

**image**

Required. The value is the full Docker image name, including image tag. The same way you specify them for starting this container in Docker. Configuration allows to have many container objects referencing the same image name, this way in Docker they would be represented by identical containers.

For example, you might have two runtime elements, with different id elements, `plc_python_128` and `plc_python_256`, both referencing the Docker image `pivotaldata/plcontainer_python:1.0.0`. The first runtime specifies a 128MB RAM limit and the second one specifies a 256MB limit that is specified by the `memory_mb` attribute of a setting element.

**command**

Required. The value is the command to be run inside of container to start the client process inside in the container. When creating a runtime element, the plcontainer utility adds a command element based on the language (the -l option).

*command* element for the python language.

```
<command>/clientdir/pyclient.sh</command>
```

*command* element for the R language.

```
<command>/clientdir/rclient.sh</command>
```

You should modify the value only if you build a custom container and want to implement some additional initialization logic before the container starts.

**Note:** This element cannot be set with the plcontainer utility. You can update the configuration file with the plcontainer runtime-edit command.

**shared_directory**

Optional. This element specifies a shared Docker shared volume for a container with access information. Multiple `shared_directory` elements are allowed. Each `shared_directory` element specifies a single shared volume. XML attributes for the `shared_directory` element:

- **host** - a directory location on the host system.
- **container** - a directory location inside of container.
- **access** - access level to the host directory, which can be either `ro` (read-only) or `rw` (read-write).

When creating a runtime element, the plcontainer utility adds a `shared_directory` element.

```
<shared_directory access="ro" container="/clientdir" host="/usr/local/greenplum-db/bin/plcontainer_clients"/>
```

For each runtime element, the container attribute of the `shared_directory` elements must be unique. For example, a runtime element cannot have two `shared_directory` elements with attribute `container="/clientdir"`. 
Warning: Allowing read-write access to a host directory requires special
consideration.

- When specifying read-write access to host directory, ensure that the
  specified host directory has the correct permissions.
- When running PL/Container user-defined functions, multiple concurrent
  Docker containers that are running on a host could change data in the host
directory. Ensure that the functions support multiple concurrent access to
the data in the host directory.

settings
Optional. This element specifies Docker container configuration information. Each
setting element contains one attribute. The element attribute specifies logging, memory,
or networking information. For example, this element enables logging.

<setting use_container_logging="yes"/>

These are the valid attributes.

cpu_share
Optional. Specify the CPU usage for each PL/Container container in the runtime. The
value of the element is a positive integer. The default value is 1024. The value is a relative
weighting of CPU usage compared to other containers.

For example, a container with a cpu_share of 2048 is allocated double the CPU slice
time compared with container with the default value of 1024.

memory_mb="size"
Optional. The value specifies the amount of memory, in MB, that each container is allowed
to use. Each container starts with this amount of RAM and twice the amount of swap
space. The container memory consumption is limited by the host system cgroups
configuration, which means in case of memory overcommit, the container is terminated by
the system.

resource_group_id="rg_groupid"
Optional. The value specifies the groupid of the resource group to assign to the PL/
Container runtime. The resource group limits the total CPU and memory resource usage
for all running containers that share this runtime configuration. You must specify the
groupid of the resource group. If you do not assign a resource group to a PL/Container
runtime configuration, its container instances are limited only by system resources. For
information about managing PL/Container resources, see About PL/Container Resource
Management.

roles="list_of_roles"
Optional. The value is a Greenplum Database role name or a comma-separated list of
roles. PL/Container runs a container that uses the PL/Container runtime configuration
only for the listed roles. If the attribute is not specified, any Greenplum Database role
can run an instance of this container runtime configuration. For example, you create a
UDF that specifies the plcontainer language and identifies a # container: runtime
configuration that has the roles attribute set. When a role (user) runs the UDF, PL/
Container checks the list of roles and runs the container only if the role is on the list.

use_container_logging="{yes | no}" Optional. Enables or disables Docker logging for the container. The attribute value yes
enables logging. The attribute value no disables logging (the default).

The Greenplum Database server configuration parameter log_min_messages controls
the PL/Container log level. The default log level is warning. For information about PL/
Container log information, see Notes.
By default, the PL/Container log information is sent to a system service. On Red Hat 7 or CentOS 7 systems, the log information is sent to the `journald` service. On Red Hat 6 or CentOS 6 systems, the log is sent to the `syslogd` service.

### Updating the PL/Container Configuration

You can add a `runtime` element to the PL/Container configuration file with the `plcontainer runtime-add` command. The command options specify information such as the runtime ID, Docker image, and language. You can use the `plcontainer runtime-replace` command to update an existing `runtime` element. The utility updates the configuration file on the master and all segment instances.

The PL/Container configuration file can contain multiple `runtime` elements that reference the same Docker image specified by the XML element `image`. In the example configuration file, the `runtime` elements contain `id` elements named `plc_python_128` and `plc_python_256`, both referencing the Docker container `pivotaldata/plcontainer_python:1.0.0`. The first `runtime` element is defined with a 128MB RAM limit and the second one with a 256MB RAM limit.

```xml
<configuration>
  <runtime>
    <id>plc_python_128</id>
    <image>pivotaldata/plcontainer_python:1.0.0</image>
    <command>/client</command>
    <shared_directory access="ro" container="/clientdir" host="/usr/local/gpdb/bin/plcontainer_clients"/>
    <setting memory_mb="128"/>
  </runtime>

  <runtime>
    <id>plc_python_256</id>
    <image>pivotaldata/plcontainer_python:1.0.0</image>
    <command>/client</command>
    <shared_directory access="ro" container="/clientdir" host="/usr/local/gpdb/bin/plcontainer_clients"/>
    <setting memory_mb="256"/>
    <setting resource_group_id="16391"/>
  </runtime>
</configuration>
```

### Notes

- PL/Container does not support the Greenplum Database domain object.
- PL/Container maintains the configuration file `plcontainer_configuration.xml` in the data directory of all Greenplum Database segment instances: master, standby master, primary, and mirror. This query lists the Greenplum Database system data directories:

  ```sql
  SELECT hostname, datadir FROM gp_segment_configuration;
  ```

  A sample PL/Container configuration file is in `$GPHOME/share/postgresql/plcontainer`.

- When Greenplum Database executes a PL/Container UDF, Query Executer (QE) processes start Docker containers and reuse them as needed. After a certain amount of idle time, a QE process quits and destroys its Docker containers. You can control the amount of idle time with the Greenplum Database server configuration parameter `gp_vmem_idle_resource_timeout`. Controlling the idle time might help with Docker container reuse and avoid the overhead of creating and starting a Docker container.

  **Warning:** Changing `gp_vmem_idle_resource_timeout` value might affect performance due to resource issues. The parameter also controls the freeing of Greenplum Database resources other than Docker containers.

- If a PL/Container Docker container exceeds the maximum allowed memory, it is terminated and an out of memory warning is displayed. On Red Hat 6 or CentOS 6 systems that are configured with Docker
version 1.7.1, the out of memory warning is also displayed if the PL/Container Docker container main program (PID 1) is terminated.

- In some cases, when PL/Container is running in a high concurrency environment, the Docker daemon hangs with log entries that indicate a memory shortage. This can happen even when the system seems to have adequate free memory.

The issue seems to be triggered by a combination of two factors, the aggressive virtual memory requirement of the Go language (golang) runtime that is used by PL/Container, and the Greenplum Database Linux server kernel parameter setting for `overcommit_memory`. The parameter is set to 2 which does not allow memory overcommit.

A workaround that might help is to increase the amount of swap space and increase the Linux server kernel parameter `overcommit_ratio`. If the issue still occurs after the changes, there might be memory shortage. You should check free memory on the system and add more RAM if needed. You can also decrease the cluster load.

- PL/Container does not limit the Docker base device size, the size of the Docker container. In some cases, the Docker daemon controls the base device size. For example, if the Docker storage driver is `devicemapper`, the Docker daemon `--storage-opt` option flag `dm.basesize` controls the base device size. The default base device size for devicemapper is 10GB. The Docker command `docker info` displays Docker system information including the storage driver. The base device size is displayed in Docker 1.12 and later. For information about Docker storage drivers, see the Docker information `Daemon storage-driver`.

When setting the Docker base device size, the size must be set on all Greenplum Database hosts.

- When PL/Container logging is enabled, you can set the log level with the Greenplum Database server configuration parameter `log_min_messages`. The default log level is `warning`. The parameter controls the PL/Container log level and also controls the Greenplum Database log level.
  - PL/Container logging is enabled or disabled for each runtime ID with the setting attribute `use_container_logging`. The default is no logging.
  - The PL/Container log information is the information from the UDF that is run in the Docker container. By default, the PL/Container log information is sent to a system service. On Red Hat 7 or CentOS 7 systems, the log information is sent to the `journald` service. On Red Hat 6 or CentOS 6 systems, the log information is sent to the `syslogd` service. The PL/Container log information is sent to the log file of the host were the Docker container runs.
  - The Greenplum Database log information is sent to log file on the Greenplum Database master.

When testing or troubleshooting a PL/Container UDF, you can change the Greenplum Database log level with the `SET` command. You can set the parameter in the session before you run your PL/Container UDF. This example sets the log level to `debug1`.

```sql
SET log_min_messages='debug1' ;
```

**Note:** The parameter `log_min_messages` controls both the Greenplum Database and PL/Container logging, increasing the log level might affect Greenplum Database performance even if a PL/Container UDF is not running.

### Installing Docker

To use PL/Container, Docker must be installed on all Greenplum Database host systems. The these instructions show how to set up the Docker service on CentOS 7. Installing on RHEL 7 is a similar process.

Before performing the Docker installation ensure these requirements are met.

- The CentOS `extras` repository is accessible.
- The user has sudo privileges or is root.

See also the Docker site installation instructions for CentOS [https://docs.docker.com/engine/installation/linux/centos/](https://docs.docker.com/engine/installation/linux/centos/). For a list of Docker commands, see the Docker engine Run Reference [https://docs.docker.com/engine/reference/run/](https://docs.docker.com/engine/reference/run/).
Installing Docker on CentOS 7

These steps install the docker package and start the docker service as a user with sudo privileges.

1. Install dependencies required for Docker

   ```bash
   sudo yum install -y yum-utils device-mapper-persistent-data lvm2
   ```

2. Add the Docker repo

   ```bash
   sudo yum-config-manager --add-repo https://download.docker.com/linux/centos/docker-ce.repo
   ```

3. Update yum cache

   ```bash
   sudo yum makecache fast
   ```

4. Install Docker

   ```bash
   sudo yum -y install docker-ce
   ```

5. Start Docker daemon.

   ```bash
   sudo systemctl start docker
   ```

6. To give access to the Docker daemon and docker commands, assign the Greenplum Database administrator (gpadmin) to the group docker.

   ```bash
   sudo usermod -aG docker gpadmin
   ```

7. Exit the session and login again to update the privileges.

8. Run a Docker command to test the Docker installation. This command lists the currently running Docker containers.

   ```bash
   docker ps
   ```

This command configures Docker to start when the host system starts.

```bash
sudo systemctl start docker.service
```

After you have installed Docker on all Greenplum Database hosts, restart the Greenplum Database system to give Greenplum Database access to Docker.

```bash
gpstop -ra
```

Installing Docker on CentOS 6

These steps install the Docker package and start the docker service as a user with sudo privileges.

1. Install EPEL package

   ```bash
   sudo yum -y install epel-release
   ```

2. Install Docker

   ```bash
   sudo yum -y install docker-io
   ```

3. Create a docker group

   ```bash
   sudo groupadd docker
   ```
4. Start Docker

```
sudo service docker start
```

5. To give access to the Docker daemon and docker commands, assign the Greenplum Database administrator (gpadmin) to the group docker.

```
sudo usermod -aG docker gpadmin
```

6. Exit the session and login again to update the privileges.

7. Run a Docker command to test the Docker installation. This command lists the currently running Docker containers.

```
docker ps
```
This command configures Docker to start when the host system starts.

```
sudo chkconfig docker on
```

After you have installed Docker on all Greenplum Database hosts, restart the Greenplum Database system to give Greenplum Database access to Docker.

```
gpstop -ra
```

About PL/Java

With the Greenplum Database PL/Java extension, you can write Java methods using your favorite Java IDE and install the JAR files that contain those methods into Greenplum Database.

Greenplum Database PL/Java package is based on the open source PL/Java 1.5.0. Greenplum Database PL/Java provides the following features.

- Ability to execute PL/Java functions with Java 8 or Java 11.
- Ability to specify Java runtime.
- Standardized utilities (modeled after the SQL 2003 proposal) to install and maintain Java code in the database.
- Standardized mappings of parameters and result. Complex types as well as sets are supported.
- An embedded, high performance, JDBC driver utilizing the internal Greenplum Database SPI routines.
- Metadata support for the JDBC driver. Both `DatabaseMetaData` and `ResultSetMetaData` are included.
- The ability to return a ResultSet from a query as an alternative to building a ResultSet row by row.
- Full support for savepoints and exception handling.
- The ability to use IN, INOUT, and OUT parameters.
- Two separate Greenplum Database languages:
  - `pljava`, TRUSTED PL/Java language
  - `pljavau`, UNTRUSTED PL/Java language
- Transaction and Savepoint listeners enabling code execution when a transaction or savepoint is committed or rolled back.
- Integration with GNU GCJ on selected platforms.

A function in SQL will appoint a static method in a Java class. In order for the function to execute, the appointed class must be available on the class path specified by the Greenplum Database server configuration parameter `pljava_classpath`. The PL/Java extension adds a set of functions that helps installing and maintaining the java classes. Classes are stored in normal Java archives, JAR files. A JAR file can optionally contain a deployment descriptor that in turn contains SQL commands to be executed when the JAR is deployed or undeployed. The functions are modeled after the standards proposed for SQL 2003.

PL/Java implements a standardized way of passing parameters and return values. Complex types and sets are passed using the standard JDBC ResultSet class.

A JDBC driver is included in PL/Java. This driver calls Greenplum Database internal SPI routines. The driver is essential since it is common for functions to make calls back to the database to fetch data. When PL/Java functions fetch data, they must use the same transactional boundaries that are used by the main function that entered PL/Java execution context.

PL/Java is optimized for performance. The Java virtual machine executes within the same process as the backend to minimize call overhead. PL/Java is designed with the objective to enable the power of Java to the database itself so that database intensive business logic can execute as close to the actual data as possible.

The standard Java Native Interface (JNI) is used when bridging calls between the backend and the Java VM.

About Greenplum Database PL/Java

There are a few key differences between the implementation of PL/Java in standard PostgreSQL and Greenplum Database.
**Functions**

The following functions are not supported in Greenplum Database. The classpath is handled differently in a distributed Greenplum Database environment than in the PostgreSQL environment.

- sqlj.install_jar
- sqlj.replace_jar
- sqlj.remove_jar
- sqlj.get_classpath
- sqlj.set_classpath

Greenplum Database uses the `pljava_classpath` server configuration parameter in place of the `sqlj.set_classpath` function.

**Server Configuration Parameters**

The following server configuration parameters are used by PL/Java in Greenplum Database. These parameters replace the `pljava.*` parameters that are used in the standard PostgreSQL PL/Java implementation:

- `pljava_classpath`
  
  A colon (:) separated list of the jar files containing the Java classes used in any PL/Java functions. The jar files must be installed in the same locations on all Greenplum Database hosts. With the trusted PL/Java language handler, jar file paths must be relative to the `$GPHOME/lib/postgresql/java/` directory. With the untrusted language handler (javaU language tag), paths may be relative to `$GPHOME/lib/postgresql/java/` or absolute.

  The server configuration parameter `pljava_classpath_insecure` controls whether the server configuration parameter `pljava_classpath` can be set by a user without Greenplum Database superuser privileges. When `pljava_classpath_insecure` is enabled, Greenplum Database developers who are working on PL/Java functions do not have to be database superusers to change `pljava_classpath`.

  **Warning:** Enabling `pljava_classpath_insecure` exposes a security risk by giving non-administrator database users the ability to run unauthorized Java methods.

- `pljava_statement_cache_size`
  
  Sets the size in KB of the Most Recently Used (MRU) cache for prepared statements.

- `pljava_release_lingering_savepoints`
  
  If `TRUE`, lingering savepoints will be released on function exit. If `FALSE`, they will be rolled back.

- `pljava_vmoptions`
  
  Defines the start up options for the Greenplum Database Java VM.

See the *Greenplum Database Reference Guide* for information about the Greenplum Database server configuration parameters.

**Installing Java**

PL/Java requires a Java runtime environment on each Greenplum Database host. Ensure that the same Java environment is at the same location on all hosts: masters and segments. The command `java -version` displays the Java version.

The commands that you use to install Java depend on the host system operating system and Java version. This list describes how to install OpenJDK 8 or 11 (Java 8 JDK or Java 11 JDK) on RHEL/CentOS or Ubuntu.
### Installing PL/Java

For Greenplum Database, the PL/Java extension is available as a package. Download the package from the Greenplum Database page on Pivotal Network and then install it with the Greenplum Package Manager (`gppkg`).

The `gppkg` utility installs Greenplum Database extensions, along with any dependencies, on all hosts across a cluster. It also automatically installs extensions on new hosts in the case of system expansion and segment recovery.

To install and use PL/Java:

1. Specify the Java version used by PL/Java. Set the environment variables `JAVA_HOME` and `LD_LIBRARY_PATH` in the `greenplum_path.sh`.

### RHEL 7/CentOS 7 - This yum command installs OpenJDK 8 or 11.

```
$ sudo yum install java-<version>-openjdk-devel
```

For OpenJDK 8 the version is 1.8.0, for OpenJDK 11 the version is 11.

### RHEL 6/CentOS 6

- **Java 8** - This yum command installs OpenJDK 8.
  ```
  $ sudo yum install java-1.8.0-openjdk-devel
  ```

- **Java 11** - Download the OpenJDK 11 tar file from [http://jdk.java.net/archive/](http://jdk.java.net/archive/) and install and configure the operating system to use Java 11.
  1. This example `tar` command installs the OpenJDK 11 in `/usr/lib/jvm`.
     ```
     $ sudo tar xzf openjdk-11.0.2_linux-x64_bin.tar.gz --directory /usr/lib/jvm
     ```
  2. Run these two commands to add OpenJDK 11 to the `update-alternatives` command. The `update-alternatives` command maintains symbolic links that determine the default version of operating system commands.
     ```
     $ sudo sh -c 'for bin in /usr/lib/jvm/jdk-11.0.2/bin/*; do update-alternatives --install /usr/bin/$(basename $bin) $(basename $bin) $bin 100; done'
     $ sudo sh -c 'for bin in /usr/lib/jvm/jdk-11.0.2/bin/*; do update-alternatives --set $(basename $bin) $bin; done'
     ```
     The second command returns some `failed to read link` errors that can be ignored.

### Ubuntu - These apt commands install OpenJDK 8 or 11.

```
$ sudo apt update
$ sudo apt install openjdk-<version>-jdk
```

For OpenJDK 8 the version is 8, for OpenJDK 11 the version is 11.

After installing OpenJDK on a RHEL or CentOS system, run this `update-alternatives` command to change the default Java. Enter the number that represents the OpenJDK version to use as the default.

```
$ sudo update-alternatives --config java
```

The `update-alternatives` command is not required on Ubuntu systems.

**Note:** When configuring host systems, you can use the `gpssh` utility to run bash shell commands on multiple remote hosts.
2. Install the Greenplum Database PL/Java extension.
3. Enable the language for each database where you intend to use PL/Java.
4. Install user-created JAR files containing Java methods into the same directory on all Greenplum Database hosts.
5. Add the name of the JAR file to the Greenplum Database server configuration parameter `pljava_classpath`. The parameter lists the installed JAR files. For information about the parameter, see the Greenplum Database Reference Guide.

**Installing the Greenplum PL/Java Extension**

Before you install the PL/Java extension, make sure that your Greenplum database is running, you have sourced `greenplum_path.sh`, and that the `$MASTER_DATA_DIRECTORY` and `$GPHOME` variables are set.

1. Download the PL/Java extension package from Pivotal Network then copy it to the master host.
2. Install the software extension package by running the `gppkg` command. This example installs the PL/Java extension package on a Linux system:

   ```bash
   $ gppkg -i pljava-1.4.3-gp5-rhelosversion_x86_64.gppkg
   ```

3. Ensure that the environment variables `JAVA_HOME` and `LD_LIBRARY_PATH` are set properly in `$GPHOME/greenplum_path.sh` on all Greenplum Database hosts.
   - Set the `JAVA_HOME` variable to the directory where your Java Runtime is installed. For example, for Oracle JRE this directory would be `/usr/java/latest`. For OpenJDK, the directory is `/usr/lib/jvm`. This example changes the environment variable to use `/usr/lib/jvm`.
     ```bash
     export JAVA_HOME=/usr/lib/jvm
     ```
   - Set the `LD_LIBRARY_PATH` to include the directory with the Java server runtime libraries. PL/Java depends on `libjvm.so` and the shared object should be in your `LD_LIBRARY_PATH`. By default, `libjvm.so` is available in `$JAVA_HOME/lib/server` with JDK 11, or in `$JAVA_HOME/jre/lib/amd64/server` with JDK 8. This example adds the JDK 11 directory to the environment variable.
     ```bash
     export LD_LIBRARY_PATH=$GPHOME/lib:$GPHOME/ext/python/lib:$JAVA_HOME/lib/server:$LD_LIBRARY_PATH
     ```

   This example `gpscp` command copies the file to all hosts specified in the file `gphosts_file`.

   ```bash
   $ gpscp -f gphosts_file $GPHOME/greenplum_path.sh ==:$GPHOME/greenplum_path.sh
   ```

4. Reload `greenplum_path.sh`.

   ```bash
   $ source $GPHOME/greenplum_path.sh
   ```

5. Restart Greenplum Database.

   ```bash
   $ gpstop -r
   ```

**Enabling PL/Java and Installing JAR Files**

Perform the following steps as the Greenplum Database administrator `gpadmin`.

1. Enable PL/Java in a database by executing the `CREATE EXTENSION` command to register the language. For example, this command enables PL/Java in the `testdb` database:

   ```sql
   $ psql -d testdb -c 'CREATE EXTENSION pljava;'
   ```
**Note:** The PL/Java `install.sql` script, used in previous releases to register the language, is deprecated. Also using the deprecated `createlang` command to register PL/Java generates an error.

2. Copy your Java archives (JAR files) to the same directory on all Greenplum Database hosts. This example uses the Greenplum Database `gpscp` utility to copy the file `myclasses.jar` to the directory `$GPHOME/lib/postgresql/java/`:

   ```
   $ gpscp -f gphosts_file myclasses.jar 
   =:/usr/local/greenplum-db/lib/postgresql/java/
   ```

   The file `gphosts_file` contains a list of the Greenplum Database hosts.

3. Set the `pljava_classpath` server configuration parameter in the master `postgresql.conf` file. For this example, the parameter value is a colon (:) separated list of the JAR files. For example:

   ```
   $ gpconfig -c pljava_classpath -v 'examples.jar:myclasses.jar'
   ```

   The file `examples.jar` is installed when you install the PL/Java extension package with the `gppkg` utility.

   **Note:** If you install JAR files in a directory other than `$GPHOME/lib/postgresql/java/`, you must specify the absolute path to the JAR file. Each JAR file must be in the same location on all Greenplum Database hosts. For more information about specifying the location of JAR files, see the information about the `pljava_classpath` server configuration parameter in the Greenplum Database Reference Guide.

4. Reload the `postgresql.conf` file.

   ```
   $ gpstop -u
   ```

5. (optional) Greenplum provides an `examples.sql` file containing sample PL/Java functions that you can use for testing. Run the commands in this file to create the test functions (which use the Java classes in `examples.jar`).

   ```
   $ psql -f $GPHOME/share/postgresql/pljava/examples.sql
   ```

**Uninstalling PL/Java**

- Remove PL/Java Support for a Database
- Uninstall the Java JAR files and Software Package

**Remove PL/Java Support for a Database**

Use the `DROP EXTENSION` command to remove support for PL/Java from a database. For example, this command disables the PL/Java language in the `testdb` database:

   ```
   $ psql -d testdb -c 'DROP EXTENSION pljava;' 
   ```

The default command fails if any existing objects (such as functions) depend on the language. Specify the `CASCADE` option to also drop all dependent objects, including functions that you created with PL/Java.

   **Note:** The PL/Java `uninstall.sql` script, used in previous releases to remove the language registration, is deprecated. Also using the deprecated `droplang` command to remove support for PL/Java generates an error.

**Uninstall the Java JAR files and Software Package**

If no databases have PL/Java as a registered language, remove the Java JAR files and uninstall the Greenplum PL/Java extension with the `gppkg` utility.
1. Remove the `pljava_classpath` server configuration parameter from the `postgresql.conf` file on all Greenplum Database hosts. For example:

   
   ```
   $ gpconfig -r pljava_classpath
   ```

2. Remove the JAR files from the directories where they were installed on all Greenplum Database hosts. For information about JAR file installation directories, see `Enabling PL/Java and Installing JAR Files`.

3. Use the Greenplum `gppkg` utility with the `-r` option to uninstall the PL/Java extension. This example uninstalls the PL/Java extension on a Linux system:

   
   ```
   $ gppkg -r pljava-1.4.3
   ```

   You can run the `gppkg` utility with the options `-q --all` to list the installed extensions and their versions.

4. Remove any updates you made to `greenplum_path.sh` for PL/Java.

5. Reload `greenplum_path.sh` and restart the database

   
   ```
   $ source $GPHOME/greenplum_path.sh
   $ gpstop -r
   ```

### Writing PL/Java functions

Information about writing functions with PL/Java.

- **SQL Declaration**
- **Type Mapping**
- **NULL Handling**
- **Complex Types**
- **Returning Complex Types**
- **Functions That Return Sets**
- **Returning a SETOF <scalar type>**
- **Returning a SETOF <complex type>**

#### SQL Declaration

A Java function is declared with the name of a class and a static method on that class. The class will be resolved using the classpath that has been defined for the schema where the function is declared. If no classpath has been defined for that schema, the public schema is used. If no classpath is found there either, the class is resolved using the system classloader.

The following function can be declared to access the static method `getProperty` on `java.lang.System` class:

   ```
   CREATE FUNCTION getsysprop(VARCHAR) 
   RETURNS VARCHAR 
   AS 'java.lang.System.getProperty' 
   LANGUAGE java;
   ```

Run the following command to return the Java `user.home` property:

   ```
   SELECT getsysprop('user.home');
   ```

#### Type Mapping

Scalar types are mapped in a straight forward way. This table lists the current mappings.
Table 110: PL/Java data type mapping

<table>
<thead>
<tr>
<th>PostgreSQL</th>
<th>Java</th>
</tr>
</thead>
<tbody>
<tr>
<td>bool</td>
<td>boolean</td>
</tr>
<tr>
<td>char</td>
<td>byte</td>
</tr>
<tr>
<td>int2</td>
<td>short</td>
</tr>
<tr>
<td>int4</td>
<td>int</td>
</tr>
<tr>
<td>int8</td>
<td>long</td>
</tr>
<tr>
<td>varchar</td>
<td>java.lang.String</td>
</tr>
<tr>
<td>text</td>
<td>java.lang.String</td>
</tr>
<tr>
<td>bytea</td>
<td>byte[]</td>
</tr>
<tr>
<td>date</td>
<td>java.sql.Date</td>
</tr>
<tr>
<td>time</td>
<td>java.sql.Time (stored value treated as local time)</td>
</tr>
<tr>
<td>timetz</td>
<td>java.sql.Time</td>
</tr>
<tr>
<td>timestamp</td>
<td>java.sql.Timestamp (stored value treated as local time)</td>
</tr>
<tr>
<td>timestamptz</td>
<td>java.sql.Timestamp</td>
</tr>
<tr>
<td>complex</td>
<td>java.sql.ResultSet</td>
</tr>
<tr>
<td>setof complex</td>
<td>java.sql.ResultSet</td>
</tr>
</tbody>
</table>

All other types are mapped to java.lang.String and will utilize the standard textin/textout routines registered for respective type.

**NULL Handling**

The scalar types that map to Java primitives can not be passed as **NULL** values. To pass **NULL** values, those types can have an alternative mapping. You enable this mapping by explicitly denoting it in the method reference.

```sql
CREATE FUNCTION trueIfEvenOrNull(integer)
    RETURNS bool
    AS 'foo.fee.Fum.trueIfEvenOrNull(java.lang.Integer)'
    LANGUAGE java;
```

The Java code would be similar to this:

```java
package foo.fee;
public class Fum
{
    static boolean trueIfEvenOrNull(Integer value)
    {
        return (value == null)
            ? true
            : (value.intValue() % 2) == 0;
    }
}```
The following two statements both yield true:

```sql
SELECT trueIfEvenOrNull(NULL);
SELECT trueIfEvenOrNull(4);
```

In order to return `NULL` values from a Java method, you use the object type that corresponds to the primitive (for example, you return `java.lang.Integer` instead of `int`). The PL/Java resolve mechanism finds the method regardless. Since Java cannot have different return types for methods with the same name, this does not introduce any ambiguity.

### Complex Types

A complex type will always be passed as a read-only `java.sql.ResultSet` with exactly one row. The ResultSet is positioned on its row so a call to `next()` should not be made. The values of the complex type are retrieved using the standard getter methods of the ResultSet.

Example:

```sql
CREATE TYPE complexTest
    AS(base integer, incbase integer, ctime timestamptz);
CREATE FUNCTION useComplexTest(complexTest)
    RETURNS VARCHAR
    AS 'foo.fee.Fum.useComplexTest'
    IMMUTABLE LANGUAGE java;
```

In the Java class `Fum`, we add the following static method:

```java
public static String useComplexTest(ResultSet complexTest)
    throws SQLException
{
    int base = complexTest.getInt(1);
    int incbase = complexTest.getInt(2);
    Timestamp ctime = complexTest.getTimestamp(3);
    return "Base = \"" + base + ", incbase = \"" + incbase + ", ctime = \"" + ctime + \""";
}
```

### Returning Complex Types

Java does not stipulate any way to create a ResultSet. Hence, returning a ResultSet is not an option. The SQL-2003 draft suggests that a complex return value should be handled as an IN/OUT parameter. PL/Java implements a ResultSet that way. If you declare a function that returns a complex type, you will need to use a Java method with boolean return type with a last parameter of type `java.sql.ResultSet`. The parameter will be initialized to an empty updateable ResultSet that contains exactly one row.

Assume that the `complexTest` type in previous section has been created.

```sql
CREATE FUNCTION createComplexTest(int, int)
    RETURNS complexTest
    AS 'foo.fee.Fum.createComplexTest'
    IMMUTABLE LANGUAGE java;
```

The PL/Java method resolve will now find the following method in the `Fum` class:

```java
public static boolean complexReturn(int base, int increment,
    ResultSet receiver)
    throws SQLException
{
    receiver.updateInt(1, base);
```
receiver.updateInt(2, base + increment);
receiver.updateTimestamp(3, new
     Timestamp(System.currentTimeMillis()));
return true;
}

The return value denotes if the receiver should be considered as a valid tuple (true) or NULL (false).

**Functions That Return Sets**

When returning result set, you should not build a result set before returning it, because building a large result set would consume a large amount of resources. It is better to produce one row at a time. Incidentally, that is what the Greenplum Database backend expects a function with SETOF return to do. You can return a SETOF a scalar type such as an int, float or varchar, or you can return a SETOF a complex type.

**Returning a SETOF <scalar type>**

In order to return a set of a scalar type, you need create a Java method that returns something that implements the java.util.Iterator interface. Here is an example of a method that returns a SETOF varchar:

```
CREATE FUNCTION javatest.getSystemProperties()
    RETURNS SETOF varchar
    AS 'foo.fee.Bar.getNames'
    IMMUTABLE LANGUAGE java;
```

This simple Java method returns an iterator:

```
package foo.fee;
import java.util.Iterator;

public class Bar
{
    public static Iterator getNames()
    {
        ArrayList names = new ArrayList();
        names.add("Lisa");
        names.add("Bob");
        names.add("Bill");
        names.add("Sally");
        return names.iterator();
    }
}
```

**Returning a SETOF <complex type>**

A method returning a SETOF <complex type> must use either the interface org.postgresql.pljava.ResultSetProvider or org.postgresql.pljava.ResultSetHandle. The reason for having two interfaces is that they cater for optimal handling of two distinct use cases. The former is for cases when you want to dynamically create each row that is to be returned from the SETOF function. The latter makes is in cases where you want to return the result of an executed query.

**Using the ResultSetProvider Interface**

This interface has two methods. The boolean assignRowValues(java.sql.ResultSet tupleBuilder, int rowNumber) and the void close() method. The Greenplum Database query evaluator will call the assignRowValues repeatedly until it returns false or until the evaluator decides that it does not need any more rows. Then it calls close.
You can use this interface the following way:

```sql
CREATE FUNCTION javatest.listComplexTests(int, int) 
  RETURNS SETOF complexTest 
  AS 'foo.fee.Fum.listComplexTest' 
  IMMUTABLE LANGUAGE java;
```

The function maps to a static java method that returns an instance that implements the `ResultSetProvider` interface.

```java
public class Fum implements ResultSetProvider {
  private final int m_base;
  private final int m_increment;
  public Fum(int base, int increment) {
    m_base = base;
    m_increment = increment;
  }
  public boolean assignRowValues(ResultSet receiver, int currentRow)
      throws SQLException {
    // Stop when we reach 12 rows.
    //
    if(currentRow >= 12)
      return false;
    receiver.updateInt(1, m_base);
    receiver.updateInt(2, m_base + m_increment * currentRow);
    receiver.updateTimestamp(3, new Timestamp(System.currentTimeMillis()));
    return true;
  }
  public void close() {
    // Nothing needed in this example
  }
  public static ResultSetProvider listComplexTests(int base, int increment)
      throws SQLException {
    return new Fum(base, increment);
  }
}
```

The `listComplexTests` method is called once. It may return `NULL` if no results are available or an instance of the `ResultSetProvider`. Here the Java class `Fum` implements this interface so it returns an instance of itself. The method `assignRowValues` will then be called repeatedly until it returns false. At that time, `close` will be called.

**Using the ResultSetHandle Interface**

This interface is similar to the `ResultSetProvider` interface in that it has a `close()` method that will be called at the end. But instead of having the evaluator call a method that builds one row at a time, this method has a method that returns a ResultSet. The query evaluator will iterate over this set and deliver the ResultSet contents, one tuple at a time, to the caller until a call to `next()` returns false or the evaluator decides that no more rows are needed.

Here is an example that executes a query using a statement that it obtained using the default connection. The SQL suitable for the deployment descriptor looks like this:

```sql
CREATE FUNCTION javatest.listSupers()
```
RETURNS SETOF pg_user
AS 'org.postgresql.pljava.example.Users.listSupers'
LANGUAGE java;

CREATE FUNCTION javatest.listNonSupers()
RETURNS SETOF pg_user
AS 'org.postgresql.pljava.example.Users.listNonSupers'
LANGUAGE java;

And in the Java package org.postgresql.pljava.example a class Users is added:

```java
public class Users implements ResultSetHandle
{
    private final String m_filter;
    private Statement m_statement;
    public Users(String filter)
    {
        m_filter = filter;
    }
    public ResultSet getResultSet()
        throws SQLException
    {
        m_statement =
            DriverManager.getConnection("jdbc:default:connection").createStatement();
        return m_statement.executeQuery("SELECT * FROM pg_user
WHERE " + m_filter);
    }
    public void close()
        throws SQLException
    {
        m_statement.close();
    }
    public static ResultSetHandle listSupers()
    {
        return new Users("usesuper = true");
    }
    public static ResultSetHandle listNonSupers()
    {
        return new Users("usesuper = false");
    }
}
```

**Using JDBC**

PL/Java contains a JDBC driver that maps to the PostgreSQL SPI functions. A connection that maps to the current transaction can be obtained using the following statement:

```java
Connection conn =
    DriverManager.getConnection("jdbc:default:connection");
```

After obtaining a connection, you can prepare and execute statements similar to other JDBC connections. These are limitations for the PL/Java JDBC driver:

- The transaction cannot be managed in any way. Thus, you cannot use methods on the connection such as:
  - `commit()`
  - `rollback()`
- `setAutoCommit()`
- `setTransactionIsolation()`

  - Savepoints are available with some restrictions. A savepoint cannot outlive the function in which it was set and it must be rolled back or released by that same function.
  - A ResultSet returned from `executeQuery()` are always `FETCH_FORWARD` and `CONCUR_READ_ONLY`.
  - Meta-data is only available in PL/Java 1.1 or higher.
  - CallableStatement (for stored procedures) is not implemented.
  - The types `Clob` or `Blob` are not completely implemented, they need more work. The types `byte[]` and `String` can be used for `bytea` and `text` respectively.

### Exception Handling

You can catch and handle an exception in the Greenplum Database backend just like any other exception. The backend `ErrorData` structure is exposed as a property in a class called `org.postgresql.pljava.ServerException` (derived from `java.sql.SQLException`) and the Java try/catch mechanism is synchronized with the backend mechanism.

**Important:** You will not be able to continue executing backend functions until your function has returned and the error has been propagated when the backend has generated an exception unless you have used a savepoint. When a savepoint is rolled back, the exceptional condition is reset and you can continue your execution.

### Savepoints

Greenplum Database savepoints are exposed using the `java.sql.Connection` interface. Two restrictions apply.

- A savepoint must be rolled back or released in the function where it was set.
- A savepoint must not outlive the function where it was set

### Logging

PL/Java uses the standard Java Logger. Hence, you can write things like:

```java
Logger.getAnonymousLogger().info("Time is " + new Date(System.currentTimeMillis()));
```

At present, the logger uses a handler that maps the current state of the Greenplum Database configuration setting `log_min_messages` to a valid Logger level and that outputs all messages using the Greenplum Database backend function `elog()`.

**Note:** The `log_min_messages` setting is read from the database the first time a PL/Java function in a session is executed. On the Java side, the setting does not change after the first PL/Java function execution in a specific session until the Greenplum Database session that is working with PL/Java is restarted.

The following mapping apply between the Logger levels and the Greenplum Database backend levels.

**Table 111: PL/Java Logging Levels**

<table>
<thead>
<tr>
<th>java.util.logging.Level</th>
<th>Greenplum Database Level</th>
</tr>
</thead>
<tbody>
<tr>
<td>SEVERE ERROR</td>
<td>ERROR</td>
</tr>
<tr>
<td>WARNING</td>
<td>WARNING</td>
</tr>
<tr>
<td>CONFIG</td>
<td>LOG</td>
</tr>
<tr>
<td>INFO</td>
<td>INFO</td>
</tr>
<tr>
<td>java.util.logging.Level</td>
<td>Greenplum Database Level</td>
</tr>
<tr>
<td>-------------------------</td>
<td>--------------------------</td>
</tr>
<tr>
<td>FINE</td>
<td>DEBUG1</td>
</tr>
<tr>
<td>FINER</td>
<td>DEBUG2</td>
</tr>
<tr>
<td>FINEST</td>
<td>DEBUG3</td>
</tr>
</tbody>
</table>

**Security**

• *Installation*
• *Trusted Language*

**Installation**

Only a database superuser can install PL/Java. The PL/Java utility functions are installed using SECURITY DEFINER so that they execute with the access permissions that where granted to the creator of the functions.

**Trusted Language**

PL/Java is a trusted language. The trusted PL/Java language has no access to the file system as stipulated by PostgreSQL definition of a trusted language. Any database user can create and access functions in a trusted language.

PL/Java also installs a language handler for the language javau. This version is not trusted and only a superuser can create new functions that use it. Any user can call the functions.

**Some PL/Java Issues and Solutions**

When writing the PL/Java, mapping the JVM into the same process-space as the Greenplum Database backend code, some concerns have been raised regarding multiple threads, exception handling, and memory management. Here are brief descriptions explaining how these issues where resolved.

• *Multi-threading*
• *Exception Handling*
• *Java Garbage Collector Versus palloc() and Stack Allocation*

**Multi-threading**

Java is inherently multi-threaded. The Greenplum Database backend is not. There is nothing stopping a developer from utilizing multiple Threads class in the Java code. Finalizers that call out to the backend might have been spawned from a background Garbage Collection thread. Several third party Java-packages that are likely to be used make use of multiple threads. How can this model coexist with the Greenplum Database backend in the same process?

**Solution**

The solution is simple. PL/Java defines a special object called the Backend.THREADLOCK. When PL/Java is initialized, the backend immediately grabs this objects monitor (i.e. it will synchronize on this object). When the backend calls a Java function, the monitor is released and then immediately regained when the call returns. All calls from Java out to backend code are synchronized on the same lock. This ensures that only one thread at a time can call the backend from Java, and only at a time when the backend is awaiting the return of a Java function call.
**Exception Handling**

Java makes frequent use of try/catch/finally blocks. Greenplum Database sometimes use an exception mechanism that calls `longjmp` to transfer control to a known state. Such a jump would normally effectively bypass the JVM.

**Solution**

The backend now allows errors to be caught using the macros `PG_TRY/PG_CATCH/PG_END_TRY` and in the catch block, the error can be examined using the `ErrorData` structure. PL/Java implements a `java.sql.SQLException` subclass called `org.postgresql.pljava.ServerException`. The `ErrorData` can be retrieved and examined from that exception. A catch handler is allowed to issue a rollback to a savepoint. After a successful rollback, execution can continue.

**Java Garbage Collector Versus palloc() and Stack Allocation**

Primitive types are always be passed by value. This includes the `String` type (this is a must since Java uses double byte characters). Complex types are often wrapped in Java objects and passed by reference. For example, a Java object can contain a pointer to a `palloc`ed or stack allocated memory and use native JNI calls to extract and manipulate data. Such data will become stale once a call has ended. Further attempts to access such data will at best give very unpredictable results but more likely cause a memory fault and a crash.

**Solution**

The PL/Java contains code that ensures that stale pointers are cleared when the MemoryContext or stack where they where allocated goes out of scope. The Java wrapper objects might live on but any attempt to use them will result in a stale native handle exception.

**Example**

The following simple Java example creates a JAR file that contains a single method and runs the method.

**Note:** The example requires Java SDK to compile the Java file.

The following method returns a substring.

```java
{  
  public static String substring(String text, int beginIndex, int endIndex)  
    {  
      return text.substring(beginIndex, endIndex);  
    }  
}
```

Enter the java code in a text file `example.class`.

**Contents of the file manifest.txt:**

```ini
Manifest-Version: 1.0
Main-Class: Example
Specification-Title: "Example"
Specification-Version: "1.0"
Created-By: 1.6.0_35-b10-428-11M3811
Build-Date: 01/20/2013 10:09 AM
```

Compile the java code:

```bash
javac *.java
```
Create a JAR archive named analytics.jar that contains the class file and the manifest file MANIFEST file in the JAR.

```bash
jar cfm analytics.jar manifest.txt *.class
```

Upload the jar file to the Greenplum master host.

Run the `gpscp` utility to copy the jar file to the Greenplum Java directory. Use the `-f` option to specify the file that contains a list of the master and segment hosts.

```bash
gpscp -f gphosts_file analytics.jar =:/usr/local/greenplum-db/lib/postgresql/java/
```

Use the `gpconfig` utility to set the Greenplum `pljava_classpath` server configuration parameter. The parameter lists the installed jar files.

```bash
gpconfig -c pljava_classpath -v 'analytics.jar'
```

Run the `gpstop` utility with the `-u` option to reload the configuration files.

```bash
gpstop -u
```

From the `psql` command line, run the following command to show the installed jar files.

```bash
show pljava_classpath
```

The following SQL commands create a table and define a Java function to test the method in the jar file:

```sql
create table temp (a varchar) distributed randomly;
insert into temp values ('my string');
--Example function
create or replace function java_substring(varchar, int, int) returns varchar as 'Example.substring' language java;
--Example execution
select java_substring(a, 1, 5) from temp;
```

You can place the contents in a file, `mysample.sql` and run the command from a `psql` command line:

```bash
> \i mysample.sql
```

The output is similar to this:

```
java_substring
-------------
y st
(1 row)
```

**PL/Perl Language**

This chapter includes the following information:

- About Greenplum PL/Perl
- Greenplum Database PL/Perl Limitations
About Greenplum PL/Perl

With the Greenplum Database PL/Perl extension, you can write user-defined functions in Perl that take advantage of its advanced string manipulation operators and functions. PL/Perl provides both trusted and untrusted variants of the language.

PL/Perl is embedded in your Greenplum Database distribution. Greenplum Database PL/Perl requires Perl to be installed on the system of each database host.

Refer to the PostgreSQL PL/Perl documentation for additional information.

Greenplum Database PL/Perl Limitations

Limitations of the Greenplum Database PL/Perl language include:

- Greenplum Database does not support PL/Perl triggers.
- PL/Perl functions cannot call each other directly.
- SPI is not yet fully implemented.
- If you fetch very large data sets using `spi_exec_query()`, you should be aware that these will all go into memory. You can avoid this problem by using `spi_query()/spi_fetchrow()`. A similar problem occurs if a set-returning function passes a large set of rows back to Greenplum Database via a return statement. Use `return_next` for each row returned to avoid this problem.
- When a session ends normally, not due to a fatal error, PL/Perl executes any `END` blocks that you have defined. No other actions are currently performed. (File handles are not automatically flushed and objects are not automatically destroyed.)

Trusted/Untrusted Language

PL/Perl includes trusted and untrusted language variants.

The PL/Perl trusted language is named `plperl`. The trusted PL/Perl language restricts file system operations, as well as `require`, `use`, and other statements that could potentially interact with the operating system or database server process. With these restrictions in place, any Greenplum Database user can create and execute functions in the trusted `plperl` language.

The PL/Perl untrusted language is named `plperlu`. You cannot restrict the operation of functions you create with the `plperlu` untrusted language. Only database superusers have privileges to create untrusted PL/Perl user-defined functions. And only database superusers and other database users that are explicitly granted the permissions can execute untrusted PL/Perl user-defined functions.

PL/Perl has limitations with respect to communication between interpreters and the number of interpreters running in a single process. Refer to the PostgreSQL Trusted and Untrusted PL/Perl documentation for additional information.

Enabling and Removing PL/Perl Support

You must register the PL/Perl language with a database before you can create and execute a PL/Perl user-defined function within that database. To remove PL/Perl support, you must explicitly remove the extension from each database in which it was registered. You must be a database superuser or owner to register or remove trusted languages in Greenplum databases.

**Note:** Only database superusers may register or remove support for the untrusted PL/Perl language `plperlu`.

Before you enable or remove PL/Perl support in a database, ensure that:

- Your Greenplum Database is running.
You have sourced `greenplum_path.sh`.
You have set the `$MASTER_DATA_DIRECTORY` and `$GPHOME` environment variables.

### Enabling PL/Perl Support

For each database in which you want to enable PL/Perl, register the language using the SQL `CREATE EXTENSION` command. For example, run the following command as the `gpadmin` user to register the trusted PL/Perl language for the database named `testdb`:

```bash
$ psql -d testdb -c 'CREATE EXTENSION plperl;'
```

**Note:** Using the deprecated `createlang` command to enable PL/Perl generates an error.

### Removing PL/Perl Support

To remove support for PL/Perl from a database, run the SQL `DROP EXTENSION` command. For example, run the following command as the `gpadmin` user to remove support for the trusted PL/Perl language from the database named `testdb`:

```bash
$ psql -d testdb -c 'DROP EXTENSION plperl;'
```

The default command fails if any existing objects (such as functions) depend on the language. Specify the `CASCADE` option to also drop all dependent objects, including functions that you created with PL/Perl.

**Note:** Using the deprecated `droplang` command to remove support for PL/Perl generates an error.

### Developing Functions with PL/Perl

You define a PL/Perl function using the standard SQL `CREATE FUNCTION` syntax. The body of a PL/Perl user-defined function is ordinary Perl code. The PL/Perl interpreter wraps this code inside a Perl subroutine.

You can also create an anonymous code block with PL/Perl. An anonymous code block, called with the SQL `DO` command, receives no arguments, and whatever value it might return is discarded. Otherwise, a PL/Perl anonymous code block behaves just like a function. Only database superusers create an anonymous code block with the untrusted `plperlu` language.

The syntax of the `CREATE FUNCTION` command requires that you write the PL/Perl function body as a string constant. While it is more convenient to use dollar-quoting, you can choose to use escape string syntax (`E'` ) provided that you double any single quote marks and backslashes used in the body of the function.

PL/Perl arguments and results are handled as they are in Perl. Arguments you pass in to a PL/Perl function are accessed via the `@_` array. You return a result value with the `return` statement, or as the last expression evaluated in the function. A PL/Perl function cannot directly return a non-scalar type because you call it in a scalar context. You can return non-scalar types such as arrays, records, and sets in a PL/Perl function by returning a reference.

PL/Perl treats null argument values as "undefined". Adding the `STRICT` keyword to the `LANGUAGE` subclause instructs Greenplum Database to immediately return null when any of the input arguments are null. When created as `STRICT`, the function itself need not perform null checks.

The following PL/Perl function utilizes the `STRICT` keyword to return the greater of two integers, or null if any of the inputs are null:

```perl
CREATE FUNCTION perl_max (integer, integer) RETURNS integer AS $$
  if ($_[0] > $_[1]) { return $_[0]; }
  return $_[1];
$$;
```
$$ LANGUAGE plperl STRICT;

SELECT perl_max( 1, 3 );
  perl_max
--------
     3
(1 row)

SELECT perl_max( 1, null );
  perl_max
--------
(1 row)

PL/Perl considers anything in a function argument that is not a reference to be a string, the standard Greenplum Database external text representation. The argument values supplied to a PL/Perl function are simply the input arguments converted to text form (just as if they had been displayed by a \texttt{SELECT} statement). In cases where the function argument is not an ordinary numeric or text type, you must convert the Greenplum Database type to a form that is more usable by Perl. Conversely, the \texttt{return} and \texttt{return_next} statements accept any string that is an acceptable input format for the function's declared return type.

Refer to the PostgreSQL \textit{PL/Perl Functions and Arguments} documentation for additional information, including composite type and result set manipulation.

\textbf{Built-in PL/Perl Functions}

PL/Perl includes built-in functions to access the database, including those to prepare and perform queries and manipulate query results. The language also includes utility functions for error logging and string manipulation.

The following example creates a simple table with an integer and a text column. It creates a PL/Perl user-defined function that takes an input string argument and invokes the \texttt{spi_exec_query()} built-in function to select all columns and rows of the table. The function returns all rows in the query results where the \texttt{v} column includes the function input string.

```
CREATE TABLE test (  
i int,  
v varchar  );
INSERT INTO test (i, v) VALUES (1, 'first line');
INSERT INTO test (i, v) VALUES (2, 'line2');
INSERT INTO test (i, v) VALUES (3, '3rd line');
INSERT INTO test (i, v) VALUES (4, 'different');

CREATE OR REPLACE FUNCTION return_match(varchar) RETURNS SETOF test AS $$
  # store the input argument
  $ss = @_[0];

  # run the query
  my $rv = spi_exec_query('select i, v from test;');

  # retrieve the query status
  my $status = $rv->{status};

  # retrieve the number of rows returned in the query
  my $nrows = $rv->{processed};

  # loop through all rows, comparing column v value with input argument
  foreach my $rn (0 .. $nrows - 1) {
    my $row = $rv->{rows}[$rn];
```
Refer to the PostgreSQL PL/Perl Built-in Functions documentation for a detailed discussion of available functions.

**Global Values in PL/Perl**

You can use the global hash map `%_SHARED` to share data, including code references, between PL/Perl function calls for the lifetime of the current session.

The following example uses `%_SHARED` to share data between the user-defined `set_var()` and `get_var()` PL/Perl functions:

```perl
CREATE OR REPLACE FUNCTION set_var(name text, val text) RETURNS text AS $$
  if ($_SHARED{$_[0]} = $_[1]) {
    return 'ok';
  } else {
    return "cannot set shared variable $_[0] to $_[1]";
  }
$$ LANGUAGE plperl;

CREATE OR REPLACE FUNCTION get_var(name text) RETURNS text AS $$
  return $_SHARED{$_[0]};
$$ LANGUAGE plperl;

SELECT set_var('key1', 'value1');
  set_var
     ---------
     ok
     (1 row)

SELECT get_var('key1');
  get_var
     ---------
     value1
     (1 row)
```

For security reasons, PL/Perl creates a separate Perl interpreter for each role. This prevents accidental or malicious interference by one user with the behavior of another user's PL/Perl functions. Each such interpreter retains its own value of the `%_SHARED` variable and other global state. Two PL/Perl functions share the same value of `%_SHARED` if and only if they are executed by the same SQL role.

There are situations where you must take explicit steps to ensure that PL/Perl functions can share data in `%_SHARED`. For example, if an application executes under multiple SQL roles (via `SECURITY DEFINER` functions, use of `SET ROLE`, etc.) in a single session, make sure that functions that need to communicate are owned by the same user, and mark these functions as `SECURITY DEFINER`. 
Notes
Additional considerations when developing PL/Perl functions:

• PL/Perl internally utilizes the UTF-8 encoding. It converts any arguments provided in other encodings to UTF-8, and converts return values from UTF-8 back to the original encoding.
• Nesting named PL/Perl subroutines retains the same dangers as in Perl.
• Only the untrusted PL/Perl language variant supports module import. Use `plperlu` with care.
• Any module that you use in a `plperlu` function must be available from the same location on all Greenplum Database hosts.

PL/pgSQL Language
This section contains an overview of the Greenplum Database PL/pgSQL language.

• About Greenplum Database PL/pgSQL
• PL/pgSQL Plan Caching
• PL/pgSQL Examples
• References

About Greenplum Database PL/pgSQL

Greenplum Database PL/pgSQL is a loadable procedural language that is installed and registered by default with Greenplum Database. You can create user-defined functions using SQL statements, functions, and operators.

With PL/pgSQL you can group a block of computation and a series of SQL queries inside the database server, thus having the power of a procedural language and the ease of use of SQL. Also, with PL/pgSQL you can use all the data types, operators and functions of Greenplum Database SQL.

The PL/pgSQL language is a subset of Oracle PL/SQL. Greenplum Database PL/pgSQL is based on Postgres PL/pgSQL. The Postgres PL/pgSQL documentation is at https://www.postgresql.org/docs/9.4/plpgsql.html

When using PL/pgSQL functions, function attributes affect how Greenplum Database creates query plans. You can specify the attribute `IMMUTABLE`, `STABLE`, or `VOLATILE` as part of the `LANGUAGE` clause to classify the type of function. For information about the creating functions and function attributes, see the `CREATE FUNCTION` command in the Greenplum Database Reference Guide.

You can run PL/SQL code blocks as anonymous code blocks. See the `DO` command in the Greenplum Database Reference Guide.

Greenplum Database SQL Limitations

When using Greenplum Database PL/pgSQL, limitations include

• Triggers are not supported
• Cursors are forward moving only (not scrollable)
• Updatable cursors (`UPDATE...WHERE CURRENT OF` and `DELETE...WHERE CURRENT OF`) are not supported.

For information about Greenplum Database SQL conformance, see Summary of Greenplum Features in the Greenplum Database Reference Guide.
The PL/pgSQL Language

PL/pgSQL is a block-structured language. The complete text of a function definition must be a block. A block is defined as:

```
[ label ]
[ DECLARE
  declarations ]
BEGIN
  statements
END [ label ];
```

Each declaration and each statement within a block is terminated by a semicolon (;). A block that appears within another block must have a semicolon after END, as shown in the previous block. The END that concludes a function body does not require a semicolon.

A label is required only if you want to identify the block for use in an EXIT statement, or to qualify the names of variables declared in the block. If you provide a label after END, it must match the label at the block's beginning.

**Important:** Do not confuse the use of the BEGIN and END keywords for grouping statements in PL/pgSQL with the database commands for transaction control. The PL/pgSQL BEGIN and END keywords are only for grouping; they do not start or end a transaction. Functions are always executed within a transaction established by an outer query — they cannot start or commit that transaction, since there would be no context for them to execute in. However, a PL/pgSQL block that contains an EXCEPTION clause effectively forms a subtransaction that can be rolled back without affecting the outer transaction. For more about the EXCEPTION clause, see the PostgreSQL documentation on trapping errors at https://www.postgresql.org/docs/9.4/plpgsql-control-structures.html#PLPGSQL-ERROR-TRAPPING.

Keywords are case-insensitive. Identifiers are implicitly converted to lowercase unless double-quoted, just as they are in ordinary SQL commands.

Comments work the same way in PL/pgSQL code as in ordinary SQL:

- A double dash (--) starts a comment that extends to the end of the line.
- A /* starts a block comment that extends to the matching occurrence of */.

Block comments nest.

Any statement in the statement section of a block can be a subblock. Subblocks can be used for logical grouping or to localize variables to a small group of statements.

Variables declared in a subblock mask any similarly-named variables of outer blocks for the duration of the subblock. You can access the outer variables if you qualify their names with their block's label. For example this function declares a variable named quantity several times:

```
CREATE FUNCTION testfunc() RETURNS integer AS $$
<< outerblock >>
DECLARE
  quantity integer := 30;
BEGIN
  RAISE NOTICE 'Quantity here is %', quantity;  -- Prints 30
  quantity := 50;
  -- Create a subblock
  DECLARE
    quantity integer := 80;
  BEGIN
    RAISE NOTICE 'Quantity here is %', quantity;  -- Prints 80
```

```
EXECUTING SQL COMMANDS

You can execute SQL commands with PL/pgSQL statements such as **EXECUTE**, **PERFORM**, and **SELECT ... INTO**. For information about the PL/pgSQL statements, see [https://www.postgresql.org/docs/9.4/plpgsql-statements.html](https://www.postgresql.org/docs/9.4/plpgsql-statements.html).

**Note:** The PL/pgSQL statement **SELECT INTO** is not supported in the **EXECUTE** statement.

PL/pgSQL Plan Caching

A PL/pgSQL function’s volatility classification has implications on how Greenplum Database caches plans that reference the function. Refer to **Function Volatility and Plan Caching** in the Greenplum Database Administrator Guide for information on plan caching considerations for Greenplum Database function volatility categories.

When a PL/pgSQL function executes for the first time in a database session, the PL/pgSQL interpreter parses the function’s SQL expressions and commands. The interpreter creates a prepared execution plan as each expression and SQL command is first executed in the function. The PL/pgSQL interpreter reuses the execution plan for a specific expression and SQL command for the life of the database connection. While this reuse substantially reduces the total amount of time required to parse and generate plans, errors in a specific expression or command cannot be detected until run time when that part of the function is executed.

Greenplum Database will automatically re-plan a saved query plan if there is any schema change to any relation used in the query, or if any user-defined function used in the query is redefined. This makes the reuse of a prepared plan transparent in most cases.

The SQL commands that you use in a PL/pgSQL function must refer to the same tables and columns on every execution. You cannot use a parameter as the name of a table or a column in an SQL command.

PL/pgSQL caches a separate query plan for each combination of actual argument types in which you invoke a polymorphic function to ensure that data type differences do not cause unexpected failures.

Refer to the PostgreSQL Plan Caching documentation for a detailed discussion of plan caching considerations in the PL/pgSQL language.

PL/pgSQL Examples

The following are examples of PL/pgSQL user-defined functions.

**Example: Aliases for Function Parameters**

Parameters passed to functions are named with identifiers such as $1, $2. Optionally, aliases can be declared for $n parameter names for increased readability. Either the alias or the numeric identifier can then be used to refer to the parameter value.

There are two ways to create an alias. The preferred way is to give a name to the parameter in the **CREATE FUNCTION** command, for example:

```sql
CREATE FUNCTION sales_tax(subtotal real) RETURNS real AS $$
BEGIN
    RETURN subtotal * 0.06;
END;
```
You can also explicitly declare an alias, using the declaration syntax:

```sql
name ALIAS FOR $n;
```

This example, creates the same function with the `DECLARE` syntax.

```sql
CREATE FUNCTION sales_tax(real) RETURNS real AS $$
DECLARE
    subtotal ALIAS FOR $1;
BEGIN
    RETURN subtotal * 0.06;
END;
$$ LANGUAGE plpgsql;
```

**Example: Using the Data Type of a Table Column**

When declaring a variable, you can use the `%TYPE` construct to specify the data type of a variable or table column. This is the syntax for declaring a variable whose type is the data type of a table column:

```sql
name table.column_name%TYPE;
```

You can use the `%TYPE` construct to declare variables that will hold database values. For example, suppose you have a column named `user_id` in your `users` table. To declare a variable named `my_userid` with the same data type as the `users.user_id` column:

```sql
my_userid users.user_id%TYPE;
```

`%TYPE` is particularly valuable in polymorphic functions, since the data types needed for internal variables may change from one call to the next. Appropriate variables can be created by applying `%TYPE` to the function’s arguments or result placeholders.

**Example: Composite Type Based on a Table Row**

A variable of a composite type is called a row variable. The following syntax declares a composite variable based on table row:

```sql
name table_name%ROWTYPE;
```

Such a row variable can hold a whole row of a `SELECT` or `FOR` query result, so long as that query’s column set matches the declared type of the variable. The individual fields of the row value are accessed using the usual dot notation, for example `rowvar.column`.

Parameters to a function can be composite types (complete table rows). In that case, the corresponding identifier `$n` will be a row variable, and fields can be selected from it, for example `$1.user_id`.

Only the user-defined columns of a table row are accessible in a row-type variable, not the OID or other system columns. The fields of the row type inherit the table’s field size or precision for data types such as `char(n)`.

The next example function uses a row variable composite type. Before creating the function, create the table that is used by the function with this command.

```sql
CREATE TABLE table1 (  
    f1 text,
    f2 numeric,
    f3 integer
  ) distributed by (f1);
```
This `INSERT` command adds data to the table.

```sql
INSERT INTO table1 values
('test1', 14.1, 3),
('test2', 52.5, 2),
('test3', 32.22, 6),
('test4', 12.1, 4);
```

This function uses a column `%TYPE` variable and `%ROWTYPE` composite variable based on `table1`.

```sql
CREATE OR REPLACE FUNCTION t1_calc( name text) RETURNS integer
AS $$
DECLARE
t1_row   table1%ROWTYPE;
calc_int table1.f3%TYPE;
BEGIN
SELECT * INTO t1_row FROM table1 WHERE table1.f1 = $1 ;
calc_int = (t1_row.f2 * t1_row.f3)::integer ;
RETURN calc_int ;
END;
$$ LANGUAGE plpgsql VOLATILE;
```

**Note:** The previous function is classified as a `VOLATILE` function because function values could change within a single table scan.

The following `SELECT` command uses the function.

```sql
select t1_calc( 'test1' );
```

**Note:** The example PL/pgSQL function uses `SELECT` with the `INTO` clause. It is different from the SQL command `SELECT INTO`. If you want to create a table from a `SELECT` result inside a PL/pgSQL function, use the SQL command `CREATE TABLE AS`.

### Example: Using a Variable Number of Arguments

You can declare a PL/pgSQL function to accept variable numbers of arguments, as long as all of the optional arguments are of the same data type. You must mark the last argument of the function as `VARIADIC` and declare the argument using an array type. You can refer to a function that includes `VARIADIC` arguments as a variadic function.

For example, this variadic function returns the minimum value of a variable array of numerics:

```sql
CREATE FUNCTION mleast (VARIADIC numeric[])
RETURNS numeric AS $$
DECLARE minval numeric;
BEGIN
SELECT min($1[i]) FROM generate_subscripts( $1, 1) g(i) INTO minval;
RETURN minval;
END;
$$ LANGUAGE plpgsql;
CREATE FUNCTION
SELECT mleast(10, -1, 5, 4.4);
mleast
-------
-1
(1 row)
```

Effectively, all of the actual arguments at or beyond the `VARIADIC` position are gathered up into a one-dimensional array.
You can pass an already-constructed array into a variadic function. This is particularly useful when you want to pass arrays between variadic functions. Specify VARIADIC in the function call as follows:

```sql
SELECT mleast(VARIADIC ARRAY[10, -1, 5, 4.4]);
```

This prevents PL/pgSQL from expanding the function’s variadic parameter into its element type.

**Example: Using Default Argument Values**

You can declare PL/pgSQL functions with default values for some or all input arguments. The default values are inserted whenever the function is called with fewer than the declared number of arguments. Because arguments can only be omitted from the end of the actual argument list, you must provide default values for all arguments after an argument defined with a default value.

For example:

```sql
CREATE FUNCTION use_default_args(a int, b int DEFAULT 2, c int DEFAULT 3)
RETURNS int AS $$
DECLARE
    sum int;
BEGIN
    sum := $1 + $2 + $3;
    RETURN sum;
END;
$$ LANGUAGE plpgsql;

SELECT use_default_args(10, 20, 30);
use_default_args
------------------
  60
(1 row)

SELECT use_default_args(10, 20);
use_default_args
------------------
  33
(1 row)

SELECT use_default_args(10);
use_default_args
------------------
  15
(1 row)
```

You can also use the = sign in place of the keyword DEFAULT.

**Example: Using Polymorphic Data Types**

PL/pgSQL supports the polymorphic anyelement, anyarray, anyenum, and anynonarray types. Using these types, you can create a single PL/pgSQL function that operates on multiple data types. Refer to Greenplum Database Data Types for additional information on polymorphic type support in Greenplum Database.

A special parameter named $0 is created when the return type of a PL/pgSQL function is declared as a polymorphic type. The data type of $0 identifies the return type of the function as deduced from the actual input types.

In this example, you create a polymorphic function that returns the sum of two values:

```sql
CREATE FUNCTION add_two_values(v1 anyelement, v2 anyelement)
RETURNS anyelement AS $$
DECLARE
    sum ALIAS FOR $0;
```
BEGIN
    sum := v1 + v2;
    RETURN sum;
END;$ LANGUAGE plpgsql;

Execute `add_two_values()` providing integer input values:

```sql
SELECT add_two_values(1, 2);
add_two_values
----------
   3
(1 row)
```

The return type of `add_two_values()` is integer, the type of the input arguments. Now execute `add_two_values()` providing float input values:

```sql
SELECT add_two_values (1.1, 2.2);
add_two_values
-----------
   3.3
(1 row)
```

The return type of `add_two_values()` in this case is float.

You can also specify `VARIADIC` arguments in polymorphic functions.

**Example: Anonymous Block**

This example executes the statements in the `t1_calc()` function from a previous example as an anonymous block using the `DO` command. In the example, the anonymous block retrieves the input value from a temporary table.

```sql
CREATE TEMP TABLE list AS VALUES ('test1') DISTRIBUTED RANDOMLY;
DO $$
DECLARE
    t1_row   table1%ROWTYPE;
    calc_int table1.f3%TYPE;
BEGIN
    SELECT * INTO t1_row FROM table1, list WHERE table1.f1 = list.column1;
    calc_int = (t1_row.f2 * t1_row.f3)::integer;
    RAISE NOTICE 'calculated value is %', calc_int;
END $$ LANGUAGE plpgsql;
```

PL/Python Language

This section contains an overview of the Greenplum Database PL/Python Language.

- About Greenplum PL/Python
- Enabling and Removing PL/Python support
- Developing Functions with PL/Python
- Installing Python Modules
- Examples
- References

About Greenplum PL/Python

PL/Python is a loadable procedural language. With the Greenplum Database PL/Python extension, you can write a Greenplum Database user-defined functions in Python that take advantage of Python features and modules to quickly build robust database applications.

You can run PL/Python code blocks as anonymous code blocks. See the do command in the Greenplum Database Reference Guide.

The Greenplum Database PL/Python extension is installed by default with Greenplum Database. Greenplum Database installs a version of Python and PL/Python. This is location of the Python installation that Greenplum Database uses:

```
$GPHOME/ext/python/
```

Greenplum Database PL/Python Limitations

- Greenplum Database does not support PL/Python triggers.
- PL/Python is available only as a Greenplum Database untrusted language.
- Updatable cursors (UPDATE...WHERE CURRENT OF and DELETE...WHERE CURRENT OF) are not supported.

Enabling and Removing PL/Python support

The PL/Python language is installed with Greenplum Database. To create and run a PL/Python user-defined function (UDF) in a database, you must register the PL/Python language with the database.

Enabling PL/Python Support

For each database that requires its use, register the PL/Python language with the SQL command CREATE EXTENSION. Because PL/Python is an untrusted language, only superusers can register PL/Python with a database. For example, running this command as the gpadmin user registers PL/Python with the database named testdb:

```
$ psql -d testdb -c 'CREATE EXTENSION plpythonu;'
```

PL/Python is registered as an untrusted language.

**Note:** Using the deprecated createlang command to enable PL/Python generates an error.

Removing PL/Python Support

For a database that no longer requires the PL/Python language, remove support for PL/Python with the SQL command DROP EXTENSION. Because PL/Python is an untrusted language, only superusers can
remove support for the PL/Python language from a database. For example, running this command as the gpadmin user removes support for PL/Python from the database named testdb:

$ psql -d testdb -c 'DROP EXTENSION plpythonu;'  

The default command fails if any existing objects (such as functions) depend on the language. Specify the CASCADE option to also drop all dependent objects, including functions that you created with PL/Python.

Note: Using the deprecated droplang command to remove support for PL/Python generates an error.

**Developing Functions with PL/Python**

The body of a PL/Python user-defined function is a Python script. When the function is called, its arguments are passed as elements of the array `args[]`. Named arguments are also passed as ordinary variables to the Python script. The result is returned from the PL/Python function with `return` statement, or `yield` statement in case of a result-set statement.

**Arrays and Lists**

You pass SQL array values into PL/Python functions with a Python list. Similarly, PL/Python functions return SQL array values as a Python list. In the typical PL/Python usage pattern, you will specify an array with `[]`.

The following example creates a PL/Python function that returns an array of integers:

```
CREATE FUNCTION return_py_int_array()
  RETURNS int[]
AS $$
  return [1, 11, 21, 31]
$$ LANGUAGE plpythonu;

SELECT return_py_int_array();
```

```
return_py_int_array
---------------------
{1,11,21,31}
(1 row)
```

PL/Python treats multi-dimensional arrays as lists of lists. You pass a multi-dimensional array to a PL/Python function using nested Python lists. When a PL/Python function returns a multi-dimensional array, the inner lists at each level must all be of the same size.

The following example creates a PL/Python function that takes a multi-dimensional array of integers as input. The function displays the type of the provided argument, and returns the multi-dimensional array:

```
CREATE FUNCTION return_multidim_py_array(x int4[])
  RETURNS int4[]
AS $$
  plpy.info(x, type(x))
  return x
$$ LANGUAGE plpythonu;

SELECT * FROM return_multidim_py_array(ARRAY[[1,2,3], [4,5,6]]);
```

```
INFO:  ([1, 2, 3], [4, 5, 6], <type 'list'>)
CONTEXT:  PL/Python function "return_multidim_py_type"
return_multidim_py_array
--------------------------
{{1,2,3},{4,5,6}}
(1 row)
```
PL/Python also accepts other Python sequences, such as tuples, as function arguments for backwards compatibility with Greenplum versions where multi-dimensional arrays were not supported. In such cases, the Python sequences are always treated as one-dimensional arrays because they are ambiguous with composite types.

**Composite Types**

You pass composite-type arguments to a PL/Python function using Python mappings. The element names of the mapping are the attribute names of the composite types. If an attribute has the null value, its mapping value is `None`.

You can return a composite type result as a sequence type (tuple or list). You must specify a composite type as a tuple, rather than a list, when it is used in a multi-dimensional array. You cannot return an array of composite types as a list because it would be ambiguous to determine whether the list represents a composite type or another array dimension. In the typical usage pattern, you will specify composite type tuples with `()`. In the following example, you create a composite type and a PL/Python function that returns an array of the composite type:

```sql
CREATE TYPE type_record AS (
    first text,
    second int4
);

CREATE FUNCTION composite_type_as_list()
    RETURNS type_record[]
AS $$
    return [(['first', 1], ['second', 1]), [('first', 2), ('second', 2)],
            [('first', 3), ('second', 3)]];
$$ LANGUAGE plpythonu;

SELECT * FROM composite_type_as_list();
```

Refer to the PostgreSQL Arrays, Lists documentation for additional information on PL/Python handling of arrays and composite types.

**Executing and Preparing SQL Queries**

The PL/Python `plpy` module provides two Python functions to execute an SQL query and prepare an execution plan for a query, `plpy.execute` and `plpy.prepare`. Preparing the execution plan for a query is useful if you run the query from multiple Python functions.

PL/Python also supports the `plpy.subtransaction()` function to help manage `plpy.execute` calls in an explicit subtransaction. See Explicit Subtransactions in the PostgreSQL documentation for additional information about `plpy.subtransaction()`.

`plpy.execute`

Calling `plpy.execute` with a query string and an optional limit argument causes the query to be run and the result to be returned in a Python result object. The result object emulates a list or dictionary object. The rows returned in the result object can be accessed by row number and column name. The result set row numbering starts with 0 (zero). The result object can be modified. The result object has these additional methods:
• `nrows` that returns the number of rows returned by the query.
• `status` which is the `SPI_execute()` return value.

For example, this Python statement in a PL/Python user-defined function executes a query.

```python
rv = plpy.execute("SELECT * FROM my_table", 5)
```

The `plpy.execute` function returns up to 5 rows from `my_table`. The result set is stored in the `rv` object. If `my_table` has a column `my_column`, it would be accessed as:

```python
my_col_data = rv[i]["my_column"]
```

Since the function returns a maximum of 5 rows, the index `i` can be an integer between 0 and 4.

**plpy.prepare**

The function `plpy.prepare` prepares the execution plan for a query. It is called with a query string and a list of parameter types, if you have parameter references in the query. For example, this statement can be in a PL/Python user-defined function:

```python
plan = plpy.prepare("SELECT last_name FROM my_users WHERE first_name = $1", [ "text" ])
```

The string `text` is the data type of the variable that is passed for the variable `$1`. After preparing a statement, you use the function `plpy.execute` to run it:

```python
rv = plpy.execute(plan, [ "Fred" ], 5)
```

The third argument is the limit for the number of rows returned and is optional.

When you prepare an execution plan using the PL/Python module the plan is automatically saved. See the Postgres Server Programming Interface (SPI) documentation for information about the execution plans [https://www.postgresql.org/docs/9.4/spi.html](https://www.postgresql.org/docs/9.4/spi.html).

To make effective use of saved plans across function calls you use one of the Python persistent storage dictionaries SD or GD.

The global dictionary SD is available to store data between function calls. This variable is private static data. The global dictionary GD is public data, available to all Python functions within a session. Use GD with care.

Each function gets its own execution environment in the Python interpreter, so that global data and function arguments from `myfunc` are not available to `myfunc2`. The exception is the data in the GD dictionary, as mentioned previously.

This example uses the SD dictionary:

```sql
CREATE FUNCTION usesavedplan() RETURNS trigger AS $$
if SD.has_key("plan"):
    plan = SD["plan"]
else:
    plan = plpy.prepare("SELECT 1")
SD["plan"] = plan

# rest of function
$$ LANGUAGE plpythonu;
```

**Handling Python Errors and Messages**

The Python module `plpy` implements these functions to manage errors and messages:
The message functions `plpy.error` and `plpy.fatal` raise a Python exception which, if uncaught, propagates out to the calling query, causing the current transaction or subtransaction to be aborted. The functions `raise plpy.ERROR(msg)` and `raise plpy.FATAL(msg)` are equivalent to calling `plpy.error` and `plpy.fatal`, respectively. The other message functions only generate messages of different priority levels.

Whether messages of a particular priority are reported to the client, written to the server log, or both is controlled by the Greenplum Database server configuration parameters `log_min_messages` and `client_min_messages`. For information about the parameters see the *Greenplum Database Reference Guide*.

### Using the dictionary GD To Improve PL/Python Performance

In terms of performance, importing a Python module is an expensive operation and can affect performance. If you are importing the same module frequently, you can use Python global variables to load the module on the first invocation and not require importing the module on subsequent calls. The following PL/Python function uses the GD persistent storage dictionary to avoid importing a module if it has already been imported and is in the GD.

```plaintext
psql=#
  CREATE FUNCTION pytest() returns text as $$
    if 'mymodule' not in GD:
      import mymodule
    GD['mymodule'] = mymodule
    return GD['mymodule'].sumd([1,2,3])
  $$;
```

### Installing Python Modules

When you install a Python module on Greenplum Database, the Greenplum Database Python environment must have the module added to it across all segment hosts and mirror hosts in the cluster. When expanding Greenplum Database, you must add the Python modules to the new segment hosts. You can use the Greenplum Database utilities `gpssh` and `gpscp` run commands on Greenplum Database hosts and copy files to the hosts. For information about the utilities, see the *Greenplum Database Utility Guide*.

As part of the Greenplum Database installation, the `gpadmin` user environment is configured to use Python that is installed with Greenplum Database.

To check the Python environment, you can use the `which` command:

```plaintext
which python
```

The command returns the location of the Python installation. The Python installed with Greenplum Database is in the Greenplum Database `ext/python` directory.

```
/path_to_greenplum-db/ext/python/bin/python
```

When running shell commands on remote hosts with `gpssh`, you can specify the `-s` option. When the option is specified, `gpssh` sources the `greenplum_path.sh` file before running commands on the remote
hosts. For example, this command should display the Python installed with Greenplum Database on each host.

```bash
gpssh -f gpdb_hosts which python
```

If it does not, you can add the `-s` to source `greenplum_path.sh` on the remote hosts before running the command.

```bash
gpssh -s -f gpdb_hosts which python
```

To display the list of currently installed Python modules, run this command.

```bash
python -c "help('modules')"
```

Run `gpssh` in interactive mode to display Python modules on remote hosts. This example starts `gpssh` in interactive mode and lists the Python modules on the Greenplum Database host `sdw1`.

```bash
$ gpssh -s -h sdw1
=> python -c "help('modules')"
. . .
=> exit
$
```

Greenplum Database provides a collection of data science-related Python libraries that can be used with the Greenplum Database PL/Python language. You can download these libraries in `.gppkg` format from Pivotal Network. For information about the libraries, see Python Data Science Module Package.

These sections describe installing and testing Python modules:

- Installing Python pip
- Installing Python Packages with pip
- Building and Installing Python Modules Locally
- Testing Installed Python Modules

### Installing Python pip

The Python utility `pip` installs Python packages that contain Python modules and other resource files from versioned archive files.

Run this command to install `pip`.

```bash
python -m ensurepip --default-pip
```

The command runs the `ensurepip` module to bootstrap (install and configure) the `pip` utility from the local Python installation.

You can run this command to ensure the `pip`, `setuptools` and `wheel` projects are current. Current Python projects ensure that you can install Python packages from source distributions or pre-built distributions (wheels).

```bash
python -m pip install --upgrade pip setuptools wheel
```

You can use `gpssh` to run the commands on the Greenplum Database hosts. This example runs `gpssh` in interactive mode to install `pip` on the hosts listed in the file `gpdb_hosts`.

```bash
$ gpssh -s -f gpdb_hosts
 => python -m ensurepip --default-pip
 [centos6-mdw1] Ignoring indexes: https://pypi.python.org/simple
 [centos6-mdw1] Collecting setuptools
 [centos6-mdw1] Collecting pip
```
The "=>" is the inactive prompt for gpssh. The utility displays the output from each host. The exit command exits from gpssh interactive mode.

This gpssh command runs a single command on all hosts listed in the file gpdb_hosts.

gpssh -s -f gpdb_hosts python -m pip install --upgrade pip setuptools wheel

The utility displays the output from each host.

For more information about installing Python packages, see https://packaging.python.org/tutorials/installing-packages/.

**Installing Python Packages with pip**

After installing pip, you can install Python packages. This command installs the numpy and scipy packages.

`python -m pip install --user numpy scipy`

The `--user` option attempts to avoid conflicts when installing Python packages.

You can use gpssh to run the command on the Greenplum Database hosts.

For information about these and other Python packages, see References.

**Building and Installing Python Modules Locally**

If you are building a Python module, you must ensure that the build creates the correct executable. For example on a Linux system, the build should create a 64-bit executable.

Before building a Python module to be installed, ensure that the appropriate software to build the module is installed and properly configured. The build environment is required only on the host where you build the module.

You can use the Greenplum Database utilities gpssh and gpscp to run commands on Greenplum Database hosts and to copy files to the hosts.

**Testing Installed Python Modules**

You can create a simple PL/Python user-defined function (UDF) to validate that Python a module is available in the Greenplum Database. This example tests the NumPy module.

This PL/Python UDF imports the NumPy module. The function returns success if the module is imported, and failure if an import error occurs.

```sql
CREATE OR REPLACE FUNCTION plpy_test(x int) returns text as $$
  try:
    from numpy import *
  return 'SUCCESS'
except ImportError, e:
  return 'FAILURE'
$$
```
Create a table that contains data on each Greenplum Database segment instance. Depending on the size of your Greenplum Database installation, you might need to generate more data to ensure data is distributed to all segment instances.

```sql
CREATE TABLE DIST AS (SELECT x FROM generate_series(1,50) x ) DISTRIBUTED RANDOMLY ;
```

This `SELECT` command runs the UDF on the segment hosts where data is stored in the primary segment instances.

```sql
SELECT gp_segment_id, plpy_test(x) AS status
FROM dist
GROUP BY gp_segment_id, status
ORDER BY gp_segment_id, status;
```

The `SELECT` command returns `SUCCESS` if the UDF imported the Python module on the Greenplum Database segment instance. If the `SELECT` command returns `FAILURE`, you can find the segment host of the segment instance host. The Greenplum Database system table `gp_segment_configuration` contains information about mirroring and segment configuration. This command returns the host name for a segment ID.

```sql
SELECT hostname, content AS seg_ID FROM gp_segment_configuration
WHERE content = seg_id ;
```

If `FAILURE` is returned, these are some possible causes:

- A problem accessing required libraries. For the NumPy example, a Greenplum Database might have a problem accessing the OpenBLAS libraries or the Python libraries on a segment host.

  Make sure you get no errors when running command on the segment host as the `gpadmin` user. This `gpssh` command tests importing the numpy module on the segment host `mdw1`.

  ```bash
  gpssh -s -h mdw1 python -c "import numpy"
  ```

- If the Python import command does not return an error, environment variables might not be configured in the Greenplum Database environment. For example, the Greenplum Database might not have been restarted after installing the Python Package on the host system.

**Examples**

This PL/Python UDF returns the maximum of two integers:

```sql
CREATE FUNCTION pymax (a integer, b integer) RETURNS integer AS $$
if (a is None) or (b is None):
  return None
if a > b:
  return a
return b
$$ LANGUAGE plpythonu;
```

You can use the `STRICT` property to perform the null handling instead of using the two conditional statements.

```sql
CREATE FUNCTION pymax (a integer, b integer) RETURNS integer AS $$
return max(a,b)
$$
```
$$ LANGUAGE plpythonu STRICT ;

You can run the user-defined function `pymax` with `SELECT` command. This example runs the UDF and shows the output.

```sql
SELECT ( pymax(123, 43));
column1
-------
   123
(1 row)
```

This example that returns data from an SQL query that is run against a table. These two commands create a simple table and add data to the table.

```sql
CREATE TABLE sales (id int, year int, qtr int, day int, region text)
   DISTRIBUTED BY (id) ;
INSERT INTO sales VALUES
   (1, 2014, 1,1, 'usa'),
   (2, 2002, 2,2, 'europe'),
   (3, 2014, 3,3, 'asia'),
   (4, 2014, 4,4, 'usa'),
   (5, 2014, 1,5, 'europe'),
   (6, 2014, 2,6, 'asia'),
   (7, 2002, 3,7, 'usa') ;
```

This PL/Python UDF executes a `SELECT` command that returns 5 rows from the table. The Python function returns the `region` value from the row specified by the input value. In the Python function, the row numbering starts from 0. Valid input for the function is an integer between 0 and 4.

```sql
CREATE OR REPLACE FUNCTION mypytest(a integer)
   RETURNS setof text
AS $$
   rv = plpy.execute("SELECT * FROM sales ORDER BY id", 5)
   region =[]
   region.append(rv[a]["region"])
   return region
$$ language plpythonu EXECUTE ON MASTER;

Running this `SELECT` statement returns the `region` column value from the third row of the result set.

```sql
SELECT mypytest(2) ;
```

This command deletes the UDF from the database.

```sql
DROP FUNCTION mypytest(integer) ;
```

This example executes the PL/Python function in the previous example as an anonymous block with the `DO` command. In the example, the anonymous block retrieves the input value from a temporary table.

```sql
CREATE TEMP TABLE mytemp AS VALUES (2) DISTRIBUTED RANDOMLY;
DO $$
   temprow = plpy.execute("SELECT * FROM mytemp", 1)
   myval = temprow[0]["column1"]
   rv = plpy.execute("SELECT * FROM sales ORDER BY id", 5)
   region = rv[myval]["region"]
   plpy.notice("region is %s" % region)
$$ language plpythonu;
```

For information about Python Package Index (PyPI), see https://pypi.python.org/pypi.

These are some Python modules that can be installed:

- SciPy library provides user-friendly and efficient numerical routines such as routines for numerical integration and optimization. The SciPy site includes other similar Python libraries http://www.scipy.org/index.html.
- Natural Language Toolkit (nltk) is a platform for building Python programs to work with human language data. http://www.nltk.org/. For information about installing the toolkit see http://www.nltk.org/install.html.

PL/R Language

This chapter contains the following information:

- About Greenplum Database PL/R
- Installing R
- Installing PL/R
- Uninstalling PL/R
- Enabling PL/R Language Support
- Examples
- Downloading and Installing R Packages
- Displaying R Library Information
- Loading R Modules at Startup
- References

About Greenplum Database PL/R

PL/R is a procedural language. With the Greenplum Database PL/R extension you can write database functions in the R programming language and use R packages that contain R functions and data sets.

For information about supported PL/R versions, see the Greenplum Database Release Notes.

Installing R

For RHEL and CentOS, installing the PL/R package installs R in $GPHOME/ext/R-<version> and updates $GPHOME/greenplum_path.sh for Greenplum Database to use R.

To use PL/R on Ubuntu host systems, you must install and configure R on all Greenplum Database host systems before installing PL/R.

Note: You can use the gpssh utility to run bash shell commands on multiple remote hosts.

1. To install R, run these apt commands on all host systems.

   $ sudo apt update & & sudo apt install r-base

   Installing r-base also installs dependent packages including r-base-core.
2. To configure Greenplum Database to use R, add the `R_HOME` environment variable to `$GPHOME/greenplum_path.sh` on all hosts. This example command returns the R home directory.

```
$ R RHOME
/usr/lib/R
```

Using the previous R home directory as an example, add this line to the file on all hosts.

```
export R_HOME=/usr/lib/R
```

3. Source `$GPHOME/greenplum_path.sh` and restart Greenplum Database. For example, run these commands on the Greenplum Database master host.

```
$ source $GPHOME/greenplum_path.sh
$ gpstop -r
```

### Installing PL/R

The PL/R extension is available as a package. Download the package from Pivotal Network and install it with the Greenplum Package Manager (gppkg).

The `gppkg` utility installs Greenplum Database extensions, along with any dependencies, on all hosts across a cluster. It also automatically installs extensions on new hosts in the case of system expansion and segment recovery.

#### Installing the Extension Package

Before you install the PL/R extension, make sure that your Greenplum Database is running, you have sourced `greenplum_path.sh`, and that the `$MASTER_DATA_DIRECTORY` and `$GPHOME` variables are set.

1. Download the PL/R extension package from Pivotal Network.
2. Copy the PL/R package to the Greenplum Database master host.
3. Install the software extension package by running the `gppkg` command. This example installs the PL/R extension on a Linux system:

```
$ gppkg -i plr-3.0.3-gp6-rhel7_x86_64.gppkg
```

4. Source the file `$GPHOME/greenplum_path.sh`.
5. Restart Greenplum Database.

```
$ gpstop -r
```

### Enabling PL/R Language Support

For each database that requires its use, register the PL/R language with the SQL command `CREATE EXTENSION`. Because PL/R is an untrusted language, only superusers can register PL/R with a database. For example, run this command as the `gpadmin` user to register the language with the database named `testdb`:

```
$ psql -d testdb -c 'CREATE EXTENSION plr;'
```

PL/R is registered as an untrusted language.

**Note:** Using the deprecated `createlang` command to enable PL/R generates an error.

### Uninstalling PL/R

- Remove PL/R Support for a Database
• Uninstall the Extension Package
• Uninstall R (Ubuntu)

When you remove PL/R language support from a database, the PL/R routines that you created in the database will no longer work.

**Remove PL/R Support for a Database**

For a database that no longer requires the PL/R language, remove support for PL/R with the SQL command `DROP EXTENSION`. Because PL/R is an untrusted language, only superusers can remove support for the PL/R language from a database. For example, run this command as the `gpadmin` user to remove support for PL/R from the database named `testdb`:

```
$ psql -d testdb -c 'DROP EXTENSION plr;'
```

The default command fails if any existing objects (such as functions) depend on the language. Specify the `CASCADE` option to also drop all dependent objects, including functions that you created with PL/R.

**Note:** Using the deprecated `droplang` command to remove support for PL/R generates an error.

**Uninstall the Extension Package**

If no databases have PL/R as a registered language, uninstall the Greenplum PL/R extension with the `gppkg` utility. This example uninstalls PL/R package version 3.0.3.

```
$ gppkg -r plr-3.0.3
```

On RHEL and CentOS systems, uninstalling the extension uninstalls the R software that was installed with the extension.

You can run the `gppkg` utility with the options `-q --all` to list the installed extensions and their versions.

For Ubuntu systems, remove the `R_HOME` environment variable from `greenplum_path.sh` on all Greenplum Database host systems.

Source the file `$GPHOME/greenplum_path.sh` and restart the database.

```
$ gpstop -r
```

**Uninstall R (Ubuntu)**

For Ubuntu systems, remove R from all Greenplum Database host systems. These commands remove R from an Ubuntu system.

```
$ sudo apt remove r-base
$ sudo apt remove r-base-core
```

Removing `r-base` does not uninstall the R executable. Removing `r-base-core` uninstalls the R executable.

**Examples**

The following are simple PL/R examples.

**Example 1: Using PL/R for single row operators**

This function generates an array of numbers with a normal distribution using the R function `rnorm()`.

```
CREATE OR REPLACE FUNCTION r_norm(n integer, mean float8, std_dev float8) RETURNS float8[] AS $$
$$
```

The following `CREATE TABLE` command uses the `r_norm()` function to populate the table. The `r_norm()` function creates an array of 10 numbers.

```sql
CREATE TABLE test_norm_var
AS SELECT id, r_norm(10,0,1) as x
FROM (SELECT generate_series(1,30:: bigint) AS ID) foo
DISTRIBUTED BY (id);
```

**Example 2: Returning PL/R data.frames in Tabular Form**

Assuming your PL/R function returns an R `data.frame` as its output, unless you want to use arrays of arrays, some work is required to see your `data.frame` from PL/R as a simple SQL table:

- Create a `TYPE` in a Greenplum database with the same dimensions as your R `data.frame`:
  ```sql
  CREATE TYPE t1 AS ...;
  ```
- Use this `TYPE` when defining your PL/R function
  ```sql
  ... RETURNS SET OF t1 AS ...;
  ```

Sample SQL for this is given in the next example.

**Example 3: Hierarchical Regression using PL/R**

The SQL below defines a `TYPE` and runs hierarchical regression using PL/R:

```sql
--Create TYPE to store model results
DROP TYPE IF EXISTS wj_model_results CASCADE;
CREATE TYPE wj_model_results AS (
  cs text, coefext float, ci_95_lower float, ci_95_upper float,
  ci_90_lower float, ci_90_upper float, ci_80_lower float,
  ci_80_upper float);

--Create PL/R function to run model in R
DROP FUNCTION IF EXISTS wj_plr_RE(float [], text []);
CREATE FUNCTION wj_plr_RE(response float [], cs text [])
RETURNS SETOF wj_model_results AS
$$
library(arm)

y<- log(response)

cs<- cs
d_temp<- data.frame(y,cs)
m0 <- lmer (y ~ 1 + (1 | cs), data=d_temp)
cs_unique<- sort(unique(cs))
n_cs_unique<- length(cs_unique)
temp_m0<- data.frame(matrix0,n_cs_unique, 7))
for (i in 1:n_cs_unique){temp_m0[i,]<-
  c(exp(coef(m0)$cs[i,1] + c(0,-1.96,1.96,-1.65,1.65,-1.28,1.28)*se.ranef(m0)$cs[i]))}
names(temp_m0)<- c("Coefest", "CI_95_Lower", "CI_95_Upper", "CI_90_Lower", "CI_90_Upper", "CI_80_Lower", "CI_80_Upper")
temp_m0_v2<- data.frames(cs_unique, temp_m0)
return(temp_m0_v2)
$$
LANGUAGE 'plr';
```
--Run modeling plr function and store model results in a table
DROP TABLE IF EXISTS wj_model_results_roi;
CREATE TABLE wj_model_results_roi AS SELECT * FROM wj_plr_RE((SELECT wj_droi2_array),
(SELECT cs FROM wj_droi2_array));

Downloading and Installing R Packages

R packages are modules that contain R functions and data sets. You can install R packages to extend R and PL/R functionality in Greenplum Database.

Greenplum Database provides a collection of data science-related R libraries that can be used with the Greenplum Database PL/R language. You can download these libraries in .gppkg format from Pivotal Network. For information about the libraries, see R Data Science Library Package.

Note: If you expand Greenplum Database and add segment hosts, you must install the R packages in the R installation of the new hosts.

1. For an R package, identify all dependent R packages and each package web URL. The information can be found by selecting the given package from the following navigation page:
https://cran.r-project.org/web/packages/available_packages_by_name.html

As an example, the page for the R package arm indicates that the package requires the following R libraries: Matrix, lattice, lm4, R2WinBUGS, coda, abind, foreign, and MASS.

You can also try installing the package with R CMD INSTALL command to determine the dependent packages.

For the R installation included with the Greenplum Database PL/R extension, the required R packages are installed with the PL/R extension. However, the Matrix package requires a newer version.

2. From the command line, use the wget utility to download the .tar.gz files for the arm package to the Greenplum Database master host:

wget https://cran.r-project.org/src/contrib/Archive/arm/arm_1.5-03.tar.gz

wget https://cran.r-project.org/src/contrib/Archive/Matrix/Matrix_0.9996875-1.tar.gz

3. Use the gscp utility and the hosts_all file to copy the .tar.gz files to the same directory on all nodes of the Greenplum Database cluster. The hosts_all file contains a list of all the Greenplum Database segment hosts. You might require root access to do this.

gscp -f hosts_all Matrix_0.9996875-1.tar.gz =:/home/gpadmin

gscp -f /hosts_all arm_1.5-03.tar.gz =:/home/gpadmin

4. Use the gpssh utility in interactive mode to log into each Greenplum Database segment host (gpssh -f all_hosts). Install the packages from the command prompt using the R CMD INSTALL command. Note that this may require root access. For example, this R install command installs the packages for the arm package.

$R_HOME/bin/R CMD INSTALL Matrix_0.9996875-1.tar.gz arm_1.5-03.tar.gz
5. Ensure that the package is installed in the $R_HOME/library directory on all the segments (the gpssh can be use to install the package). For example, this gpssh command list the contents of the R library directory.

```
gpssh -s -f all_hosts "ls $R_HOME/library"
```

The gpssh option -s sources the greenplum_path.sh file before running commands on the remote hosts.

6. Test if the R package can be loaded.

This function performs a simple test to if an R package can be loaded:

```
CREATE OR REPLACE FUNCTION R_test_require(fname text)
RETURNS boolean AS
$BODY$
  return(require(fname,character.only=T))
$BODY$
LANGUAGE 'plr';
```

This SQL command checks if the R package arm can be loaded:

```
SELECT R_test_require('arm');
```

### Displaying R Library Information

You can use the R command line to display information about the installed libraries and functions on the Greenplum Database host. You can also add and remove libraries from the R installation. To start the R command line on the host, log into the host as the gadmin user and run the script R from the directory $GPHOME/ext/R-3.3.3/bin.

This R function lists the available R packages from the R command line:

```
> library()
```

Display the documentation for a particular R package

```
> library(help="package_name")
> help(package="package_name")
```

Display the help file for an R function:

```
> help("function_name")
> ?function_name
```

To see what packages are installed, use the R command `installed.packages()`. This will return a matrix with a row for each package that has been installed. Below, we look at the first 5 rows of this matrix.

```
> installed.packages()
```

Any package that does not appear in the installed packages matrix must be installed and loaded before its functions can be used.

An R package can be installed with `install.packages()`:

```
> install.packages("package_name")
> install.packages("mypkg", dependencies = TRUE, type="source")
```
Load a package from the R command line.

```r
> library("package_name")
```

An R package can be removed with `remove.packages`

```r
> remove.packages("package_name")
```

You can use the R command `-e` option to run functions from the command line. For example, this command displays help on the R package MASS.

```r
$ R -e 'help("MASS")'
```

**Loading R Modules at Startup**

PL/R can automatically load saved R code during interpreter initialization. To use this feature, you create the `plr_modules` database table and then insert the R modules you want to auto-load into the table. If the table exists, PL/R will load the code it contains into the interpreter.

In a Greenplum Database system, table rows are usually distributed so that each row exists at only one segment instance. The R interpreter at each segment instance, however, needs to load all of the modules, so a normally distributed table will not work. You must create the `plr_modules` table as a replicated table in the default schema so that all rows in the table are present at every segment instance. For example:

```sql
CREATE TABLE public.plr_modules {
    modseq int4,
    modsrc text
} DISTRIBUTED REPLICATED;
```

* [https://cran.r-project.org/web/packages/PivotalR/](https://cran.r-project.org/web/packages/PivotalR/) - The home page for PivotalR, a package that provides an R interface to operate on Greenplum Database tables and views that is similar to the R `data.frame`. PivotalR also supports using the machine learning package `MADlib` directly from R.

The following links highlight key topics from the R documentation.

**MADlib Extension for Analytics**

This chapter includes the following information:

- About MADlib
- About Deep Learning
- Installing MADlib
- Upgrading MADlib
- Uninstalling MADlib
- Examples
- References
About MADlib

MADlib is an open-source library for scalable in-database analytics. With the Greenplum Database MADlib extension, you can use MADlib functionality in a Greenplum Database.

MADlib provides data-parallel implementations of mathematical, statistical and machine-learning methods for structured and unstructured data. It provides an suite of SQL-based algorithms for machine learning, data mining and statistics that run at scale within a database engine, with no need for transferring data between Greenplum Database and other tools.

MADlib requires the \texttt{m4} macro processor version 1.4.13 or later.

MADlib can be used with PivotalR, an R package that enables users to interact with data resident in Greenplum Database using the R client. See About MADlib, R, and PivotalR.

About Deep Learning

Deep learning is a type of machine learning, originally inspired by biology of the brain, that uses a class of algorithms called artificial neural networks. Given the important use cases that can be effectively addressed with deep learning, it is starting to become a more important part of enterprise computing.

Deep learning support for Keras and TensorFlow was added to Apache MADlib starting with the 1.16 release. Refer to the following documents for more information about deep learning on Greenplum using Apache MADlib:

\begin{itemize}
\item MADlib user documentation
\item Supported libraries and configuration instructions
\end{itemize}

Installing MADlib

To install MADlib on Greenplum Database, you first install a compatible Greenplum MADlib package and then install the MADlib function libraries on all databases that will use MADlib.

The \texttt{gppkg} utility installs Greenplum Database extensions, along with any dependencies, on all hosts across a cluster. It also automatically installs extensions on new hosts in the case of system expansion segment recovery.

\textbf{Installing the Greenplum Database MADlib Package}

Before you install the MADlib package, make sure that your Greenplum database is running, you have sourced \texttt{greenplum\_path.sh}, and that the \texttt{MASTER\_DATA\_DIRECTORY} and \texttt{GPHOME} variables are set.

1. Download the MADlib extension package from Pivotal Network.
2. Copy the MADlib package to the Greenplum Database master host.
3. Unpack the MADlib distribution package. For example:
\begin{verbatim}
$ tar xzvf madlib-1.16+2-gp6-rhel7-x86_64.tar.gz
\end{verbatim}
4. Install the software package by running the \texttt{gppkg} command. For example:
\begin{verbatim}
$ gppkg -i ./madlib-1.16+2-gp6-rhel7-x86_64/madlib-1.16+2-gp6-rhel7-
x86_64.gppkg
\end{verbatim}
Adding MADlib Functions to a Database

After installing the MADlib package, run the `madpack` command to add MADlib functions to Greenplum Database. `madpack` is in `$GPHOME/madlib/bin`.

```
$ madpack [-s schema_name] -p greenplum -c user@host:port/database install
```

For example, this command creates MADlib functions in the Greenplum database `testdb` running on server `mdw` on port `5432`. The `madpack` command logs in as the user `gpadmin` and prompts for password. The target schema is `madlib`.

```
$ madpack -s madlib -p greenplum -c gpadmin@mdw:5432/testdb install
```

After installing the functions, The Greenplum Database `gpadmin` superuser role should grant all privileges on the target schema (in the example `madlib`) to users who will be accessing MADlib functions. Users without access to the functions will get the error `ERROR: permission denied for schema MADlib`.

The `madpack install-check` option runs test using Madlib modules to check the MADlib installation:

```
$ madpack -s madlib -p greenplum -c gpadmin@mdw:5432/testdb install-check
```

**Note:** The command `madpack -h` displays information for the utility.

Upgrading MADlib

You upgrade an installed MADlib package with the Greenplum Database `gppkg` utility and the MADlib `madpack` command.

For information about the upgrade paths that MADlib supports, see the MADlib support and upgrade matrix in the [MADlib FAQ page](#).

Upgrading a MADlib Package

To upgrade MADlib, run the `gppkg` utility with the `-u` option. This command upgrades an installed MADlib package to MADlib 1.16+2.

```
$ gppkg -u madlib-1.16+2-gp6-rhel7-x86_64.gppkg
```

Upgrading MADlib Functions

After you upgrade the MADlib package from one major version to another, run `madpack upgrade` to upgrade the MADlib functions in a database schema.

**Note:** Use `madpack upgrade` only if you upgraded a major MADlib package version, for example from 1.15 to 1.16. You do not need to update the functions within a patch version upgrade, for example from 1.16+1 to 1.16+2.

This example command upgrades the MADlib functions in the schema `madlib` of the Greenplum Database `test`.

```
madpack -s madlib -p greenplum -c gpadmin@mdw:5432/testdb upgrade
```

Uninstalling MADlib

- Remove MADlib objects from the database
- Uninstall the Greenplum Database MADlib Package
When you remove MADlib support from a database, routines that you created in the database that use MADlib functionality will no longer work.

**Remove MADlib objects from the database**

Use the `madpack uninstall` command to remove MADlib objects from a Greenplum database. For example, this command removes MADlib objects from the database testdb.

```
$ madpack -s madlib -p greenplum -c gpadmin@mdw:5432/testdb uninstall
```

**Uninstall the Greenplum Database MADlib Package**

If no databases use the MADlib functions, use the Greenplum `gppkg` utility with the `-r` option to uninstall the MADlib package. When removing the package you must specify the package and version. This example uninstalls MADlib package version 1.16.

```
$ gppkg -r madlib-1.16+2-gp5-rhel7-x86_64
```

You can run the `gppkg` utility with the options `-q` `--all` to list the installed extensions and their versions. After you uninstall the package, restart the database.

```
$ gpstop -r
```

**Examples**

Following are examples using the Greenplum MADlib extension:

- **Linear Regression**
- **Association Rules**
- **Naive Bayes Classification**

See the MADlib documentation for additional examples.

**Linear Regression**

This example runs a linear regression on the table `regr_example`. The dependent variable data are in the `y` column and the independent variable data are in the `x1` and `x2` columns.

The following statements create the `regr_example` table and load some sample data:

```sql
DROP TABLE IF EXISTS regr_example;
CREATE TABLE regr_example (  
id int,
y int,
x1 int,
x2 int
);
INSERT INTO regr_example VALUES  
(1, 5, 2, 3),  
(2, 10, 7, 2),  
(3, 6, 4, 1),  
(4, 8, 3, 4);
```

The MADlib `linregr_train()` function produces a regression model from an input table containing training data. The following `SELECT` statement runs a simple multivariate regression on the `regr_example` table and saves the model in the `reg_example_model` table.

```sql
SELECT madlib.linregr_train (  
    'regr_example', -- source table
```

```
);  
```

```
```
The `madlib.linregr_train()` function can have additional arguments to set grouping columns and to calculate the heteroskedasticity of the model.

**Note:** The intercept is computed by setting one of the independent variables to a constant 1, as shown in the preceding example.

Running this query against the `regr_example` table creates the `regr_example_model` table with one row of data:

```sql
SELECT * FROM regr_example_model;
```

<table>
<thead>
<tr>
<th>id</th>
<th>y</th>
<th>x1</th>
<th>x2</th>
<th>predict</th>
<th>residual</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>5</td>
<td>2</td>
<td>3</td>
<td>5.46296296296297</td>
<td>-0.462962962962971</td>
</tr>
<tr>
<td>3</td>
<td>6</td>
<td>4</td>
<td>1</td>
<td>10.1851851851852</td>
<td>-0.185185185185201</td>
</tr>
<tr>
<td>2</td>
<td>10</td>
<td>7</td>
<td>2</td>
<td>7.62962962962964</td>
<td>0.370370370370364</td>
</tr>
<tr>
<td>4</td>
<td>8</td>
<td>3</td>
<td>4</td>
<td>10.1851851851852</td>
<td>-0.185185185185201</td>
</tr>
</tbody>
</table>

The model saved in the `regr_example_model` table can be used with the MADlib linear regression prediction function, `madlib.linregr_predict()`, to view the residuals:

```sql
SELECT regr_example.*,
madlib.linregr_predict ( ARRAY[1, x1, x2], m.coef ) as predict,
y - madlib.linregr_predict ( ARRAY[1, x1, x2], m.coef ) as residual
FROM regr_example, regr_example_model m;
```

**Association Rules**

This example demonstrates the association rules data mining technique on a transactional data set. Association rule mining is a technique for discovering relationships between variables in a large data set. This example considers items in a store that are commonly purchased together. In addition to market basket analysis, association rules are also used in bioinformatics, web analytics, and other fields.

The example analyzes purchase information for seven transactions that are stored in a table with the MADlib function `MADlib.assoc_rules`. The function assumes that the data is stored in two columns with a single item and transaction ID per row. Transactions with multiple items consist of multiple rows with one row per item.
These commands create the table.

```sql
DROP TABLE IF EXISTS test_data;
CREATE TABLE test_data (  
    trans_id INT,
    product text
);
```

This INSERT command adds the data to the table.

```sql
INSERT INTO test_data VALUES
    (1, 'beer'),
    (1, 'diapers'),
    (1, 'chips'),
    (2, 'beer'),
    (2, 'diapers'),
    (3, 'beer'),
    (3, 'diapers'),
    (4, 'beer'),
    (4, 'chips'),
    (5, 'beer'),
    (6, 'beer'),
    (6, 'diapers'),
    (6, 'chips'),
    (7, 'beer'),
    (7, 'diapers');
```

The MADlib function `madlib.assoc_rules()` analyzes the data and determines association rules with the following characteristics.

- A support value of at least .40. Support is the ratio of transactions that contain X to all transactions.
- A confidence value of at least .75. Confidence is the ratio of transactions that contain X to transactions that contain Y. One could view this metric as the conditional probability of X given Y.

This SELECT command determines association rules, creates the table `assoc_rules`, and adds the statistics to the table.

```sql
SELECT * FROM madlib.assoc_rules (  
    .40,  -- support
    .75,  -- confidence
    'trans_id',  -- transaction column
    'product',  -- product purchased column
    'test_data',  -- table name
    'public',  -- schema name
    false);  -- display processing details
```

This is the output of the SELECT command. There are two rules that fit the characteristics.

<table>
<thead>
<tr>
<th>output_schema</th>
<th>output_table</th>
<th>total_rules</th>
<th>total_time</th>
</tr>
</thead>
<tbody>
<tr>
<td>public</td>
<td>assoc_rules</td>
<td>2</td>
<td>00:00:01.153283</td>
</tr>
</tbody>
</table>

(1 row)

To view the association rules, you can run this SELECT command.

```sql
SELECT pre, post, support FROM assoc_rules
    ORDER BY support DESC;
```
This is the output. The `pre` and `post` columns are the itemsets of left and right hand sides of the association rule respectively.

<table>
<thead>
<tr>
<th>pre</th>
<th>post</th>
<th>support</th>
</tr>
</thead>
<tbody>
<tr>
<td>diapers</td>
<td>beer</td>
<td>0.714285714285714</td>
</tr>
<tr>
<td>chips</td>
<td>beer</td>
<td>0.428571428571429</td>
</tr>
</tbody>
</table>

Based on the data, beer and diapers are often purchased together. To increase sales, you might consider placing beer and diapers closer together on the shelves.

**Naive Bayes Classification**

Naive Bayes analysis predicts the likelihood of an outcome of a class variable, or category, based on one or more independent variables, or attributes. The class variable is a non-numeric categorial variable, a variable that can have one of a limited number of values or categories. The class variable is represented with integers, each integer representing a category. For example, if the category can be one of "true", "false", or "unknown," the values can be represented with the integers 1, 2, or 3.

The attributes can be of numeric types and non-numeric, categorial, types. The training function has two signatures – one for the case where all attributes are numeric and another for mixed numeric and categorial types. Additional arguments for the latter identify the attributes that should be handled as numeric values. The attributes are submitted to the training function in an array.

The MADlib Naive Bayes training functions produce a features probabilities table and a class priors table, which can be used with the prediction function to provide the probability of a class for the set of attributes.

**Naive Bayes Example 1 - Simple All-numeric Attributes**

In the first example, the class variable is either 1 or 2 and there are three integer attributes.

1. The following commands create the input table and load sample data.

```sql
DROP TABLE IF EXISTS class_example CASCADE;
CREATE TABLE class_example (id int, class int, attributes int[]);
INSERT INTO class_example VALUES
(1, 1, '{1, 2, 3}'),
(2, 1, '{1, 4, 3}'),
(3, 2, '{0, 2, 2}'),
(4, 1, '{1, 2, 1}'),
(5, 2, '{1, 2, 2}'),
(6, 2, '{0, 1, 3}');
```

Actual data in production scenarios is more extensive than this example data and yields better results. Accuracy of classification improves significantly with larger training data sets.

2. Train the model with the `create_nb_prepared_data_tables()` function.

```sql
SELECT * FROM madlib.create_nb_prepared_data_tables (class_example, 'class', 'attributes', 3, 'example_feature_probs', 'example_priors');
```

3. Create a table with data to classify using the model.

```sql
DROP TABLE IF EXISTS class_example_topredict;
```
CREATE TABLE class_example_topredict (id int, attributes int[]);

INSERT INTO class_example_topredict VALUES
(1, '{1, 3, 2}'),
(2, '{4, 2, 2}'),
(3, '{2, 1, 1}');

4. Create a classification view using the feature probabilities, class priors, and class_example_topredict tables.

SELECT madlib.create_nb_probs_view ('example_feature_probs',    -- feature probabilities output table
'rexample_priors',           -- class priors output table
'class_example_topredict',  -- table with data to classify
'id',                        -- name of the key column
'attributes',               -- name of the attributes column
3,                          -- number of attributes
'exmaple_classified'         -- name of the view to create
);

5. Display the classification results.

SELECT * FROM example_classified;

<table>
<thead>
<tr>
<th>key</th>
<th>class</th>
<th>nb_prob</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>1</td>
<td>0.4</td>
</tr>
<tr>
<td>1</td>
<td>2</td>
<td>0.6</td>
</tr>
<tr>
<td>3</td>
<td>1</td>
<td>0.5</td>
</tr>
<tr>
<td>3</td>
<td>2</td>
<td>0.5</td>
</tr>
<tr>
<td>2</td>
<td>1</td>
<td>0.25</td>
</tr>
<tr>
<td>2</td>
<td>2</td>
<td>0.75</td>
</tr>
</tbody>
</table>

(6 rows)

Naive Bayes Example 2 – Weather and Outdoor Sports

This example calculates the probability that the user will play an outdoor sport, such as golf or tennis, based on weather conditions.

The table weather_example contains the example values.

The identification column for the table is day, an integer type.

The play column holds the dependent variable and has two classifications:

- 0 - No
- 1 - Yes

There are four attributes: outlook, temperature, humidity, and wind. These are categorical variables. The MADlib create_nb_classify_view() function expects the attributes to be provided as an array of INTEGER, NUMERIC, or FLOAT8 values, so the attributes for this example are encoded with integers as follows:

- outlook may be sunny (1), overcast (2), or rain (3).
- temperature may be hot (1), mild (2), or cool (3).
- humidity may be high (1) or normal (2).
- wind may be strong (1) or weak (2).

The following table shows the training data, before encoding the variables.

<table>
<thead>
<tr>
<th>day</th>
<th>play</th>
<th>outlook</th>
<th>temperature</th>
<th>humidity</th>
<th>wind</th>
</tr>
</thead>
<tbody>
<tr>
<td>2</td>
<td>No</td>
<td>Sunny</td>
<td>Hot</td>
<td>High</td>
<td>Strong</td>
</tr>
<tr>
<td>4</td>
<td>Yes</td>
<td>Rain</td>
<td>Mild</td>
<td>High</td>
<td>Weak</td>
</tr>
<tr>
<td>6</td>
<td>No</td>
<td>Rain</td>
<td>Cool</td>
<td>Normal</td>
<td>Strong</td>
</tr>
</tbody>
</table>
1. Create the training table.

```sql
DROP TABLE IF EXISTS weather_example;
CREATE TABLE weather_example (day int, play int, attrs int[]);
INSERT INTO weather_example VALUES
( 2, 0, '{1,1,1,1}'), -- sunny, hot, high, strong
( 4, 1, '{3,2,1,2}'), -- rain, mild, high, weak
( 6, 0, '{3,3,2,1}'), -- rain, cool, normal, strong
( 8, 0, '{1,2,1,2}'), -- sunny, mild, high, weak
(10, 1, '{3,2,2,2}'), -- rain, mild, normal, weak
(12, 1, '{2,2,1,1}'), -- etc.
(14, 0, '{3,2,1,1}'),
( 1, 0, '{1,1,1,2}'),
( 3, 1, '{2,1,1,2}'),
( 5, 1, '{3,3,2,2}'),
( 7, 1, '{2,3,2,1}'),
( 9, 1, '{1,3,2,2}'),
(11, 1, '{1,2,2,1}'),
(13, 1, '{2,1,2,2}');
```

2. Create the model from the training table.

```sql
SELECT madlib.create_nb_prepared_data_tables ('weather_example', -- training source table
'play', -- dependent class column
'attrs', -- attributes column
4, -- number of attributes
'weather_probs', -- feature probabilities output table
'weather_priors' -- class priors
);
```

3. View the feature probabilities:

```sql
SELECT * FROM weather_probs;
class | attr | value | cnt | attr_cnt
-------+------+-------+-----+----------
 1     | 3    | 2     | 6   | 2
 1     | 1    | 2     | 4   | 3
 0     | 1    | 1     | 3   | 3
 0     | 1    | 3     | 2   | 3
 0     | 3    | 1     | 4   | 2
 1     | 4    | 1     | 3   | 2
 1     | 2    | 3     | 3   | 3
 1     | 2    | 1     | 2   | 3
 0     | 2    | 2     | 2   | 3
 0     | 4    | 2     | 2   | 2
```
4. To classify a group of records with a model, first load the data into a table. In this example, the table `t1` has four rows to classify.

```sql
DROP TABLE IF EXISTS t1;
CREATE TABLE t1 (
    id integer,
    attributes integer[]);
insert into t1 values
    (1, '{1, 2, 1, 1}'),
    (2, '{3, 3, 2, 1}'),
    (3, '{2, 1, 2, 2}'),
    (4, '{3, 1, 1, 2}');
```

5. Use the MADlib `create_nb_classify_view()` function to classify the rows in the table.

```sql
SELECT madlib.create_nb_classify_view (
    'weather_probs',      -- feature probabilities table
    'weather_priors',     -- classPriorsName
    't1',                 -- table containing values to classify
    'id',                 -- key column
    'attributes',         -- attributes column
    4,                    -- number of attributes
    't1_out'              -- output table name
);
```

The result is four rows, one for each record in the `t1` table.

```sql
SELECT * FROM t1_out ORDER BY key;
key | nb_classification
-----+-------------------
1 | {0}
2 | {1}
3 | {1}
4 | {0}
(4 rows)
```

References

MADlib documentation is at [http://madlib.apache.org/documentation.html](http://madlib.apache.org/documentation.html).

PivotalR is a first class R package that enables users to interact with data resident in Greenplum Database and MADLib using an R client.

About MADlib, R, and PivotalR

The R language is an open-source language that is used for statistical computing. PivotalR is an R package that enables users to interact with data resident in Greenplum Database using the R client. Using PivotalR requires that MADlib is installed on the Greenplum Database.
PivotalR allows R users to leverage the scalability and performance of in-database analytics without leaving the R command line. The computational work is executed in-database, while the end user benefits from the familiar R interface. Compared with respective native R functions, there is an increase in scalability and a decrease in running time. Furthermore, data movement, which can take hours for very large data sets, is eliminated with PivotalR.

Key features of the PivotalR package:

- Explore and manipulate data in the database with R syntax. SQL translation is performed by PivotalR.
- Use the familiar R syntax for predictive analytics algorithms, for example linear and logistic regression. PivotalR accesses the MADlib in-database analytics function calls.
- Comprehensive documentation package with examples in standard R format accessible from an R client.
- The PivotalR package also supports access to the MADlib functionality.

For information about PivotalR, including supported MADlib functionality, see [https://cwiki.apache.org/confluence/display/MADLIB/PivotalR](https://cwiki.apache.org/confluence/display/MADLIB/PivotalR).

The R package for PivotalR can be found at [https://cran.r-project.org/web/packages/PivotalR/index.html](https://cran.r-project.org/web/packages/PivotalR/index.html).

**PostGIS Geospatial Extension**

This chapter contains the following information:

- About PostGIS
- Greenplum PostGIS Extension
- Enabling and Removing PostGIS Support
- Usage
- PostGIS Extension Support and Limitations
- PostGIS Support Scripts

**About PostGIS**

PostGIS is a spatial database extension for PostgreSQL that allows GIS (Geographic Information Systems) objects to be stored in the database. The Greenplum Database PostGIS extension includes support for GiST-based R-Tree spatial indexes and functions for analysis and processing of GIS objects.

The Greenplum Database PostGIS extension supports the optional PostGIS raster data type and most PostGIS Raster functions. With the PostGIS Raster objects, PostGIS geometry data type offers a single set of overlay SQL functions (such as `ST_Intersects`) operating seamlessly on vector and raster geospatial data. PostGIS Raster uses the GDAL (Geospatial Data Abstraction Library) translator library for raster geospatial data formats that presents a single raster abstract data model to a calling application.

For information about Greenplum Database PostGIS extension support, see [PostGIS Extension Support and Limitations](https://cwiki.apache.org/confluence/display/MADLIB/PivotalR).

For information about PostGIS, see [http://postgis.refractions.net/](http://postgis.refractions.net/)

For information about GDAL, see [http://www.gdal.org](http://www.gdal.org).

**Greenplum PostGIS Extension**

Greenplum Database supports the PostGIS extension with these component versions.

- PostGIS 2.1.5
- Proj 4.8.0
- Geos 3.4.2
Greenplum Database Reference Guide

- GDAL 1.11.1
- Json 0.12
- Expat 2.1.0

For the information about supported extension packages and software versions see the Greenplum Database Release Notes.

Major enhancements and changes in PostGIS 2.1.5 from 2.0.3 include new PostGIS Raster functions. For a list of new and enhanced functions in PostGIS 2.1, see the PostGIS documentation PostGIS Functions new or enhanced in 2.1.

For a list of breaking changes in PostGIS 2.1, see PostGIS functions breaking changes in 2.1.

For a comprehensive list of PostGIS changes in PostGIS 2.1.5 and earlier, see PostGIS 2.1 Appendix A Release 2.1.5.

Greenplum Database PostGIS Limitations

The Greenplum Database PostGIS extension does not support the following features:

- Topology
- A small number of user defined functions and aggregates
- PostGIS long transaction support
- Geometry and geography type modifier

For information about Greenplum Database PostGIS support, see PostGIS Extension Support and Limitations.

Enabling and Removing PostGIS Support

The Greenplum Database PostGIS extension contains the postgis_manager.sh script that installs or removes both the PostGIS and PostGIS Raster features in a database. After the PostGIS extension package is installed, the script is in $GPHOME/share/postgresql/contrib/postgis-2.1/. The postgis_manager.sh script runs SQL scripts that install or remove PostGIS and PostGIS Raster from a database.

For information about the PostGIS and PostGIS Raster SQL scripts, and required PostGIS Raster environment variables, see PostGIS Support Scripts.

Enabling PostGIS Support

Run the postgis_manager.sh script specifying the database and with the install option to install PostGIS and PostGIS Raster. This example installs PostGIS and PostGIS Raster objects in the database mydatabase.

postgis_manager.sh mydatabase install

The script runs all the PostGIS SQL scripts that enable PostGIS in a database: install/postgis.sql, install/rtpostgis.sql install/spatial_ref_sys.sql, install/postgis_comments.sql, and install/raster_comments.sql.

The postGIS package installation adds these lines to the greenplum_path.sh file for PostGIS Raster support.

export GDAL_DATA=$GPHOME/share/gdal
export POSTGIS_ENABLE_OUTDB_RASTERS=0
export POSTGIS_GDAL_ENABLED_DRIVERS=DABLE_ALL
Enabling GDAL Raster Drivers

PostGIS uses GDAL raster drivers when processing raster data with commands such as `ST_AsJPEG()`. As the default, PostGIS disables all raster drivers. You enable raster drivers by setting the value of the POSTGIS_GDAL_ENABLED_DRIVERS environment variable in the greenplum_path.sh file on all Greenplum Database hosts.

To see the list of supported GDAL raster drivers for a Greenplum Database system, run the raster2pgsql utility with the `-G` option on the Greenplum Database master.

```
raster2pgsql -G
```

The command lists the driver long format name. The GDAL Raster Formats table at [http://www.gdal.org/formats_list.html](http://www.gdal.org/formats_list.html) lists the long format names and the corresponding codes that you specify as the value of the environment variable. For example, the code for the long name Portable Network Graphics is PNG. This example export line enables four GDAL raster drivers.

```
export POSTGIS_GDAL_ENABLED_DRIVERS="GTiff PNG JPEG GIF"
```

The gpstop -r command restarts the Greenplum Database system to use the updated settings in the greenplum_path.sh file.

After you have updated the greenplum_path.sh file on all hosts, and have restarted the Greenplum Database system, you can display the enabled raster drivers with the `ST_GDALDrivers()` function. This SELECT command lists the enabled raster drivers.

```
SELECT short_name, long_name FROM ST_GDALDrivers();
```

Removing PostGIS Support

Run the postgis_manager.sh script specifying the database and with the `uninstall` option to remove PostGIS and PostGIS Raster. This example removes PostGIS and PostGIS Raster support from the database mydatabase.

```
postgis_manager.sh mydatabase uninstall
```

The script runs both the PostGIS SQL scripts that remove PostGIS and PostGIS Raster from a database: uninstall_rtpostgis.sql and uninstall_postgis.sql.

The postgis_manager.sh script does not remove these PostGIS Raster environment variables the greenplum_path.sh file: GDAL_DATA, POSTGIS_ENABLE_OUTDB_RASTERS, POSTGIS_GDAL_ENABLED_DRIVERS. The environment variables are removed when you uninstall the PostGIS extension package with the gppkg utility.

Usage

The following example SQL statements create non-OpenGIS tables and geometries.

```
CREATE TABLE geom_test ( gid int4, geom geometry, 
  name varchar(25) );
INSERT INTO geom_test ( gid, geom, name ) 
  VALUES ( 1, 'POLYGON((0 0 0,0 5 0,5 5 0,5 0 0,0 0 0))', '3D Square' );
INSERT INTO geom_test ( gid, geom, name ) 
  VALUES ( 2, 'LINESTRING(1 1 1,5 5 5,7 7 5)', '3D Line' );
INSERT INTO geom_test ( gid, geom, name ) 
  VALUES ( 3, 'MULTIPOINT(3 4,8 9)', '2D Aggregate Point' );
SELECT * from geom_test WHERE geom &&
  Box3D(ST_GeomFromEWKT('LINESTRING(2 2 0, 3 3 0)'));
```
The following example SQL statements create a table and add a geometry column to the table with a SRID integer value that references an entry in the \textit{SPATIAL\_REF\_SYS} table. The \texttt{INSERT} statements add two geopoints to the table.

```sql
CREATE TABLE geotest (id INT4, name VARCHAR(32) );
SELECT AddGeometryColumn('geotest','geopoint', 4326,'POINT',2);
INSERT INTO geotest (id, name, geopoint)
VALUES (1, 'Olympia', ST_GeometryFromText('POINT(-122.90 46.97)', 4326));
INSERT INTO geotest (id, name, geopoint)
VALUES (2, 'Renton', ST_GeometryFromText('POINT(-122.22 47.50)', 4326));
SELECT name,ST_AsText(geopoint) FROM geotest;
```

\section*{Spatial Indexes}

PostgreSQL provides support for GiST spatial indexing. The GiST scheme offers indexing even on large objects. It uses a system of lossy indexing in which smaller objects act as proxies for larger ones in the index. In the PostGIS indexing system, all objects use their bounding boxes as proxies in the index.

\section*{Building a Spatial Index}

You can build a GiST index as follows:

```sql
CREATE INDEX indexname
ON tablename
USING GIST ( geometryfield );
```

\section*{PostGIS Extension Support and Limitations}

This section describes Greenplum PostGIS extension feature support and limitations.

- \textit{Supported PostGIS Data Types}
- \textit{Supported PostGIS Index}
- \textit{Supported PostGIS Raster Data Types}
- \textit{PostGIS Extension Limitations}

The Greenplum Database PostGIS extension does not support the following features:

- Topology
- Some Raster Functions

\section*{Supported PostGIS Data Types}

Greenplum Database PostGIS extension supports these PostGIS data types:

- box2d
- box3d
- geometry
- geography

For a list of PostGIS data types, operators, and functions, see the \textit{PostGIS reference documentation}.

\section*{Supported PostGIS Raster Data Types}

Greenplum Database PostGIS supports these PostGIS Raster data types.

- geomval
- addbandarg
- rastbandarg
- raster
• reclassarg
• summarystats
• unionarg

For a list of PostGIS Raster data types, operators, and functions, see the [PostGIS Raster reference documentation](http://postgis.net/docs/manual-2.1/using_raster_dataman.html).

**Supported PostGIS Index**

Greenplum Database PostGIS extension supports the GiST (Generalized Search Tree) index.

**PostGIS Extension Limitations**

This section lists the Greenplum Database PostGIS extension limitations for user-defined functions (UDFs), data types, and aggregates.

• Data types and functions related to PostGIS topology functionality, such as TopoGeometry, are not supported by Greenplum Database.

• Functions that perform `ANALYZE` operations for user-defined data types are not supported. For example, the `ST_Estimated_Extent` function is not supported. The function requires table column statistics for user defined data types that are not available with Greenplum Database.

• These PostGIS aggregates are not supported by Greenplum Database:
  - `ST_MemCollect`
  - `ST_MakeLine`

On a Greenplum Database with multiple segments, the aggregate might return different answers if it is called several times repeatedly.

• Greenplum Database does not support PostGIS long transactions.

  PostGIS relies on triggers and the PostGIS table `public.authorization_table` for long transaction support. When PostGIS attempts to acquire locks for long transactions, Greenplum Database reports errors citing that the function cannot access the relation, `authorization_table`.

• Greenplum Database does not support type modifiers for user defined types.

  The work around is to use the `AddGeometryColumn` function for PostGIS geometry. For example, a table with PostGIS geometry cannot be created with the following SQL command:

  ```sql
  CREATE TABLE geometries(id INTEGER, geom geometry(LINestring));
  ```

  Use the `AddGeometryColumn` function to add PostGIS geometry to a table. For example, these following SQL statements create a table and add PostGIS geometry to the table:

  ```sql
  CREATE TABLE geometries(id INTEGER);
  SELECT AddGeometryColumn('public', 'geometries', 'geom', 0, 'LINestring', 2);
  ```

**PostGIS Support Scripts**

After installing the PostGIS extension package, you enable PostGIS support for each database that requires its use. To enable or remove PostGIS support in your database, you can run SQL scripts that are supplied with the PostGIS package in `$GPHOME/share/postgresql/contrib/postgis-2.1/`.

• [Scripts that Enable PostGIS and PostGIS Raster Support](http://postgis.net/docs/manual-2.1/using_raster_dataman.html)
• [Scripts that Remove PostGIS and PostGIS Raster Support](http://postgis.net/docs/manual-2.1/using_raster_dataman.html)
Instead of running the scripts individually, you can use the `postgis_manager.sh` script to run SQL scripts that enable or remove PostGIS support. See *Enabling and Removing PostGIS Support*.

You can run the PostGIS SQL scripts individually to enable or remove PostGIS support. For example, these commands run the SQL scripts `postgis.sql`, `rtpostgis.sql`, and `spatial_ref_sys.sql` in the database `mydatabase`.

```
psql -d mydatabase -f
   $GPHOME/share/postgresql/contrib/postgis-2.1/install/postgis.sql
psql -d mydatabase -f
   $GPHOME/share/postgresql/contrib/postgis-2.1/install/rtpostgis.sql
psql -d mydatabase -f
   $GPHOME/share/postgresql/contrib/postgis-2.1/install/spatial_ref_sys.sql
```

After running the scripts, the database is enabled with both PostGIS and PostGIS Raster.

**Scripts that Enable PostGIS and PostGIS Raster Support**

These scripts enable PostGIS, and the optional PostGIS Raster in a database.

- `install/postgis.sql` - Load the PostGIS objects and function definitions.
- `install/rtpostgis.sql` - Load the PostGIS raster object and function definitions.

  **Note:** If you are installing PostGIS Raster, PostGIS objects must be installed before PostGIS Raster. PostGIS Raster depends on PostGIS objects. Greenplum Database returns an error if `rtpostgis.sql` is run before `postgis.sql`.

These SQL scripts add data and comments to a PostGIS enabled database.

- `install/spatial_ref_sys.sql` - Populate the `spatial_ref_sys` table with a complete set of EPSG coordinate system definition identifiers. With the definition identifiers you can perform `ST_Transform()` operations on geometries.

  **Note:** If you have overridden standard entries and want to use those overrides, do not load the `spatial_ref_sys.sql` file when creating the new database.

- `install/postgis_comments.sql` - Add comments to the PostGIS functions.
- `install/raster_comments.sql` - Add comments to the PostGIS Raster functions.

You can view comments with the `psql` meta-command `\dd function_name` or from any tool that can show Greenplum Database function comments.

**PostGIS Raster Environment Variables**

The postGIS package installation adds these lines to the `greenplum_path.sh` file for PostGIS Raster support.

```
export GDAL_DATA=$GPHOME/share/gdal
export POSTGIS_ENABLE_OUTDB_RASTERS=0
export POSTGIS_GDAL_ENABLED_DRIVERS=DISABLE_ALL
```

`GDAL_DATA` specifies the location of GDAL utilities and support files used by the GDAL library. For example, the directory contains EPSG support files such as `gcs.csv` and `pcs.csv` (so called dictionaries, mostly in CSV format). The GDAL library requires the support files to properly evaluate EPSG codes.

`POSTGIS_GDAL_ENABLED_DRIVERS` sets the enabled GDAL drivers in the PostGIS environment.

`POSTGIS_ENABLE_OUTDB_RASTERS` is a boolean configuration option to enable access to out of database raster bands.
Scripts that Remove PostGIS and PostGIS Raster Support

To remove PostGIS support from a database, run SQL scripts that are supplied with the PostGIS extension package in $GPHOME/share/postgresql/contrib/postgis-2.1/

**Note:** If you installed PostGIS Raster, you must uninstall PostGIS Raster before you uninstall the PostGIS objects. PostGIS Raster depends on PostGIS objects. Greenplum Database returns an error if PostGIS objects are removed before PostGIS Raster.

These scripts remove PostGIS and PostGIS Raster objects from a database.

- `uninstall/uninstall_rtpostgis.sql` - Removes the PostGIS Raster object and function definitions.
- `uninstall/uninstall_postgis.sql` - Removes the PostGIS objects and function definitions.

After PostGIS support has been removed from all databases in the Greenplum Database system, you can remove the PostGIS extension package. For example, this `gppkg` command removes the PostGIS extension package.

```
gppkg -r postgis-2.1.5+pivotal.2
```

Restart Greenplum Database after removing the package.

```
gpstop -r
```

Ensure that these lines for PostGIS Raster support are removed from the `greenplum_path.sh` file.

```
export GDAL_DATA=$GPHOME/share/gdal
export POSTGIS_ENABLE_OUTDB_RASTERS=0
export POSTGIS_GDAL_ENABLED_DRIVERS=DISABLE_ALL
```
Additional Supplied Modules

This section describes additional modules available in the Greenplum Database installation. These modules may be PostgreSQL- or Greenplum-sourced.

The following Greenplum Database and PostgreSQL contrib modules are installed; refer to the linked module documentation for usage instructions.

- **auto_explain** - Provides a means for logging execution plans of slow statements automatically.
- **citext** - Provides a case-insensitive, multibyte-aware text data type.
- **dblink** - Provides connections to other Greenplum databases.
- **diskquota** - Allows administrators to set disk usage quotas for Greenplum Database roles and schemas.
- **fuzzystrmatch** - Determines similarities and differences between strings.
- **gp_sparse_vector** - Implements a Greenplum Database data type that uses compressed storage of zeros to make vector computations on floating point numbers faster.
- **hstore** - Provides a data type for storing sets of key/value pairs within a single PostgreSQL value.
- **orafce** - Provides Greenplum Database-specific Oracle SQL compatibility functions.
- **pageinspect** - Provides functions for low level inspection of the contents of database pages; available to superusers only.
- **pgcrypto** - Provides cryptographic functions for Greenplum Database.
- **sslinfo** - Provides information about the SSL certificate that the current client provided when connecting to Greenplum.

### auto_explain

The auto_explain module provides a means for logging execution plans of slow statements automatically, without having to run `EXPLAIN` by hand.

The Greenplum Database auto_explain module was runs only on the Greenplum Database master segment host. It is otherwise equivalent in functionality to the PostgreSQL auto_explain module.

#### Loading the Module

The auto_explain module provides no SQL-accessible functions. To use it, simply load it into the server. You can load it into an individual session by entering this command as a superuser:

```sql
LOAD 'auto_explain';
```

More typical usage is to preload it into some or all sessions by including `auto_explain` in `session_preload_libraries` or `shared_preload_libraries` in `postgresql.conf`. Then you can track unexpectedly slow queries no matter when they happen. However, this does introduce overhead for all queries.

#### Module Documentation

See auto_explain in the PostgreSQL documentation for detailed information about the configuration parameters that control this module’s behavior.

### citext

The citext module provides a case-insensitive character string data type, citext. Essentially, it internally calls the `lower()` function when comparing values. Otherwise, it behaves almost exactly like the `text` data type.
The Greenplum Database \texttt{citext} module is equivalent to the PostgreSQL \texttt{citext} module. There are no Greenplum Database or MPP-specific considerations for the module.

### Installing and Registering the Module

The \texttt{citext} module is installed when you install Greenplum Database. Before you can use any of the data types, operators, or functions defined in the module, you must register the \texttt{citext} extension in each database in which you want to use the objects. Refer to \textit{Installing Additional Supplied Modules} for more information.

### Module Documentation

See \texttt{citext} in the PostgreSQL documentation for detailed information about the data types, operators, and functions defined in this module.

---

**\texttt{dblink}**

The \texttt{dblink} module supports connections to other Greenplum Database databases from within a database session. These databases can reside in the same Greenplum Database system, or in a remote system.

Greenplum Database supports \texttt{dblink} connections between databases in Greenplum Database installations with the same major version number. You can also use \texttt{dblink} to connect to other Greenplum Database installations that use compatible \texttt{libpq} libraries.

\textbf{Note:} \texttt{dblink} is intended for database users to perform short ad hoc queries in other databases. \texttt{dblink} is not intended for use as a replacement for external tables or for administrative tools such as \texttt{gpcopy}.

The Greenplum Database \texttt{dblink} module is a modified version of the PostgreSQL \texttt{dblink} module. There are some restrictions and limitations when you use the module in Greenplum Database.

### Installing and Registering the Module

The \texttt{dblink} module is installed when you install Greenplum Database. Before you can use any of the functions defined in the module, you must register the \texttt{dblink} extension in each database in which you want to use the functions. Refer to \textit{Installing Additional Supplied Modules} for more information.

### Greenplum Database Considerations

In this release of Greenplum Database, statements that modify table data cannot use named or implicit \texttt{dblink} connections. Instead, you must provide the connection string directly in the \texttt{dblink()} function. For example:

```sql
gpadmin=# CREATE TABLE testdbllocal (a int, b text) DISTRIBUTED BY (a);
CREATE TABLE
gpadmin=# INSERT INTO testdbllocal select * FROM dblink('dbname=postgres',
'SELECT * FROM testdblink') AS dbltab(id int, product text);
INSERT 0 2
```

The Greenplum Database version of \texttt{dblink} disables the following asynchronous functions:

- \texttt{dblink\_send\_query()}
- \texttt{dblink\_is\_busy()}
- \texttt{dblink\_get\_result()}
Using dblink

The following procedure identifies the basic steps for configuring and using `dblink` in Greenplum Database. The examples use `dblink_connect()` to create a connection to a database and `dblink()` to execute an SQL query.

1. Begin by creating a sample table to query using the `dblink` functions. These commands create a small table in the `postgres` database, which you will later query from the `testdb` database using `dblink`:

$ psql -d postgres
psql (9.4.20)
Type "help" for help.

postgres=# CREATE TABLE testdblink (a int, b text) DISTRIBUTED BY (a);
CREATE TABLE
postgres=# INSERT INTO testdblink VALUES (1, 'Cheese'), (2, 'Fish');
INSERT 0 2
postgres=# \
$

2. Log into a different database as a superuser. In this example, the superuser `gpadmin` logs into the database `testdb`. If the `dblink` functions are not already available, register the `dblink` extension in the database:

$ psql -d testdb
psql (9.4beta1)
Type "help" for help.

testdb=# CREATE EXTENSION dblink;
CREATE EXTENSION

3. Use the `dblink_connect()` function to create either an implicit or a named connection to another database. The connection string that you provide should be a `libpq`-style keyword/value string. This example creates a connection named `mylocalconn` to the `postgres` database on the local Greenplum Database system:

```
testdb=# SELECT dblink_connect('mylocalconn', 'dbname=postgres
user=gpadmin');
dblink_connect
----------------
OK
(1 row)
```

**Note:** If a `user` is not specified, `dblink_connect()` uses the value of the `PGUSER` environment variable when Greenplum Database was started. If `PGUSER` is not set, the default is the system user that started Greenplum Database.

4. Use the `dblink()` function to query a database using a configured connection. Keep in mind that this function returns a record type, so you must assign the columns returned in the `dblink()` query. For example, the following command uses the named connection to query the table you created earlier:

```
testdb=# SELECT * FROM dblink('mylocalconn', 'SELECT * FROM testdblink')
    AS dbltab(id int, product text);
  id | product
  ----+---------
   1 | Cheese
   2 | Fish
(2 rows)
```
To connect to the local database as another user, specify the user in the connection string. This example connects to the database as the user test_user. Using dblink_connect(), a superuser can create a connection to another local database without specifying a password.

```
testdb=# SELECT dblink_connect('localconn2', 'dbname=postgres user=test_user');
```

To make a connection to a remote database system, include host and password information in the connection string. For example, to create an implicit dblink connection to a remote system:

```
testdb=# SELECT dblink_connect('host=remotehost port=5432 dbname=postgres user=gpadmin password=secret');
```

### Using dblink as a Non-Superuser

To make a connection to a database with dblink_connect(), non-superusers must include host, user, and password information in the connection string. The host, user, and password information must be included even when connecting to a local database. For example, the user test_user can create a dblink connection to the local system mdw with this command:

```
testdb=> SELECT dblink_connect('host=mdw port=5432 dbname=postgres user=test_user password=secret');
```

If non-superusers need to create dblink connections that do not require a password, they can use the dblink_connect_u() function. The dblink_connect_u() function is identical to dblink_connect(), except that it allows non-superusers to create connections that do not require a password.

dblink_connect_u() is initially installed with all privileges revoked from PUBLIC, making it un-callable except by superusers. In some situations, it may be appropriate to grant EXECUTE permission on dblink_connect_u() to specific users who are considered trustworthy, but this should be done with care.

**Warning:** If a Greenplum Database system has configured users with an authentication method that does not involve a password, then impersonation and subsequent escalation of privileges can occur when a non-superuser executes dblink_connect_u(). The dblink connection will appear to have originated from the user specified by the function. For example, a non-superuser can execute dblink_connect_u() and specify a user that is configured with trust authentication.

Also, even if the dblink connection requires a password, it is possible for the password to be supplied from the server environment, such as a ~/.pgpass file belonging to the server’s user. It is recommended that any ~/.pgpass file belonging to the server’s user not contain any records specifying a wildcard host name.

1. **As a superuser, grant the EXECUTE privilege on the dblink_connect_u() functions in the user database.** This example grants the privilege to the non-superuser test_user on the functions with the signatures for creating an implicit or a named dblink connection.

```
testdb=# GRANT EXECUTE ON FUNCTION dblink_connect_u(text) TO test_user;
testdb=# GRANT EXECUTE ON FUNCTION dblink_connect_u(text, text) TO test_user;
```

2. **Now test_user can create a connection to another local database without a password.** For example, test_user can log into the testdb database and execute this command to create a connection named testconn to the local postgres database.

```
testdb=> SELECT dblink_connect_u('testconn', 'dbname=postgres user=test_user');
```
Note: If a user is not specified, dblink_connect_u() uses the value of the PGUSER environment variable when Greenplum Database was started. If PGUSER is not set, the default is the system user that started Greenplum Database.

3. test_user can use the dblink() function to execute a query using a dblink connection. For example, this command uses the dblink connection named testconn created in the previous step. test_user must have appropriate access to the table.

```sql
testdb=> SELECT * FROM dblink('testconn', 'SELECT * FROM testdblink') AS dbltab(id int, product text);
```

Additional Module Documentation

Refer to dblink in the PostgreSQL documentation for detailed information about the individual functions in this module.

diskquota

The diskquota module allows Greenplum Database administrators to limit the amount of disk space used by schemas or roles in a database.

Installing and Registering the Module

The diskquota module is installed when you install Greenplum Database.

Before you can use the module, you must perform these steps:

1. Create the diskquota database. The diskquota module uses this database to store the list of databases where the module is enabled.

   ```
   $ createdb diskquota;
   ```

2. Add the diskquota shared library to the Greenplum Database shared_preload_libraries server configuration parameter and restart Greenplum Database.

   ```
   $ gpconfig -c shared_preload_libraries -v 'diskquota'
   $ gpstop -ar
   ```

3. Register the diskquota extension in databases where you want to enforce disk usage quotas. diskquota can be registered in up to ten databases.

   ```
   $ psql -d testdb -c "CREATE EXTENSION diskquota"
   ```

4. If you register the diskquota extension in a database that already contains data, you must initialize the diskquota table size data by running the diskquota.init_table_size_table() UDF in the database. In a database with many files, this can take a long time. The diskquota module cannot be used until the initialization is complete.

   ```
   =# SELECT diskquota.init_table_size_table();
   ```

About the diskquota Module

A Greenplum Database superuser can set disk usage quotas for schemas and roles. A schema quota sets a limit on disk space used by all tables that belong to a schema. A role quota sets a limit on disk space used by all tables that are owned by a role.

Diskquota processes running on the master and segment hosts check disk usage periodically and place schemas or roles on a blacklist when they reach their quota.
When a query plan has been generated for a query that would add data, and the schema or role is on the blacklist, the query is cancelled before it can start. An error message reports the quota that has been exceeded. A query that does not add data, such as a simple `SELECT` query, is allowed to run even when the role or schema is on the blacklist.

Diskquota enforces soft limits for disk usage. Quotas are only checked before a query executes. If the quota is not exceeded when the query is about to run, the query is allowed to run, even if it causes the quota to be exceeded.

There is some delay after a quota has been reached before the schema or role is added to the blacklist. Other queries could add more data during the delay. The delay occurs because `diskquota` processes that calculate the disk space used by each table execute periodically with a pause between executions (two seconds by default). The delay also occurs when disk usage falls beneath a quota, due to operations such as `DROP`, `TRUNCATE`, or `VACUUM FULL` that remove data. Administrators can change the amount of time between disk space checks by setting the `diskquota.naptime` server configuration parameter.

If a query is unable to run because the schema or role has been blacklisted, an administrator can increase the exceeded quota to allow the query to execute. The `show_fast_schema_quota_view` and `show_fast_role_quota_view` views can be used to find the schemas or roles that have exceeded their limits.

### Using the `diskquota` Module

#### Setting Disk Quotas

Use the `diskquota.set_schema_quota()` and `diskquota.set_role_quota()` user-defined functions in a database to set, update, or delete disk quota limits for schemas and roles in the database. The functions take two arguments: the schema or role name, and the quota to set. The quota can be specified in units of MB, GB, TB, or PB, for example '2TB'.

The following example sets a 250GB quota for the `acct` schema:

```sql
$ SELECT diskquota.set_schema_quota('acct', '250GB');
```

This example sets a 500MB quota for the `nickd` role:

```sql
$ SELECT diskquota.set_role_quota(nickd, '500MB');
```

To change a quota, call the `diskquota.set_schema_quota()` or `diskquota.set_role_quota()` function again with the new quota value.

To remove a quota, set the quota value to '-1'.

#### Displaying Disk Quotas and Disk Usage

The `diskquota` module provides two views to display active quotas and the current computed disk space used.

The `diskquota.show_fast_schema_quota_view` view lists active quotas for schemas in the current database. The `nspsize_in_bytes` column contains the calculated size for all tables that belong to the schema.

```sql
=# SELECT * FROM diskquota.show_fast_schema_quota_view;
<table>
<thead>
<tr>
<th>schema_name</th>
<th>schema_oid</th>
<th>quota_in_mb</th>
<th>nspsize_in_bytes</th>
</tr>
</thead>
<tbody>
<tr>
<td>acct</td>
<td>16561</td>
<td>256000</td>
<td>131072</td>
</tr>
<tr>
<td>analytics</td>
<td>16519</td>
<td>1073741824</td>
<td>144670720</td>
</tr>
<tr>
<td>eng</td>
<td>16560</td>
<td>5242880</td>
<td>117833728</td>
</tr>
<tr>
<td>public</td>
<td>2200</td>
<td>250</td>
<td>3014656</td>
</tr>
</tbody>
</table>
(4 rows)
```
The `diskquota.show_fast_role_quota_view` view lists the active quotas for roles in the current database. The `rolsize_in_bytes` column contains the calculated size for all tables that are owned by the role.

```
=# SELECT * FROM diskquota.show_fast_role_quota_view;
role_name | role_oid | quota_in_mb | rolsize_in_bytes
-----------+----------+-------------+------------------
 mdach     |    16558 |         500 |           131072
 adam      |    16557 |         300 |        117833728
 nickd     |    16577 |         500 |        144670720
(3 rows)
```

### Setting the Delay Between Disk Usage Updates

The `diskquota.naptime` server configuration parameter specifies how frequently (in seconds) the table sizes are recalculated. The smaller the `naptime` value, the less delay in detecting changes in disk usage. This example sets the `naptime` to ten seconds.

```
$ gpconfig -c diskquota.naptime -v 10
```

### Configuring diskquota Shared Memory

The `diskquota` module uses shared memory to save the blacklist and to save the active table list. The blacklist shared memory can hold up to 1MiB of database objects that exceed the quota limit. If the blacklist shared memory fills, data may be loaded into some schemas or roles after they have reached their quota limit.

Active table shared memory holds up to 1MiB of active tables by default. Active tables are tables that may have changed sizes since `diskquota` last recalculated the table sizes. `diskquota` hook functions are called when the storage manager on each Greenplum Database segment creates, extends, or truncates a table file. The hook functions store the identity of the file in shared memory so that its file size can be recalculated the next time the table size data is refreshed.

If the shared memory for active tables fills, `diskquota` may fail to detect a change in disk usage. The amount of active table shared memory can be adjusted by setting the `diskquota.max_active_tables` server configuration parameter. This example changes the active table shared memory to 2MiB:

```
$ gpconfig -c diskquota.max_active_tables -v '2MiB'
```

Shared memory is allocated when Greenplum Database starts up, so a server restart is required after you change the value of the `diskquota.max_active_tables` parameter.

### Notes

The `diskquota` module can be enabled in up to ten databases. One diskquota worker process is created on the Greenplum Database master host for each diskquota-enabled database.

The disk usage for a role is defined as the total of disk usage on all segments for all tables the role owns. Although a role is a cluster-level database object, the disk usage for roles is calculated separately for each database.

The disk usage of a schema is defined as the total of disk usage on all segments for all tables in the schema.

The disk usage for a table includes the table data, indexes, toast tables, and free space map. For append-optimized tables, the calculation includes the visibility map and index, and the block directory table.

The `diskquota` module cannot detect a newly created table inside of an uncommitted transaction. The size of the new table is not included in the disk usage calculated for the corresponding schema or role until
after the transaction has committed. Similarly, a table created using the `CREATE TABLE AS` command is not included in disk usage statistics until the command has completed.

Deleting rows or running `VACUUM` on a table does not release disk space, so these operations cannot alone remove a schema or role from the diskquota blacklist. The disk space used by a table can be reduced by running `VACUUM FULL` or `TRUNCATE TABLE`.

The diskquota module supports high availability features provided by the background worker framework. The diskquota launcher process only runs on the active master node. The postmaster on the standby master does not start the diskquota launcher process when it is in standby mode. When the master is down and the administrator runs the `gpactivatestandby` command, the standby master changes its role to master and the diskquota launcher process is forked automatically. Using the diskquota-enabled database list in the diskquota database, the diskquota launcher creates the diskquota worker processes that manage disk quotas for each database.

**Examples**

This example demonstrates how to set up a schema quota and then observe diskquota behavior as data is added to the schema.

1. Create a database named `test` and log in to it.

   ```bash
   $ createdb test
   $ psql -d test
   ```

2. Create the diskquota extension in the database.

   ```sql
   \# CREATE EXTENSION diskquota;
   CREATE EXTENSION
   ```

3. Create the `s1` schema.

   ```sql
   \# CREATE SCHEMA s1;
   CREATE SCHEMA
   ```

4. Set a 1MB disk quota for the `s1` schema.

   ```sql
   \# SELECT diskquota.set_schema_quota('s1', '1MB');
   set_schema_quota
   ------------------
   (1 row)
   ```

5. The following commands create a table in the `s1` schema and insert a small amount of data into it. The schema has no data yet, so it is not on the blacklist.

   ```sql
   \# SET search_path TO s1;
   SET
   \# CREATE TABLE a(i int);
   CREATE TABLE
   \# INSERT INTO a SELECT generate_series(1,100);
   INSERT 0 100
   ```

6. This command inserts a large amount of data, enough to exceed the 1MB quota that was set for the schema. Before the `INSERT` command, the `s1` schema is still not on the blacklist, so this command should be allowed to run, even though it will exceed the limit set for the schema.

   ```sql
   \# INSERT INTO a SELECT generate_series(1,10000000);
   INSERT 0 10000000
   ```
7. This command attempts to insert a small amount of data. Because the previous command exceeded the schema's disk quota limit, the schema should be blacklisted and any data loading command should be cancelled.

```sql
=# INSERT INTO a SELECT generate_series(1,100);
ERROR: schema's disk space quota exceeded with name:s1
```

8. This command removes the quota from the `s1` schema by setting it to `-1` and again inserts a small amount of data. A 5-second sleep before the `INSERT` command ensures that the `diskquota` table size data is updated before the command is run.

```sql
=# SELECT diskquota.set_schema_quota('s1', '-1');
set_schema_quota
------------------
| (1 row) |
# Wait for 5 seconds to ensure the blacklist is updated
#=
=# SELECT pg_sleep(5);
#=
=# INSERT INTO a SELECT generate_series(1,100);
INSERT 0 100
```

**fuzzystrmatch**

The `fuzzystrmatch` module provides functions to determine similarities and distance between strings based on various algorithms.

The Greenplum Database `fuzzystrmatch` module is equivalent to the PostgreSQL `fuzzystrmatch` module. There are no Greenplum Database or MPP-specific considerations for the module.

**Installing and Registering the Module**

The `fuzzystrmatch` module is installed when you install Greenplum Database. Before you can use any of the functions defined in the module, you must register the `fuzzystrmatch` extension in each database in which you want to use the functions. Refer to `Installing Additional Supplied Modules` for more information.

**Module Documentation**

See `fuzzystrmatch` in the PostgreSQL documentation for detailed information about the individual functions in this module.

**gp_sparse_vector**

The `gp_sparse_vector` module implements a Greenplum Database data type and associated functions that use compressed storage of zeros to make vector computations on floating point numbers faster.

The `gp_sparse_vector` module is a Greenplum Database extension.

**Installing and Registering the Module**

The `gp_sparse_vector` module is installed when you install Greenplum Database. Before you can use any of the functions defined in the module, you must register the `gp_sparse_vector` extension in each database where you want to use the functions. Refer to `Installing Additional Supplied Modules` for more information.
Using the gp_sparse_vector Module

When you use arrays of floating point numbers for various calculations, you will often have long runs of zeros. This is common in scientific, retail optimization, and text processing applications. Each floating point number takes 8 bytes of storage in memory and/or disk. Saving those zeros is often impractical. There are also many computations that benefit from skipping over the zeros.

For example, suppose the following array of doubles is stored as a float8[] in Greenplum Database:

```
'{0, 33, <40,000 zeros>, 12, 22 }'::float8[]
```

This type of array arises often in text processing, where a dictionary may have 40-100K terms and the number of words in a particular document is stored in a vector. This array would occupy slightly more than 320KB of memory/disk, most of it zeros. Any operation that you perform on this data works on 40,001 fields that are not important.

The Greenplum Database built-in array datatype utilizes a bitmap for null values, but it is a poor choice for this use case because it is not optimized for float8[] or for long runs of zeros instead of nulls, and the bitmap is not run-length-encoding (RLE) compressed. Even if each zero were stored as a NULL in the array, the bitmap for nulls would use 5KB to mark the nulls, which is not nearly as efficient as it could be.

The Greenplum Database gp_sparse_vector module defines a data type and a simple RLE-based scheme that is biased toward being efficient for zero value bitmaps. This scheme uses only 6 bytes for bitmap storage.

**Note:** The sparse vector data type defined by the gp_sparse_vector module is named svec. svec supports only float8 vector values.

You can construct an svec directly from a float array as follows:

```
SELECT ('{0, 13, 37, 53, 0, 71 }'::float8[])::svec;
```

The gp_sparse_vector module supports the vector operators <, >, *, **, /, =, +, sum(), vec_count_nonzero(), and so on. These operators take advantage of the efficient sparse storage format, making computations on svecs faster.

The plus (+) operator adds each of the terms of two vectors of the same dimension together. For example, if vector a = {0,1,5} and vector b = {4,3,2}, you would compute the vector addition as follows:

```
SELECT ('{0,1,5}'::float8[]::svec + '{4,3,2}'::float8[]::svec)::float8[];
```

```
float8
-------
(4,4,7)
```

A vector dot product (%*%) between vectors a and b returns a scalar result of type float8. Compute the dot product ((0*4+1*3+5*2)=13) as follows:

```
SELECT '{0,1,5}'::float8[]::svec %*% '{4,3,2}'::float8[]::svec;
```

```
?column?
-------
13
```

Special vector aggregate functions are also useful. sum() is self explanatory. vec_count_nonzero() evaluates the count of non-zero terms found in a set of svec and returns an svec with the counts. For instance, for the set of vectors {0,1,5}, {10,0,3}, {0,0,3}, {0,1,0}, the count of non-zero terms would be {1,2,3}. Use vec_count_nonzero() to compute the count of these vectors:

```
CREATE TABLE listvecs( a svec );
```

```
INSERT INTO listvecs VALUES ('{0,1,5}'::float8[]),
```

```sql
('{10,0,3}'::float8[]),
('{0,3}'::float8[]),
('{0,1,0}'::float8[]);
```

SELECT vec_count_nonzero( a )::float8[] FROM listvecs;

<table>
<thead>
<tr>
<th>count_vec</th>
</tr>
</thead>
<tbody>
<tr>
<td>{1,2,3}</td>
</tr>
</tbody>
</table>

### Additional Module Documentation

Refer to the gp_sparse_vector READMEs in the Greenplum Database github repository for additional information about this module.

Apache MADlib includes an extended implementation of sparse vectors. See the MADlib Documentation for a description of this MADlib module.

### Example

A text classification example that describes a dictionary and some documents follows. You will create Greenplum Database tables representing a dictionary and some documents. You then perform document classification using vector arithmetic on word counts and proportions of dictionary words in each document.

Suppose that you have a dictionary composed of words in a text array. Create a table to store the dictionary data and insert some data (words) into the table. For example:

```sql
CREATE TABLE features (dictionary text[][]) DISTRIBUTED RANDOMLY;
INSERT INTO features
VALUES
('{am, before, being, bothered, corpus, document, i, in, is, me, never, now, 'one, really, second, the, third, this, until}');
```

You have a set of documents, also defined as an array of words. Create a table to represent the documents and insert some data into the table:

```sql
CREATE TABLE documents(docnum int, document text[]) DISTRIBUTED RANDOMLY;
INSERT INTO documents VALUES
(1, '{this, is, one, document, in, the, corpus}'),
(2, '{i, am, the, second, document, in, the, corpus}'),
(3, '{being, third, never, really, bothered, me, until, now}'),
(4, '{the, document, before, me, is, the, third, document}');
```

Using the dictionary and document tables, find the dictionary words that are present in each document. To do this, you first prepare a Sparse Feature Vector, or SFV, for each document. An SFV is a vector of dimension \( N \), where \( N \) is the number of dictionary words, and each SFV contains a count of each dictionary word in the document.

You can use the `gp_extract_feature_histogram()` function to create an SFV from a document. `gp_extract_feature_histogram()` outputs an svec for each document that contains the count of each of the dictionary words in the ordinal positions of the dictionary.

```sql
SELECT gp_extract_feature_histogram(
    (SELECT dictionary FROM features LIMIT 1), document)::float8[], document
FROM documents ORDER BY docnum;
```

<table>
<thead>
<tr>
<th>gp_extract_feature_histogram</th>
<th>document</th>
</tr>
</thead>
<tbody>
<tr>
<td>----------------------------</td>
<td>----------</td>
</tr>
</tbody>
</table>
+------------------------------|----------|

The SFV of the second document, "i am the second document in the corpus", is
\( (1,3*0,1,1,1,6*0,1,2) \). The word "am" is the first ordinate in the dictionary, and there is 1 instance
of it in the SFV. The word "before" has no instances in the document, so its value is 0; and so on.

gp_extract_feature_histogram() is very speed optimized - it is a single routine version of a hash
join that processes large numbers of documents into their SFVs in parallel at the highest possible speeds.

For the next part of the processing, generate a sparse vector of the dictionary dimension (19). The vectors
that you generate for each document are referred to as the corpus.

```
CREATE table corpus (docnum int, feature_vector svec) DISTRIBUTED RANDOMLY;
INSERT INTO corpus
(SELECT docnum,
 gp_extract_feature_histogram(
  (select dictionary FROM features LIMIT 1), document) from
documents);
```

Count the number of times each feature occurs at least once in all documents:
```
SELECT (vec_count_nonzero(feature_vector))::float8[] AS count_in_document
FROM corpus;
```

```
count_in_document
-----------------------------------------
{1,1,1,1,2,3,1,2,2,1,1,1,1,3,2,1,1}
```

Count all occurrences of each term in all documents:
```
SELECT (sum(feature_vector))::float8[] AS sum_in_document FROM corpus;
```

```
sum_in_document
-----------------------------------------
{1,1,1,1,2,4,1,2,2,1,1,1,1,5,2,1,1}
```

The remainder of the classification process is vector math. The count is turned into a weight that reflects
Term Frequency / Inverse Document Frequency (tf/idf). The calculation for a given term in a given
document is:
```
#_times_term_appears_in_this_doc * log( #_docs / #_docs_the_term_appears_in )
```

#_docs is the total number of documents (4 in this case). Note that there is one divisor for each dictionary
word and its value is the number of times that word appears in the document.
For example, the term "document" in document 1 would have a weight of $1 \times \log(4/3)$. In document 4, the term would have a weight of $2 \times \log(4/3)$. Terms that appear in every document would have weight 0.

This single vector for the whole corpus is then scalar product multiplied by each document SFV to produce the tf/idf.

Calculate the tf/idf:

```sql
SELECT docnum, (feature_vector*logidf)::float8[] AS tf_idf
FROM (SELECT log(count(feature_vector)/
vec_count_nonzero(feature_vector)) AS logidf FROM corpus)
AS foo, corpus ORDER BY docnum;
```

<table>
<thead>
<tr>
<th>docnum</th>
<th>tf_idf</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>{0,0,0,0,0.693147180559945,0.287682072451781,0,0.693147180559945,0.693147180559945,0,0,0.693147180559945,0,0,0,1.38629436111989,0,0,0.287682072451781,0,0}</td>

</tr>
<tr>
<td>3</td>
<td>{0,0,1.38629436111989,1.38629436111989,0,0,0,0,0,0.693147180559945,1.38629436111989,1.38629436111989,0,1.38629436111989,0,0,0.693147180559945,0,1.38629436111989}</td>
</tr>
<tr>
<td>4</td>
<td>{0,1.38629436111989,0,0,0,0.575364144903562,0,0,0.693147180559945,0.693147180559945,0,0,0,0,0,0.575364144903562,0.693147180559945,0,0}</td>
</tr>
</tbody>
</table>

You can determine the angular distance between one document and the rest of the documents using the ACOS of the dot product of the document vectors:

```sql
CREATE TABLE weights AS
(SELECT docnum, (feature_vector*logidf) tf_idf
FROM (SELECT log(count(feature_vector)/
vec_count_nonzero(feature_vector)) AS logidf FROM corpus) foo, corpus ORDER BY docnum)
DISTRIBUTED RANDOMLY;
```

Calculate the angular distance between the first document and every other document:

```sql
SELECT docnum, trunc((180.*(ACOS(dmin(1.,(tf_idf%*%testdoc)/
(l2norm(tf_idf)*l2norm(testdoc))))/(4.*ATAN(1.))))::numeric,2)
AS angular_distance FROM weights,
(SELECT tf_idf testdoc FROM weights WHERE docnum = 1 LIMIT 1) foo
ORDER BY 1;
```

<table>
<thead>
<tr>
<th>docnum</th>
<th>angular_distance</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>0.00</td>
</tr>
<tr>
<td>2</td>
<td>78.82</td>
</tr>
<tr>
<td>3</td>
<td>90.00</td>
</tr>
<tr>
<td>4</td>
<td>80.02</td>
</tr>
</tbody>
</table>

You can see that the angular distance between document 1 and itself is 0 degrees, and between document 1 and 3 is 90 degrees because they share no features at all.

**hstore**

The `hstore` module implements a data type for storing sets of (key,value) pairs within a single Greenplum Database data field. This can be useful in various scenarios, such as rows with many attributes that are rarely examined, or semi-structured data.
The Greenplum Database hstore module is equivalent to the PostgreSQL hstore module. There are no Greenplum Database or MPP-specific considerations for the module.

Installing and Registering the Module

The hstore module is installed when you install Greenplum Database. Before you can use any of the data types or functions defined in the module, you must register the hstore extension in each database in which you want to use the objects. Refer to Installing Additional Supplied Modules for more information.

Module Documentation

See hstore in the PostgreSQL documentation for detailed information about the data types and functions defined in this module.

orafce

The orafce module provides Oracle Compatibility SQL functions in Greenplum Database. These functions target PostgreSQL but can also be used in Greenplum.

The Greenplum Database orafce module is a modified version of the open source Orafce PostgreSQL module extension. The modified orafce source files for Greenplum Database can be found in the gpcontrib/orafce directory in the Greenplum Database open source project. The source reflects the Orafce 3.6.1 release and additional commits to 3af70a28f6.

There are some restrictions and limitations when you use the module in Greenplum Database.

Installing and Registering the Module

Note: Always use the Oracle Compatibility Functions module included with your Greenplum Database version. Before upgrading to a new Greenplum Database version, uninstall the compatibility functions from each of your databases, and then, when the upgrade is complete, reinstall the compatibility functions from the new Greenplum Database release. See the Greenplum Database release notes for upgrade prerequisites and procedures.

The orafce module is installed when you install Greenplum Database. Before you can use any of the functions defined in the module, you must register the orafce extension in each database in which you want to use the functions. Refer to Installing Additional Supplied Modules for more information.

Greenplum Database Considerations

The following functions are available by default in Greenplum Database and do not require installing the Oracle Compatibility Functions:

• sinh()
• tanh()
• cosh()
• decode() (See Greenplum Implementation Differences for more information.)

Greenplum Implementation Differences

There are differences in the implementation of the compatibility functions in Greenplum Database from the original PostgreSQL orafce module extension implementation. Some of the differences are as follows:

• The original orafce module implementation performs a decimal round off, the Greenplum Database implementation does not:
  • 2.00 becomes 2 in the original module implementation
  • 2.00 remains 2.00 in the Greenplum Database implementation
The provided Oracle compatibility functions handle implicit type conversions differently. For example, using the `decode` function:

\[
decode(expression, value, return [,value, return]...)
\[

The original `orafce` module implementation automatically converts `expression` and each `value` to the data type of the first `value` before comparing. It automatically converts `return` to the same data type as the first result.

The Greenplum Database implementation restricts `return` and `default` to be of the same data type. The `expression` and `value` can be different types if the data type of `value` can be converted into the data type of the `expression`. This is done implicitly. Otherwise, `decode` fails with an invalid input syntax error. For example:

```sql
SELECT decode('a','M',true,false);
CASE
-----
f
(1 row)
SELECT decode(1,'M',true,false);
ERROR: Invalid input syntax for integer: "M"
LINE 1: SELECT decode(1,'M',true,false);
```

- Numbers in `bigint` format are displayed in scientific notation in the original `orafce` module implementation but not in the Greenplum Database implementation:
  - `9223372036854775` displays as `9.2234E+15` in the original implementation
  - `9223372036854775` remains `9223372036854775` in the Greenplum Database implementation
- The default date and timestamp format in the original `orafce` module implementation is different than the default format in the Greenplum Database implementation. If the following code is executed:

  ```sql
  CREATE TABLE TEST(date1 date, time1 timestamp, time2 timestamp with time zone);
  INSERT INTO TEST VALUES ('2001-11-11','2001-12-13 01:51:15','2001-12-13 01:51:15 -08:00');
  SELECT DECODE(date1, '2001-11-11', '2001-01-01') FROM TEST;
  ```

  The Greenplum Database implementation returns the row, but the original implementation returns no rows.

  **Note:** The correct syntax when using the original `orafce` implementation to return the row is:

  ```sql
  SELECT DECODE(to_char(date1, 'YYYY-MM-DD'), '2001-11-11', '2001-01-01') FROM TEST
  ```

- The functions in the Oracle Compatibility Functions `dbms_alert` package are not implemented for Greenplum Database.
- The `decode()` function is removed from the Greenplum Database Oracle Compatibility Functions. The Greenplum Database parser internally converts a `decode()` function call to a `CASE` statement.

### Using orafce

Some Oracle Compatibility Functions reside in the `oracle` schema. To access them, set the search path for the database to include the `oracle` schema name. For example, this command sets the default search path for a database to include the `oracle` schema:

```sql
ALTER DATABASE db_name SET search_path = "$user", public, oracle;
```
Note the following differences when using the Oracle Compatibility Functions with PostgreSQL vs. using them with Greenplum Database:

- If you use validation scripts, the output may not be exactly the same as with the original orafce module implementation.
- The functions in the Oracle Compatibility Functions dbms_pipe package execute only on the Greenplum Database master host.
- The upgrade scripts in the Orafce project do not work with Greenplum Database.

### Additional Module Documentation

Refer to the README and Greenplum Database orafce documentation in the Greenplum Database github repository for detailed information about the individual functions and supporting objects provided in this module.

#### pageinspect

The pageinspect module provides functions for low level inspection of the contents of database pages. pageinspect is available only to Greenplum Database superusers.

The Greenplum Database pageinspect module is based on the PostgreSQL pageinspect module. The Greenplum version of the module differs only in that it does not allow inspection of pages belonging to append-optimized or external relations.

### Installing and Registering the Module

The pageinspect module is installed when you install Greenplum Database. Before you can use any of the functions defined in the module, you must register the pageinspect extension in each database in which you want to use the functions. Refer to Installing Additional Supplied Modules for more information.

### Module Documentation

See pageinspect in the PostgreSQL documentation for detailed information about the individual functions in this module.

**Note:** For pageinspect functions that read data from a database, the function reads data only from the segment instance where the function is executed. For example, the get_raw_page() function returns a block number out of range error when you try to read data from a user-defined table on the Greenplum Database master because there is no data in the table on the master segment. The function will read data from a system catalog table on the master segment.

#### pgcrypto

Greenplum Database is installed with an optional module of encryption/decryption functions called pgcrypto. The pgcrypto functions allow database administrators to store certain columns of data in encrypted form. This adds an extra layer of protection for sensitive data, as data stored in Greenplum Database in encrypted form cannot be read by anyone who does not have the encryption key, nor can it be read directly from the disks.

**Note:** The pgcrypto functions run inside the database server, which means that all the data and passwords move between pgcrypto and the client application in clear-text. For optimal security, consider also using SSL connections between the client and the Greenplum master server.

### Installing and Registering the Module

The pgcrypto module is installed when you install Greenplum Database. Before you can use any of the functions defined in the module, you must register the pgcrypto extension in each database in which you want to use the functions. Refer to Installing Additional Supplied Modules for more information.
**Additional Module Documentation**

Refer to `pgcrypto` in the PostgreSQL documentation for more information about the individual functions in this module.

**sslinfo**

The `sslinfo` module provides information about the SSL certificate that the current client provided when connecting to Greenplum. Most functions in this module return NULL if the current connection does not use SSL.

The Greenplum Database `sslinfo` module is equivalent to the PostgreSQL `sslinfo` module. There are no Greenplum Database or MPP-specific considerations for the module.

**Installing and Registering the Module**

The `sslinfo` module is installed when you install Greenplum Database. Before you can use any of the functions defined in the module, you must register the `sslinfo` extension in each database in which you want to use the functions. Refer to *Installing Additional Supplied Modules* for more information.

**Module Documentation**

See `sslinfo` in the PostgreSQL documentation for detailed information about the individual functions in this module.
Character Set Support

The character set support in Greenplum Database allows you to store text in a variety of character sets, including single-byte character sets such as the ISO 8859 series and multiple-byte character sets such as EUC (Extended Unix Code), UTF-8, and Mule internal code. All supported character sets can be used transparently by clients, but a few are not supported for use within the server (that is, as a server-side encoding). The default character set is selected while initializing your Greenplum Database array using `gpinitsystem`. It can be overridden when you create a database, so you can have multiple databases each with a different character set.

Table 112: Greenplum Database Character Sets

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Language</th>
<th>Server?</th>
<th>Bytes/Char</th>
<th>Aliases</th>
</tr>
</thead>
<tbody>
<tr>
<td>BIG5</td>
<td>Big Five</td>
<td>Traditional Chinese</td>

</table>

11 The SQL_ASCII setting behaves considerably differently from the other settings. Byte values 0-127 are interpreted according to the ASCII standard, while byte values 128-255 are taken as uninterpreted characters. If you are working with any non-ASCII data, it is unwise to use the SQL_ASCII setting as a client encoding. SQL_ASCII is not supported as a server encoding.
Setting the Character Set

gpinitsystem defines the default character set for a Greenplum Database system by reading the setting of the \texttt{ENCODING} parameter in the \texttt{gp_init_config} file at initialization time. The default character set is \texttt{UNICODE} or \texttt{UTF8}.

You can create a database with a different character set besides what is used as the system-wide default. For example:

\begin{verbatim}
=> CREATE DATABASE korean WITH ENCODING 'EUC_KR';
\end{verbatim}

Important: Although you can specify any encoding you want for a database, it is unwise to choose an encoding that is not what is expected by the locale you have selected. The \texttt{LC_COLLATE} and \texttt{LC_CTYPE} settings imply a particular encoding, and locale-dependent operations (such as sorting) are likely to misinterpret data that is in an incompatible encoding.

Since these locale settings are frozen by gpinitsystem, the apparent flexibility to use different encodings in different databases is more theoretical than real.

One way to use multiple encodings safely is to set the locale to \texttt{C} or \texttt{POSIX} during initialization time, thus disabling any real locale awareness.

Character Set Conversion Between Server and Client

Greenplum Database supports automatic character set conversion between server and client for certain character set combinations. The conversion information is stored in the master \texttt{pg_conversion} system catalog table. Greenplum Database comes with some predefined conversions or you can create a new conversion using the SQL command \texttt{CREATE CONVERSION}.

</tr>
</tbody>
</table>
To enable automatic character set conversion, you have to tell Greenplum Database the character set (encoding) you would like to use in the client. There are several ways to accomplish this:

- Using the `\encoding` command in `psql`, which allows you to change client encoding on the fly.
- Using `SET client_encoding TO`.

To set the client encoding, use the following SQL command:

```
=> SET CLIENT_ENCODING TO 'value';
```

To query the current client encoding:

```
=> SHOW client_encoding;
```

To return to the default encoding:

```
=> RESET client_encoding;
```

- Using the `PGCLIENTENCODING` environment variable. When `PGCLIENTENCODING` is defined in the client's environment, that client encoding is automatically selected when a connection to the server is made. (This can subsequently be overridden using any of the other methods mentioned above.)
- Setting the configuration parameter `client_encoding`. If `client_encoding` is set in the master `postgresql.conf` file, that client encoding is automatically selected when a connection to Greenplum Database is made. (This can subsequently be overridden using any of the other methods mentioned above.)

If the conversion of a particular character is not possible " suppose you chose EUC_JP for the server and LATIN1 for the client, then some Japanese characters do not have a representation in LATIN1 " then an error is reported.

If the client character set is defined as `SQL_ASCII`, encoding conversion is disabled, regardless of the server's character set. The use of `SQL_ASCII` is unwise unless you are working with all-ASCII data. `SQL_ASCII` is not supported as a server encoding.

### Server Character Set | Available Client Character Sets
--- | ---
WIN1254 | WIN1254, UTF8
WIN1255 | WIN1255, UTF8
WIN1256 | WIN1256, UTF8
WIN1257 | WIN1257, UTF8
WIN1258 | WIN1258, UTF8
Server Configuration Parameters

There are many Greenplum server configuration parameters that affect the behavior of the Greenplum Database system. Many of these configuration parameters have the same names, settings, and behaviors as in a regular PostgreSQL database system.

- **Parameter Types and Values** describes the parameter data types and values.
- **Setting Parameters** describes limitations on who can change them and where or when they can be set.
- **Parameter Categories** organizes parameters by functionality.
- **Configuration Parameters** lists the parameter descriptions in alphabetic order.

Parameter Types and Values

All parameter names are case-insensitive. Every parameter takes a value of one of the following types: Boolean, integer, floating point, enum, or string.

Boolean values may be specified as ON, OFF, TRUE, FALSE, YES, NO, 1, 0 (all case-insensitive).

Enum-type parameters are specified in the same manner as string parameters, but are restricted to a limited set of values. Enum parameter values are case-insensitive.

Some settings specify a memory size or time value. Each of these has an implicit unit, which is either kilobytes, blocks (typically eight kilobytes), milliseconds, seconds, or minutes. Valid memory size units are kB (kilobytes), MB (megabytes), and GB (gigabytes). Valid time units are ms (milliseconds), s (seconds), min (minutes), h (hours), and d (days). Note that the multiplier for memory units is 1024, not 1000. A valid time expression contains a number and a unit. When specifying a memory or time unit using the `SET` command, enclose the value in quotes. For example:

```
SET statement_mem TO '200MB';
```

Note: There is no space between the value and the unit names.

Setting Parameters

Many of the configuration parameters have limitations on who can change them and where or when they can be set. For example, to change certain parameters, you must be a Greenplum Database superuser. Other parameters require a restart of the system for the changes to take effect. A parameter that is classified as `session` can be set at the system level (in the `postgresql.conf` file), at the database-level (using `ALTER DATABASE`), at the role-level (using `ALTER ROLE`), at the database- and role-level (`ALTER ROLE...IN DATABASE...SET`, or at the session-level (using `SET`). System parameters can only be set in the `postgresql.conf` file.

In Greenplum Database, the master and each segment instance has its own `postgresql.conf` file (located in their respective data directories). Some parameters are considered `local` parameters, meaning that each segment instance looks to its own `postgresql.conf` file to get the value of that parameter. You must set local parameters on every instance in the system (master and segments). Others parameters are considered `master` parameters. Master parameters need only be set at the master instance.

This table describes the values in the `Settable Classifications` column of the table in the description of a server configuration parameter.
### Table 114: Settable Classifications

<table>
<thead>
<tr>
<th>Set Classification</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>master or local</td>
<td>A <em>master</em> parameter only needs to be set in the <code>postgresql.conf</code> file of the Greenplum master instance. The value for this parameter is then either passed to (or ignored by) the segments at run time. A local parameter must be set in the <code>postgresql.conf</code> file of the master AND each segment instance. Each segment instance looks to its own configuration to get the value for the parameter. Local parameters always requires a system restart for changes to take effect.</td>
</tr>
<tr>
<td>session or system</td>
<td><em>Session</em> parameters can be changed on the fly within a database session, and can have a hierarchy of settings: at the system level (<code>postgresql.conf</code>), at the database level (<code>ALTER DATABASE...SET</code>), at the role level (<code>ALTER ROLE...SET</code>), at the database and role level (<code>ALTER ROLE...IN DATABASE...SET</code>), or at the session level (<code>SET</code>). If the parameter is set at multiple levels, then the most granular setting takes precedence (for example, session overrides database and role, database and role overrides role, role overrides database, and database overrides system). A <em>system</em> parameter can only be changed via the <code>postgresql.conf</code> file(s).</td>
</tr>
<tr>
<td>restart or reload</td>
<td>When changing parameter values in the <code>postgresql.conf</code> file(s), some require a <em>restart</em> of Greenplum Database for the change to take effect. Other parameter values can be refreshed by just reloading the server configuration file (using <code>gpstop -u</code>), and do not require stopping the system.</td>
</tr>
<tr>
<td>superuser</td>
<td>These session parameters can only be set by a database superuser. Regular database users cannot set this parameter.</td>
</tr>
<tr>
<td>read only</td>

**Parameter Categories**

Configuration parameters affect categories of server behaviors, such as resource consumption, query tuning, and authentication. The following topics describe Greenplum configuration parameter categories.

- *Connection and Authentication Parameters*
- *System Resource Consumption Parameters*
- *GPORCA Parameters*
- *Query Tuning Parameters*
Connection and Authentication Parameters

These parameters control how clients connect and authenticate to Greenplum Database.

**Connection Parameters**

- `gp_connection_send_timeout`
- `gp_vmem_idle_resource_timeout`
- `listen_addresses`
- `max_connections`
- `max_prepared_transactions`
- `superuser_reserved_connections`
- `tcp_keepalives_count`
- `tcp_keepalives_idle`
- `tcp_keepalives_interval`
- `unix_socket_directory`
- `unix_socket_group`
- `unix_socket_permissions`

**Security and Authentication Parameters**

- `authentication_timeout`
- `db_user_namespace`
- `krb_caseins_users`
- `krb_server_keyfile`
- `password_encryption`
- `password_hash_algorithm`
- `ssl`
- `ssl_ciphers`

System Resource Consumption Parameters

These parameters set the limits for system resources consumed by Greenplum Database.

**Memory Consumption Parameters**

These parameters control system memory usage.

- `gp_vmem_idle_resource_timeout`
- `gp_resource_group_memory_limit` (resource group-based resource management)
- `gp_vmem_protect_limit` (resource queue-based resource management)
- `gp_workfile_limit_per_query`
- `gp_workfile_limit_per_segment`
- `maintenance_work_mem`
- `max_stack_depth`
**OS Resource Parameters**

- `max_files_per_process`
- `shared_preload_libraries`

**Cost-Based Vacuum Delay Parameters**

**Warning:** Do not use cost-based vacuum delay because it runs asynchronously among the segment instances. The vacuum cost limit and delay is invoked at the segment level without taking into account the state of the entire Greenplum Database array.

You can configure the execution cost of `VACUUM` and `ANALYZE` commands to reduce the I/O impact on concurrent database activity. When the accumulated cost of I/O operations reaches the limit, the process performing the operation sleeps for a while, then resets the counter and continues execution.

- `vacuum_cost_delay`
- `vacuum_cost_limit`
- `vacuum_cost_page_hit`
- `vacuum_cost_page_miss`
- `vacuum_cost_page_dirty`

**Transaction ID Management Parameters**

- `xid_stop_limit`
- `xid_warn_limit`

**GPORCA Parameters**

These parameters control the usage of GPORCA by Greenplum Database. For information about GPORCA, see About GPORCA in the Greenplum Database Administrator Guide.

- `gp_enable_relsize_collection`
- `optimizer`
- `optimizer_analyze_root_partition`
- `optimizer_array_expansion_threshold`
- `optimizer_cte_inlining_bound`
- `optimizer_control`
- `optimizer_enable_associativity`
- `optimizer_enable_dml`
- `optimizer_enable_master_only_queries`
- `optimizer_force_agg_skew_avoidance`
- `optimizer_force_multistage_agg`
- `optimizer_force_three_stage_scalar_dqa`
- `optimizer_join_arity_for_associativity_commutativity`
- `optimizer_join_order`
- `optimizer_join_order_threshold`
- `optimizer_mdcache_size`
- `optimizer_metadata_caching`
- `optimizer_parallel_union`
- `optimizer_penalize_skew`
- `optimizer_print_missing_stats`
- `optimizer_print_optimization_stats`
- `optimizer_sort_factor`
- `optimizer_use_gpdb_allocators`
Query Tuning Parameters
These parameters control aspects of SQL query processing such as query operators and operator settings and statistics sampling.

Postgres Planner Control Parameters
The following parameters control the types of plan operations the Postgres Planner can use. Enable or disable plan operations to force the Postgres Planner to choose a different plan. This is useful for testing and comparing query performance using different plan types.

- enable_bitmapscan
- enable_groupagg
- enable_hashagg
- enable_hashjoin
- enable_indexscan
- enable_mergejoin
- enable_nestloop
- enable_seqscan
- enable_sort
- enable_tidscan
- gp_enable_agg_distinct
- gp_enable_agg_distinct_pruning
- gp_enable_direct_dispatch
- gp_enable_fast_sri
- gp_enable_groupext_distinct_gather
- gp_enable_groupext_distinct_pruning
- gp_enable_multiphase_agg
- gp_enable_predicate_propagation
- gp_enable_preunique
- gp_enable_relsize_collection
- gp_enable_sort_distinct
- gp_enable_sort_limit

Postgres Planner Costing Parameters
Warning: Do not adjust these query costing parameters. They are tuned to reflect Greenplum Database hardware configurations and typical workloads. All of these parameters are related. Changing one without changing the others can have adverse affects on performance.

- cpu_index_tuple_cost
- cpu_operator_cost
- cpu_tuple_cost
- cursor_tuple_fraction
- effective_cache_size
- gp_motion_cost_per_row
- gp_segments_for_planner
- random_page_cost
- seq_page_cost

Database Statistics Sampling Parameters
These parameters adjust the amount of data sampled by an ANALYZE operation. Adjusting these parameters affects statistics collection system-wide. You can configure statistics collection on particular tables and columns by using the ALTER TABLE SET STATISTICS clause.

- default_statistics_target

Sort Operator Configuration Parameters

- gp_enable_sort_distinct
Aggregate Operator Configuration Parameters

- gp_enable_sort_limit
- gp_enable_agg_distinct
- gp_enable_agg_distinct_pruning
- gp_enable_multiphase_agg
- gp_enable_preunique
- gp_enable_groupext_distinct_gather
- gp_enable_groupext_distinct_pruning
- gp_workfile_compression

Join Operator Configuration Parameters

- join_collapse_limit
- gp_adjust_selectivity_for_outerjoins
- gp_hashjoin_tuples_per_bucket
- gp_statistics_use_fkeys
- gp_workfile_compression

Other Postgres Planner Configuration Parameters

- from_collapse_limit
- gp_enable_predicate_propagation
- gp_max_plan_size
- gp_statistics_pullup_from_child_partition

Query Plan Execution

Control the query plan execution.

- gp_max_slices

Error Reporting and Logging Parameters

These configuration parameters control Greenplum Database logging.

Log Rotation

- log_rotation_age
- log_rotation_size
- log_truncate_on_rotation

When to Log

- client_min_messages
- gp_interconnect_debug_retry_interval
- log_error_verbosity
- log_min_duration_statement
- log_min_error_statement
- log_min_messages
- optimizer_minidump
What to Log

- debug_pretty_print
- debug_print_parse
- debug_print_plan
- debug_print_prelim_plan
- debug_print_rewritten
- debug_print_slice_table
- log_autostats
- log_connections
- log_disconnections
- log_dispatch_stats
- log_duration
- log_executor_stats
- log_hostname
- gp_log_interconnect
- log_parser_stats
- log_planner_stats
- log_statement
- log_statement_stats
- log_timezone
- gp_debug_linger
- gp_log_format
- gp_reraise_signal

System Monitoring Parameters

These configuration parameters control Greenplum Database data collection and notifications related to database monitoring.

Greenplum Performance Database

The following parameters configure the data collection agents that populate the `gpperfmon` database.

- `gp_enable_gpperfmon`
- `gp_gpperfmon_send_interval`
- `gpperfmon_log_alert_level`
- `gpperfmon_port`

Query Metrics Collection Parameters

These parameters enable and configure query metrics collection. When enabled, Greenplum Database saves metrics to shared memory during query execution. These metrics are used by Pivotal Greenplum Command Center, which is included with Pivotal’s commercial version of Greenplum Database.

- `gp_enable_query_metrics`
- `gp_instrument_shmemp_size`

Runtime Statistics Collection Parameters

These parameters control the server statistics collection feature. When statistics collection is enabled, you can access the statistics data using the `pg_stat` family of system catalog views.

- `stats_queue_level`
- `update_process_title`

Automatic Statistics Collection Parameters

When automatic statistics collection is enabled, you can run `ANALYZE` automatically in the same transaction as an `INSERT`, `UPDATE`, `DELETE`, `COPY` or `CREATE TABLE...AS SELECT` statement when a certain threshold of rows is affected (`on_change`), or when a newly generated table has no statistics (`on_no_stats`). To enable this feature, set the following server configuration parameters in your Greenplum Database master `postgresql.conf` file and restart Greenplum Database:
gp_autostats_mode
gp_autostats_mode_in_functions
gp_autostats_on_change_threshold
log_autostats

Warning: Depending on the specific nature of your database operations, automatic statistics collection can have a negative performance impact. Carefully evaluate whether the default setting of on_no_stats is appropriate for your system.

Client Connection Default Parameters
These configuration parameters set defaults that are used for client connections.

Statement Behavior Parameters

check_function_bodies
default_tablespace
default_transaction_deferrable
default_transaction_isolation
default_transaction_read_only
search_path
statement_timeout
temp_tablespaces
vacuum_freeze_min_age

Locale and Formatting Parameters

client_encoding
DateStyle
extra_float_digits
IntervalStyle
lc_collate
lc_ctype
lc_monetary
lc_numeric
lc_time
TimeZone

Other Client Default Parameters

dynamic_library_path
explain_pretty_print
local_preload_libraries

Lock Management Parameters
These configuration parameters set limits for locks and deadlocks.

deadlock_timeout
lock_timeout
gp_enable_global_deadlock_detector
max_locks_per_transaction
gp_global_deadlock_detector_period
**Resource Management Parameters (Resource Queues)**

The following configuration parameters configure the Greenplum Database resource management feature (resource queues), query prioritization, memory utilization and concurrency control.

- `gp_resqueue_memory_policy`
- `gp_resqueue_priority`
- `gp_resqueue_priority_cpucores_per_segment`
- `gp_resqueue_priority_sweeper_interval`
- `gp_vmem_idle_resource_timeout`
- `gp_vmem_protect_limit`
- `gp_vmem_protect_segworker_cache_limit`
- `max_resource_queues`
- `max_resource_portals_per_transaction`
- `max_statement_mem`
- `resource_cleanup_gangs_on_wait`
- `resource_select_only`
- `runaway_detector_activation_percent`
- `statement_mem`
- `stats_queue_level`
- `vmem_process_interrupt`

**Resource Management Parameters (Resource Groups)**

The following parameters configure the Greenplum Database resource group workload management feature.

- `gp_resgroup_memory_policy`
- `gp_resource_group_bypass`
- `gp_resource_group_cpu_limit`
- `gp_resource_group_memory_limit`
- `gp_resource_manager`
- `gp_vmem_idle_resource_timeout`
- `gp_vmem_protect_segworker_cache_limit`
- `max_statement_mem`
- `memory_spill_ratio`
- `statement_mem`
- `vmem_process_interrupt`

**External Table Parameters**

The following parameters configure the external tables feature of Greenplum Database.

- `gp_external_enable_exec`
- `gp_external_enable_filter_pushdown`
- `gp_external_max_segs`
- `gp_initial_bad_row_limit`
- `gp_reject_percent_threshold`
- `readable_external_table_timeout`
- `writable_external_table_bufsize`
- `verify_gpfdsists_cert`

**Database Table Parameters**

The following parameter configures default option settings for Greenplum Database tables.

- `gp_create_table_random_default_distribution`
- `gp_default_storage_options`
- `gp_enable_exchange_default_partition`
- `gp_enable_segment_copy_checking`
gp_use_legacy_hashops

**Append-Optimized Table Parameters**
The following parameters configure the append-optimized tables feature of Greenplum Database.

max_appendonly_tables
gp_appendonly_compaction
gp_appendonly_compaction_threshold
validate_previous_free_tid

**Past Version Compatibility Parameters**
The following parameters provide compatibility with older PostgreSQL and Greenplum Database versions. You do not need to change these parameters in Greenplum Database.

**PostgreSQL**
array_nulls
backslash_quote
escape_string_warning
regex_flavor
standard_conforming_strings
transform_null_equals

**Greenplum Database**
gp_ignore_error_table

**Greenplum Database Array Configuration Parameters**
The parameters in this topic control the configuration of the Greenplum Database array and its components: segments, master, distributed transaction manager, master mirror, and interconnect.

**Interconnect Configuration Parameters**
gp_interconnect_fc_method
gp_interconnect_queue_depth
gp_interconnect_setup_timeout
gp_interconnect_snd_queue_depth
gp_interconnect_type
gp_max_packet_size

**Note:** Greenplum Database supports only the UDPIFC (default) and TCP interconnect types.

**Dispatch Configuration Parameters**
gp_cached_segworkers_threshold
gp_enable_direct_dispatch
gp_segment_connect_timeout
gp_set_proc_affinity
Fault Operation Parameters

- gp_set_read_only
- gp_fts_probe_interval
- gp_fts_probe_retries
- gp_fts_probe_timeout
- gp_fts_probe_threadcount
- gp_log_fts

Distributed Transaction Management Parameters

- gp_max_local_distributed_cache

Read-Only Parameters

- gp_command_count
- gp_content
- gp_dbid
- gp_role
- gp_session_id
- gp_server_version
- gp_server_version_num

Greenplum Mirroring Parameters for Master and Segments

These parameters control the configuration of the replication between Greenplum Database primary master and standby master.

- keep_wal_segments
- repl_catchup_within_range
- replication_timeout
- wal_receiver_status_interval

Greenplum PL/Java Parameters

The parameters in this topic control the configuration of the Greenplum Database PL/Java language.

- pljava_classpath
- pljava_classpath_insecure
- pljava_statement_cache_size
- pljava_release_lingering_savepoints
- pljava_vmoptions

XML Data Parameters

The parameters in this topic control the configuration of the Greenplum Database XML data type.

- xmlbinary
- xmloption
## Configuration Parameters

Descriptions of the Greenplum Database server configuration parameters listed alphabetically.

<table>
<thead>
<tr>

<td>optimizer_print_missing_stats</td>
</tr>
<tr>
<td>extra_float_digits</td>
<td>optimizer_print_optimization_stats</td>
</tr>
</tbody>
</table>
### application_name

Sets the application name for a client session. For example, if connecting via `psql`, this will be set to `psql`. Setting an application name allows it to be reported in log messages and statistics views.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>string</td>
<td></td>
<td>master</td>
</tr>
<tr>
<td></td>
<td></td>
<td>session</td>
</tr>
<tr>
<td></td>
<td></td>
<td>reload</td>
</tr>
</tbody>
</table>

### array_nulls

This controls whether the array input parser recognizes unquoted NULL as specifying a null array element. By default, this is on, allowing array values containing null values to be entered. Greenplum Database versions before 3.0 did not support null values in arrays, and therefore would treat NULL as specifying a normal array element with the string value 'NULL'.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>on</td>
<td>master</td>
</tr>
<tr>
<td></td>
<td></td>
<td>session</td>
</tr>
<tr>
<td></td>
<td></td>
<td>reload</td>
</tr>
</tbody>
</table>

### authentication_timeout

Maximum time to complete client authentication. This prevents hung clients from occupying a connection indefinitely.
**Value Range** | **Default** | **Set Classifications**
---|---|---
Any valid time expression (number and unit) | 1min | local
| system
| restart

**backslash_quote**

This controls whether a quote mark can be represented by `\` in a string literal. The preferred, SQL-standard way to represent a quote mark is by doubling it (""") but PostgreSQL has historically also accepted `\`. However, use of `\` creates security risks because in some client character set encodings, there are multibyte characters in which the last byte is numerically equivalent to ASCII `\`.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
</table>
on (allow `\` always) | safe_encoding | master
| session
| reload
off (reject always)
safe_encoding (allow only if client encoding does not allow ASCII `\` within a multibyte character) |

**block_size**

Reports the size of a disk block.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
</table>
number of bytes | 32768 | read only

**bonjour_name**

Specifies the Bonjour broadcast name. By default, the computer name is used, specified as an empty string. This option is ignored if the server was not compiled with Bonjour support.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
</table>
string | unset | master
| system
| restart

**check_function_bodies**

When set to off, disables validation of the function body string during `CREATE FUNCTION`. Disabling validation is occasionally useful to avoid problems such as forward references when restoring function definitions from a dump.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
</table>
Boolean | on | master
| session
| reload
**client_encoding**

Sets the client-side encoding (character set). The default is to use the same as the database encoding. See *Supported Character Sets* in the PostgreSQL documentation.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>character set</td>
<td>UTF8</td>
<td>master, session, reload</td>
</tr>
</tbody>
</table>

**client_min_messages**

Controls which message levels are sent to the client. Each level includes all the levels that follow it. The later the level, the fewer messages are sent.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>DEBUG5</td>
<td>NOTICE</td>
<td>master, session, reload</td>
</tr>
<tr>
<td>DEBUG4</td>
<td></td>
<td></td>
</tr>
<tr>
<td>DEBUG3</td>
<td></td>
<td></td>
</tr>
<tr>
<td>DEBUG2</td>
<td></td>
<td></td>
</tr>
<tr>
<td>DEBUG1</td>
<td></td>
<td></td>
</tr>
<tr>
<td>LOG</td>
<td></td>
<td></td>
</tr>
<tr>
<td>NOTICE</td>
<td></td>
<td></td>
</tr>
<tr>
<td>WARNING</td>
<td></td>
<td></td>
</tr>
<tr>
<td>ERROR</td>
<td></td>
<td></td>
</tr>
<tr>
<td>FATAL</td>
<td></td>
<td></td>
</tr>
<tr>
<td>PANIC</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

*INFO* level messages are always sent to the client.

**cpu_index_tuple_cost**

For the Postgres Planner, sets the estimate of the cost of processing each index row during an index scan. This is measured as a fraction of the cost of a sequential page fetch.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>floating point</td>
<td>0.005</td>
<td>master, session, reload</td>
</tr>
</tbody>
</table>

**cpu_operator_cost**

For the Postgres Planner, sets the estimate of the cost of processing each operator in a WHERE clause. This is measured as a fraction of the cost of a sequential page fetch.
**Value Range** | **Default** | **Set Classifications**
---|---|---
floating point | 0.0025 | master, session, reload

**cpu_tuple_cost**
For the Postgres Planner, sets the estimate of the cost of processing each row during a query. This is measured as a fraction of the cost of a sequential page fetch.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>floating point</td>
<td>0.01</td>
<td>master, session, reload</td>
</tr>
</tbody>
</table>

**cursor_tuple_fraction**
Tells the Postgres Planner how many rows are expected to be fetched in a cursor query, thereby allowing the Postgres Planner to use this information to optimize the query plan. The default of 1 means all rows will be fetched.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>integer</td>
<td>1</td>
<td>master, session, reload</td>
</tr>
</tbody>
</table>

**data_checksums**
Reports whether checksums are enabled for heap data storage in the database system. Checksums for heap data are enabled or disabled when the database system is initialized and cannot be changed.

Heap data pages store heap tables, catalog tables, indexes, and database metadata. Append-optimized storage has built-in checksum support that is unrelated to this parameter.

Greenplum Database uses checksums to prevent loading data corrupted in the file system into memory managed by database processes. When heap data checksums are enabled, Greenplum Database computes and stores checksums on heap data pages when they are written to disk. When a page is retrieved from disk, the checksum is verified. If the verification fails, an error is generated and the page is not permitted to load into managed memory.

If the `ignore_checksum_failure` configuration parameter has been set to on, a failed checksum verification generates a warning, but the page is allowed to be loaded into managed memory. If the page is then updated, it is flushed to disk and replicated to the mirror. This can cause data corruption to propagate to the mirror and prevent a complete recovery. Because of the potential for data loss, the `ignore_checksum_failure` parameter should only be enabled when needed to recover data. See `ignore_checksum_failure` for more information.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>on</td>
<td>read only</td>
</tr>
</tbody>
</table>
DateStyle
Sets the display format for date and time values, as well as the rules for interpreting ambiguous date input values. This variable contains two independent components: the output format specification and the input/output specification for year/month/day ordering.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt;format&gt;, &lt;date style&gt;</td>
<td>ISO, MDY</td>
<td>master, session,</td>
</tr>
<tr>
<td>where:</td>
<td></td>
<td>reload</td>
</tr>
<tr>
<td>&lt;format&gt; is ISO, Postgres, SQL,</td>
<td></td>
<td></td>
</tr>
<tr>
<td>or German</td>
<td></td>
<td></td>
</tr>
<tr>
<td>&lt;date style&gt; is DMY, MDY, or</td>
<td></td>
<td></td>
</tr>
<tr>
<td>YMD</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

db_user_namespace
This enables per-database user names. If on, you should create users as username@dbname. To create ordinary global users, simply append @ when specifying the user name in the client.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>off</td>
<td>local</td>
</tr>
<tr>
<td></td>
<td></td>
<td>system</td>
</tr>
<tr>
<td></td>
<td></td>
<td>restart</td>
</tr>
</tbody>
</table>

deadlock_timeout
The time to wait on a lock before checking to see if there is a deadlock condition. On a heavily loaded server you might want to raise this value. Ideally the setting should exceed your typical transaction time, so as to improve the odds that a lock will be released before the waiter decides to check for deadlock.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>Any valid time expression</td>
<td>1s</td>
<td>local</td>
</tr>
<tr>
<td>(number and unit)</td>
<td></td>
<td>system</td>
</tr>
<tr>
<td></td>
<td></td>
<td>restart</td>
</tr>
</tbody>
</table>

debug_assertions
Turns on various assertion checks.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>off</td>
<td>local</td>
</tr>
<tr>
<td></td>
<td></td>
<td>system</td>
</tr>
<tr>
<td></td>
<td></td>
<td>restart</td>
</tr>
</tbody>
</table>
**debug_pretty_print**

Indents debug output to produce a more readable but much longer output format. `client_min_messages` or `log_min_messages` must be DEBUG1 or lower.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>on</td>
<td>master</td>
</tr>
<tr>
<td></td>
<td></td>
<td>session</td>
</tr>
<tr>
<td></td>
<td></td>
<td>reload</td>
</tr>
</tbody>
</table>

**debug_print_parse**

For each executed query, prints the resulting parse tree. `client_min_messages` or `log_min_messages` must be DEBUG1 or lower.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>off</td>
<td>master</td>
</tr>
<tr>
<td></td>
<td></td>
<td>session</td>
</tr>
<tr>
<td></td>
<td></td>
<td>reload</td>
</tr>
</tbody>
</table>

**debug_print_plan**

For each executed query, prints the Greenplum parallel query execution plan. `client_min_messages` or `log_min_messages` must be DEBUG1 or lower.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>off</td>
<td>master</td>
</tr>
<tr>
<td></td>
<td></td>
<td>session</td>
</tr>
<tr>
<td></td>
<td></td>
<td>reload</td>
</tr>
</tbody>
</table>

**debug_print_prelim_plan**

For each executed query, prints the preliminary query plan. `client_min_messages` or `log_min_messages` must be DEBUG1 or lower.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>off</td>
<td>master</td>
</tr>
<tr>
<td></td>
<td></td>
<td>session</td>
</tr>
<tr>
<td></td>
<td></td>
<td>reload</td>
</tr>
</tbody>
</table>

**debug_print_rewritten**

For each executed query, prints the query rewriter output. `client_min_messages` or `log_min_messages` must be DEBUG1 or lower.
### Value Range

<table>
<thead>
<tr>
<th>Option</th>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>Boolean</td>
<td>off</td>
<td>master</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>session</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>reload</td>
</tr>
</tbody>
</table>

### debug_print_slice_table

For each executed query, prints the Greenplum query slice plan. `client_min_messages` or `log_min_messages` must be DEBUG1 or lower.

### Value Range

<table>
<thead>
<tr>
<th>Option</th>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>Boolean</td>
<td>off</td>
<td>master</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>session</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>reload</td>
</tr>
</tbody>
</table>

### default_statistics_target

Sets the default statistics sampling target (the number of values that are stored in the list of common values) for table columns that have not had a column-specific target set via `ALTER TABLE SET STATISTICS`. Larger values may improve the quality of the Postgres Planner estimates.

### Value Range

<table>
<thead>
<tr>
<th>Option</th>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>default_statistics_target</td>
<td>0 &gt; Integer &gt; 10000</td>
<td>100</td>
<td>master</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>session</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>reload</td>
</tr>
</tbody>
</table>

### default_tablespace

The default tablespace in which to create objects (tables and indexes) when a `CREATE` command does not explicitly specify a tablespace.

### Value Range

<table>
<thead>
<tr>
<th>Option</th>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>default_tablespace</td>
<td>name of a tablespace</td>
<td>unset</td>
<td>master</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>session</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>reload</td>
</tr>
</tbody>
</table>

### default_text_search_config

Selects the text search configuration that is used by those variants of the text search functions that do not have an explicit argument specifying the configuration. See *Using Full Text Search* for further information. The built-in default is `pg_catalog.simple`, but `initdb` will initialize the configuration file with a setting that corresponds to the chosen `lc_ctype` locale, if a configuration matching that locale can be identified.
default_transaction_deferrable

When running at the SERIALizable isolation level, a deferrable read-only SQL transaction may be delayed before it is allowed to proceed. However, once it begins executing it does not incur any of the overhead required to ensure serializability; so serialization code will have no reason to force it to abort because of concurrent updates, making this option suitable for long-running read-only transactions.

This parameter controls the default deferrable status of each new transaction. It currently has no effect on read-write transactions or those operating at isolation levels lower than SERIALizable. The default is off.

Note: Setting default_transaction_deferrable to on has no effect in Greenplum Database. Only read-only, SERIALizable transactions can be deferred. However, Greenplum Database does not support the SERIALizable transaction isolation level. See SET TRANSACTION.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>off</td>
<td>master, session,</td>
</tr>
<tr>
<td></td>
<td></td>
<td>reload</td>
</tr>
</tbody>
</table>

default_transaction_isolation

Controls the default isolation level of each new transaction. Greenplum Database treats read uncommitted the same as read committed, and treats serializable the same as repeatable read.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>read committed</td>
<td>read committed</td>
<td>master, session,</td>
</tr>
<tr>
<td>read uncommitted</td>
<td></td>
<td>reload</td>
</tr>
<tr>
<td>repeatable read</td>
<td></td>
<td></td>
</tr>
<tr>
<td>serializable</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

default_transaction_read_only

Controls the default read-only status of each new transaction. A read-only SQL transaction cannot alter non-temporary tables.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>off</td>
<td>master, session,</td>
</tr>
<tr>
<td></td>
<td></td>
<td>reload</td>
</tr>
</tbody>
</table>
**dynamic_library_path**

If a dynamically loadable module needs to be opened and the file name specified in the `CREATE FUNCTION` or `LOAD` command does not have a directory component (i.e. the name does not contain a slash), the system will search this path for the required file. The compiled-in PostgreSQL package library directory is substituted for `$libdir`. This is where the modules provided by the standard PostgreSQL distribution are installed.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>a list of absolute directory paths separated by colons</td>
<td><code>$libdir</code></td>
<td><code>local</code></td>
</tr>
<tr>
<td></td>
<td></td>
<td><code>system</code></td>
</tr>
<tr>
<td></td>
<td></td>
<td><code>restart</code></td>
</tr>
</tbody>
</table>

**effective_cache_size**

Sets the assumption about the effective size of the disk cache that is available to a single query for the Postgres Planner. This is factored into estimates of the cost of using an index; a higher value makes it more likely index scans will be used, a lower value makes it more likely sequential scans will be used. This parameter has no effect on the size of shared memory allocated by a Greenplum server instance, nor does it reserve kernel disk cache; it is used only for estimation purposes.

Set this parameter to a number of 32K blocks (for example, 512 for 16MB), or specify the size of the effective cache (for example, '32MB' for 1024 blocks). The `gpconfig` utility and `SHOW` command display the effective cache size value in units such as 'MB' or 'kB'.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>floating point</td>
<td>512 (16GB)</td>
<td>master</td>
</tr>
<tr>
<td></td>
<td></td>
<td>session</td>
</tr>
<tr>
<td></td>
<td></td>
<td>reload</td>
</tr>
</tbody>
</table>

**enable_bitmapscan**

Enables or disables the use of bitmap-scan plan types by the Postgres Planner. Note that this is different than a Bitmap Index Scan. A Bitmap Scan means that indexes will be dynamically converted to bitmaps in memory when appropriate, giving faster index performance on complex queries against very large tables. It is used when there are multiple predicates on different indexed columns. Each bitmap per column can be compared to create a final list of selected tuples.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>on</td>
<td>master</td>
</tr>
<tr>
<td></td>
<td></td>
<td>session</td>
</tr>
<tr>
<td></td>
<td></td>
<td>reload</td>
</tr>
</tbody>
</table>

**enable_groupagg**

Enables or disables the use of group aggregation plan types by the Postgres Planner.
<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>on</td>
<td>master session</td>
</tr>
</tbody>
</table>

**enable_hashagg**

Enables or disables the use of hash aggregation plan types by the Postgres Planner.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>on</td>
<td>master session</td>
</tr>
</tbody>
</table>

**enable_hashjoin**

Enables or disables the use of hash-join plan types by the Postgres Planner.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>on</td>
<td>master session</td>
</tr>
</tbody>
</table>

**enable_indexscan**

Enables or disables the use of index-scan plan types by the Postgres Planner.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>on</td>
<td>master session</td>
</tr>
</tbody>
</table>

**enable_mergejoin**

Enables or disables the use of merge-join plan types by the Postgres Planner. Merge join is based on the idea of sorting the left- and right-hand tables into order and then scanning them in parallel. So, both data types must be capable of being fully ordered, and the join operator must be one that can only succeed for pairs of values that fall at the ‘same place’ in the sort order. In practice this means that the join operator must behave like equality.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>off</td>
<td>master session</td>
</tr>
</tbody>
</table>
**enable_nestloop**

Enables or disables the use of nested-loop join plans by the Postgres Planner. It's not possible to suppress nested-loop joins entirely, but turning this variable off discourages the Postgres Planner from using one if there are other methods available.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>off</td>
<td>master</td>
</tr>
<tr>
<td></td>
<td></td>
<td>session</td>
</tr>
<tr>
<td></td>
<td></td>
<td>reload</td>
</tr>
</tbody>
</table>

**enable_seqscan**

Enables or disables the use of sequential scan plan types by the Postgres Planner. It's not possible to suppress sequential scans entirely, but turning this variable off discourages the Postgres Planner from using one if there are other methods available.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>on</td>
<td>master</td>
</tr>
<tr>
<td></td>
<td></td>
<td>session</td>
</tr>
<tr>
<td></td>
<td></td>
<td>reload</td>
</tr>
</tbody>
</table>

**enable_sort**

Enables or disables the use of explicit sort steps by the Postgres Planner. It's not possible to suppress explicit sorts entirely, but turning this variable off discourages the Postgres Planner from using one if there are other methods available.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>on</td>
<td>master</td>
</tr>
<tr>
<td></td>
<td></td>
<td>session</td>
</tr>
<tr>
<td></td>
<td></td>
<td>reload</td>
</tr>
</tbody>
</table>

**enable_tidscan**

Enables or disables the use of tuple identifier (TID) scan plan types by the Postgres Planner.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>on</td>
<td>master</td>
</tr>
<tr>
<td></td>
<td></td>
<td>session</td>
</tr>
<tr>
<td></td>
<td></td>
<td>reload</td>
</tr>
</tbody>
</table>

**escape_string_warning**

When on, a warning is issued if a backslash (\) appears in an ordinary string literal ("...") syntax. Escape string syntax (E'...') should be used for escapes, because in future versions, ordinary strings will have the SQL standard-conforming behavior of treating backslashes literally.
**explainPrettyPrint**

Determines whether EXPLAIN VERBOSE uses the indented or non-indented format for displaying detailed query-tree dumps.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>on</td>
<td>master, session, reload</td>
</tr>
</tbody>
</table>

**extraFloatDigits**

Adjusts the number of digits displayed for floating-point values, including float4, float8, and geometric data types. The parameter value is added to the standard number of digits. The value can be set as high as 3, to include partially-significant digits; this is especially useful for dumping float data that needs to be restored exactly. Or it can be set negative to suppress unwanted digits.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>integer</td>
<td>0</td>
<td>master, session, reload</td>
</tr>
</tbody>
</table>

**fromCollapseLimit**

The Postgres Planner will merge sub-queries into upper queries if the resulting FROM list would have no more than this many items. Smaller values reduce planning time but may yield inferior query plans.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>1-n</td>
<td>20</td>
<td>master, session, reload</td>
</tr>
</tbody>
</table>

**gpAdjustSelectivityForOuterJoins**

Enables the selectivity of NULL tests over outer joins.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>on</td>
<td>master, session, reload</td>
</tr>
</tbody>
</table>
**gp_appendonly_compaction**

Enables compacting segment files during `VACUUM` commands. When disabled, `VACUUM` only truncates the segment files to the EOF value, as is the current behavior. The administrator may want to disable compaction in high I/O load situations or low space situations.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>on</td>
<td>master, session, reload</td>
</tr>
</tbody>
</table>

**gp_appendonly_compaction_threshold**

Specifies the threshold ratio (as a percentage) of hidden rows to total rows that triggers compaction of the segment file when `VACUUM` is run without the `FULL` option (a lazy vacuum). If the ratio of hidden rows in a segment file on a segment is less than this threshold, the segment file is not compacted, and a log message is issued.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>integer (%)</td>
<td>10</td>
<td>master, session, reload</td>
</tr>
</tbody>
</table>

**gp_autostats_mode**

Specifies the mode for triggering automatic statistics collection with `ANALYZE`. The `on_no_stats` option triggers statistics collection for `CREATE TABLE AS SELECT`, `INSERT`, or `COPY` operations on any table that has no existing statistics.

The `on_change` option triggers statistics collection only when the number of rows affected exceeds the threshold defined by `gp_autostats_on_change_threshold`. Operations that can trigger automatic statistics collection with `on_change` are:

- `CREATE TABLE AS SELECT`
- `UPDATE`
- `DELETE`
- `INSERT`
- `COPY`

Default is `on_no_stats`.

**Note:** For partitioned tables, automatic statistics collection is not triggered if data is inserted from the top-level parent table of a partitioned table.

Automatic statistics collection is triggered if data is inserted directly in a leaf table (where the data is stored) of the partitioned table. Statistics are collected only on the leaf table.
gp_autostats_mode_in_functions

Specifies the mode for triggering automatic statistics collection with `ANALYZE` for statements in procedural language functions. The `none` option disables statistics collection. The `on_no_stats` option triggers statistics collection for `CREATE TABLE AS SELECT`, `INSERT`, or `COPY` operations that are executed in functions on any table that has no existing statistics.

The `on_change` option triggers statistics collection only when the number of rows affected exceeds the threshold defined by `gp_autostats_on_change_threshold`. Operations in functions that can trigger automatic statistics collection with `on_change` are:

- `CREATE TABLE AS SELECT`
- `UPDATE`
- `DELETE`
- `INSERT`
- `COPY`

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>none</td>
<td>on_no_stats</td>
<td>master</td>
</tr>
<tr>
<td>on_change</td>
<td></td>
<td>session</td>
</tr>
<tr>
<td>on_no_stats</td>
<td></td>
<td>reload</td>
</tr>
</tbody>
</table>

gp_autostats_on_change_threshold

Specifies the threshold for automatic statistics collection when `gp_autostats_mode` is set to `on_change`. When a triggering table operation affects a number of rows exceeding this threshold, `ANALYZE` is added and statistics are collected for the table.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>integer</td>
<td>2147483647</td>
<td>master</td>
</tr>
<tr>
<td></td>
<td></td>
<td>session</td>
</tr>
<tr>
<td></td>
<td></td>
<td>reload</td>
</tr>
</tbody>
</table>

gp_cached_segworkers_threshold

When a user starts a session with Greenplum Database and issues a query, the system creates groups or 'gangs' of worker processes on each segment to do the work. After the work is done, the segment worker processes are destroyed except for a cached number which is set by this parameter. A lower setting conserves system resources on the segment hosts, but a higher setting may improve performance for power-users that want to issue many complex queries in a row.
### gp_command_count

Shows how many commands the master has received from the client. Note that a single SQL command might actually involve more than one command internally, so the counter may increment by more than one for a single query. This counter also is shared by all of the segment processes working on the command.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>integer &gt; 0</td>
<td>5</td>
<td>master, session, reload</td>
</tr>
</tbody>
</table>

### gp_connection_send_timeout

Timeout for sending data to unresponsive Greenplum Database user clients during query processing. A value of 0 disables the timeout, Greenplum Database waits indefinitely for a client. When the timeout is reached, the query is cancelled with this message:

Could not send data to client: Connection timed out.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>number of seconds</td>
<td>3600 (1 hour)</td>
<td>master, system, reload</td>
</tr>
</tbody>
</table>

### gp_content

The local content id if a segment.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>integer</td>
<td></td>
<td>read only</td>
</tr>
</tbody>
</table>

### gp_create_table_random_default_distribution

Controls table creation when a Greenplum Database table is created with a `CREATE TABLE` or `CREATE TABLE AS` command that does not contain a `DISTRIBUTED BY` clause.

For `CREATE TABLE`, if the value of the parameter is `off` (the default), and the table creation command does not contain a `DISTRIBUTED BY` clause, Greenplum Database chooses the table distribution key based on the command:

- If a `LIKE` or `INHERITS` clause is specified, then Greenplum copies the distribution key from the source or parent table.
- If a `PRIMARY KEY` or `UNIQUE` constraints are specified, then Greenplum chooses the largest subset of all the key columns as the distribution key.
- If neither constraints nor a `LIKE` or `INHERITS` clause is specified, then Greenplum chooses the first suitable column as the distribution key. (Columns with geometric or user-defined data types are not eligible as Greenplum distribution key columns.)
If the value of the parameter is set to on, Greenplum Database follows these rules to create a table when the \texttt{DISTRIBUTED BY} clause is not specified:

- If \texttt{PRIMARY KEY} or \texttt{UNIQUE} columns are not specified, the distribution of the table is random (\texttt{DISTRIBUTED RANDOMLY}). Table distribution is random even if the table creation command contains the \texttt{LIKE} or \texttt{INHERITS} clause.
- If \texttt{PRIMARY KEY} or \texttt{UNIQUE} columns are specified, a \texttt{DISTRIBUTED BY} clause must also be specified. If a \texttt{DISTRIBUTED BY} clause is not specified as part of the table creation command, the command fails.

For a \texttt{CREATE TABLE AS} command that does not contain a distribution clause:

- If the Postgres Planner creates the table, and the value of the parameter is \texttt{off}, the table distribution policy is determined based on the command.
- If the Postgres Planner creates the table, and the value of the parameter is \texttt{on}, the table distribution policy is random.
- If GPORCA creates the table, the table distribution policy is random. The parameter value has no affect.

For information about the Postgres Planner and GPORCA, see "Querying Data" in the \textit{Greenplum Database Administrator Guide}.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>boolean</td>
<td>off</td>
<td>master system reload</td>
</tr>
</tbody>
</table>

\textbf{gp\_dbid}

The local content dbid if a segment.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>integer</td>
<td></td>
<td>read only</td>
</tr>
</tbody>
</table>

\textbf{gp\_debug\_linger}

Number of seconds for a Greenplum process to linger after a fatal internal error.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>Any valid time expression (number and unit)</td>
<td>0</td>
<td>master session reload</td>
</tr>
</tbody>
</table>

\textbf{gp\_default\_storage\_options}

Set the default values for the following table storage options when a table is created with the \texttt{CREATE TABLE} command.

- \texttt{appendoptimized}
  
  \textbf{Note:} You use the \texttt{appendoptimized=value} syntax to specify the append-optimized table storage type. \texttt{appendoptimized} is a thin alias for the \texttt{appendonly} legacy storage option. Greenplum Database stores \texttt{appendonly} in the catalog, and displays the same when listing the storage options for append-optimized tables.

- \texttt{blocksize}
• checksum
• compressstype
• compresslevel
• orientation

Specify multiple storage option values as a comma separated list.

You can set the storage options with this parameter instead of specifying the table storage options in the WITH of the CREATE TABLE command. The table storage options that are specified with the CREATE TABLE command override the values specified by this parameter.

Not all combinations of storage option values are valid. If the specified storage options are not valid, an error is returned. See the CREATE TABLE command for information about table storage options.

The defaults can be set for a database and user. If the server configuration parameter is set at different levels, this the order of precedence, from highest to lowest, of the table storage values when a user logs into a database and creates a table:

1. The values specified in a CREATE TABLE command with the WITH clause or ENCODING clause
2. The value of gp_default_storage_options that set for the user with the ALTER ROLE...SET command
3. The value of gp_default_storage_options that is set for the database with the ALTER DATABASE...SET command
4. The value of gp_default_storage_options that is set for the Greenplum Database system with the gpconfig utility

The parameter value is not cumulative. For example, if the parameter specifies the appendoptimized and compressstype options for a database and a user logs in and sets the parameter to specify the value for the orientation option, the appendoptimized, and compressstype values set at the database level are ignored.

This example ALTER DATABASE command sets the default orientation and compressstype table storage options for the database mytest.

```
ALTER DATABASE mytest SET gp_default_storage_options = 'orientation=column,
compressstype=rle_type'
```

To create an append-optimized table in the mytest database with column-oriented table and RLE compression. The user needs to specify only appendoptimized=TRUE in the WITH clause.

This example gpconfig utility command sets the default storage option for a Greenplum Database system. If you set the defaults for multiple table storage options, the value must be enclosed in single quotes.

```
gpconfig -c 'gp_default_storage_options' -v 'appendoptimized=true,
orientation=column'
```

This example gpconfig utility command shows the value of the parameter. The parameter value must be consistent across the Greenplum Database master and all segments.

```
gpconfig -s 'gp_default_storage_options'
```
<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>appendoptimized= TRUE</td>
<td>FALSE</td>
<td></td>
</tr>
<tr>
<td>blocksize= integer between 8192 and 2097152</td>
<td></td>
<td></td>
</tr>
<tr>
<td>checksum= TRUE</td>
<td>FALSE</td>
<td></td>
</tr>
<tr>
<td>compressstype= ZLIB</td>
<td>ZSTD</td>
<td>QUICKLZ2</td>
</tr>
<tr>
<td>compresslevel= integer between 0 and 19</td>
<td></td>
<td></td>
</tr>
<tr>
<td>orientation= ROW</td>
<td>COLUMN</td>
<td></td>
</tr>
</tbody>
</table>

**Note:** 1 The set classification when the parameter is set at the system level with the `gpconfig` utility.

**Note:** 2 QuickLZ compression is available only in the commercial release of Pivotal Greenplum Database.

### gp_dynamic_partition_pruning
Enables plans that can dynamically eliminate the scanning of partitions.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>on/off</td>
<td>on</td>
<td>master session reload</td>
</tr>
</tbody>
</table>

### gp_enable_agg_distinct
Enables or disables two-phase aggregation to compute a single distinct-qualified aggregate. This applies only to subqueries that include a single distinct-qualified aggregate function.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>on</td>
<td>master session reload</td>
</tr>
</tbody>
</table>

### gp_enable_agg_distinct_pruning
Enables or disables three-phase aggregation and join to compute distinct-qualified aggregates. This applies only to subqueries that include one or more distinct-qualified aggregate functions.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>on</td>
<td>master session reload</td>
</tr>
</tbody>
</table>
gp_enable_direct_dispatch

Enables or disables the dispatching of targeted query plans for queries that access data on a single segment. When on, queries that target rows on a single segment will only have their query plan dispatched to that segment (rather than to all segments). This significantly reduces the response time of qualifying queries as there is no interconnect setup involved. Direct dispatch does require more CPU utilization on the master.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>on</td>
<td>master</td>
</tr>
<tr>
<td></td>
<td></td>
<td>system</td>
</tr>
<tr>
<td></td>
<td></td>
<td>restart</td>
</tr>
</tbody>
</table>

gp_enable_exchange_default_partition

Controls availability of the `EXCHANGE DEFAULT PARTITION` clause for `ALTER TABLE`. The default value for the parameter is `off`. The clause is not available and Greenplum Database returns an error if the clause is specified in an `ALTER TABLE` command.

If the value is `on`, Greenplum Database returns a warning stating that exchanging the default partition might result in incorrect results due to invalid data in the default partition.

**Warning:** Before you exchange the default partition, you must ensure the data in the table to be exchanged, the new default partition, is valid for the default partition. For example, the data in the new default partition must not contain data that would be valid in other leaf child partitions of the partitioned table. Otherwise, queries against the partitioned table with the exchanged default partition that are executed by GPORCA might return incorrect results.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>off</td>
<td>master</td>
</tr>
<tr>
<td></td>
<td></td>
<td>session</td>
</tr>
<tr>
<td></td>
<td></td>
<td>reload</td>
</tr>
</tbody>
</table>

gp_enable_fast_sri

When set to `on`, the Postgres Planner plans single row inserts so that they are sent directly to the correct segment instance (no motion operation required). This significantly improves performance of single-row-insert statements.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>on</td>
<td>master</td>
</tr>
<tr>
<td></td>
<td></td>
<td>session</td>
</tr>
<tr>
<td></td>
<td></td>
<td>reload</td>
</tr>
</tbody>
</table>

gp_enable_global_deadlock_detector

Controls whether the Greenplum Database Global Deadlock Detector is enabled to manage concurrent `UPDATE` and `DELETE` operations on heap tables to improve performance. See Global Deadlock Detector in the Greenplum Database Administrator Guide. The default is `off`, the Global Deadlock Detector is disabled.
If the Global Deadlock Detector is disabled (the default), Greenplum Database executes concurrent update and delete operations on a heap table serially.

If the Global Deadlock Detector is enabled, concurrent updates are permitted and the Global Deadlock Detector determines when a deadlock exists, and breaks the deadlock by cancelling one or more backend processes associated with the youngest transaction(s) involved.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>off</td>
<td>master</td>
</tr>
<tr>
<td></td>
<td></td>
<td>system</td>
</tr>
<tr>
<td></td>
<td></td>
<td>restart</td>
</tr>
</tbody>
</table>

**gp_enable_gpperfmon**

Enables or disables the data collection agents that populate the gpperfmon database.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>off</td>
<td>local</td>
</tr>
<tr>
<td></td>
<td></td>
<td>system</td>
</tr>
<tr>
<td></td>
<td></td>
<td>restart</td>
</tr>
</tbody>
</table>

**gp_enable_groupext_distinct_gather**

Enables or disables gathering data to a single node to compute distinct-qualified aggregates on grouping extension queries. When this parameter and gp_enable_groupext_distinct_pruning are both enabled, the Postgres Planner uses the cheaper plan.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>on</td>
<td>master</td>
</tr>
<tr>
<td></td>
<td></td>
<td>session</td>
</tr>
<tr>
<td></td>
<td></td>
<td>reload</td>
</tr>
</tbody>
</table>

**gp_enable_groupext_distinct_pruning**

Enables or disables three-phase aggregation and join to compute distinct-qualified aggregates on grouping extension queries. Usually, enabling this parameter generates a cheaper query plan that the Postgres Planner will use in preference to existing plan.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>on</td>
<td>master</td>
</tr>
<tr>
<td></td>
<td></td>
<td>session</td>
</tr>
<tr>
<td></td>
<td></td>
<td>reload</td>
</tr>
</tbody>
</table>

**gp_enable_multiphase_agg**

Enables or disables the use of two or three-stage parallel aggregation plans Postgres Planner. This approach applies to any subquery with aggregation. If gp_enable_multiphase_agg is off, then gp_enable_agg_distinct and gp_enable_agg_distinct_pruning are disabled.
<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>on</td>
<td>master session reload</td>
</tr>
</tbody>
</table>

**gp_enable_predicate_propagation**

When enabled, the Postgres Planner applies query predicates to both table expressions in cases where the tables are joined on their distribution key column(s). Filtering both tables prior to doing the join (when possible) is more efficient.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>on</td>
<td>master session reload</td>
</tr>
</tbody>
</table>

**gp_enable_preunique**

Enables two-phase duplicate removal for `SELECT DISTINCT` queries (not `SELECT COUNT(DISTINCT)`). When enabled, it adds an extra `SORT DISTINCT` set of plan nodes before motioning. In cases where the distinct operation greatly reduces the number of rows, this extra `SORT DISTINCT` is much cheaper than the cost of sending the rows across the Interconnect.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>on</td>
<td>master session reload</td>
</tr>
</tbody>
</table>

**gp_enable_query_metrics**

Enables collection of query metrics. When query metrics collection is enabled, Greenplum Database collects metrics during query execution. The default is off.

After changing this configuration parameter, Greenplum Database must be restarted for the change to take effect.

The Greenplum Database metrics collection extension, when enabled, sends the collected metrics over UDP to a Pivotal Greenplum Command Center agent.

**Note:** The metrics collection extension is included in Pivotal's commercial version of Greenplum Database. Pivotal Greenplum Command Center is supported only with Pivotal Greenplum Database.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>off</td>
<td>master system restart</td>
</tr>
</tbody>
</table>
**gp_enable_relsize_collection**

Enables GPORCA and the Postgres Planner to use the estimated size of a table (pg_relation_size function) if there are no statistics for the table. By default, GPORCA and the planner use a default value to estimate the number of rows if statistics are not available. The default behavior improves query optimization time and reduces resource queue usage in heavy workloads, but can lead to suboptimal plans.

This parameter is ignored for a root partition of a partitioned table. When GPORCA is enabled and the root partition does not have statistics, GPORCA always uses the default value. You can use ANALYZE ROOTPARTITION to collect statistics on the root partition. See ANALYZE.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>off</td>
<td>master</td>
</tr>
<tr>
<td></td>
<td></td>
<td>session</td>
</tr>
<tr>
<td></td>
<td></td>
<td>reload</td>
</tr>
</tbody>
</table>

**gp_enable_segment_copy_checking**

Controls whether the distribution policy for a table (from the table DISTRIBUTED clause) is checked when data is copied into the table with the COPY FROM...ON SEGMENT command. If true, an error is returned if a row of data violates the distribution policy for a segment instance. The default is true.

If the value is false, the distribution policy is not checked. The data added to the table might violate the table distribution policy for the segment instance. Manual redistribution of table data might be required. See the ALTER TABLE clause WITH REORGANIZE.

The parameter can be set for a database system or a session. The parameter cannot be set for a specific database.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>true</td>
<td>master</td>
</tr>
<tr>
<td></td>
<td></td>
<td>session</td>
</tr>
<tr>
<td></td>
<td></td>
<td>reload</td>
</tr>
</tbody>
</table>

**gp_enable_sort_distinct**

Enable duplicates to be removed while sorting.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>on</td>
<td>master</td>
</tr>
<tr>
<td></td>
<td></td>
<td>session</td>
</tr>
<tr>
<td></td>
<td></td>
<td>reload</td>
</tr>
</tbody>
</table>

**gp_enable_sort_limit**

Enable LIMIT operation to be performed while sorting. Sorts more efficiently when the plan requires the first limit_number of rows at most.
<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>on</td>
<td>master session reload</td>
</tr>
</tbody>
</table>

**gp_external_enable_exec**

Enables or disables the use of external tables that execute OS commands or scripts on the segment hosts (CREATE EXTERNAL TABLE EXECUTE syntax). Must be enabled if using the Command Center or MapReduce features.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>on</td>
<td>master system restart</td>
</tr>
</tbody>
</table>

**gp_external_max_segs**

Sets the number of segments that will scan external table data during an external table operation, the purpose being not to overload the system with scanning data and take away resources from other concurrent operations. This only applies to external tables that use the gpfdist:// protocol to access external table data.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>integer</td>
<td>64</td>
<td>master session reload</td>
</tr>
</tbody>
</table>

**gp_external_enable_filter_pushdown**

Enable filter pushdown when reading data from external tables. If pushdown fails, a query is executed without pushing filters to the external data source (instead, Greenplum Database applies the same constraints to the result). See Defining External Tables for more information.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>on</td>
<td>master session reload</td>
</tr>
</tbody>
</table>

**gp_fts_probe_interval**

Specifies the polling interval for the fault detection process (ftsprobe). The ftsprobe process will take approximately this amount of time to detect a segment failure.
### gp_fts_probe_retries
Specifies the number of times the fault detection process (`ftsprobe`) attempts to connect to a segment before reporting segment failure.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>10 - 3600 seconds</td>
<td>1min</td>
<td>master, system, restart</td>
</tr>
</tbody>
</table>

### gp_fts_probe_threadcount
Specifies the number of `ftsprobe` threads to create. This parameter should be set to a value equal to or greater than the number of segments per host.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>1 - 128</td>
<td>16</td>
<td>master, system, restart</td>
</tr>
</tbody>
</table>

### gp_fts_probe_timeout
Specifies the allowed timeout for the fault detection process (`ftsprobe`) to establish a connection to a segment before declaring it down.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>10 - 3600 seconds</td>
<td>20 secs</td>
<td>master, system, restart</td>
</tr>
</tbody>
</table>

### gp_global_deadlock_detector_period
Specifies the executing interval (in seconds) of the global deadlock detector background worker process.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>5 - INT_MAX secs</td>
<td>120 secs</td>
<td>master, system, reload</td>
</tr>
</tbody>
</table>
**gp_log_fts**
Controls the amount of detail the fault detection process (ftsprobe) writes to the log file.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>OFF</td>
<td>TERSE</td>
<td>master</td>
</tr>
<tr>
<td>TERSE</td>
<td></td>
<td>system</td>
</tr>
<tr>
<td>VERBOSE</td>
<td></td>
<td>restart</td>
</tr>
<tr>
<td>DEBUG</td>
<td></td>
<td>master</td>
</tr>
</tbody>
</table>

**gp_log_interconnect**
Controls the amount of information that is written to the log file about communication between Greenplum Database segment instance worker processes. The default value is terse. The log information is written to both the master and segment instance logs.

Increasing the amount of logging could affect performance and increase disk space usage.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>off</td>
<td>terse</td>
<td>master</td>
</tr>
<tr>
<td>terse</td>
<td></td>
<td>session</td>
</tr>
<tr>
<td>verbose</td>
<td></td>
<td>reload</td>
</tr>
<tr>
<td>debug</td>
<td></td>
<td>master</td>
</tr>
</tbody>
</table>

**gp_log_gang**
Controls the amount of information that is written to the log file about query worker process creation and query management. The default value is OFF, do not log information.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>OFF</td>
<td>OFF</td>
<td>master</td>
</tr>
<tr>
<td>TERSE</td>
<td></td>
<td>session</td>
</tr>
<tr>
<td>VERBOSE</td>
<td></td>
<td>restart</td>
</tr>
<tr>
<td>DEBUG</td>
<td></td>
<td>master</td>
</tr>
</tbody>
</table>

**gp_gpperfmon_send_interval**
Sets the frequency that the Greenplum Database server processes send query execution updates to the data collection agent processes used to populate the gpperfmon database. Query operations executed during this interval are sent through UDP to the segment monitor agents. If you find that an excessive number of UDP packets are dropped during long-running, complex queries, you may consider increasing this value.
### gpperfmon_log_alert_level

Controls which message levels are written to the gpperfmon log. Each level includes all the levels that follow it. The later the level, the fewer messages are sent to the log.

**Note:** If the gpperfmon database is installed and is monitoring the database, the default value is warning.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>none</td>
<td>none</td>
<td>local</td>
</tr>
<tr>
<td>warning</td>
<td></td>
<td>system</td>
</tr>
<tr>
<td>error</td>
<td></td>
<td>restart</td>
</tr>
<tr>
<td>fatal</td>
<td></td>
<td></td>
</tr>
<tr>
<td>panic</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

### gp_hashjoin_tuples_per_bucket

Sets the target density of the hash table used by HashJoin operations. A smaller value will tend to produce larger hash tables, which can increase join performance.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>integer</td>
<td>5</td>
<td>master</td>
</tr>
<tr>
<td></td>
<td></td>
<td>session</td>
</tr>
<tr>
<td></td>
<td></td>
<td>reload</td>
</tr>
</tbody>
</table>

### gp_ignore_error_table (Deprecated)

Controls Greenplum Database behavior when the deprecated INTO ERROR TABLE clause is specified in a CREATE EXTERNAL TABLE or COPY command.

The default value is `false`, Greenplum Database returns an error if the INTO ERROR TABLE clause is specified in a command.

If the value is `true`, Greenplum Database ignores the clause, issues a warning, and executes the command without the INTO ERROR TABLE clause. In Greenplum Database 5.x and later, you access the error log information with built-in SQL functions. See the CREATE EXTERNAL TABLE or COPY command.

You can set this value to `true` to avoid the Greenplum Database error when you run applications that execute CREATE EXTERNAL TABLE or COPY commands that include the Greenplum Database 4.3.x INTO ERROR TABLE clause.

The INTO ERROR TABLE clause was deprecated and removed in Greenplum Database 5. In Greenplum Database 7, this parameter will be removed as well, causing all INTO ERROR TABLE invocations be yield a syntax error.
gp_initial_bad_row_limit

For the parameter value $n$, Greenplum Database stops processing input rows when you import data with the `COPY` command or from an external table if the first $n$ rows processed contain formatting errors. If a valid row is processed within the first $n$ rows, Greenplum Database continues processing input rows.

Setting the value to 0 disables this limit.

The `SEGMENT REJECT LIMIT` clause can also be specified for the `COPY` command or the external table definition to limit the number of rejected rows.

`INT_MAX` is the largest value that can be stored as an integer on your system.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>Integer 0 - INT_MAX</td>
<td>1000</td>
<td>master, session, reload</td>
</tr>
</tbody>
</table>

gp_instrument_shmem_size

The amount of shared memory, in kilobytes, allocated for query metrics. The default is 5120 and the maximum is 131072. At startup, if `gp_enable_query_metrics` is set to on, Greenplum Database allocates space in shared memory to save query metrics. This memory is organized as a header and a list of slots. The number of slots needed depends on the number of concurrent queries and the number of execution plan nodes per query. The default value, 5120, is based on a Greenplum Database system that executes a maximum of about 250 concurrent queries with 120 nodes per query. If the `gp_enable_query_metrics` configuration parameter is off, or if the slots are exhausted, the metrics are maintained in local memory instead of in shared memory.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>Integer 0 - 131072</td>
<td>5120</td>
<td>master, system, restart</td>
</tr>
</tbody>
</table>

gp_interconnect_debug_retry_interval

Specifies the interval, in seconds, to log Greenplum Database interconnect debugging messages when the server configuration parameter `gp_log_interconnect` is set to `DEBUG`. The default is 10 seconds.

The log messages contain information about the interconnect communication between Greenplum Database segment instance worker processes. The information can be helpful when debugging network issues between segment instances.
### gp_interconnect_fc_method

Specifies the flow control method used for the default Greenplum Database UDPIFC interconnect.

For capacity based flow control, senders do not send packets when receivers do not have the capacity. Loss based flow control is based on capacity based flow control, and also tunes the sending speed according to packet losses.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>CAPACITY</td>
<td>LOSS</td>
<td>master</td>
</tr>
<tr>
<td>LOSS</td>
<td></td>
<td>session</td>
</tr>
<tr>
<td></td>
<td></td>
<td>reload</td>
</tr>
</tbody>
</table>

### gp_interconnect_queue_depth

Sets the amount of data per-peer to be queued by the Greenplum Database interconnect on receivers (when data is received but no space is available to receive it the data will be dropped, and the transmitter will need to resend it) for the default UDPIFC interconnect. Increasing the depth from its default value will cause the system to use more memory, but may increase performance. It is reasonable to set this value between 1 and 10. Queries with data skew potentially perform better with an increased queue depth. Increasing this may radically increase the amount of memory used by the system.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>1-2048</td>
<td>4</td>
<td>master</td>
</tr>
<tr>
<td></td>
<td></td>
<td>session</td>
</tr>
<tr>
<td></td>
<td></td>
<td>reload</td>
</tr>
</tbody>
</table>

### gp_interconnect_setup_timeout

Specifies the amount of time to wait for the Greenplum Database interconnect to complete setup before it times out.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>Any valid time expression (number and unit)</td>
<td>2 hours</td>
<td>master</td>
</tr>
<tr>
<td></td>
<td></td>
<td>session</td>
</tr>
<tr>
<td></td>
<td></td>
<td>reload</td>
</tr>
</tbody>
</table>

### gp_interconnect_snd_queue_depth

Sets the amount of data per-peer to be queued by the default UDPIFC interconnect on senders. Increasing the depth from its default value will cause the system to use more memory, but may increase performance. Reasonable values for this parameter are between 1 and 4. Increasing the value might radically increase the amount of memory used by the system.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>1 =&lt; Integer &lt; 4096</td>
<td>10</td>
<td>master</td>
</tr>
<tr>
<td></td>
<td></td>
<td>session</td>
</tr>
<tr>
<td></td>
<td></td>
<td>reload</td>
</tr>
</tbody>
</table>
gp_interconnect_type

Sets the networking protocol used for Greenplum Database interconnect traffic. UDPIFC specifies using UDP with flow control for interconnect traffic, and is the only value supported.

UDPIFC (the default) specifies using UDP with flow control for interconnect traffic. Specify the interconnect flow control method with `gp_interconnect_fc_method`.

With TCP as the interconnect protocol, Greenplum Database has an upper limit of 1000 segment instances - less than that if the query workload involves complex, multi-slice queries.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>UDPIFC</td>
<td>UDPIFC</td>
<td>local, system, restart</td>
</tr>
<tr>
<td>TCP</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

gp_log_format

Specifies the format of the server log files. If using `gp_toolkit` administrative schema, the log files must be in CSV format.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>csv</td>
<td>csv</td>
<td>local, system, restart</td>
</tr>
<tr>
<td>text</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

gp_max_local_distributed_cache

Sets the maximum number of distributed transaction log entries to cache in the backend process memory of a segment instance.

The log entries contain information about the state of rows that are being accessed by an SQL statement. The information is used to determine which rows are visible to an SQL transaction when executing multiple simultaneous SQL statements in an MVCC environment. Caching distributed transaction log entries locally improves transaction processing speed by improving performance of the row visibility determination process.

The default value is optimal for a wide variety of SQL processing environments.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>integer</td>
<td>1024</td>
<td>local, system, restart</td>
</tr>
</tbody>
</table>
**gp_max_packet_size**
Sets the tuple-serialization chunk size for the Greenplum Database interconnect.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>512-65536</td>
<td>8192</td>
<td>master</td>
</tr>
<tr>
<td></td>
<td></td>
<td>system</td>
</tr>
<tr>
<td></td>
<td></td>
<td>restart</td>
</tr>
</tbody>
</table>

**gp_max_plan_size**
Specifies the total maximum uncompressed size of a query execution plan multiplied by the number of Motion operators (slices) in the plan. If the size of the query plan exceeds the value, the query is cancelled and an error is returned. A value of 0 means that the size of the plan is not monitored.

You can specify a value in kB, MB, or GB. The default unit is kB. For example, a value of 200 is 200kB. A value of 1GB is the same as 1024MB or 1048576kB.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>integer</td>
<td>0</td>
<td>master</td>
</tr>
<tr>
<td></td>
<td></td>
<td>superuser</td>
</tr>
<tr>
<td></td>
<td></td>
<td>session</td>
</tr>
</tbody>
</table>

**gp_max_slices**
Specifies the maximum number of slices (portions of a query plan that are executed on segment instances) that can be generated by a query. If the query generates more than the specified number of slices, Greenplum Database returns an error and does not execute the query. The default value is 0, no maximum value.

Executing a query that generates a large number of slices might affect Greenplum Database performance. For example, a query that contains UNION or UNION ALL operators over several complex views can generate a large number of slices. You can run EXPLAIN ANALYZE on the query to view slice statistics for the query.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>0 - INT_MAX</td>
<td>0</td>
<td>master</td>
</tr>
<tr>
<td></td>
<td></td>
<td>session</td>
</tr>
<tr>
<td></td>
<td></td>
<td>reload</td>
</tr>
</tbody>
</table>

**gp_motion_cost_per_row**
Sets the Postgres Planner cost estimate for a Motion operator to transfer a row from one segment to another, measured as a fraction of the cost of a sequential page fetch. If 0, then the value used is two times the value of cpu_tuple_cost.
**gp_recursive_c te**

Controls the availability of the **RECURSIVE** keyword in the **WITH** clause of a **SELECT** [**INTO**] command, or a **DELETE**, **INSERT** or **UPDATE** command. The keyword allows a subquery in the **WITH** clause of a command to reference itself. The default value is `false`, the **RECURSIVE** keyword is not allowed in the **WITH** clause of a command.

For information about the **RECURSIVE** keyword (Beta), see the **SELECT** command and **WITH Queries (Common Table Expressions)**.

The parameter can be set for a database system, an individual database, or a session or query.

**Note:** This parameter was previously named `gp_recursive_c te_prototype`, but has been renamed to reflect the current status of the implementation.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>true</td>
<td>master</td>
</tr>
<tr>
<td></td>
<td></td>
<td>session</td>
</tr>
<tr>
<td></td>
<td></td>
<td>restart</td>
</tr>
</tbody>
</table>

**gp_reject_percent_threshold**

For single row error handling on **COPY** and external table **SELECT**s, sets the number of rows processed before **SEGMENT REJECT LIMIT n PERCENT** starts calculating.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>1-n</td>
<td>300</td>
<td>master</td>
</tr>
<tr>
<td></td>
<td></td>
<td>session</td>
</tr>
<tr>
<td></td>
<td></td>
<td>reload</td>
</tr>
</tbody>
</table>

**gp_reraise_signal**

If enabled, will attempt to dump core if a fatal server error occurs.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>on</td>
<td>master</td>
</tr>
<tr>
<td></td>
<td></td>
<td>session</td>
</tr>
<tr>
<td></td>
<td></td>
<td>reload</td>
</tr>
</tbody>
</table>

**gp_resgroup_memory_policy**

**Note:** The `gp_resgroup_memory_policy` server configuration parameter is enforced only when resource group-based resource management is active.

Used by a resource group to manage memory allocation to query operators.
When set to `auto`, Greenplum Database uses resource group memory limits to distribute memory across query operators, allocating a fixed size of memory to non-memory-intensive operators and the rest to memory-intensive operators.

When you specify `eager_free`, Greenplum Database distributes memory among operators more optimally by re-allocating memory released by operators that have completed their processing to operators in a later query stage.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>auto, eager_free</td>
<td>eager_free</td>
<td>local, system, superuser, restart/reload</td>
</tr>
</tbody>
</table>

**gp_resource_group_bypass**

*Note:* The `gp_resource_group_bypass` server configuration parameter is enforced only when resource group-based resource management is active.

Enables or disables the enforcement of resource group concurrent transaction limits on Greenplum Database resources. The default value is `false`, which enforces resource group transaction limits. Resource groups manage resources such as CPU, memory, and the number of concurrent transactions that are used by queries and external components such as PL/Container.

You can set this parameter to `true` to bypass resource group concurrent transaction limitations so that a query can run immediately. For example, you can set the parameter to `true` for a session to run a system catalog query or a similar query that requires a minimal amount of resources.

When you set this parameter to `true` and run a query, the query runs in this environment:

- The query runs inside a resource group. The resource group assignment for the query does not change.
- The query memory quota is approximately 10 MB per query. The memory is allocated from resource group shared memory or global shared memory. The query fails if there is not enough shared memory available to fulfill the memory allocation request.

This parameter can be set for a session. The parameter cannot be set within a transaction or a function.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>false</td>
<td>session</td>
</tr>
</tbody>
</table>

**gp_resource_group_cpu_limit**

*Note:* The `gp_resource_group_cpu_limit` server configuration parameter is enforced only when resource group-based resource management is active.

Identifies the maximum percentage of system CPU resources to allocate to resource groups on each Greenplum Database segment node.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>0.1 - 1.0</td>
<td>0.9</td>
<td>local, system, restart</td>
</tr>
</tbody>
</table>
gp_resource_group_memory_limit

Note: The `gp_resource_group_memory_limit` server configuration parameter is enforced only when resource group-based resource management is active.

Identifies the maximum percentage of system memory resources to allocate to resource groups on each Greenplum Database segment node.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>0.1 - 1.0</td>
<td>0.7</td>
<td>local, system, restart</td>
</tr>
</tbody>
</table>

Note: When resource group-based resource management is active, the memory allotted to a segment host is equally shared by active primary segments. Greenplum Database assigns memory to primary segments when the segment takes the primary role. The initial memory allotment to a primary segment does not change, even in a failover situation. This may result in a segment host utilizing more memory than the `gp_resource_group_memory_limit` setting permits.

For example, suppose your Greenplum Database cluster is utilizing the default `gp_resource_group_memory_limit` of 0.7 and a segment host named `seghost1` has 4 primary segments and 4 mirror segments. Greenplum Database assigns each primary segment on `seghost1` (0.7 / 4 = 0.175%) of overall system memory. If failover occurs and two mirrors on `seghost1` fail over to become primary segments, each of the original 4 primaries retain their memory allotment of 0.175%, and the two new primary segments are each allotted (0.7 / 6 = 0.116%) of system memory. `seghost1`'s overall memory allocation in this scenario is

\[
0.7 + (0.116 * 2) = 0.932\%
\]

which is above the percentage configured in the `gp_resource_group_memory_limit` setting.

gp_resource_manager

Identifies the resource management scheme currently enabled in the Greenplum Database cluster. The default scheme is to use resource queues.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>group</td>
<td>queue</td>
<td>local, system, restart</td>
</tr>
</tbody>
</table>

gp_resqueue_memory_policy

Note: The `gp_resqueue_memory_policy` server configuration parameter is enforced only when resource queue-based resource management is active.

Enables Greenplum memory management features. The distribution algorithm `eager_free` takes advantage of the fact that not all operators execute at the same time (in Greenplum Database 4.2 and later). The query plan is divided into stages and Greenplum Database eagerly frees memory allocated to a previous stage at the end of that stage's execution, then allocates the eagerly freed memory to the new stage.

When set to `none`, memory management is the same as in Greenplum Database releases prior to 4.1.
When set to `auto`, query memory usage is controlled by `statement_mem` and resource queue memory limits.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>none, auto, eager_free</td>
<td>eager_free</td>
<td>local, system, restart/reload</td>
</tr>
</tbody>
</table>

### `gp_resqueue_priority`

**Note:** The `gp_resqueue_priority` server configuration parameter is enforced only when resource queue-based resource management is active.

Enables or disables query prioritization. When this parameter is disabled, existing priority settings are not evaluated at query run time.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>on</td>
<td>local, system, restart</td>
</tr>
</tbody>
</table>

### `gp_resqueue_priority_cpucores_per_segment`

**Note:** The `gp_resqueue_priority_cpucores_per_segment` server configuration parameter is enforced only when resource queue-based resource management is active.

Specifies the number of CPU units allocated per segment instance. For example, if a Greenplum Database cluster has 10-core segment hosts that are configured with four segments, set the value for the segment instances to 2.5. For the master instance, the value would be 10. A master host typically has only the master instance running on it, so the value for the master should reflect the usage of all available CPU cores.

Incorrect settings can result in CPU under-utilization or query prioritization not working as designed.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>0.1 - 512.0</td>
<td>4</td>
<td>local, system, restart</td>
</tr>
</tbody>
</table>

### `gp_resqueue_priority_sweeper_interval`

**Note:** The `gp_resqueue_priority_sweeper_interval` server configuration parameter is enforced only when resource queue-based resource management is active.

Specifies the interval at which the sweeper process evaluates current CPU usage. When a new statement becomes active, its priority is evaluated and its CPU share determined when the next interval is reached.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>500 - 15000 ms</td>
<td>1000</td>
<td>local, system, restart</td>
</tr>
</tbody>
</table>
### gp_role

The role of this server process " set to *dispatch* for the master and *execute* for a segment.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>dispatch</td>
<td></td>
<td>read only</td>
</tr>
<tr>
<td>execute</td>
<td></td>
<td></td>
</tr>
<tr>
<td>utility</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

### gp_safefswritesize

Specifies a minimum size for safe write operations to append-optimized tables in a non-mature file system. When a number of bytes greater than zero is specified, the append-optimized writer adds padding data up to that number in order to prevent data corruption due to file system errors. Each non-mature file system has a known safe write size that must be specified here when using Greenplum Database with that type of file system. This is commonly set to a multiple of the extent size of the file system; for example, Linux ext3 is 4096 bytes, so a value of 32768 is commonly used.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>integer</td>
<td>0</td>
<td>local</td>
</tr>
<tr>
<td></td>
<td></td>
<td>system</td>
</tr>
<tr>
<td></td>
<td></td>
<td>restart</td>
</tr>
</tbody>
</table>

### gp_segment_connect_timeout

Time that the Greenplum interconnect will try to connect to a segment instance over the network before timing out. Controls the network connection timeout between master and primary segments, and primary to mirror segment replication processes.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>Any valid time expression</td>
<td>10min</td>
<td>local</td>
</tr>
<tr>
<td>(number and unit)</td>
<td></td>
<td>system</td>
</tr>
<tr>
<td></td>
<td></td>
<td>restart</td>
</tr>
</tbody>
</table>

### gp_segments_for_planner

Sets the number of primary segment instances for the Postgres Planner to assume in its cost and size estimates. If 0, then the value used is the actual number of primary segments. This variable affects the Postgres Planner’s estimates of the number of rows handled by each sending and receiving process in Motion operators.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>0-n</td>
<td>0</td>
<td>master</td>
</tr>
<tr>
<td></td>
<td></td>
<td>session</td>
</tr>
<tr>
<td></td>
<td></td>
<td>reload</td>
</tr>
</tbody>
</table>
**gp_server_version**
Reports the version number of the server as a string. A version modifier argument might be appended to the numeric portion of the version string, example: 5.0.0 beta.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>String. Examples: 5.0.0</td>
<td>n/a</td>
<td>read only</td>
</tr>
</tbody>
</table>

**gp_server_version_num**
Reports the version number of the server as an integer. The number is guaranteed to always be increasing for each version and can be used for numeric comparisons. The major version is represented as is, the minor and patch versions are zero-padded to always be double digit wide.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>Mmmpp where M is the major version, mm is the minor version zero-padded and pp is the patch version zero-padded. Example: 50000</td>
<td>n/a</td>
<td>read only</td>
</tr>
</tbody>
</table>

**gp_session_id**
A system assigned ID number for a client session. Starts counting from 1 when the master instance is first started.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>1-n</td>
<td>14</td>
<td>read only</td>
</tr>
</tbody>
</table>

**gp_set_proc_affinity**
If enabled, when a Greenplum server process (postmaster) is started it will bind to a CPU.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>off</td>
<td>master system restart</td>
</tr>
</tbody>
</table>

**gp_set_read_only**
Set to on to disable writes to the database. Any in progress transactions must finish before read-only mode takes affect.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>off</td>
<td>master system restart</td>
</tr>
</tbody>
</table>
**gp_statistics_pullup_from_child_partition**

Enables the use of statistics from child tables when planning queries on the parent table by the Postgres Planner.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>on</td>
<td>master, session, reload</td>
</tr>
</tbody>
</table>

**gp_statistics_use_fkeys**

When enabled, allows the Postgres Planner to use foreign key information stored in the system catalog to optimize joins between foreign keys and primary keys.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>off</td>
<td>master, session, reload</td>
</tr>
</tbody>
</table>

**gp_use_legacy_hashops**

For a table that is defined with a `DISTRIBUTED BY key_column` clause, this parameter controls the hash algorithm that is used to distribute table data among segment instances. The default value is `false`, use the jump consistent hash algorithm.

Setting the value to `true` uses the modulo hash algorithm that is compatible with Greenplum Database 5.x and earlier releases.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>false</td>
<td>master, session, reload</td>
</tr>
</tbody>
</table>

**gp_vmem_idle_resource_timeout**

If a database session is idle for longer than the time specified, the session will free system resources (such as shared memory), but remain connected to the database. This allows more concurrent connections to the database at one time.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>Any valid time expression (number and unit)</td>
<td>18s</td>
<td>master, system, reload</td>
</tr>
</tbody>
</table>
**gp_vmem_protect_limit**

**Note:** The `gp_vmem_protect_limit` server configuration parameter is enforced only when resource queue-based resource management is active.

Sets the amount of memory (in number of MBs) that all postgres processes of an active segment instance can consume. If a query causes this limit to be exceeded, memory will not be allocated and the query will fail. Note that this is a local parameter and must be set for every segment in the system (primary and mirrors). When setting the parameter value, specify only the numeric value. For example, to specify 4096MB, use the value 4096. Do not add the units MB to the value.

To prevent over-allocation of memory, these calculations can estimate a safe `gp_vmem_protect_limit` value.

First calculate the value `gp_vmem`. This is the Greenplum Database memory available on a host

\[
gp_vmem = \left(\frac{(SWAP + RAM) - (7.5GB + 0.05 \times RAM)}{1.7}\right)
\]

where `SWAP` is the host swap space and `RAM` is the RAM on the host in GB.

Next, calculate the `max_acting_primary_segments`. This is the maximum number of primary segments that can be running on a host when mirror segments are activated due to a failure. With mirrors arranged in a 4-host block with 8 primary segments per host, for example, a single segment host failure would activate two or three mirror segments on each remaining host in the failed host's block. The `max_acting_primary_segments` value for this configuration is 11 (8 primary segments plus 3 mirrors activated on failure).

This is the calculation for `gp_vmem_protect_limit`. The value should be converted to MB.

\[
gp_vmem_protect_limit = \frac{gp_vmem}{acting_primary_segments}
\]

For scenarios where a large number of workfiles are generated, this is the calculation for `gp_vmem` that accounts for the workfiles.

\[
gp_vmem = \left(\frac{(SWAP + RAM) - (7.5GB + 0.05 \times RAM - (300KB \times total\_\#\_workfiles))}{1.7}\right)
\]

For information about monitoring and managing workfile usage, see the *Greenplum Database Administrator Guide*.

Based on the `gp_vmem` value you can calculate the value for the `vm.overcommit_ratio` operating system kernel parameter. This parameter is set when you configure each Greenplum Database host.

\[
vm.overcommit_ratio = \frac{RAM - (0.026 \times gp_vmem)}{RAM}
\]

**Note:** The default value for the kernel parameter `vm.overcommit_ratio` in Red Hat Enterprise Linux is 50.

For information about the kernel parameter, see the *Greenplum Database Installation Guide*.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>integer</td>
<td>8192</td>
<td>local</td>
</tr>
<tr>
<td></td>
<td></td>
<td>system</td>
</tr>
<tr>
<td></td>
<td></td>
<td>restart</td>
</tr>
</tbody>
</table>
**gp_vmem_protect_segworker_cache_limit**

If a query executor process consumes more than this configured amount, then the process will not be cached for use in subsequent queries after the process completes. Systems with lots of connections or idle processes may want to reduce this number to free more memory on the segments. Note that this is a local parameter and must be set for every segment.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>number of megabytes</td>
<td>500</td>
<td>local system restart</td>
</tr>
</tbody>
</table>

**gp_workfile_compression**

Specifies whether the temporary files created, when a hash aggregation or hash join operation spills to disk, are compressed.

If your Greenplum Database installation uses serial ATA (SATA) disk drives, enabling compression might help to avoid overloading the disk subsystem with IO operations.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>off</td>
<td>master session reload</td>
</tr>
</tbody>
</table>

**gp_workfile_limit_files_per_query**

Sets the maximum number of temporary spill files (also known as workfiles) allowed per query per segment. Spill files are created when executing a query that requires more memory than it is allocated. The current query is terminated when the limit is exceeded.

Set the value to 0 (zero) to allow an unlimited number of spill files. master session reload

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>integer</td>
<td>100000</td>
<td>master session reload</td>
</tr>
</tbody>
</table>

**gp_workfile_limit_per_query**

Sets the maximum disk size an individual query is allowed to use for creating temporary spill files at each segment. The default value is 0, which means a limit is not enforced.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>kilobytes</td>
<td>0</td>
<td>master session reload</td>
</tr>
</tbody>
</table>
gp_workfile_limit_per_segment
Sets the maximum total disk size that all running queries are allowed to use for creating temporary spill files at each segment. The default value is 0, which means a limit is not enforced.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>kilobytes</td>
<td>0</td>
<td>local, system, restart</td>
</tr>
</tbody>
</table>

gpperfmon_port
Sets the port on which all data collection agents communicate with the master.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>integer</td>
<td>8888</td>
<td>master, system, restart</td>
</tr>
</tbody>
</table>

ignore_checksum_failure
Only has effect if data_checksums is enabled.
Greenplum Database uses checksums to prevent loading data that has been corrupted in the file system into memory managed by database processes.

By default, when a checksum verify error occurs when reading a heap data page, Greenplum Database generates an error and prevents the page from being loaded into managed memory. When ignore_checksum_failure is set to on and a checksum verify failure occurs, Greenplum Database generates a warning, and allows the page to be read into managed memory. If the page is then updated it is saved to disk and replicated to the mirror. If the page header is corrupt an error is reported even if this option is enabled.

Warning: Setting ignore_checksum_failure to on may propagate or hide data corruption or lead to other serious problems. However, if a checksum failure has already been detected and the page header is uncorrupted, setting ignore_checksum_failure to on may allow you to bypass the error and recover undamaged tuples that may still be present in the table.

The default setting is off, and it can only be changed by a superuser.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>off</td>
<td>local, system, restart</td>
</tr>
</tbody>
</table>

integer_datetimes
Reports whether PostgreSQL was built with support for 64-bit-integer dates and times.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>on</td>
<td>read only</td>
</tr>
</tbody>
</table>
IntervalStyle

Sets the display format for interval values. The value `sql_standard` produces output matching SQL standard interval literals. The value `postgres` produces output matching PostgreSQL releases prior to 8.4 when the `DateStyle` parameter was set to ISO.

The value `postgres_verbose` produces output matching Greenplum releases prior to 3.3 when the `DateStyle` parameter was set to non-ISO output.

The value `iso_8601` will produce output matching the time interval format with designators defined in section 4.4.3.2 of ISO 8601. See the PostgreSQL 9.4 documentation for more information.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>postgres</td>
<td>postgres</td>
<td>master</td>
</tr>
<tr>
<td>postgres_verbose</td>
<td></td>
<td>session</td>
</tr>
<tr>
<td>sql_standard</td>
<td></td>
<td>reload</td>
</tr>
<tr>
<td>iso_8601</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

joinCollapseLimit

The Postgres Planner will rewrite explicit inner `JOIN` constructs into lists of `FROM` items whenever a list of no more than this many items in total would result. By default, this variable is set the same as `fromCollapseLimit`, which is appropriate for most uses. Setting it to 1 prevents any reordering of inner JOINs. Setting this variable to a value between 1 and `fromCollapseLimit` might be useful to trade off planning time against the quality of the chosen plan (higher values produce better plans).

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>1-n</td>
<td>20</td>
<td>master</td>
</tr>
<tr>
<td></td>
<td></td>
<td>session</td>
</tr>
<tr>
<td></td>
<td></td>
<td>reload</td>
</tr>
</tbody>
</table>

keepWalSegments

For Greenplum Database master mirroring, sets the maximum number of processed WAL segment files that are saved by the by the active Greenplum Database master if a checkpoint operation occurs.

The segment files are used to synchronize the active master on the standby master.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>integer</td>
<td>5</td>
<td>master</td>
</tr>
<tr>
<td></td>
<td></td>
<td>system</td>
</tr>
<tr>
<td></td>
<td></td>
<td>reload</td>
</tr>
<tr>
<td></td>
<td></td>
<td>superuser</td>
</tr>
</tbody>
</table>

krbCaseinsUsers

Sets whether Kerberos user names should be treated case-insensitively. The default is case sensitive (off).
### krb_server_keyfile
Sets the location of the Kerberos server key file.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>path and file name</td>
<td>unset</td>
<td>master system restart</td>
</tr>
</tbody>
</table>

### lc_collate
Reports the locale in which sorting of textual data is done. The value is determined when the Greenplum Database array is initialized.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt;system dependent&gt;</td>
<td></td>
<td>read only</td>
</tr>
</tbody>
</table>

### lc_ctype
Reports the locale that determines character classifications. The value is determined when the Greenplum Database array is initialized.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt;system dependent&gt;</td>
<td></td>
<td>read only</td>
</tr>
</tbody>
</table>

### lc_messages
Sets the language in which messages are displayed. The locales available depends on what was installed with your operating system - use `locale -a` to list available locales. The default value is inherited from the execution environment of the server. On some systems, this locale category does not exist. Setting this variable will still work, but there will be no effect. Also, there is a chance that no translated messages for the desired language exist. In that case you will continue to see the English messages.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt;system dependent&gt;</td>
<td></td>
<td>local system restart</td>
</tr>
</tbody>
</table>

### lc_monetary
Sets the locale to use for formatting monetary amounts, for example with the `to_char` family of functions. The locales available depends on what was installed with your operating system - use `locale -a` to list available locales. The default value is inherited from the execution environment of the server.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt;system dependent&gt;</td>
<td></td>
<td>local system restart</td>
</tr>
</tbody>
</table>
**Value Range** | **Default** | **Set Classifications**
---|---|---
<system dependent> |  | local
|  | system
|  | restart

**lc_numeric**

Sets the locale to use for formatting numbers, for example with the `to_char` family of functions. The locales available depends on what was installed with your operating system - use `locale -a` to list available locales. The default value is inherited from the execution environment of the server.

**Value Range** | **Default** | **Set Classifications**
---|---|---
<system dependent> |  | local
|  | system
|  | restart

**lc_time**

This parameter currently does nothing, but may in the future.

**Value Range** | **Default** | **Set Classifications**
---|---|---
<system dependent> |  | local
|  | system
|  | restart

**listen_addresses**

Specifies the TCP/IP address(es) on which the server is to listen for connections from client applications - a comma-separated list of host names and/or numeric IP addresses. The special entry `*` corresponds to all available IP interfaces. If the list is empty, only UNIX-domain sockets can connect.

**Value Range** | **Default** | **Set Classifications**
---|---|---
localhost, host names, IP addresses, `*` (all available IP interfaces) | `*` | master
|  | system
|  | restart

**local_preload_libraries**

Comma separated list of shared library files to preload at the start of a client session.

**Value Range** | **Default** | **Set Classifications**
---|---|---
 |  | local
|  | system
|  | restart
**lock_timeout**

Abort any statement that waits longer than the specified number of milliseconds while attempting to acquire a lock on a table, index, row, or other database object. The time limit applies separately to each lock acquisition attempt. The limit applies both to explicit locking requests (such as `LOCK TABLE`, or `SELECT FOR UPDATE` without `NOWAIT`) and to implicitly-acquired locks. If `log_min_error_statement` is set to `ERROR` or lower, Greenplum Database logs the statement that timed out. A value of zero (the default) turns off this lock wait monitoring.

Unlike `statement_timeout`, this timeout can only occur while waiting for locks. Note that if `statement_timeout` is nonzero, it is rather pointless to set `lock_timeout` to the same or larger value, since the statement timeout would always trigger first.

Greenplum Database uses the `deadlock_timeout` and `gp_global_deadlock_detector_period` to trigger local and global deadlock detection. Note that if `lock_timeout` is turned on and set to a value smaller than these deadlock detection timeouts, Greenplum Database will abort a statement before it would ever trigger a deadlock check in that session.

**Note:** Setting `lock_timeout` in `postgresql.conf` is not recommended because it would affect all sessions.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>0 - INT_MAX millisecs</td>
<td>0 millisecs</td>
<td>master, session, reload</td>
</tr>
</tbody>
</table>

**log_autostats**

Logs information about automatic `ANALYZE` operations related to `gp_autostats_mode` and `gp_autostats_on_change_threshold`.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>off</td>
<td>master, session, reload, superuser</td>
</tr>
</tbody>
</table>

**log_connections**

This outputs a line to the server log detailing each successful connection. Some client programs, like `psql`, attempt to connect twice while determining if a password is required, so duplicate "connection received" messages do not always indicate a problem.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>off</td>
<td>local, system, restart</td>
</tr>
</tbody>
</table>
**log_disconnections**

This outputs a line in the server log at termination of a client session, and includes the duration of the session.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>off</td>
<td>local</td>
</tr>
<tr>
<td></td>
<td></td>
<td>system</td>
</tr>
<tr>
<td></td>
<td></td>
<td>restart</td>
</tr>
</tbody>
</table>

**log_dispatch_stats**

When set to "on," this parameter adds a log message with verbose information about the dispatch of the statement.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>off</td>
<td>local</td>
</tr>
<tr>
<td></td>
<td></td>
<td>system</td>
</tr>
<tr>
<td></td>
<td></td>
<td>restart</td>
</tr>
</tbody>
</table>

**log_duration**

Causes the duration of every completed statement which satisfies *log_statement* to be logged.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>off</td>
<td>master</td>
</tr>
<tr>
<td></td>
<td></td>
<td>session</td>
</tr>
<tr>
<td></td>
<td></td>
<td>reload</td>
</tr>
<tr>
<td></td>
<td></td>
<td>superuser</td>
</tr>
</tbody>
</table>

**log_error_verbosity**

Controls the amount of detail written in the server log for each message that is logged.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>TERSE</td>
<td>DEFAULT</td>
<td>master</td>
</tr>
<tr>
<td>DEFAULT</td>
<td></td>
<td>session</td>
</tr>
<tr>
<td>VERBOSE</td>
<td></td>
<td>reload</td>
</tr>
<tr>
<td></td>
<td></td>
<td>superuser</td>
</tr>
</tbody>
</table>

**log_executor_stats**

For each query, write performance statistics of the query executor to the server log. This is a crude profiling instrument. Cannot be enabled together with *log_statement_stats*. 
### log_hostname

By default, connection log messages only show the IP address of the connecting host. Turning on this option causes logging of the IP address and host name of the Greenplum Database master. Note that depending on your host name resolution setup this might impose a non-negligible performance penalty.

<table>
<thead>
<tr>
<th>Value Range</th>

<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>off</td>
<td>local</td>
</tr>
<tr>
<td></td>
<td></td>
<td>system</td>
</tr>
<tr>
<td></td>
<td></td>
<td>restart</td>
</tr>
</tbody>
</table>

### log_min_duration_statement

Logs the statement and its duration on a single log line if its duration is greater than or equal to the specified number of milliseconds. Setting this to 0 will print all statements and their durations. -1 disables the feature. For example, if you set it to 250 then all SQL statements that run 250ms or longer will be logged. Enabling this option can be useful in tracking down unoptimized queries in your applications.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>

<td>session</td>
</tr>
<tr>
<td></td>
<td></td>
<td>reload</td>
</tr>
<tr>
<td></td>
<td></td>
<td>superuser</td>
</tr>
</tbody>
</table>

### log_min_error_statement

Controls whether or not the SQL statement that causes an error condition will also be recorded in the server log. All SQL statements that cause an error of the specified level or higher are logged. The default is PANIC (effectively turning this feature off for normal use). Enabling this option can be helpful in tracking down the source of any errors that appear in the server log.
log_min_messages

Controls which message levels are written to the server log. Each level includes all the levels that follow it. The later the level, the fewer messages are sent to the log.

If the Greenplum Database PL/Container extension is installed. This parameter also controls the PL/Container log level. For information about the extension, see PL/Container Language.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>

<tr>
<td></td>
<td></td>
<td>session</td>
</tr>
<tr>
<td></td>
<td></td>
<td>reload</td>
</tr>
<tr>
<td></td>
<td></td>
<td>superuser</td>
</tr>
</tbody>
</table>

**log_planner_stats**

For each query, write performance statistics of the Postgres Planner to the server log. This is a crude profiling instrument. Cannot be enabled together with `log_statement_stats`.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>off</td>
<td>master</td>
</tr>
<tr>
<td></td>
<td></td>
<td>session</td>
</tr>
<tr>
<td></td>
<td></td>
<td>reload</td>
</tr>
<tr>
<td></td>
<td></td>
<td>superuser</td>
</tr>
</tbody>
</table>

**log_rotation_age**

Determines the amount of time Greenplum Database writes messages to the active log file. When this amount of time has elapsed, the file is closed and a new log file is created. Set to zero to disable time-based creation of new log files.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>Any valid time expression (number and unit)</td>
<td>1d</td>
<td>local</td>
</tr>
<tr>
<td></td>
<td></td>
<td>system</td>
</tr>
<tr>
<td></td>
<td></td>
<td>restart</td>
</tr>
</tbody>
</table>

**log_rotation_size**

Determines the size of an individual log file that triggers rotation. When the log file size is equal to or greater than this size, the file is closed and a new log file is created. Set to zero to disable size-based creation of new log files.

The maximum value is INT_MAX/1024. If an invalid value is specified, the default value is used. INT_MAX is the largest value that can be stored as an integer on your system.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>number of kilobytes</td>
<td>1048576</td>
<td>local</td>
</tr>
<tr>
<td></td>
<td></td>
<td>system</td>
</tr>
<tr>
<td></td>
<td></td>
<td>restart</td>
</tr>
</tbody>
</table>

**log_statement**

Controls which SQL statements are logged. DDL logs all data definition commands like CREATE, ALTER, and DROP commands. MOD logs all DDL statements, plus INSERT, UPDATE, DELETE, TRUNCATE, and COPY FROM. PREPARE and EXPLAIN ANALYZE statements are also logged if their contained command is of an appropriate type.
**log_statement_stats**

For each query, write total performance statistics of the query parser, planner, and executor to the server log. This is a crude profiling instrument.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>off</td>
<td>master</td>
</tr>
<tr>
<td></td>
<td></td>
<td>session</td>
</tr>
<tr>
<td></td>
<td></td>
<td>reload</td>
</tr>
<tr>
<td></td>
<td></td>
<td>superuser</td>
</tr>
</tbody>
</table>

**log_temp_files**

Controls logging of temporary file names and sizes. Temporary files can be created for sorts, hashes, temporary query results and spill files. A log entry is made in `pg_log` for each temporary file when it is deleted. Depending on the source of the temporary files, the log entry could be created on either the master and/or segments. A `log_temp_files` value of zero logs all temporary file information, while positive values log only files whose size is greater than or equal to the specified number of kilobytes. The default setting is `-1`, which disables logging. Only superusers can change this setting.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>Integer</td>
<td>-1</td>
<td>local</td>
</tr>
<tr>
<td></td>
<td></td>
<td>system</td>
</tr>
<tr>
<td></td>
<td></td>
<td>restart</td>
</tr>
</tbody>
</table>

**log_timezone**

Sets the time zone used for timestamps written in the log. Unlike `TimeZone`, this value is system-wide, so that all sessions will report timestamps consistently. The default is `unknown`, which means to use whatever the system environment specifies as the time zone.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>string</td>
<td>unknown</td>
<td>local</td>
</tr>
<tr>
<td></td>
<td></td>
<td>system</td>
</tr>
<tr>
<td></td>
<td></td>
<td>restart</td>
</tr>
</tbody>
</table>

**log_truncate_on_rotation**

Truncates (overwrites), rather than appends to, any existing log file of the same name. Truncation will occur only when a new file is being opened due to time-based rotation. For example, using this setting in
combination with a log_filename such as gpseg#-%H.log would result in generating twenty-four hourly log files and then cyclically overwriting them. When off, pre-existing files will be appended to in all cases.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>off</td>
<td>local, system, restart</td>
</tr>
</tbody>
</table>

**maintenance_work_mem**

Specifies the maximum amount of memory to be used in maintenance operations, such as VACUUM and CREATE INDEX. It defaults to 16 megabytes (16MB). Larger settings might improve performance for vacuuming and for restoring database dumps.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>Integer</td>
<td>16</td>
<td>local, system, restart</td>
</tr>
</tbody>
</table>

**max_appendonly_tables**

Sets the maximum number of concurrent transactions that can write to or update append-optimized tables. Transactions that exceed the maximum return an error.

Operations that are counted are INSERT, UPDATE, COPY, and VACUUM operations. The limit is only for in-progress transactions. Once a transaction ends (either aborted or committed), it is no longer counted against this limit.

For operations against a partitioned table, each subpartition (child table) that is an append-optimized table and is changed counts as a single table towards the maximum. For example, a partitioned table p_tbl is defined with three subpartitions that are append-optimized tables p_tbl_a01, p_tbl_a02, and p_tbl_a03. An INSERT or UPDATE command against the partitioned table p_tbl that changes append-optimized tables p_tbl_a01 and p_tbl_a02 is counted as two transactions.

Increasing the limit allocates more shared memory on the master host at server start.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>integer &gt; 0</td>
<td>10000</td>
<td>master, system, restart</td>
</tr>
</tbody>
</table>

**max_connections**

The maximum number of concurrent connections to the database server. In a Greenplum Database system, user client connections go through the Greenplum master instance only. Segment instances should allow 5-10 times the amount as the master. When you increase this parameter, max_prepared_transactions must be increased as well. For more information about limiting concurrent connections, see "Configuring Client Authentication" in the Greenplum Database Administrator Guide.

Increasing this parameter may cause Greenplum Database to request more shared memory. Increasing this parameter might cause Greenplum Database to request more shared memory. See shared_buffers for information about Greenplum server instance shared memory buffers.
### max_files_per_process

Sets the maximum number of simultaneously open files allowed to each server subprocess. If the kernel is enforcing a safe per-process limit, you don’t need to worry about this setting. Some platforms such as BSD, the kernel will allow individual processes to open many more files than the system can really support.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>integer</td>
<td>1000</td>
<td>local</td>
</tr>
<tr>
<td></td>
<td></td>
<td>system</td>
</tr>
<tr>
<td></td>
<td></td>
<td>restart</td>
</tr>
</tbody>
</table>

### max_function_args

Reports the maximum number of function arguments.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>integer</td>
<td>100</td>
<td>read only</td>
</tr>
</tbody>
</table>

### max_identifier_length

Reports the maximum identifier length.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>integer</td>
<td>63</td>
<td>read only</td>
</tr>
</tbody>
</table>

### max_index_keys

Reports the maximum number of index keys.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>integer</td>
<td>32</td>
<td>read only</td>
</tr>
</tbody>
</table>

### max_locks_per_transaction

The shared lock table is created with room to describe locks on `max_locks_per_transaction` * (`max_connections` + `max_prepared_transactions`) objects, so no more than this many distinct objects can be locked at any one time. This is not a hard limit on the number of locks taken by any one transaction, but rather a maximum average value. You might need to raise this value if you have clients that touch many different tables in a single transaction.
max_prepared_transactions

Sets the maximum number of transactions that can be in the prepared state simultaneously. Greenplum uses prepared transactions internally to ensure data integrity across the segments. This value must be at least as large as the value of `max_connections` on the master. Segment instances should be set to the same value as the master.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>integer</td>
<td>128</td>
<td>local</td>
</tr>
<tr>
<td></td>
<td></td>
<td>system</td>
</tr>
<tr>
<td></td>
<td></td>
<td>restart</td>
</tr>
</tbody>
</table>

max_resource_portals_per_transaction

Note: The `max_resource_portals_per_transaction` server configuration parameter is enforced only when resource queue-based resource management is active.

Sets the maximum number of simultaneously open user-declared cursors allowed per transaction. Note that an open cursor will hold an active query slot in a resource queue. Used for resource management.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>integer</td>
<td>250 on master</td>
<td>local</td>
</tr>
<tr>
<td></td>
<td>250 on segments</td>
<td>system</td>
</tr>
<tr>
<td></td>
<td></td>
<td>restart</td>
</tr>
</tbody>
</table>

max_resource_queues

Note: The `max_resource_queues` server configuration parameter is enforced only when resource queue-based resource management is active.

Sets the maximum number of resource queues that can be created in a Greenplum Database system. Note that resource queues are system-wide (as are roles) so they apply to all databases in the system.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>integer</td>
<td>9</td>
<td>master</td>
</tr>
<tr>
<td></td>
<td></td>
<td>system</td>
</tr>
<tr>
<td></td>
<td></td>
<td>restart</td>
</tr>
</tbody>
</table>

max_stack_depth

Specifies the maximum safe depth of the server's execution stack. The ideal setting for this parameter is the actual stack size limit enforced by the kernel (as set by `ulimit -s` or local equivalent), less a safety margin of a megabyte or so. Setting the parameter higher than the actual kernel limit will mean that a runaway recursive function can crash an individual backend process.
### max_statement_mem

Sets the maximum memory limit for a query. Helps avoid out-of-memory errors on a segment host during query processing as a result of setting `statement_mem` too high.

Taking into account the configuration of a single segment host, calculate `max_statement_mem` as follows:

\[
\frac{\text{seghost_physical_memory}}{\text{average_number_concurrent_queries}}
\]

When changing both `max_statement_mem` and `statement_mem`, `max_statement_mem` must be changed first, or listed first in the `postgresql.conf` file.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>number of kilobytes</td>
<td>2MB</td>
<td>local, system, restart</td>
</tr>
</tbody>
</table>

### memory_spill_ratio

**Note:** The `memory_spill_ratio` server configuration parameter is enforced only when resource group-based resource management is active.

Sets the memory usage threshold percentage for memory-intensive operators in a transaction. When a transaction reaches this threshold, it spills to disk.

The default `memory_spill_ratio` percentage is the value defined for the resource group assigned to the currently active role. You can set `memory_spill_ratio` at the session level to selectively set this limit on a per-query basis. For example, if you have a specific query that spills to disk and requires more memory, you may choose to set a larger `memory_spill_ratio` to increase the initial memory allocation.

You can specify an integer percentage value from 0 to 100 inclusive. If you specify a value of 0, Greenplum Database uses the `statement_mem` server configuration parameter value to control the initial query operator memory amount.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>0 - 100</td>
<td>20</td>
<td>master, session, reload</td>
</tr>
</tbody>
</table>

### optimizer

Enables or disables GPORCA when running SQL queries. The default is on. If you disable GPORCA, Greenplum Database uses only the Postgres Planner.
GPORCA co-exists with the Postgres Planner. With GPORCA enabled, Greenplum Database uses GPORCA to generate an execution plan for a query when possible. If GPORCA cannot be used, then the Postgres Planner is used.

The optimizer parameter can be set for a database system, an individual database, or a session or query.

For information about the Postgres Planner and GPORCA, see Querying Data in the Greenplum Database Administrator Guide.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>on</td>
<td>master session reload</td>
</tr>
</tbody>
</table>

optimizer_analyze_root_partition

For a partitioned table, controls whether the ROOTPARTITION keyword is required to collect root partition statistics when the ANALYZE command is run on the table. GPORCA uses the root partition statistics when generating a query plan. The Postgres Planner does not use these statistics.

The default setting for the parameter is on, the ANALYZE command can collect root partition statistics without the ROOTPARTITION keyword. Root partition statistics are collected when you run ANALYZE on the root partition, or when you run ANALYZE on a child leaf partition of the partitioned table and the other child leaf partitions have statistics. When the value is off, you must run ANALYZE ROOTPARTITION to collect root partition statistics.

When the value of the server configuration parameter optimizer is on (the default), the value of this parameter should also be on. For information about collecting table statistics on partitioned tables, see ANALYZE.

For information about the Postgres Planner and GPORCA, see Querying Data in the Greenplum Database Administrator Guide.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>on</td>
<td>master session reload</td>
</tr>
</tbody>
</table>

optimizer_arrayExpansion_threshold

When GPORCA is enabled (the default) and is processing a query that contains a predicate with a constant array, the optimizer_arrayExpansion_threshold parameter limits the optimization process based on the number of constants in the array. If the array in the query predicate contains more than the number elements specified by parameter, GPORCA disables the transformation of the predicate into its disjunctive normal form during query optimization.

The default value is 100.

For example, when GPORCA is executing a query that contains an IN clause with more than 100 elements, GPORCA does not transform the predicate into its disjunctive normal form during query optimization to reduce optimization time consume less memory. The difference in query processing can be seen in the filter condition for the IN clause of the query EXPLAIN plan.
Changing the value of this parameter changes the trade-off between a shorter optimization time and lower memory consumption, and the potential benefits from constraint derivation during query optimization, for example conflict detection and partition elimination.

The parameter can be set for a database system, an individual database, or a session or query.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>Integer &gt; 0</td>
<td>25</td>
<td>master, session, reload</td>
</tr>
</tbody>
</table>

**optimizer_control**

Controls whether the server configuration parameter optimizer can be changed with SET, the RESET command, or the Greenplum Database utility `gpconfig`. If the optimizer_control parameter value is on, users can set the optimizer parameter. If the optimizer_control parameter value is off, the optimizer parameter cannot be changed.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>on</td>
<td>master, system, restart, superuser</td>
</tr>
</tbody>
</table>

**optimizer_cte_inlining_bound**

When GPORCA is enabled (the default), this parameter controls the amount of inlining performed for common table expression (CTE) queries (queries that contain a WHERE clause). The default value, 0, disables inlining.

The parameter can be set for a database system, an individual database, or a session or query.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>Decimal &gt;= 0</td>
<td>0</td>
<td>master, session, reload</td>
</tr>
</tbody>
</table>

**optimizer_enable_associativity**

When GPORCA is enabled (the default), this parameter controls whether the join associativity transform is enabled during query optimization. The transform analyzes join orders. For the default value off, only the GPORCA dynamic programming algorithm for analyzing join orders is enabled. The join associativity transform largely duplicates the functionality of the newer dynamic programming algorithm.

If the value is on, GPORCA can use the associativity transform during query optimization.

The parameter can be set for a database system, an individual database, or a session or query.

For information about GPORCA, see About GPORCA in the Greenplum Database Administrator Guide.
### optimizer_enable_dml

When GPORCA is enabled (the default) and this parameter is `true` (the default), GPORCA attempts to execute DML commands such as `INSERT`, `UPDATE`, and `DELETE`. If GPORCA cannot execute the command, Greenplum Database falls back to the Postgres Planner.

When set to `false`, Greenplum Database always falls back to the Postgres Planner when performing DML commands.

The parameter can be set for a database system, an individual database, or a session or query.

For information about GPORCA, see *About GPORCA* in the *Greenplum Database Administrator Guide*.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>off</td>
<td>master, session, reload</td>
</tr>
</tbody>
</table>

### optimizer_enable_master_only_queries

When GPORCA is enabled (the default), this parameter allows GPORCA to execute catalog queries that run only on the Greenplum Database master. For the default value `off`, only the Postgres Planner can execute catalog queries that run only on the Greenplum Database master.

The parameter can be set for a database system, an individual database, or a session or query.

**Note:** Enabling this parameter decreases performance of short running catalog queries. To avoid this issue, set this parameter only for a session or a query.

For information about GPORCA, see *About GPORCA* in the *Greenplum Database Administrator Guide*.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>true</td>
<td>master, session, reload</td>
</tr>
</tbody>
</table>

### optimizer_force_agg_skew_avoidance

When GPORCA is enabled (the default), this parameter affects the query plan alternatives that GPORCA considers when 3 stage aggregate plans are generated. When the value is `true`, the default, GPORCA considers only 3 stage aggregate plans where the intermediate aggregation uses the `GROUP BY` and `DISTINCT` columns for distribution to reduce the effects of processing skew.

If the value is `false`, GPORCA can also consider a plan that uses `GROUP BY` columns for distribution. These plans might perform poorly when processing skew is present.

For information about GPORCA, see *About GPORCA* in the *Greenplum Database Administrator Guide*. 

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>off</td>
<td>master, session, reload</td>
</tr>
<tr>
<td>Value Range</td>
<td>Default</td>
<td>Set Classifications</td>
</tr>
<tr>
<td>-------------------</td>
<td>---------</td>
<td>---------------------</td>
</tr>
<tr>
<td>Boolean</td>
<td>true</td>
<td>master</td>
</tr>
<tr>
<td></td>
<td></td>
<td>session</td>
</tr>
<tr>
<td></td>
<td></td>
<td>reload</td>
</tr>
</tbody>
</table>

`optimizer_force_multistage_agg`

For the default settings, GPORCA is enabled and this parameter is `false`, GPORCA makes a cost-based choice between a one- or two-stage aggregate plan for a scalar distinct qualified aggregate. When `true`, GPORCA chooses a multi-stage aggregate plan when such a plan alternative is generated.

The parameter can be set for a database system, an individual database, or a session or query.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>true</td>
<td>master</td>
</tr>
<tr>
<td></td>
<td></td>
<td>session</td>
</tr>
<tr>
<td></td>
<td></td>
<td>reload</td>
</tr>
</tbody>
</table>

`optimizer_force_three_stage_scalar_dqa`

For the default settings, GPORCA is enabled and this parameter is `true`, GPORCA chooses a plan with multistage aggregates when such a plan alternative is generated. When the value is `false`, GPORCA makes a cost based choice rather than a heuristic choice.

The parameter can be set for a database system, an individual database, or a session, or query.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>true</td>
<td>master</td>
</tr>
<tr>
<td></td>
<td></td>
<td>session</td>
</tr>
<tr>
<td></td>
<td></td>
<td>reload</td>
</tr>
</tbody>
</table>

`optimizer_join arity_for_associativity_commutativity`

The value is an optimization hint to limit the number of join associativity and join commutativity transformations explored during query optimization. The limit controls the alternative plans that GPORCA considers during query optimization. For example, the default value of 18 is an optimization hint for GPORCA to stop exploring join associativity and join commutativity transformations when an n-ary join operator has more than 18 children during optimization.

For a query with a large number of joins, specifying a lower value improves query performance by limiting the number of alternate query plans that GPORCA evaluates. However, setting the value too low might cause GPORCA to generate a query plan that performs sub-optimally.

This parameter has no effect when the `optimizer_join_order` parameter is set to `query` or `greedy`.

This parameter can be set for a database system or a session.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>integer &gt; 0</td>
<td>18</td>
<td>local</td>
</tr>
<tr>
<td></td>
<td></td>
<td>system</td>
</tr>
<tr>
<td></td>
<td></td>
<td>reload</td>
</tr>
</tbody>
</table>
**optimizer_join_order**

When GPORCA is enabled, this parameter sets the optimization level for join ordering during query optimization by specifying which types of join ordering alternatives to evaluate.

- **query** - Uses the join order specified in the query.
- **greedy** - Evaluates the join order specified in the query and alternatives based on minimum cardinalities of the relations in the joins.
- **exhaustive** - Applies transformation rules to find and evaluate all join ordering alternatives.

The default value is `exhaustive`. Setting this parameter to `query` or `greedy` can generate a suboptimal query plan. However, if the administrator is confident that a satisfactory plan is generated with the `query` or `greedy` setting, query optimization time can be improved by setting the parameter to the lower optimization level.

Setting this parameter to `query` or `greedy` overrides the `optimizer_join_order_threshold` and `optimizer_join_arity_for_associativity_commutativity` parameters.

This parameter can be set for an individual database, a session, or a query.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>query</td>
<td>exhaustive</td>
<td>master</td>
</tr>
<tr>
<td>greedy</td>
<td></td>
<td>session</td>
</tr>
<tr>
<td>exhaustive</td>
<td></td>
<td>reload</td>
</tr>
</tbody>
</table>

**optimizer_join_order_threshold**

When GPORCA is enabled (the default), this parameter sets the maximum number of join children for which GPORCA will use the dynamic programming-based join ordering algorithm. You can set this value for a single query or for an entire session.

This parameter has no effect when the `optimizer_join_query` parameter is set to `query` or `greedy`.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>0 - 12</td>
<td>10</td>
<td>master</td>
</tr>
<tr>
<td></td>
<td></td>
<td>session</td>
</tr>
<tr>
<td></td>
<td></td>
<td>reload</td>
</tr>
</tbody>
</table>

**optimizer_mdcache_size**

Sets the maximum amount of memory on the Greenplum Database master that GPORCA uses to cache query metadata (optimization data) during query optimization. The memory limit session based. GPORCA caches query metadata during query optimization with the default settings: GPORCA is enabled and `optimizer_metadata_caching` is on.

The default value is 16384 (16MB). This is an optimal value that has been determined through performance analysis.

You can specify a value in KB, MB, or GB. The default unit is KB. For example, a value of 16384 is 16384KB. A value of 1GB is the same as 1024MB or 1048576KB. If the value is 0, the size of the cache is not limited.

This parameter can be set for a database system, an individual database, or a session or query.
optimizer_metadata_caching

When GPORCA is enabled (the default), this parameter specifies whether GPORCA caches query metadata (optimization data) in memory on the Greenplum Database master during query optimization. The default for this parameter is on, enable caching. The cache is session based. When a session ends, the cache is released. If the amount of query metadata exceeds the cache size, then old, unused metadata is evicted from the cache.

If the value is off, GPORCA does not cache metadata during query optimization.

This parameter can be set for a database system, an individual database, or a session or query.

The server configuration parameter optimizer_mdcache_size controls the size of the query metadata cache.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>on</td>
<td>master</td>
</tr>
<tr>
<td></td>
<td></td>
<td>session</td>
</tr>
<tr>
<td></td>
<td></td>
<td>reload</td>
</tr>
</tbody>
</table>

optimizer_minidump

GPORCA generates minidump files to describe the optimization context for a given query. The information in the file is not in a format that can be easily used for debugging or troubleshooting. The minidump file is located under the master data directory and uses the following naming format:

Minidump_date_time.mdp

The minidump file contains this query related information:

- Catalog objects including data types, tables, operators, and statistics required by GPORCA
- An internal representation (DXL) of the query
- An internal representation (DXL) of the plan produced by GPORCA
- System configuration information passed to GPORCA such as server configuration parameters, cost and statistics configuration, and number of segments
- A stack trace of errors generated while optimizing the query

Setting this parameter to ALWAYS generates a minidump for all queries. Set this parameter to ONERROR to minimize total optimization time.

For information about GPORCA, see About GPORCA in the Greenplum Database Administrator Guide.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>

<td>master</td>
</tr>
<tr>
<td>ALWAYS</td>
<td></td>
<td>session</td>
</tr>
<tr>
<td></td>
<td></td>
<td>reload</td>
</tr>
</tbody>
</table>
**optimizer_nestloop_factor**

This parameter adds a costing factor to GPORCA to prioritize hash joins instead of nested loop joins during query optimization. The default value of 1024 was chosen after evaluating numerous workloads with uniformly distributed data. 1024 should be treated as the practical upper bound setting for this parameter. If you find the GPORCA selects hash joins more often than it should, reduce the value to shift the costing factor in favor of nested loop joins.

The parameter can be set for a database system, an individual database, or a session or query.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>INT_MAX &gt; 1</td>
<td>1024</td>
<td>master session reload</td>
</tr>
</tbody>
</table>

**optimizer_parallel_union**

When GPORCA is enabled (the default), `optimizer_parallel_union` controls the amount of parallelization that occurs for queries that contain a `UNION` or `UNION ALL` clause.

When the value is `off`, the default, GPORCA generates a query plan where each child of an `APPEND(UNION)` operator is in the same slice as the `APPEND` operator. During query execution, the children are executed in a sequential manner.

When the value is `on`, GPORCA generates a query plan where a redistribution motion node is under an `APPEND(UNION)` operator. During query execution, the children and the parent `APPEND` operator are on different slices, allowing the children of the `APPEND(UNION)` operator to execute in parallel on segment instances.

The parameter can be set for a database system, an individual database, or a session or query.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>boolean</td>
<td>off</td>
<td>master session reload</td>
</tr>
</tbody>
</table>

**optimizer_penalize_skew**

When GPORCA is enabled (the default), this parameter allows GPORCA to penalize the local cost of a HashJoin with a skewed Redistribute Motion as child to favor a Broadcast Motion during query optimization. The default value is `true`.

GPORCA determines there is skew for a Redistribute Motion when the NDV (number of distinct values) is less than the number of segments.

The parameter can be set for a database system, an individual database, or a session or query.

For information about GPORCA, see `About GPORCA` in the *Greenplum Database Administrator Guide*.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>true</td>
<td>master session reload</td>
</tr>
</tbody>
</table>
optimizer_print_missing_stats

When GPORCA is enabled (the default), this parameter controls the display of table column information about columns with missing statistics for a query. The default value is true, display the column information to the client. When the value is false, the information is not sent to the client.

The information is displayed during query execution, or with the EXPLAIN or EXPLAIN ANALYZE commands.

The parameter can be set for a database system, an individual database, or a session.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>true</td>
<td>master</td>
</tr>
<tr>
<td></td>
<td></td>
<td>session</td>
</tr>
<tr>
<td></td>
<td></td>
<td>reload</td>
</tr>
</tbody>
</table>

optimizer_print_optimization_stats

When GPORCA is enabled (the default), this parameter enables logging of GPORCA query optimization statistics for various optimization stages for a query. The default value is off, do not log optimization statistics. To log the optimization statistics, this parameter must be set to on and the parameter client_min_messages must be set to log.

- set optimizer_print_optimization_stats = on;
- set client_min_messages = 'log';

The information is logged during query execution, or with the EXPLAIN or EXPLAIN ANALYZE commands.

This parameter can be set for a database system, an individual database, or a session or query.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>off</td>
<td>master</td>
</tr>
<tr>
<td></td>
<td></td>
<td>session</td>
</tr>
<tr>
<td></td>
<td></td>
<td>reload</td>
</tr>
</tbody>
</table>

optimizer_sort_factor

When GPORCA is enabled (the default), optimizer_sort_factor controls the cost factor to apply to sorting operations during query optimization. The default value 1 specifies the default sort cost factor. The value is a ratio of increase or decrease from the default factor. For example, a value of 2.0 sets the cost factor at twice the default, and a value of 0.5 sets the factor at half the default.

The parameter can be set for a database system, an individual database, or a session or query.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>Decimal &gt; 0</td>
<td>1</td>
<td>master</td>
</tr>
<tr>
<td></td>
<td></td>
<td>session</td>
</tr>
<tr>
<td></td>
<td></td>
<td>reload</td>
</tr>
</tbody>
</table>

optimizer_use_gpdb Allocators

When GPORCA is enabled (the default) and this parameter is true (the default), GPORCA uses Greenplum Database memory management when executing queries. When set to false, GPORCA uses
GPORCA-specific memory management. Greenplum Database memory management allows for faster optimization, reduced memory usage during optimization, and improves GPORCA support of vmem limits when compared to GPORCA-specific memory management.

For information about GPORCA, see About GPORCA in the Greenplum Database Administrator Guide.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>true</td>
<td>master, system, restart</td>
</tr>
</tbody>
</table>

**password_encryption**

When a password is specified in `CREATE USER` or `ALTER USER` without writing either `ENCRYPTED` or `UNENCRYPTED`, this option determines whether the password is to be encrypted.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>on</td>
<td>master, session, reload</td>
</tr>
</tbody>
</table>

**password_hash_algorithm**

Specifies the cryptographic hash algorithm that is used when storing an encrypted Greenplum Database user password. The default algorithm is MD5.

For information about setting the password hash algorithm to protect user passwords, see “Protecting Passwords in Greenplum Database” in the Greenplum Database Administrator Guide.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>MD5</td>
<td>MD5</td>
<td>master, session, reload, superuser</td>
</tr>
<tr>
<td>SHA-256</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**pljava_classpath**

A colon (:) separated list of jar files or directories containing jar files needed for PL/Java functions. The full path to the jar file or directory must be specified, except the path can be omitted for jar files in the `$GPHOME/lib/postgresql/java` directory. The jar files must be installed in the same locations on all Greenplum hosts and readable by the `gpadmin` user.

The `pljava_classpath` parameter is used to assemble the PL/Java classpath at the beginning of each user session. Jar files added after a session has started are not available to that session.

If the full path to a jar file is specified in `pljava_classpath` it is added to the PL/Java classpath. When a directory is specified, any jar files the directory contains are added to the PL/Java classpath. The search does not descend into subdirectories of the specified directories. If the name of a jar file is included in `pljava_classpath` with no path, the jar file must be in the `$GPHOME/lib/postgresql/java` directory.

**Note:** Performance can be affected if there are many directories to search or a large number of jar files.
If `pljava_classpath_insecure` is `false`, setting the `pljava_classpath` parameter requires superuser privilege. Setting the classpath in SQL code will fail when the code is executed by a user without superuser privilege. The `pljava_classpath` parameter must have been set previously by a superuser or in the `postgresql.conf` file. Changing the classpath in the `postgresql.conf` file requires a reload (`gpstop -u`).

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>string</td>
<td></td>
<td>master</td>
</tr>
<tr>
<td></td>
<td></td>
<td>session</td>
</tr>
<tr>
<td></td>
<td></td>
<td>reload</td>
</tr>
<tr>
<td></td>
<td></td>
<td>superuser</td>
</tr>
</tbody>
</table>

**pljava_classpath_insecure**

Controls whether the server configuration parameter `pljava_classpath` can be set by a user without Greenplum Database superuser privileges. When `true`, `pljava_classpath` can be set by a regular user. Otherwise, `pljava_classpath` can be set only by a database superuser. The default is `false`.

**Warning:** Enabling this parameter exposes a security risk by giving non-administrator database users the ability to run unauthorized Java methods.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>false</td>
<td>master</td>
</tr>
<tr>
<td></td>
<td></td>
<td>session</td>
</tr>
<tr>
<td></td>
<td></td>
<td>restart</td>
</tr>
<tr>
<td></td>
<td></td>
<td>superuser</td>
</tr>
</tbody>
</table>

**pljava_statement_cache_size**

Sets the size in KB of the JRE MRU (Most Recently Used) cache for prepared statements.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>number of kilobytes</td>
<td>10</td>
<td>master</td>
</tr>
<tr>

</tr>
<tr>
<td></td>
<td></td>
<td>restart</td>
</tr>
<tr>
<td></td>
<td></td>
<td>superuser</td>
</tr>
</tbody>
</table>

**pljava_release_lingering_savepoints**

If `true`, lingering savepoints used in PL/Java functions will be released on function exit. If `false`, savepoints will be rolled back.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>true</td>
<td>master</td>
</tr>
<tr>
<td></td>
<td></td>
<td>system</td>
</tr>
<tr>
<td></td>
<td></td>
<td>restart</td>
</tr>
<tr>
<td></td>
<td></td>
<td>superuser</td>
</tr>
</tbody>
</table>
**pljava_vmoptions**

Defines the startup options for the Java VM. The default value is an empty string (""").

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>string</td>
<td></td>
<td>master</td>
</tr>
<tr>
<td></td>
<td></td>
<td>system</td>
</tr>
<tr>
<td></td>
<td></td>
<td>reload</td>
</tr>
<tr>
<td></td>
<td></td>
<td>superuser</td>
</tr>
</tbody>
</table>

**port**

The database listener port for a Greenplum instance. The master and each segment has its own port. Port numbers for the Greenplum system must also be changed in the `gp_segment_configuration` catalog. You must shut down your Greenplum Database system before changing port numbers.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>any valid port number</td>
<td>5432</td>
<td>local</td>
</tr>
<tr>
<td></td>
<td></td>
<td>system</td>
</tr>
<tr>
<td></td>
<td></td>
<td>restart</td>
</tr>
</tbody>
</table>

**random_page_cost**

Sets the estimate of the cost of a nonsequentially fetched disk page for the Postgres Planner. This is measured as a multiple of the cost of a sequential page fetch. A higher value makes it more likely a sequential scan will be used, a lower value makes it more likely an index scan will be used.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>floating point</td>
<td>100</td>
<td>master</td>
</tr>
<tr>
<td></td>
<td></td>
<td>session</td>
</tr>
<tr>
<td></td>
<td></td>
<td>reload</td>
</tr>
</tbody>
</table>

**readable_external_table_timeout**

When an SQL query reads from an external table, the parameter value specifies the amount of time in seconds that Greenplum Database waits before cancelling the query when data stops being returned from the external table.

The default value of 0, specifies no time out. Greenplum Database does not cancel the query.

If queries that use gpfdist run a long time and then return the error "intermittent network connectivity issues", you can specify a value for readable_external_table_timeout. If no data is returned by gpfdist for the specified length of time, Greenplum Database cancels the query.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>integer &gt;= 0</td>
<td>0</td>
<td>master</td>
</tr>
<tr>
<td></td>
<td></td>
<td>system</td>
</tr>
<tr>
<td></td>
<td></td>
<td>reload</td>
</tr>
</tbody>
</table>
repl_catchup_within_range

For Greenplum Database master mirroring, controls updates to the active master. If the number of WAL segment files that have not been processed by the walsender exceeds this value, Greenplum Database updates the active master.

If the number of segment files does not exceed the value, Greenplum Database blocks updates to the to allow the walsender process the files. If all WAL segments have been processed, the active master is updated.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>0 - 64</td>
<td>1</td>
<td>master</td>
</tr>

<td></td>
<td>system</td>
</tr>
<tr>
<td></td>
<td></td>
<td>reload</td>
</tr>
<tr>
<td></td>
<td></td>
<td>superuser</td>
</tr>
</tbody>
</table>

replication_timeout

For Greenplum Database master mirroring, sets the maximum time in milliseconds that the walsender process on the active master waits for a status message from the walreceiver process on the standby master. If a message is not received, the walsender logs an error message.

The wal_receiver_status_interval controls the interval between walreceiver status messages.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>

</tbody>
</table>

resource_cleanup_gangs_on_wait

Note: The resource_cleanup_gangs_on_wait server configuration parameter is enforced only when resource queue-based resource management is active.

If a statement is submitted through a resource queue, clean up any idle query executor worker processes before taking a lock on the resource queue.
### resource_select_only

**Note:** The `resource_select_only` server configuration parameter is enforced only when resource queue-based resource management is active.

Sets the types of queries managed by resource queues. If set to on, then `SELECT`, `SELECT INTO`, `CREATE TABLE AS SELECT`, and `DECLARE CURSOR` commands are evaluated. If set to off `INSERT`, `UPDATE`, and `DELETE` commands will be evaluated as well.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>on</td>
<td>master</td>
</tr>
<tr>
<td></td>
<td></td>
<td>system</td>
</tr>
<tr>
<td></td>
<td></td>
<td>restart</td>
</tr>
</tbody>
</table>

### runaway_detector_activation_percent

**Note:** The `runaway_detector_activation_percent` server configuration parameter is enforced only when resource queue-based resource management is active.

Sets the percentage of Greenplum Database vmem memory that triggers the termination of queries. If the percentage of vmem memory that is utilized for a Greenplum Database segment exceeds the specified value, Greenplum Database terminates queries based on memory usage, starting with the query consuming the largest amount of memory. Queries are terminated until the percentage of utilized vmem is below the specified percentage.

Specify the maximum vmem value for active Greenplum Database segment instances with the server configuration parameter `gp_vmem_protect_limit`.

For example, if vmem memory is set to 10GB, and the value of `runaway_detector_activation_percent` is 90 (90%), Greenplum Database starts terminating queries when the utilized vmem memory exceeds 9 GB.

A value of 0 disables the automatic termination of queries based on percentage of vmem that is utilized.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>percentage (integer)</td>
<td>90</td>
<td>local</td>
</tr>
<tr>
<td></td>
<td></td>
<td>system</td>
</tr>
<tr>
<td></td>
<td></td>
<td>restart</td>
</tr>
</tbody>
</table>

### search_path

Specifies the order in which schemas are searched when an object is referenced by a simple name with no schema component. When there are objects of identical names in different schemas, the one found first in the search path is used. The system catalog schema, `pg_catalog`, is always searched, whether it is mentioned in the path or not. When objects are created without specifying a particular target schema, they will be placed in the first schema listed in the search path. The current effective value of the search path can be examined via the SQL function `current_schemas()`. `current_schemas()` shows how the requests appearing in `search_path` were resolved.
### seq_page_cost

For the Postgres Planner, sets the estimate of the cost of a disk page fetch that is part of a series of sequential fetches.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>floating point</td>
<td>1</td>
<td>master, session, reload</td>
</tr>
</tbody>
</table>

### server_encoding

Reports the database encoding (character set). It is determined when the Greenplum Database array is initialized. Ordinarily, clients need only be concerned with the value of `client_encoding`.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt;system dependent&gt;</td>
<td>UTF8</td>
<td>read only</td>
</tr>
</tbody>
</table>

### server_version

Reports the version of PostgreSQL that this release of Greenplum Database is based on.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>string</td>
<td>9.4.20</td>
<td>read only</td>
</tr>
</tbody>
</table>

### server_version_num

Reports the version of PostgreSQL that this release of Greenplum Database is based on as an integer.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>integer</td>
<td>90420</td>
<td>read only</td>
</tr>
</tbody>
</table>

### shared_buffers

Sets the amount of memory a Greenplum Database segment instance uses for shared memory buffers. This setting must be at least 128KB and at least 16KB times `max_connections`.

Each Greenplum Database segment instance calculates and attempts to allocate certain amount of shared memory based on the segment configuration. The value of `shared_buffers` is significant portion of this shared memory calculation, but is not all it. When setting `shared_buffers`, the values for the operating system parameters `SHMMAX` or `SHMALL` might also need to be adjusted.

The operating system parameter `SHMMAX` specifies maximum size of a single shared memory allocation. The value of `SHMMAX` must be greater than this value:

\[
\text{shared_buffers} + \text{other_seg_shmem}
\]
The value of `other_seg_shmem` is the portion the Greenplum Database shared memory calculation that is not accounted for by the `shared_buffers` value. The `other_seg_shmem` value will vary based on the segment configuration.

With the default Greenplum Database parameter values, the value for `other_seg_shmem` is approximately 111MB for Greenplum Database segments and approximately 79MB for the Greenplum Database master.

The operating system parameter `SHMALL` specifies the maximum amount of shared memory on the host. The value of `SHMALL` must be greater than this value:

\[
(\text{num\_instances\_per\_host} \ast (\text{shared\_buffers} + \text{other\_seg\_shmem})) + \text{other\_app\_shared\_mem}
\]

The value of `other_app_shared_mem` is the amount of shared memory that is used by other applications and processes on the host.

When shared memory allocation errors occur, possible ways to resolve shared memory allocation issues are to increase `SHMMAX` or `SHMALL`, or decrease `shared_buffers` or `max_connections`.

See the `Greenplum Database Installation Guide` for information about the Greenplum Database values for the parameters `SHMMAX` and `SHMALL`.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>integer &gt; 16K * max_connections</td>
<td>125MB</td>
<td>local, system, restart</td>
</tr>
</tbody>
</table>

**shared_preload_libraries**

A comma-separated list of shared libraries that are to be preloaded at server start. PostgreSQL procedural language libraries can be preloaded in this way, typically by using the syntax `'$libdir/plXXX'` where XXX is `pgsql`, `perl`, `tcl`, or `python`. By preloading a shared library, the library startup time is avoided when the library is first used. If a specified library is not found, the server will fail to start.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td>local, system, restart</td>
</tr>
</tbody>
</table>

**ssl**

Enables SSL connections.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>off</td>
<td>master, system, restart</td>
</tr>
</tbody>
</table>

**ssl_ciphers**

Specifies a list of SSL ciphers that are allowed to be used on secure connections. See the openssl manual page for a list of supported ciphers.
### standard_conforming_strings

Determines whether ordinary string literals ("...") treat backslashes literally, as specified in the SQL standard. The default value is on. Turn this parameter off to treat backslashes in string literals as escape characters instead of literal backslashes. Applications may check this parameter to determine how string literals are processed. The presence of this parameter can also be taken as an indication that the escape string syntax (E'...') is supported.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>string</td>
<td>ALL</td>
<td>master, system, restart</td>
</tr>
</tbody>
</table>

### statement_mem

Allocates segment host memory per query. The amount of memory allocated with this parameter cannot exceed `max_statement_mem` or the memory limit on the resource queue or resource group through which the query was submitted. If additional memory is required for a query, temporary spill files on disk are used.

If you are using resource groups to control resource allocation in your Greenplum Database cluster:

- Greenplum Database uses `statement_mem` to control query memory usage when the resource group `MEMORY_SPILL_RATIO` is set to 0.
- You can use the following calculation to estimate a reasonable `statement_mem` value:

  ```sql
  rg_perseg_mem = ((RAM * (vm.overcommit_ratio / 100) + SWAP) *
  gp_resource_group_memory_limit) / num_active_primary_segments
  statement_mem = rg_perseg_mem / max_expected_concurrent_queries
  ```

If you are using resource queues to control resource allocation in your Greenplum Database cluster:

- When `gp_resqueue_memory_policy` = auto, `statement_mem` and resource queue memory limits control query memory usage.
- You can use the following calculation to estimate a reasonable `statement_mem` value for a wide variety of situations:

  ```sql
  (gp_vmem_protect_limitGB * .9) / max_expected_concurrent_queries
  ```

For example, with a `gp_vmem_protect_limit` set to 8192MB (8GB) and assuming a maximum of 40 concurrent queries with a 10% buffer, you would use the following calculation to determine the `statement_mem` value:

```
(8GB * .9) / 40 = .18GB = 184MB
```

When changing both `max_statement_mem` and `statement_mem`, `max_statement_mem` must be changed first, or listed first in the `postgresql.conf` file.
<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>number of kilobytes</td>
<td>128MB</td>
<td>master, session, reload</td>
</tr>
</tbody>
</table>

**statement_timeout**

Abort any statement that takes over the specified number of milliseconds. 0 turns off the limitation.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>number of milliseconds</td>
<td>0</td>
<td>master, session, reload</td>
</tr>
</tbody>
</table>

**stats_queue_level**

Note: The `stats_queue_level` server configuration parameter is enforced only when resource queue-based resource management is active.

Collects resource queue statistics on database activity.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>off</td>
<td>master, session, reload</td>
</tr>
</tbody>
</table>

**superuser_reserved_connections**

Determines the number of connection slots that are reserved for Greenplum Database superusers.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>integer &lt; max_connections</td>
<td>3</td>
<td>local, system, restart</td>
</tr>
</tbody>
</table>

**tcp_keepalives_count**

How many keepalives may be lost before the connection is considered dead. A value of 0 uses the system default. If TCP_KEEPCNT is not supported, this parameter must be 0.

Use this parameter for all connections that are not between a primary and mirror segment.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>number of lost keepalives</td>
<td>0</td>
<td>local, system, restart</td>
</tr>
</tbody>
</table>
**tcp_keepalives_idle**

Number of seconds between sending keepalives on an otherwise idle connection. A value of 0 uses the system default. If TCP_KEEPIDLE is not supported, this parameter must be 0.

Use this parameter for all connections that are not between a primary and mirror segment.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>number of seconds</td>
<td>0</td>
<td>local</td>
</tr>
<tr>
<td></td>
<td></td>
<td>system</td>
</tr>
<tr>
<td></td>
<td></td>
<td>restart</td>
</tr>
</tbody>
</table>

**tcp_keepalives_interval**

How many seconds to wait for a response to a keepalive before retransmitting. A value of 0 uses the system default. If TCP_KEEPINTVL is not supported, this parameter must be 0.

Use this parameter for all connections that are not between a primary and mirror segment.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>number of seconds</td>
<td>0</td>
<td>local</td>
</tr>
<tr>
<td></td>
<td></td>
<td>system</td>
</tr>
<tr>
<td></td>
<td></td>
<td>restart</td>
</tr>
</tbody>
</table>

**temp_buffers**

Sets the maximum memory, in blocks, to allow for temporary buffers by each database session. These are session-local buffers used only for access to temporary tables. The setting can be changed within individual sessions, but only up until the first use of temporary tables within a session. The cost of setting a large value in sessions that do not actually need a lot of temporary buffers is only a buffer descriptor for each block, or about 64 bytes, per increment. However if a buffer is actually used, an additional 32768 bytes will be consumed.

You can set this parameter to the number of 32K blocks (for example, 1024 to allow 32MB for buffers), or specify the maximum amount of memory to allow (for example '48MB' for 1536 blocks). The gpconfig utility and SHOW command report the maximum amount of memory allowed for temporary buffers.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>integer</td>
<td>1024 (32MB)</td>
<td>master</td>
</tr>
<tr>
<td></td>
<td></td>
<td>session</td>
</tr>
<tr>
<td></td>
<td></td>
<td>reload</td>
</tr>
</tbody>
</table>

**temp_tablespaces**

Specifies tablespaces in which to create temporary objects (temp tables and indexes on temp tables) when a CREATE command does not explicitly specify a tablesapce. Temporary files for purposes such as sorting large data sets are also created in these tablespaces.

The value is a comma-separated list of names of tablespaces. When there is more than one name in the list, Greenplum chooses a random member of the list each time a temporary object is to be created; except that within a transaction, successively created temporary objects are placed in successive tablespaces.
from the list. If the selected element of the list is an empty string, Greenplum automatically uses the default tablespace of the current database instead.

When `temp_tablespaces` is set interactively, specifying a nonexistent tablespace is an error, as is specifying a tablespace for which the user does not have `CREATE` privilege. However, when using a previously set value, nonexistent tablespaces are ignored, as are tablespaces for which the user lacks `CREATE` privilege. In particular, this rule applies when using a value set in `postgresql.conf`.

The default value is an empty string, which results in all temporary objects being created in the default tablespace of the current database.

See also `default_tablespace`.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>one or more tablespace names</td>
<td>unset</td>
<td>master, session,</td>
</tr>
<tr>
<td></td>
<td></td>
<td>reload</td>
</tr>
</tbody>
</table>

### TimeZone

Sets the time zone for displaying and interpreting time stamps. The default is to use whatever the system environment specifies as the time zone. See *Date/Time Keywords* in the PostgreSQL documentation.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>time zone abbreviation</td>
<td></td>
<td>local, restart</td>
</tr>
</tbody>
</table>

### timezone_abbreviations

Sets the collection of time zone abbreviations that will be accepted by the server for date time input. The default is `Default`, which is a collection that works in most of the world. `Australia` and `India`, and other collections can be defined for a particular installation. Possible values are names of configuration files stored in `$GPHOME/share/postgresql/timezonesets/`.

To configure Greenplum Database to use a custom collection of timezones, copy the file that contains the timezone definitions to the directory `$GPHOME/share/postgresql/timezonesets/` on the Greenplum Database master and segment hosts. Then set value of the server configuration parameter `timezone_abbreviations` to the file. For example, to use a file `custom` that contains the default timezones and the WIB (Waktu Indonesia Barat) timezone.

1. Copy the file `Default` from the directory `$GPHOME/share/postgresql/timezonesets/` the file `custom`. Add the WIB timezone information from the file `Asia.txt` to the `custom`.
2. Copy the file `custom` to the directory `$GPHOME/share/postgresql/timezonesets/` on the Greenplum Database master and segment hosts.
3. Set value of the server configuration parameter `timezone_abbreviations` to `custom`.
4. Reload the server configuration file (`gpstop -u`).

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>string</td>
<td>Default</td>
<td>master, session,</td>
</tr>
<tr>
<td></td>
<td></td>
<td>reload</td>
</tr>
</tbody>
</table>
**track_activity_query_size**
Sets the maximum length limit for the query text stored in `query` column of the system catalog view `pg_stat_activity`. The minimum length is 1024 characters.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>integer</td>
<td>1024</td>
<td>local</td>
</tr>
<tr>
<td></td>
<td></td>
<td>system</td>
</tr>
<tr>
<td></td>
<td></td>
<td>restart</td>
</tr>
</tbody>
</table>

**transaction_isolation**
Sets the current transaction's isolation level.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>read committed</td>
<td>read committed</td>
<td>master</td>
</tr>
<tr>
<td>serializable</td>
<td></td>
<td>session</td>
</tr>
<tr>
<td></td>
<td></td>
<td>reload</td>
</tr>
</tbody>
</table>

**transaction_read_only**
Sets the current transaction's read-only status.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>off</td>
<td>master</td>
</tr>
<tr>
<td></td>
<td></td>
<td>session</td>
</tr>
<tr>
<td></td>
<td></td>
<td>reload</td>
</tr>
</tbody>
</table>

**transform_null_equals**
When on, expressions of the form `expr = NULL` (or `NULL = expr`) are treated as `expr IS NULL`, that is, they return true if `expr` evaluates to the null value, and false otherwise. The correct SQL-spec-compliant behavior of `expr = NULL` is to always return null (unknown).

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>off</td>
<td>master</td>
</tr>
<tr>
<td></td>
<td></td>
<td>session</td>
</tr>
<tr>
<td></td>
<td></td>
<td>reload</td>
</tr>
</tbody>
</table>

**unix_socket_directory**
Specifies the directory of the UNIX-domain socket on which the server is to listen for connections from client applications.
<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>directory path</td>
<td>unset</td>
<td>local system restart</td>
</tr>
</tbody>
</table>

**unix_socket_group**

Sets the owning group of the UNIX-domain socket. By default this is an empty string, which uses the default group for the current user.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>UNIX group name</td>
<td>unset</td>
<td>local system restart</td>
</tr>
</tbody>
</table>

**unix_socket_permissions**

Sets the access permissions of the UNIX-domain socket. UNIX-domain sockets use the usual UNIX file system permission set. Note that for a UNIX-domain socket, only write permission matters.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>numeric UNIX file permission mode (as accepted by the <code>chmod</code> or <code>umask</code> commands)</td>
<td>511</td>
<td>local system restart</td>
</tr>
</tbody>
</table>

**update_process_title**

Enables updating of the process title every time a new SQL command is received by the server. The process title is typically viewed by the `ps` command.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>on</td>
<td>local system restart</td>
</tr>
</tbody>
</table>

**vacuum_cost_delay**

The length of time that the process will sleep when the cost limit has been exceeded. 0 disables the cost-based vacuum delay feature.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>milliseconds &lt; 0 (in multiples of 10)</td>
<td>0</td>
<td>local system restart</td>
</tr>
</tbody>
</table>
**vacuum_cost_limit**

The accumulated cost that will cause the vacuuming process to sleep.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>integer &gt; 0</td>
<td>200</td>
<td>local system restart</td>
</tr>
</tbody>
</table>

**vacuum_cost_page_dirty**

The estimated cost charged when vacuum modifies a block that was previously clean. It represents the extra I/O required to flush the dirty block out to disk again.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>integer &gt; 0</td>
<td>20</td>
<td>local system restart</td>
</tr>
</tbody>
</table>

**vacuum_cost_page_hit**

The estimated cost for vacuuming a buffer found in the shared buffer cache. It represents the cost to lock the buffer pool, lookup the shared hash table and scan the content of the page.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>integer &gt; 0</td>
<td>1</td>
<td>local system restart</td>
</tr>
</tbody>
</table>

**vacuum_cost_page_miss**

The estimated cost for vacuuming a buffer that has to be read from disk. This represents the effort to lock the buffer pool, lookup the shared hash table, read the desired block in from the disk and scan its content.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>integer &gt; 0</td>
<td>10</td>
<td>local system restart</td>
</tr>
</tbody>
</table>

**vacuum_freeze_min_age**

Specifies the cutoff age (in transactions) that VACUUM should use to decide whether to replace transaction IDs with FrozenXID while scanning a table.

For information about VACUUM and transaction ID management, see "Managing Data" in the *Greenplum Database Administrator Guide* and the *PostgreSQL documentation*. 
**validate_previous_free_tid**

Enables a test that validates the free tuple ID (TID) list. The list is maintained and used by Greenplum Database. Greenplum Database determines the validity of the free TID list by ensuring the previous free TID of the current free tuple is a valid free tuple. The default value is `true`, enable the test.

If Greenplum Database detects a corruption in the free TID list, the free TID list is rebuilt, a warning is logged, and a warning is returned by queries for which the check failed. Greenplum Database attempts to execute the queries.

**Note:** If a warning is returned, please contact Pivotal Support.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>integer 0-100000000000</td>
<td>100000000</td>
<td>local system restart</td>
</tr>
</tbody>
</table>

**verify_gpfdists_cert**

When a Greenplum Database external table is defined with the `gpfdists` protocol to use SSL security, this parameter controls whether SSL certificate authentication is enabled. The default is `true`, SSL authentication is enabled when Greenplum Database communicates with the `gpfdist` utility to either read data from or write data to an external data source.

The value `false` disables SSL certificate authentication. These SSL exceptions are ignored:

- The self-signed SSL certificate that is used by `gpfdist` is not trusted by Greenplum Database.
- The host name contained in the SSL certificate does not match the host name that is running `gpfdist`.

You can set the value to `false` to disable authentication when testing the communication between the Greenplum Database external table and the `gpfdist` utility that is serving the external data.

**Warning:** Disabling SSL certificate authentication exposes a security risk by not validating the `gpfdists` SSL certificate.

For information about the `gpfdists` protocol, see `gpfdists:// Protocol`. For information about running the `gpfdist` utility, see `gpfdist`.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>true</td>
<td>master session reload</td>
</tr>
</tbody>
</table>

**vmem_process_interrupt**

Enables checking for interrupts before reserving vmem memory for a query during Greenplum Database query execution. Before reserving further vmem for a query, check if the current session for the query
has a pending query cancellation or other pending interrupts. This ensures more responsive interrupt processing, including query cancellation requests. The default is `off`.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td><code>off</code></td>
<td>master, session, reload</td>
</tr>
</tbody>
</table>

### `wal_receiver_status_interval`

For Greenplum Database master mirroring, sets the interval in seconds between `walreceiver` process status messages that are sent to the active master. Under heavy loads, the time might be longer.

The value of `replication_timeout` controls the time that the `walsender` process waits for a `walreceiver` message.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>integer 0- INT_MAX/1000</td>
<td>10 sec</td>
<td>master, system, reload, superuser</td>
</tr>
</tbody>
</table>

### `writable_external_table_bufsize`

Size of the buffer (in KB) that Greenplum Database uses for network communication, such as the `gpfdist` utility and external web tables (that use http). Greenplum Database stores data in the buffer before writing the data out. For information about `gpfdist`, see the Greenplum Database Utility Guide.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>integer 32 - 131072 (32KB - 128MB)</td>
<td>64</td>
<td>local, session, reload</td>
</tr>
</tbody>
</table>

### `xid_stop_limit`

The number of transaction IDs prior to the ID where transaction ID wraparound occurs. When this limit is reached, Greenplum Database stops creating new transactions to avoid data loss due to transaction ID wraparound.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>integer 10000000 - 2000000000</td>
<td>1000000000</td>
<td>local, system, restart</td>
</tr>
</tbody>
</table>

### `xid_warn_limit`

The number of transaction IDs prior to the limit specified by `xid_stop_limit`. When Greenplum Database reaches this limit, it issues a warning to perform a VACUUM operation to avoid data loss due to transaction ID wraparound.
xmlbinary

Specifies how binary values are encoded in XML data. For example, when `bytea` values are converted to XML. The binary data can be converted to either base64 encoding or hexadecimal encoding. The default is base64.

The parameter can be set for a database system, an individual database, or a session.

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>integer 10000000 - 2000000000</td>
<td>500000000</td>
<td>local</td>
</tr>
<tr>
<td></td>
<td></td>
<td>system</td>
</tr>
<tr>
<td></td>
<td></td>
<td>restart</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>base64</td>
<td>base64</td>
<td>master</td>
</tr>
<tr>
<td>hex</td>
<td></td>
<td>session</td>
</tr>
<tr>
<td></td>
<td></td>
<td>reload</td>
</tr>
</tbody>
</table>

xmloption

Specifies whether XML data is to be considered as an XML document (document) or XML content fragment (content) for operations that perform implicit parsing and serialization. The default is content.

This parameter affects the validation performed by `xml_is_well_formed()`. If the value is document, the function checks for a well-formed XML document. If the value is content, the function checks for a well-formed XML content fragment.

**Note:** An XML document that contains a document type declaration (DTD) is not considered a valid XML content fragment. If `xmloption` set to content, XML that contains a DTD is not considered valid XML.

To cast a character string that contains a DTD to the `xml` data type, use the `xmlparse` function with the document keyword, or change the `xmloption` value to document.

The parameter can be set for a database system, an individual database, or a session. The SQL command to set this option for a session is also available in Greenplum Database.

```sql
SET XML OPTION { DOCUMENT | CONTENT }
```

<table>
<thead>
<tr>
<th>Value Range</th>
<th>Default</th>
<th>Set Classifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>document</td>
<td>content</td>
<td>master</td>
</tr>
<tr>
<td>content</td>
<td></td>
<td>session</td>
</tr>
<tr>
<td></td>
<td></td>
<td>reload</td>
</tr>
</tbody>
</table>
System Catalogs

This reference describes the Greenplum Database system catalog tables and views. System tables prefixed with `gp_` relate to the parallel features of Greenplum Database. Tables prefixed with `pg_` are either standard PostgreSQL system catalog tables supported in Greenplum Database, or are related to features Greenplum that provides to enhance PostgreSQL for data warehousing workloads. Note that the global system catalog for Greenplum Database resides on the master instance.

**Warning:** Changes to Pivotal Greenplum Database system catalog tables or views are not supported. If a catalog table or view is changed by the customer, the Pivotal Greenplum Database cluster is not supported. The cluster must be reinitialized and restored by the customer.

**System Views**

Greenplum Database provides the following system views not available in PostgreSQL.

• `gp_distributed_log`
• `gp_distributed_xacts`
• `gpadgetbase`
• `gp_resgroup_config`
• `gp_resgroup_status`
• `gp_resgroup_status_per_host`
• `gp_resgroup_status_per_segment`
• `gp_resqueue_status`
• `gp_transaction_log`
• `gpexpand.expansion_progress`
• `pg_max_external_files`
• `pg_partition_columns`
• `pg_partition_templates`
• `pg_partitions`
• `pg_resqueue_attributes`
• `pg_resqueue_status` (Deprecated. Use `gp_toolkit.gp_resqueue_status`.)
- *pg_stat_activity*
- *pg_stat_replication*
- *pg_stat_resqueues*
- *session_level_memory_consumption* (See “Viewing Session Memory Usage Information” in the [Greenplum Database Administrator Guide](#).

For more information about the standard system views supported in PostgreSQL and Greenplum Database, see the following sections of the PostgreSQL documentation:

- *System Views*
- *Statistics Collector Views*
- *The Information Schema*

**System Catalogs Definitions**

System catalog table and view definitions in alphabetical order.

**foreign_data_wrapper_options**

The *foreign_data_wrapper_options* view contains all of the options defined for foreign-data wrappers in the current database. Greenplum Database displays only those foreign-data wrappers to which the current user has access (by way of being the owner or having some privilege).

**Table 115: foreign_data_wrapper_options**

<table>
<thead>
<tr>
<th>column</th>
<th>type</th>
<th>references</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>
<td>foreign_data_wrapper_catalog</td>
<td>sql_identifier</td>
<td></td>
<td>Name of the database in which the foreign-data wrapper is defined (always the current database).</td>
</tr>
<tr>
<td>foreign_data_wrapper_name</td>
<td>sql_identifier</td>
<td></td>
<td>Name of the foreign-data wrapper.</td>
</tr>
<tr>
<td>option_name</td>
<td>sql_identifier</td>
<td></td>
<td>Name of an option.</td>
</tr>
<tr>
<td>option_value</td>
<td>character_data</td>
<td></td>
<td>Value of the option.</td>
</tr>
</tbody>
</table>

**foreign_data_wrappers**

The *foreign_data_wrappers* view contains all foreign-data wrappers defined in the current database. Greenplum Database displays only those foreign-data wrappers to which the current user has access (by way of being the owner or having some privilege).

**Table 116: foreign_data_wrappers**

<table>
<thead>
<tr>
<th>column</th>
<th>type</th>
<th>references</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>
<td>foreign_data_wrapper_catalog</td>
<td>sql_identifier</td>
<td></td>
<td>Name of the database in which the foreign-data wrapper is defined (always the current database).</td>
</tr>
<tr>
<td>foreign_data_wrapper_name</td>
<td>sql_identifier</td>
<td></td>
<td>Name of the foreign-data wrapper.</td>

<td>character_data</td>
<td></td>
<td>File name of the library that implements this foreign-data wrapper.</td>
</tr>
<tr>
<td>foreign_data_wrapper_language</td>
<td>character_data</td>
<td></td>
<td>Language used to implement the foreign-data wrapper.</td>
</tr>
</tbody>
</table>

**foreign_server_options**

The `foreign_server_options` view contains all of the options defined for foreign servers in the current database. Greenplum Database displays only those foreign servers to which the current user has access (by way of being the owner or having some privilege).

Table 117: foreign_server_options

<table>
<thead>
<tr>
<th>column</th>
<th>type</th>
<th>references</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>
<td>foreign_server_catalog</td>
<td>sql_identifier</td>
<td></td>
<td>Name of the database in which the foreign server is defined (always the current database).</td>

<td>sql_identifier</td>
<td></td>
<td>Name of the foreign server.</td>
</tr>
<tr>
<td>foreign_data_wrapper_catalog</td>
<td>sql_identifier</td>
<td></td>
<td>Name of the database in which the foreign-data wrapper used by the foreign server is defined (always the current database).</td>
</tr>
</tbody>
</table>
## foreign_table_options

The `foreign_table_options` view contains all of the options defined for foreign tables in the current database. Greenplum Database displays only those foreign tables to which the current user has access (by way of being the owner or having some privilege).

**Table 119: foreign_table_options**

<table>
<thead>
<tr>
<th>column</th>
<th>type</th>
<th>references</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>
<td>foreign_table_catalog</td>
<td>sql_identifier</td>
<td></td>
<td>Name of the database in which the foreign table is defined (always the current database).</td>

<td>Value of the option.</td>
</tr>
</tbody>
</table>

## foreign_tables

The `foreign_tables` view contains all foreign tables defined in the current database. Greenplum Database displays only those foreign tables to which the current user has access (by way of being the owner or having some privilege).

**Table 120: foreign_tables**

<table>
<thead>
<tr>
<th>column</th>
<th>type</th>
<th>references</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>
<td>foreign_table_catalog</td>
<td>sql_identifier</td>
<td></td>
<td>Name of the database in which the foreign table is defined (always the current database).</td>
</tr>
</tbody>
</table>
column | type | references | description |
-------|------|------------|-------------|
foreign_table_schema | sql_identifier | | Name of the schema that contains the foreign table. |
foreign_table_name | sql_identifier | | Name of the foreign table. |
foreign_server_catalog | sql_identifier | | Name of the database in which the foreign server is defined (always the current database). |
foreign_server_name | sql_identifier | | Name of the foreign server. |

gp_configuration_history
The gp_configuration_history table contains information about system changes related to fault detection and recovery operations. The fts_probe process logs data to this table, as do certain related management utilities such as gprecoverseg and gpinitsystem. For example, when you add a new segment and mirror segment to the system, records for these events are logged to gp_configuration_history.

The event descriptions stored in this table may be helpful for troubleshooting serious system issues in collaboration with Pivotal Support technicians.

This table is populated only on the master. This table is defined in the pg_global tablespace, meaning it is globally shared across all databases in the system.

Table 121: pg_catalog.gp_configuration_history

column | type | references | description |
-------|------|------------|-------------|
time | timestamp with time zone | | Timestamp for the event recorded. |
dbid | smallint | gp_segment_configuration.dbid | System-assigned ID. The unique identifier of a segment (or master) instance. |
desc | text | | Text description of the event. |

For information about gprecoverseg and gpinitsystem, see the Greenplum Database Utility Guide.

gp_distributed_log
The gp_distributed_log view contains status information about distributed transactions and their associated local transactions. A distributed transaction is a transaction that involves modifying data on the segment instances. Greenplum's distributed transaction manager ensures that the segments stay in synch. This view allows you to see the status of distributed transactions.
Table 122: `pg_catalog.gp_distributed_log`

<table>
<thead>
<tr>
<th>column</th>
<th>type</th>
<th>references</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>
<td>segment_id</td>
<td>smallint</td>
<td><code>gp_segment_configuration.content</code></td>
<td>The content id if the segment. The master is always -1 (no content).</td>
</tr>
<tr>
<td>dbid</td>
<td>small_int</td>
<td><code>gp_segment_configuration.dbid</code></td>
<td>The unique id of the segment instance.</td>
</tr>
<tr>
<td>distributed_xid</td>
<td>xid</td>
<td></td>
<td>The global transaction id.</td>
</tr>
<tr>
<td>distributed_id</td>
<td>text</td>
<td></td>
<td>A system assigned ID for a distributed transaction.</td>
</tr>
<tr>
<td>status</td>
<td>text</td>
<td></td>
<td>The status of the distributed transaction (Committed or Aborted).</td>
</tr>
<tr>
<td>local_transaction</td>
<td>xid</td>
<td></td>
<td>The local transaction ID.</td>
</tr>
</tbody>
</table>

**gp_distributed_xacts**

The `gp_distributed_xacts` view contains information about Greenplum Database distributed transactions. A distributed transaction is a transaction that involves modifying data on the segment instances. Greenplum’s distributed transaction manager ensures that the segments stay in synch. This view allows you to see the currently active sessions and their associated distributed transactions.

Table 123: `pg_catalog.gp_distributed_xacts`

<table>
<thead>
<tr>
<th>column</th>
<th>type</th>
<th>references</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>
<td>distributed_xid</td>
<td>xid</td>
<td></td>
<td>The transaction ID used by the distributed transaction across the Greenplum Database array.</td>
</tr>
<tr>
<td>distributed_id</td>
<td>text</td>
<td></td>
<td>The distributed transaction identifier. It has 2 parts — a unique timestamp and the distributed transaction number.</td>
</tr>
<tr>
<td>state</td>
<td>text</td>
<td></td>
<td>The current state of this session with regards to distributed transactions.</td>
</tr>
<tr>
<td>gp_session_id</td>
<td>int</td>
<td></td>
<td>The ID number of the Greenplum Database session associated with this transaction.</td>
</tr>
<tr>
<td>column</td>
<td>type</td>
<td>references</td>
<td>description</td>
</tr>
<tr>
<td>------------------------</td>
<td>---------</td>
<td>------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>xmin_distributed _ snapshot</td>
<td>xid</td>
<td></td>
<td>The minimum distributed transaction number found among all open transactions when this transaction was started. It is used for MVCC distributed snapshot purposes.</td>
</tr>
</tbody>
</table>

### gp_distribution_policy

The **gp_distribution_policy** table contains information about Greenplum Database tables and their policy for distributing table data across the segments. This table is populated only on the master. This table is not globally shared, meaning each database has its own copy of this table.

**Table 124: pg_catalog.gp_distribution_policy**

<table>
<thead>
<tr>
<th>column</th>
<th>type</th>
<th>references</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>
<td>localoid</td>
<td>oid</td>
<td>pg_class.oid</td>
<td>The table object identifier (OID).</td>
</tr>
<tr>
<td>policytype</td>
<td>char</td>
<td></td>
<td>The table distribution policy:</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>• p - Partitioned policy. Table data is distributed among segment instances.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>• r - Replicated policy. Table data is replicated on each segment instance.</td>
</tr>
<tr>
<td>numsegments</td>
<td>integer</td>
<td></td>
<td>The number of segment instances on which the table data is distributed.</td>
</tr>
<tr>
<td>distkey</td>
<td>int2vector</td>
<td>pg_attribute.attnum</td>
<td>The column number(s) of the distribution column(s).</td>
</tr>
<tr>
<td>distclass</td>
<td>oidvector</td>
<td>pg_opclass.oid</td>
<td>The operator class identifier(s) of the distribution column(s).</td>
</tr>
</tbody>
</table>

### gpexpand.expansion_progress

The **gpexpand.expansion_progress** view contains information about the status of a system expansion operation. The view provides calculations of the estimated rate of table redistribution and estimated time to completion.

Status for specific tables involved in the expansion is stored in **gpexpand.status_detail**.
Table 125: gpexpand.expansion_progress

<table>
<thead>
<tr>
<th>column</th>
<th>type</th>
<th>references</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>text</td>
<td></td>
<td>Name for the data field provided. Includes: Bytes Left Bytes Done Estimated Expansion Rate Estimated Time to Completion Tables Expanded Tables Left</td>
</tr>
<tr>
<td>value</td>
<td>text</td>
<td></td>
<td>The value for the progress data. For example: Estimated Expansion Rate - 9.75667095996092 MB/s</td>
</tr>
</tbody>
</table>

gpexpand.status

The gpexpand.status table contains information about the status of a system expansion operation. Status for specific tables involved in the expansion is stored in gpexpand.status_detail.

In a normal expansion operation it is not necessary to modify the data stored in this table.

Table 126: gpexpand.status

<table>
<thead>
<tr>
<th>column</th>
<th>type</th>
<th>references</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>
<td>status</td>
<td>text</td>
<td></td>
<td>Tracks the status of an expansion operation. Valid values are: SETUP SETUP DONE EXPANSION STARTED EXPANSION STOPPED COMPLETED</td>
</tr>
<tr>
<td>updated</td>
<td>timestamp without time zone</td>
<td></td>
<td>Timestamp of the last change in status.</td>
</tr>
</tbody>
</table>

gpexpand.status_detail

The gpexpand.status_detail table contains information about the status of tables involved in a system expansion operation. You can query this table to determine the status of tables being expanded, or to view the start and end time for completed tables.
This table also stores related information about the table such as the oid and disk size. Overall status information for the expansion is stored in `gpexpand.status`.

In a normal expansion operation it is not necessary to modify the data stored in this table.

Table 127: `gpexpand.status_detail`

<table>
<thead>
<tr>
<th>column</th>
<th>type</th>
<th>references</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dbname</td>
<td>text</td>
<td></td>
<td>Name of the database to which the table belongs.</td>
</tr>
<tr>
<td>fq_name</td>
<td>text</td>
<td></td>
<td>Fully qualified name of the table.</td>
</tr>
<tr>
<td>table_oid</td>
<td>oid</td>
<td></td>
<td>OID of the table.</td>
</tr>
<tr>
<td>root_partition_name</td>
<td>text</td>
<td></td>
<td>For a partitioned table, the name of the root partition. Otherwise, None.</td>
</tr>
<tr>
<td>rank</td>
<td>int</td>
<td></td>
<td>Rank determines the order in which tables are expanded. The expansion utility will sort on rank and expand the lowest-ranking tables first.</td>
</tr>
<tr>
<td>external_writable</td>
<td>boolean</td>
<td></td>
<td>Identifies whether or not the table is an external writable table. (External writable tables require a different syntax to expand).</td>
</tr>
<tr>
<td>status</td>
<td>text</td>
<td></td>
<td>Status of expansion for this table. Valid values are:</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>NOT STARTED</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>IN PROGRESS</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>FINISHED</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>NO LONGER EXISTS</td>
</tr>
<tr>
<td>expansion_started</td>
<td>timestamp without timezone</td>
<td></td>
<td>Timestamp for the start of the expansion of this table. This field is only populated after a table is successfully expanded.</td>
</tr>
<tr>
<td>expansion_finished</td>
<td>timestamp without timezone</td>
<td></td>
<td>Timestamp for the completion of expansion of this table.</td>
</tr>
</tbody>
</table>
source_bytes

The size of disk space associated with the source table. Due to table bloat in heap tables and differing numbers of segments after expansion, it is not expected that the final number of bytes will equal the source number. This information is tracked to help provide progress measurement to aid in duration estimation for the end-to-end expansion operation.

---

gp_fastsequence

The gp_fastsequence table contains information about append-optimized and column-oriented tables. The last_sequence value indicates maximum row number currently used by the table.

Table 128: pg_catalog.gp_fastsequence

<table>
<thead>
<tr>
<th>column</th>
<th>type</th>
<th>references</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>
<td>objid</td>
<td>oid</td>
<td>pg_class.oid</td>
<td>Object id of the pg_aoseg.pg_aocsseg_* table used to track append-optimized file segments.</td>
</tr>
<tr>
<td>objmod</td>
<td>bigint</td>
<td></td>
<td>Object modifier.</td>
</tr>
<tr>
<td>last_sequence</td>
<td>bigint</td>
<td></td>
<td>The last sequence number used by the object.</td>
</tr>
</tbody>
</table>

---

gp_id

The gp_id system catalog table identifies the Greenplum Database system name and number of segments for the system. It also has local values for the particular database instance (segment or master) on which the table resides. This table is defined in the pg_global tablespace, meaning it is globally shared across all databases in the system.

Table 129: pg_catalog.gp_id

<table>
<thead>
<tr>
<th>column</th>
<th>type</th>
<th>references</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>
<td>gpname</td>
<td>name</td>
<td></td>
<td>The name of this Greenplum Database system.</td>
</tr>
<tr>
<td>column</td>
<td>type</td>
<td>references</td>
<td>description</td>
</tr>
<tr>
<td>------------</td>
<td>---------</td>
<td>--------------------------</td>
<td>-------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>numsegments</td>
<td>integer</td>
<td></td>
<td>The number of segments in the Greenplum Database system.</td>
</tr>
<tr>
<td>dbid</td>
<td>integer</td>
<td></td>
<td>The unique identifier of this segment (or master) instance.</td>
</tr>
<tr>
<td>content</td>
<td>integer</td>
<td></td>
<td>The ID for the portion of data on this segment instance. A primary and its mirror will have the same content ID. For a segment the value is from 0-N-1, where N is the number of segments in Greenplum Database. For the master, the value is -1.</td>
</tr>
</tbody>
</table>

### gp_pgdatabase

The `gp_pgdatabase` view shows status information about the Greenplum segment instances and whether they are acting as the mirror or the primary. This view is used internally by the Greenplum fault detection and recovery utilities to determine failed segments.

#### Table 130: pg_catalog.gp_pgdatabase

<table>
<thead>
<tr>
<th>column</th>
<th>type</th>
<th>references</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dbid</td>
<td>smallint</td>
<td>gp_segment_configuration.dbid</td>
<td>System-assigned ID. The unique identifier of a segment (or master) instance.</td>
</tr>
<tr>
<td>isprimary</td>
<td>boolean</td>
<td>gp_segment_configuration.role</td>
<td>Whether or not this instance is active. Is it currently acting as the primary segment (as opposed to the mirror).</td>
</tr>
<tr>
<td>content</td>
<td>smallint</td>
<td>gp_segment_configuration.content</td>
<td>The ID for the portion of data on an instance. A primary segment instance and its mirror will have the same content ID. For a segment the value is from 0-N-1, where N is the number of segments in Greenplum Database. For the master, the value is -1.</td>
</tr>
<tr>
<td>column</td>
<td>type</td>
<td>references</td>
<td>description</td>
</tr>
<tr>
<td>--------------</td>
<td>-----------</td>
<td>------------------------------------------------</td>
<td>------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>definedprimary</td>
<td>boolean</td>
<td>gp_segment_configuration.preferred_role</td>
<td>Whether or not this instance was defined as the primary (as opposed to the mirror) at the time the system was initialized.</td>
</tr>
</tbody>
</table>

### gp_resgroup_config

The `gp_toolkit.gp_resgroup_config` view allows administrators to see the current CPU, memory, and concurrency limits for a resource group.

**Note:** The `gp_resgroup_config` view is valid only when resource group-based resource management is active.

**Table 131: gp_toolkit.gp_resgroup_config**

<table>
<thead>
<tr>
<th>column</th>
<th>type</th>
<th>references</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>
<td>groupid</td>
<td>oid</td>
<td>pg_resgroup.oid</td>
<td>The ID of the resource group.</td>
</tr>
<tr>
<td>groupname</td>
<td>name</td>
<td>pg_resgroup.rsname</td>
<td>The name of the resource group.</td>
</tr>
<tr>
<td>concurrency</td>
<td>text</td>
<td>pg_resgroupcapability.value for pg_ resgroupcapability. reslimittype = 1</td>
<td>The concurrency (CONCURRENCY) value specified for the resource group.</td>
</tr>
<tr>
<td>cpu_rate_limit</td>
<td>text</td>
<td>pg_resgroupcapability.value for pg_ resgroupcapability. reslimittype = 2</td>
<td>The CPU limit (CPU_RATE_LIMIT) value specified for the resource group, or -1.</td>
</tr>
<tr>

<tr>
<td>memory_auditor</td>
<td>text</td>
<td>pg_resgroupcapability.value for pg_ resgroupcapability. reslimittype = 6</td>
<td>The memory auditor in use for the resource group.</td>
</tr>
</tbody>
</table>
### gp_resgroup_status

The `gp_toolkit.gp_resgroup_status` view allows administrators to see status and activity for a resource group. It shows how many queries are waiting to run and how many queries are currently active in the system for each resource group. The view also displays current memory and CPU usage for the resource group.

**Note:** The `gp_resgroup_status` view is valid only when resource group-based resource management is active.

**Table 132: gp_toolkit.gp_resgroup_status**

</tr>
</tbody>
</table>

**gp_resgroup_status_per_host**

The gp_toolkit.gp_resgroup_status_per_host view allows administrators to see current memory and CPU usage and allocation for each resource group on a per-host basis.

Memory amounts are specified in MBs.

**Note:** The gp_resgroup_status_per_host view is valid only when resource group-based resource management is active.

<table>
<thead>

</tbody>
</table>
### gp_segment_configuration

The **gp_segment_configuration** table contains information about mirroring and segment instance configuration.

#### Table 137: pg_catalog.gp_segment_configuration

<table>
<thead>
<tr>
<th>column</th>
<th>type</th>
<th>references</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dbid</td>
<td>smallint</td>
<td></td>
<td>Unique identifier of a segment (or master) instance.</td>
</tr>
<tr>
<td>content</td>
<td>smallint</td>
<td></td>
<td>The content identifier for a segment instance. A primary segment instance and its corresponding mirror will always have the same content identifier. For a segment the value is from 0 to N-1, where N is the number of primary segments in the system. For the master, the value is always -1.</td>
</tr>
<tr>
<td>role</td>
<td>char</td>
<td></td>
<td>The role that a segment is currently running as. Values are p (primary) or m (mirror).</td>
</tr>
<tr>
<td>preferred_role</td>
<td>char</td>
<td></td>
<td>The role that a segment was originally assigned at initialization time. Values are p (primary) or m (mirror).</td>
</tr>
<tr>
<td>column</td>
<td>type</td>
<td>references</td>
<td>description</td>
</tr>
<tr>
<td>------------</td>
<td>-------</td>
<td>------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>mode</td>
<td>char</td>
<td></td>
<td>The synchronization status of a segment instance with its mirror copy. Values are ( s ) (synchronized) or ( n ) (not synchronized).</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>Note: This column always shows ( n ) for the master segment and ( s ) for the standby master segment, but these values do not describe the synchronization state for the master segment. Use <code>gp_stat_replication</code> to determine the synchronization state between the master and standby master.</td>
</tr>
<tr>
<td>status</td>
<td>char</td>
<td></td>
<td>The fault status of a segment instance. Values are ( u ) (up) or ( d ) (down).</td>
</tr>
<tr>
<td>port</td>
<td>integer</td>
<td></td>
<td>The TCP port the database server listener process is using.</td>
</tr>
<tr>
<td>hostname</td>
<td>text</td>
<td></td>
<td>The hostname of a segment host.</td>
</tr>
<tr>
<td>address</td>
<td>text</td>
<td></td>
<td>The hostname used to access a particular segment instance on a segment host. This value may be the same as ( \text{hostname} ) on systems that do not have per-interface hostnames configured.</td>
</tr>
<tr>
<td>datadir</td>
<td>text</td>
<td></td>
<td>Segment instance data directory.</td>
</tr>
</tbody>
</table>

**gp_transaction_log**

The `gp_transaction_log` view contains status information about transactions local to a particular segment. This view allows you to see the status of local transactions.
Table 138: pg_catalog.gp_transaction_log

<table>
<thead>
<tr>
<th>column</th>
<th>type</th>
<th>references</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>
<td>segment_id</td>
<td>smallint</td>
<td>gp_segment_configuration.content</td>
<td>The content id if the segment. The master is always -1 (no content).</td>
</tr>
<tr>
<td>dbid</td>
<td>smallint</td>
<td>gp_segment_configuration.dbid</td>
<td>The unique id of the segment instance.</td>
</tr>
<tr>
<td>transaction</td>
<td>xid</td>
<td></td>
<td>The local transaction ID.</td>
</tr>
<tr>
<td>status</td>
<td>text</td>
<td></td>
<td>The status of the local transaction (Committed or Aborted).</td>
</tr>
</tbody>
</table>

gp_version_at_initdb

The gp_version_at_initdb table is populated on the master and each segment in the Greenplum Database system. It identifies the version of Greenplum Database used when the system was first initialized. This table is defined in the pg_global tablespace, meaning it is globally shared across all databases in the system.

Table 139: pg_catalog.gp_version

<table>
<thead>
<tr>
<th>column</th>
<th>type</th>
<th>references</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>
<td>schemaversion</td>
<td>integer</td>
<td></td>
<td>Schema version number.</td>
</tr>
<tr>
<td>productversion</td>
<td>text</td>
<td></td>
<td>Product version number.</td>
</tr>
</tbody>
</table>

pg_aggregate

The pg_aggregate table stores information about aggregate functions. An aggregate function is a function that operates on a set of values (typically one column from each row that matches a query condition) and returns a single value computed from all these values. Typical aggregate functions are sum, count, and max. Each entry in pg_aggregate is an extension of an entry in pg_proc. The pg_proc entry carries the aggregate's name, input and output data types, and other information that is similar to ordinary functions.

Table 140: pg_catalog.pg_aggregate

<table>
<thead>
<tr>
<th>column</th>
<th>type</th>
<th>references</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>
<td>aggfnoid</td>
<td>regproc</td>
<td>pg_proc.oid</td>
<td>OID of the aggregate function</td>
</tr>
<tr>
<td>aggkind</td>
<td>char</td>
<td></td>
<td>Aggregate kind: n for normal aggregates, o for ordered-set aggregates, or h for hypothetical-set aggregates</td>
</tr>
<tr>
<td>column</td>
<td>type</td>
<td>references</td>
<td>description</td>
</tr>
<tr>
<td>---------------------</td>
<td>---------</td>
<td>--------------</td>
<td>-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>aggnudirectargs</td>
<td>int2</td>
<td></td>
<td>Number of direct (non-aggregated) arguments of an ordered-set or hypothetical-set aggregate, counting a variadic array as one argument. If equal to pronargs, the aggregate must be variadic and the variadic array describes the aggregated arguments as well as the final direct arguments. Always zero for normal aggregates.</td>
</tr>
<tr>

<td>regproc</td>
<td>pg_proc.oid</td>
<td>Function to parse and validate reloptions for an index</td>
</tr>
</tbody>
</table>
**pg_amop**

The `pg_amop` table stores information about operators associated with index access method operator classes. There is one row for each operator that is a member of an operator class.

An entry's `amopmethod` must match the `opfmethod` of its containing operator family (including `amopmethod` here is an intentional denormalization of the catalog structure for performance reasons). Also, `amoplefttype` and `amoprighttype` must match the `oprleft` and `oprright` fields of the referenced `pg_operator` entry.

**Table 142: pg_catalog.pg_amop**

<table>
<thead>
<tr>
<th>column</th>
<th>type</th>
<th>references</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>
<td>oid</td>
<td>oid</td>
<td></td>
<td>Row identifier (hidden attribute; must be explicitly selected)</td>
</tr>
<tr>

<td>oid</td>
<td>pg_type.oid</td>
<td>Left-hand input data type of operator</td>
</tr>
<tr>
<td>amoprighttype</td>
<td>oid</td>
<td>pg_type.oid</td>
<td>Right-hand input data type of operator</td>
</tr>
<tr>
<td>amopstrategy</td>
<td>int2</td>
<td></td>
<td>Operator strategy number</td>
</tr>
<tr>
<td>amoppurpose</td>
<td>char</td>
<td></td>
<td>Operator purpose, either <code>s</code> for search or <code>o</code> for ordering</td>
</tr>
<tr>
<td>amopopr</td>
<td>oid</td>
<td>pg_operator.oid</td>
<td>OID of the operator</td>
</tr>
<tr>
<td>amopmethod</td>
<td>oid</td>
<td>pg_am.oid</td>
<td>Index access method for the operator family</td>
</tr>
<tr>
<td>amopsortfamily</td>
<td>oid</td>
<td>pg_opfamily.oid</td>
<td>If an ordering operator, the B-tree operator family that this entry sorts according to; zero if a search operator</td>
</tr>
</tbody>
</table>

**pg_amproc**

The `pg_amproc` table stores information about support procedures associated with index access method operator classes. There is one row for each support procedure belonging to an operator class.

**Table 143: pg_catalog.pg_amproc**

<table>
<thead>
<tr>
<th>column</th>
<th>type</th>
<th>references</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>
<td>oid</td>
<td>oid</td>
<td></td>
<td>Row identifier (hidden attribute; must be explicitly selected)</td>
</tr>
<tr>
<td>amprocfamily</td>
<td>oid</td>
<td>pg_opfamily.oid</td>
<td>The operator family this entry is for</td>
</tr>
<tr>
<td>column</td>
<td>type</td>
<td>references</td>

<td>int2</td>
<td></td>
<td>Support procedure number</td>
</tr>
<tr>
<td>amproc</td>
<td>regproc</td>
<td>pg_proc.oid</td>
<td>OID of the procedure</td>
</tr>
</tbody>
</table>

**pg_appendonly**

The `pg_appendonly` table contains information about the storage options and other characteristics of append-optimized tables.

**Table 144: pg_catalog.pg_appendonly**

<table>
<thead>
<tr>
<th>column</th>
<th>type</th>
<th>references</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>
<td>relid</td>
<td>oid</td>
<td></td>
<td>The table object identifier (OID) of the compressed table.</td>
</tr>
<tr>
<td>blocksize</td>
<td>integer</td>
<td></td>
<td>Block size used for compression of append-optimized tables. Valid values are 8K - 2M. Default is 32K.</td>
</tr>
<tr>
<td>safefswritesize</td>
<td>integer</td>
<td></td>
<td>Minimum size for safe write operations to append-optimized tables in a non-mature file system. Commonly set to a multiple of the extent size of the file system; for example, Linux ext3 is 4096 bytes, so a value of 32768 is commonly used.</td>
</tr>
<tr>
<td>compresslevel</td>
<td>smallint</td>
<td></td>
<td>The compression level, with compression ratio increasing from 1 to 19. When quicklz(^1) is specified for compressstype, valid values are 1 or 3. With zlib specified, valid values are 1-9. When zstd is specified, valid values are 1-19.</td>
</tr>
</tbody>
</table>

\(^1\) quicklz is a compression method included in Greenplum Database for improved performance.
<table>
<thead>
<tr>
<th>column</th>
<th>type</th>
<th>references</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>
<td>majorversion</td>

<td>Visibility map for the table.</td>
</tr>
<tr>
<td>visimapidxid</td>
<td>oid</td>
<td></td>
<td>B-tree index on the visibility map.</td>
</tr>
</tbody>
</table>

**Note:** ¹QuickLZ compression is available only in the commercial release of Pivotal Greenplum Database.

**pg_attrdef**

The `pg_attrdef` table stores column default values. The main information about columns is stored in `pg_attribute`. Only columns that explicitly specify a default value (when the table is created or the column is added) will have an entry here.
### Table 145: pg_catalog.pg_attrdef

<table>
<thead>
<tr>
<th>column</th>
<th>type</th>
<th>references</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>
<td>adrelid</td>
<td>oid</td>
<td>pg_class.oid</td>
<td>The table this column belongs to</td>
</tr>
<tr>
<td>adnum</td>
<td>int2</td>
<td>pg_attribute.attnum</td>
<td>The number of the column</td>
</tr>
<tr>
<td>adbin</td>
<td>text</td>
<td></td>
<td>The internal representation of the column default value</td>
</tr>
<tr>
<td>adsrc</td>
<td>text</td>
<td></td>
<td>A human-readable representation of the default value. This field is historical, and is best not used.</td>
</tr>
</tbody>
</table>

### pg_attribute

The `pg_attribute` table stores information about table columns. There will be exactly one `pg_attribute` row for every column in every table in the database. (There will also be attribute entries for indexes, and all objects that have `pg_class` entries.) The term attribute is equivalent to column.

### Table 146: pg_catalog.pg_attribute

<table>
<thead>
<tr>
<th>column</th>
<th>type</th>
<th>references</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>
<td>attrelid</td>
<td>oid</td>
<td>pg_class.oid</td>
<td>The table this column belongs to</td>
</tr>
<tr>
<td>attname</td>
<td>name</td>
<td></td>
<td>The column name.</td>
</tr>
<tr>
<td>atttypid</td>
<td>oid</td>
<td>pg_type.oid</td>
<td>The data type of this column</td>
</tr>
<tr>
<td>attstatattarget</td>
<td>int4</td>
<td></td>
<td>Controls the level of detail of statistics accumulated for this column by <code>ANALYZE</code>. A zero value indicates that no statistics should be collected. A negative value says to use the system default statistics target. The exact meaning of positive values is data type-dependent. For scalar data types, it is both the target number of &quot;most common values&quot; to collect, and the target number of histogram bins to create.</td>
</tr>
<tr>
<td>column</td>
<td>type</td>
<td>references</td>
<td>description</td>
</tr>
<tr>
<td>----------</td>
<td>---------</td>
<td>------------</td>
<td>--------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>attlen</td>
<td>int2</td>
<td></td>
<td>A copy of <code>pg_type.typlen</code> of this column's type.</td>
</tr>
<tr>
<td>attnum</td>
<td>int2</td>
<td></td>
<td>The number of the column. Ordinary columns are numbered from 1 up. System columns, such as oid, have (arbitrary) negative numbers.</td>
</tr>
<tr>
<td>attnums</td>
<td>int4</td>
<td></td>
<td>Number of dimensions, if the column is an array type; otherwise 0. (Presently, the number of dimensions of an array is not enforced, so any nonzero value effectively means it is an array.)</td>
</tr>
<tr>
<td>attcacheoff</td>
<td>int4</td>
<td></td>
<td>Always -1 in storage, but when loaded into a row descriptor in memory this may be updated to cache the offset of the attribute within the row.</td>
</tr>
<tr>
<td>atttypmod</td>
<td>int4</td>
<td></td>
<td>Records type-specific data supplied at table creation time (for example, the maximum length of a <code>varchar</code> column). It is passed to type-specific input functions and length coercion functions. The value will generally be -1 for types that do not need it.</td>
</tr>
<tr>
<td>attbyval</td>
<td>boolean</td>
<td></td>
<td>A copy of <code>pg_type.typbyval</code> of this column's type.</td>
</tr>
<tr>
<td>attstorage</td>
<td>char</td>
<td></td>
<td>Normally a copy of <code>pg_type.typstorage</code> of this column's type. For TOAST-able data types, this can be altered after column creation to control storage policy.</td>
</tr>
<tr>
<td>column</td>
<td>type</td>
<td>references</td>
<td>description</td>
</tr>
<tr>
<td>------------</td>
<td>-----------</td>
<td>------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>attalign</td>
<td>char</td>
<td></td>
<td>A copy of pg_type. typalign of this column's type.</td>
</tr>
<tr>
<td>attnotnull</td>
<td>boolean</td>
<td></td>
<td>This represents a not-null constraint. It is possible to change this column to enable or disable the constraint.</td>
</tr>
<tr>
<td>atthasdef</td>
<td>boolean</td>
<td></td>
<td>This column has a default value, in which case there will be a corresponding entry in the pg_attrdef catalog that actually defines the value.</td>
</tr>
<tr>
<td>attisdropped</td>
<td>boolean</td>
<td></td>
<td>This column has been dropped and is no longer valid. A dropped column is still physically present in the table, but is ignored by the parser and so cannot be accessed via SQL.</td>
</tr>
<tr>
<td>attislocal</td>
<td>boolean</td>
<td></td>
<td>This column is defined locally in the relation. Note that a column may be locally defined and inherited simultaneously.</td>
</tr>
<tr>
<td>attinhcount</td>
<td>int4</td>
<td></td>
<td>The number of direct ancestors this column has. A column with a nonzero number of ancestors cannot be dropped nor renamed.</td>
</tr>
<tr>
<td>attcollation</td>
<td>oid</td>
<td>pg_collation.oid</td>
<td>The defined collation of the column, or zero if the is not of a collatable data type.</td>
</tr>
<tr>
<td>attacl</td>
<td>aclitem[]</td>
<td></td>
<td>Column-level access privileges, if any have been granted specifically on this column.</td>
</tr>
<tr>
<td>attoptions</td>
<td>text[]</td>
<td></td>
<td>Attribute-level options, as &quot;keyword=value&quot; strings.</td>
</tr>
<tr>
<td>attfdwoptions</td>
<td>text[]</td>
<td></td>
<td>Attribute-level foreign data wrapper options, as &quot;keyword=value&quot; strings.</td>
</tr>
</tbody>
</table>
**pg_attribute_encoding**

The `pg_attribute_encoding` system catalog table contains column storage information.

<table>
<thead>
<tr>
<th>column</th>
<th>type</th>
<th>modifiers</th>
<th>storage</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>
<td>attrelid</td>
<td>oid</td>
<td>not null</td>
<td>plain</td>
<td>Foreign key to <code>pg_attribute.attrelid</code></td>
</tr>
<tr>
<td>attnum</td>
<td>smallint</td>
<td>not null</td>
<td>plain</td>
<td>Foreign key to <code>pg_attribute.attnum</code></td>
</tr>
<tr>
<td>attoptions</td>
<td>text [ ]</td>
<td></td>
<td>extended</td>
<td>The options</td>
</tr>
</tbody>
</table>

**pg_auth_members**

The `pg_auth_members` system catalog table shows the membership relations between roles. Any non-circular set of relationships is allowed. Because roles are system-wide, `pg_auth_members` is shared across all databases of a Greenplum Database system.

<table>
<thead>
<tr>
<th>column</th>
<th>type</th>
<th>references</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>
<td>roleid</td>
<td>oid</td>
<td><code>pg_authid.oid</code></td>
<td>ID of the parent-level (group) role</td>
</tr>
<tr>
<td>member</td>
<td>oid</td>
<td><code>pg_authid.oid</code></td>
<td>ID of a member role</td>
</tr>
<tr>
<td>grantor</td>
<td>oid</td>
<td><code>pg_authid.oid</code></td>
<td>ID of the role that granted this membership</td>
</tr>
<tr>
<td>admin_option</td>
<td>boolean</td>
<td></td>
<td>True if role member may grant membership to others</td>
</tr>
</tbody>
</table>

**pg_authid**

The `pg_authid` table contains information about database authorization identifiers (roles). A role subsumes the concepts of users and groups. A user is a role with the `rolcanlogin` flag set. Any role (with or without `rolcanlogin`) may have other roles as members. See `pg_auth_members`.

Since this catalog contains passwords, it must not be publicly readable. `pg_roles` is a publicly readable view on `pg_authid` that blanks out the password field.

Because user identities are system-wide, `pg_authid` is shared across all databases in a Greenplum Database system: there is only one copy of `pg_authid` per system, not one per database.

<table>
<thead>
<tr>
<th>column</th>
<th>type</th>

<td>text</td>
<td>Comment string from the extension control file.</td>
</tr>
</tbody>
</table>

**pg_cast**

The `pg_cast` table stores data type conversion paths, both built-in paths and those defined with `CREATE CAST`.

Note that `pg_cast` does not represent every type conversion known to the system, only those that cannot be deduced from some generic rule. For example, casting between a domain and its base type is not explicitly represented in `pg_cast`. Another important exception is that "automatic I/O conversion casts",
those performed using a data type's own I/O functions to convert to or from text or other string types, are not explicitly represented in pg_cast.

The cast functions listed in pg_cast must always take the cast source type as their first argument type, and return the cast destination type as their result type. A cast function can have up to three arguments. The second argument, if present, must be type integer; it receives the type modifier associated with the destination type, or -1 if there is none. The third argument, if present, must be type boolean; it receives true if the cast is an explicit cast, false otherwise.

It is legitimate to create a pg_cast entry in which the source and target types are the same, if the associated function takes more than one argument. Such entries represent 'length coercion functions' that coerce values of the type to be legal for a particular type modifier value.

When a pg_cast entry has different source and target types and a function that takes more than one argument, the entry converts from one type to another and applies a length coercion in a single step. When no such entry is available, coercion to a type that uses a type modifier involves two steps, one to convert between data types and a second to apply the modifier.

**Table 152: pg_catalog.pg_cast**

<table>
<thead>
<tr>
<th>column</th>
<th>type</th>

<td>oid</td>
<td>pg_proc.oid</td>
<td>The OID of the function to use to perform this cast. Zero is stored if the cast method does not require a function.</td>
</tr>
<tr>
<td>castcontext</td>
<td>char</td>
<td></td>
<td>Indicates what contexts the cast may be invoked in. e means only as an explicit cast (using CAST or :: syntax). a means implicitly in assignment to a target column, as well as explicitly. i means implicitly in expressions, as well as the other cases.</td>
</tr>
<tr>
<td>castmethod</td>
<td>char</td>
<td></td>
<td>Indicates how the cast is performed: f - The function identified in the castfunc field is used. i - The input/output functions are used. b - The types are binary-coercible, and no conversion is required.</td>
</tr>
</tbody>
</table>
The system catalog table `pg_class` catalogs tables and most everything else that has columns or is otherwise similar to a table (also known as relations). This includes indexes (see also `pg_index`), sequences, views, composite types, and TOAST tables. Not all columns are meaningful for all relation types.

### Table 153: `pg_catalog.pg_class`

<table>

<td>oid from pg_authid</td>
</tr>
</tbody>
</table>

**pg_constraint**

The `pg_constraint` system catalog table stores check, primary key, unique, and foreign key constraints on tables. Column constraints are not treated specially. Every column constraint is equivalent to some table constraint. Not-null constraints are represented in the `pg_attribute` catalog table. Check constraints on domains are stored here, too.

**Table 155: pg_catalog.pg_constraint**

<table>
<thead>
<tr>
<th>column</th>
<th>type</th>
<th>references</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>
<td>conname</td>
<td>name</td>

<tr>
<td>condefault</td>
<td>boolean</td>
<td></td>
<td>True if this is the default conversion.</td>
</tr>
</tbody>
</table>

**pg_database**

The `pg_database` system catalog table stores information about the available databases. Databases are created with the `CREATE DATABASE` SQL command. Unlike most system catalogs, `pg_database` is shared across all databases in the system. There is only one copy of `pg_database` per system, not one per database.

Table 157: `pg_catalog.pg_database`

<table>
<thead>
<tr>
<th>column</th>
<th>type</th>
<th>references</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>
<td>datname</td>
<td>name</td>

<td>A Multixact ID is used to support row locking by multiple transactions. All multixact IDs before this one have been replaced with a transaction ID in this database. This is used to track whether the database needs to be vacuumed in order to prevent multixact ID wraparound or to allow pg_multixact to be shrunk. It is the minimum of the per-table pg_class.relminmxid values.</td>
</tr>
<tr>
<td>dat_tablespace</td>
<td>oid</td>
<td>pg_tablespace.oid</td>
<td>The default tablespace for the database. Within this database, all tables for which pg_class.reltablespace is zero will be stored in this tablespace. All non-shared system catalogs will also be there.</td>
</tr>
<tr>
<td>datacl</td>
<td>aclitem[]</td>
<td></td>
<td>Database access privileges as given by GRANT and REVOKE.</td>
</tr>
</tbody>
</table>
**pg_db_role_setting**

The `pg_db_role_setting` system catalog table records the default values of server configuration settings for each role and database combination.

There is a single copy of `pg_db_role_settings` per Greenplum Database cluster. This system catalog table is shared across all databases.

You can view the server configuration settings for your Greenplum Database cluster with `psql`'s \drds meta-command.

**Table 158: pg_catalog.pg_database**

<table>
<thead>
<tr>
<th>column</th>
<th>type</th>
<th>references</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>

</tr>
<tr>
<td>setrole</td>
<td>oid</td>
<td>pg_authid.oid</td>
<td>The role to which the setting is applicable, or zero if the setting is not role-specific.</td>
</tr>
<tr>
<td>setconfig</td>
<td>text[]</td>
<td></td>
<td>Per-database- and per-role-specific defaults for user-settable server configuration parameters.</td>
</tr>
</tbody>
</table>

**pg_depend**

The `pg_depend` system catalog table records the dependency relationships between database objects. This information allows `DROP` commands to find which other objects must be dropped by `DROP CASCADE` or prevent dropping in the `DROP RESTRICT` case. See also `pg_shdepend`, which performs a similar function for dependencies involving objects that are shared across a Greenplum system.

In all cases, a `pg_depend` entry indicates that the referenced object may not be dropped without also dropping the dependent object. However, there are several subflavors identified by `deptype`:

- **DEPENDENCY_NORMAL (n)** — A normal relationship between separately-created objects. The dependent object may be dropped without affecting the referenced object. The referenced object may only be dropped by specifying `CASCADE`, in which case the dependent object is dropped, too. Example: a table column has a normal dependency on its data type.

- **DEPENDENCY_AUTO (a)** — The dependent object can be dropped separately from the referenced object, and should be automatically dropped (regardless of `RESTRICT` or `CASCADE` mode) if the referenced object is dropped. Example: a named constraint on a table is made autodependent on the table, so that it will go away if the table is dropped.

- **DEPENDENCY_INTERNAL (i)** — The dependent object was created as part of creation of the referenced object, and is really just a part of its internal implementation. A `DROP` of the dependent object will be disallowed outright (we’ll tell the user to issue a `DROP` against the referenced object, instead). A `DROP` of the referenced object will be propagated through to drop the dependent object whether `CASCADE` is specified or not.

- **DEPENDENCY_PIN (p)** — There is no dependent object; this type of entry is a signal that the system itself depends on the referenced object, and so that object must never be deleted. Entries of this type are created only by system initialization. The columns for the dependent object contain zeroes.
Table 159: pg_catalog.pg_depend

<table>
<thead>
<tr>
<th>column</th>
<th>type</th>
<th>references</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>
<td>classid</td>
<td>oid</td>
<td>pg_class.oid</td>

<tr>
<td>refobjsubid</td>
<td>int4</td>
<td></td>
<td>For a table column, this is the referenced column number. For all other object types, this column is zero.</td>
</tr>
<tr>
<td>deptype</td>
<td>char</td>
<td></td>
<td>A code defining the specific semantics of this dependency relationship.</td>
</tr>
</tbody>
</table>

**pg_description**

The pg_description system catalog table stores optional descriptions (comments) for each database object. Descriptions can be manipulated with the `COMMENT` command and viewed with `psql`'s `\d` meta-commands. Descriptions of many built-in system objects are provided in the initial contents of pg_description. See also pg_shdescription, which performs a similar function for descriptions involving objects that are shared across a Greenplum system.

Table 160: pg_catalog.pg_description

</table>

### pg_enum

The `pg_enum` table contains entries matching enum types to their associated values and labels. The internal representation of a given enum value is actually the OID of its associated row in `pg_enum`. The OIDs for a particular enum type are guaranteed to be ordered in the way the type should sort, but there is no guarantee about the ordering of OIDs of unrelated enum types.

**Table 161: pg_catalog.pg_enum**

<table>
<thead>
<tr>
<th>Column</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>enumtypid</td>
<td>oid</td>
<td>pgtype.oid</td>
<td>The OID of the <code>pg_type</code> entry owning this enum value</td>
</tr>
<tr>
<td>enumlabel</td>
<td>name</td>
<td></td>
<td>The textual label for this enum value</td>
</tr>
</tbody>
</table>

### pg_extension

The system catalog table `pg_extension` stores information about installed extensions.

**Table 162: pg_catalog.pg_extension**

<table>
<thead>
<tr>
<th>column</th>
<th>type</th>
<th>references</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>
<td>extname</td>
<td>name</td>
<td></td>
<td>Name of the extension.</td>
</tr>
<tr>
<td>extowner</td>
<td>oid</td>
<td>pg_authid.oid</td>
<td>Owner of the extension</td>
</tr>
<tr>
<td>extnamespace</td>
<td>oid</td>
<td>pg_namespace.oid</td>
<td>Schema containing the extension exported objects.</td>
</tr>
<tr>
<td>extrelocatable</td>
<td>boolean</td>
<td></td>
<td>True if the extension can be relocated to another schema.</td>
</tr>
<tr>
<td>extversion</td>
<td>text</td>
<td></td>
<td>Version name for the extension.</td>
</tr>
<tr>
<td>extconfig</td>
<td>oid[]</td>
<td>pg_class.oid</td>
<td>Array of <code>regclass</code> OIDs for the extension configuration tables, or <code>NULL</code> if none.</td>
</tr>
</tbody>
</table>
Unlike most catalogs with a namespace column, `extnamespace` does not imply that the extension belongs to that schema. Extension names are never schema-qualified. The `extnamespace` schema indicates the schema that contains most or all of the extension objects. If `extrelocatable` is `true`, then this schema must contain all schema-qualifiable objects that belong to the extension.

### pg_exttable

The `pg_exttable` system catalog table is used to track external tables and web tables created by the `CREATE EXTERNAL TABLE` command.

<table>
<thead>
<tr>
<th>column</th>
<th>type</th>
<th>references</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>
<td>extcondition</td>
<td>text[]</td>
<td></td>
<td>Array of WHERE-clause filter conditions for the extension configuration tables, or NULL if none.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>column</th>
<th>type</th>
<th>references</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>
<td>reloid</td>
<td>oid</td>
<td>pg_class.oid</td>
<td>The OID of this external table.</td>
</tr>
<tr>
<td>urilocation</td>
<td>text[]</td>
<td></td>
<td>The URI location(s) of the external table files.</td>
</tr>
<tr>
<td>execlocation</td>
<td>text[]</td>
<td></td>
<td>The ON segment locations defined for the external table.</td>
</tr>
<tr>
<td>fmttype</td>
<td>char</td>
<td></td>
<td>Format of the external table files: <code>t</code> for text, or <code>c</code> for csv.</td>
</tr>
<tr>
<td>fmtopts</td>
<td>text</td>
<td></td>
<td>Formatting options of the external table files, such as the field delimiter, null string, escape character, etc.</td>
</tr>
<tr>
<td>options</td>
<td>text[]</td>
<td></td>
<td>The options defined for the external table.</td>
</tr>
<tr>
<td>command</td>
<td>text</td>
<td></td>
<td>The OS command to execute when the external table is accessed.</td>
</tr>
<tr>
<td>rejectlimit</td>
<td>integer</td>
<td></td>
<td>The per segment reject limit for rows with errors, after which the load will fail.</td>
</tr>
<tr>
<td>rejectlimittype</td>
<td>char</td>
<td></td>
<td>Type of reject limit threshold: <code>r</code> for number of rows.</td>
</tr>
<tr>
<td>logerrors</td>
<td>bool</td>
<td></td>
<td>1 to log errors, 0 to not.</td>
</tr>
</tbody>
</table>
### pg_foreign_data_wrapper

The system catalog table **pg_foreign_data_wrapper** stores foreign-data wrapper definitions. A foreign-data wrapper is a mechanism by which you access external data residing on foreign servers.

**Table 164: pg_catalog.pg_foreign_data_wrapper**

<table>
<thead>
<tr>
<th>column</th>
<th>type</th>
<th>references</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>
<td>fdwname</td>
<td>name</td>
<td></td>
<td>Name of the foreign-data wrapper.</td>
</tr>
<tr>
<td>fdwowner</td>
<td>oid</td>
<td>pg_authid.oid</td>
<td>Owner of the foreign-data wrapper.</td>
</tr>
<tr>
<td>fdwhandler</td>
<td>oid</td>
<td>pg_proc.oid</td>
<td>A reference to a handler function that is responsible for supplying execution routines for the foreign-data wrapper. Zero if no handler is provided.</td>
</tr>
<tr>
<td>fdwvalidator</td>
<td>oid</td>
<td>pg_proc.oid</td>
<td>A reference to a validator function that is responsible for checking the validity of the options provided to the foreign-data wrapper. This function also checks the options for foreign servers and user mappings using the foreign-data wrapper. Zero if no validator is provided.</td>
</tr>
<tr>
<td>fdwacl</td>
<td>aclitem[]</td>
<td></td>
<td>Access privileges; see <code>GRANT</code> and <code>REVOKE</code> for details.</td>
</tr>
<tr>
<td>fdwoptions</td>
<td>text[]</td>
<td></td>
<td>Foreign-data wrapper-specific options, as &quot;keyword=value&quot; strings.</td>
</tr>
</tbody>
</table>

### pg_foreign_server

The system catalog table **pg_foreign_server** stores foreign server definitions. A foreign server describes a source of external data, such as a remote server. You access a foreign server via a foreign-data wrapper.
Table 165: pg_catalog.pg_foreign_server

<table>
<thead>
<tr>
<th>column</th>
<th>type</th>
<th>references</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>
<td>srvname</td>
<td>name</td>
<td></td>
<td>Name of the foreign server.</td>
</tr>
<tr>
<td>srvowner</td>
<td>oid</td>
<td>pg_authid.oid</td>
<td>Owner of the foreign server.</td>
</tr>
<tr>
<td>srvfdw</td>
<td>oid</td>
<td>pg_foreign_data_wrapper.oid</td>
<td>OID of the foreign-data wrapper of this foreign server.</td>
</tr>
<tr>
<td>srvtype</td>
<td>text</td>
<td></td>
<td>Type of server (optional).</td>
</tr>
<tr>
<td>srvversion</td>
<td>text</td>
<td></td>
<td>Version of the server (optional).</td>
</tr>
<tr>
<td>srvacl</td>
<td>aclitem[]</td>
<td></td>
<td>Access privileges; see GRANT and REVOKE for details.</td>
</tr>
<tr>
<td>srvoptions</td>
<td>text[]</td>
<td></td>
<td>Foreign server-specific options, as &quot;keyword=value&quot; strings.</td>
</tr>
</tbody>
</table>

pg_foreign_table

The system catalog table pg_foreign_table contains auxiliary information about foreign tables. A foreign table is primarily represented by a pg_class entry, just like a regular table. Its pg_foreign_table entry contains the information that is pertinent only to foreign tables and not any other kind of relation.

Table 166: pg_catalog.pg_foreign_table

<table>
<thead>
<tr>
<th>column</th>
<th>type</th>
<th>references</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ftrelid</td>
<td>oid</td>
<td>pg_class.oid</td>
<td>OID of the pg_class entry for this foreign table.</td>
</tr>
<tr>
<td>ftserver</td>
<td>oid</td>
<td>pg_foreign_server.oid</td>
<td>OID of the foreign server for this foreign table.</td>
</tr>
<tr>
<td>ftoptions</td>
<td>text[]</td>
<td></td>
<td>Foreign table options, as &quot;keyword=value&quot; strings.</td>
</tr>
</tbody>
</table>

pg_index

The pg_index system catalog table contains part of the information about indexes. The rest is mostly in pg_class.

Table 167: pg_catalog.pg_index

<table>
<thead>
<tr>
<th>column</th>
<th>type</th>
<th>references</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>
<td>indexrelid</td>
<td>oid</td>
<td>pg_class.oid</td>
<td>The OID of the pg_class entry for this index.</td>
</tr>
<tr>
<td>column</td>
<td>type</td>
<td>references</td>
<td>description</td>
</tr>
<tr>
<td>--------------</td>
<td>-------</td>
<td>------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>indrelid</td>
<td>oid</td>
<td>pg_class.oid</td>
<td>The OID of the pg_class entry for the table this index is for.</td>
</tr>
<tr>
<td>indnatts</td>
<td>int2</td>
<td></td>
<td>The number of columns in the index (duplicates pg_class.relnatts).</td>
</tr>
<tr>
<td>indisunique</td>
<td>boolean</td>
<td></td>
<td>If true, this is a unique index.</td>
</tr>
<tr>
<td>indisprimary</td>
<td>boolean</td>
<td></td>
<td>If true, this index represents the primary key of the table. (indisunique should always be true when this is true.)</td>
</tr>
<tr>
<td>indisexclusion</td>
<td>boolean</td>
<td></td>
<td>If true, this index supports an exclusion constraint</td>
</tr>
<tr>
<td>indimmediate</td>
<td>boolean</td>
<td></td>
<td>If true, the uniqueness check is enforced immediately on insertion (irrelevant if indisunique is not true)</td>
</tr>
<tr>
<td>indisclustered</td>
<td>boolean</td>
<td></td>
<td>If true, the table was last clustered on this index via the CLUSTER command.</td>
</tr>
<tr>
<td>indisvalid</td>
<td>boolean</td>
<td></td>
<td>If true, the index is currently valid for queries. False means the index is possibly incomplete: it must still be modified by INSERT/UPDATE operations, but it cannot safely be used for queries.</td>
</tr>
<tr>
<td>indcheckxmin</td>
<td>boolean</td>
<td></td>
<td>If true, queries must not use the index until the xmin of this pg_index row is below their TransactionXmin event horizon, because the table may contain broken HOT chains with incompatible rows that they can see</td>
</tr>
<tr>
<td>column</td>
<td>type</td>
<td>references</td>
<td>description</td>
</tr>
<tr>
<td>-------------</td>
<td>--------------------</td>
<td>-----------------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>indisready</td>
<td>boolean</td>
<td></td>
<td>If true, the index is currently ready for inserts. False means the index must be ignored by INSERT/UPDATE operations</td>
</tr>
<tr>
<td>indislive</td>
<td>boolean</td>
<td></td>
<td>If false, the index is in process of being dropped, and should be ignored for all purposes</td>
</tr>
<tr>
<td>indisreplident</td>
<td>boolean</td>
<td></td>
<td>If true this index has been chosen as &quot;replica identity&quot; using ALTER TABLE ... REPLICA IDENTITY USING INDEX ...</td>
</tr>
<tr>
<td>indkey</td>
<td>int2vector</td>
<td>pg_attribute.attnum</td>
<td>This is an array of indnatts values that indicate which table columns this index indexes. For example a value of 1 3 would mean that the first and the third table columns make up the index key. A zero in this array indicates that the corresponding index attribute is an expression over the table columns, rather than a simple column reference.</td>
</tr>
<tr>
<td>indcollation</td>
<td>oidvector</td>
<td></td>
<td>For each column in the index key, this contains the OID of the collation to use for the index.</td>
</tr>
<tr>
<td>indclass</td>
<td>oidvector</td>
<td>pg_opclass.oid</td>
<td>For each column in the index key this contains the OID of the operator class to use.</td>
</tr>
<tr>
<td>indoption</td>
<td>int2vector</td>
<td></td>
<td>This is an array of indnatts values that store per-column flag bits. The meaning of the bits is defined by the index's access method.</td>
</tr>
</tbody>
</table>
### indexprs

Expression trees (in nodeToString() representation) for index attributes that are not simple column references. This is a list with one element for each zero entry in indkey. NULL if all index attributes are simple references.

### indpred

Expression tree (in nodeToString() representation) for partial index predicate. NULL if not a partial index.

---

### pg_inherits

The `pg_inherits` system catalog table records information about table inheritance hierarchies. There is one entry for each direct child table in the database. (Indirect inheritance can be determined by following chains of entries.) In Greenplum Database, inheritance relationships are created by both the `INHERITS` clause (standalone inheritance) and the `PARTITION BY` clause (partitioned child table inheritance) of `CREATE TABLE`.

**Table 168: pg_catalog.pg_inherits**

<table>
<thead>
<tr>
<th>column</th>
<th>type</th>
<th>references</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>
<td>inhrelid</td>
<td>oid</td>
<td>pg_class.oid</td>
<td>The OID of the child table.</td>
</tr>
<tr>
<td>inhparent</td>
<td>oid</td>
<td>pg_class.oid</td>
<td>The OID of the parent table.</td>
</tr>
<tr>
<td>inhseqno</td>
<td>int4</td>
<td></td>
<td>If there is more than one direct parent for a child table (multiple inheritance), this number tells the order in which the inherited columns are to be arranged. The count starts at 1.</td>
</tr>
</tbody>
</table>

---

### pg_language

The `pg_language` system catalog table registers languages in which you can write functions or stored procedures. It is populated by `CREATE LANGUAGE`.

**Table 169: pg_catalog.pg_language**

<table>
<thead>
<tr>
<th>column</th>
<th>type</th>
<th>references</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>
<td>lanname</td>
<td>name</td>
<td></td>
<td>Name of the language.</td>
</tr>
<tr>
<td>column</td>
<td>type</td>
<td>references</td>
<td>description</td>
</tr>
<tr>
<td>------------</td>
<td>-----------</td>
<td>------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>lanowner</td>
<td>oid</td>
<td>pg_authid.oid</td>
<td>Owner of the language.</td>
</tr>
<tr>
<td>lanispl</td>
<td>boolean</td>
<td></td>
<td>This is false for internal languages (such as SQL) and true for user-defined languages. Currently, pg_dump still uses this to determine which languages need to be dumped, but this may be replaced by a different mechanism in the future.</td>
</tr>
<tr>
<td>lanpltrusted</td>
<td>boolean</td>
<td></td>
<td>True if this is a trusted language, which means that it is believed not to grant access to anything outside the normal SQL execution environment. Only superusers may create functions in untrusted languages.</td>
</tr>
<tr>
<td>lanplcallfoid</td>
<td>oid</td>
<td>pg_proc.oid</td>
<td>For noninternal languages this references the language handler, which is a special function that is responsible for executing all functions that are written in the particular language.</td>
</tr>
<tr>
<td>laninline</td>
<td>oid</td>
<td>pg_proc.oid</td>
<td>This references a function that is responsible for executing inline anonymous code blocks (see the \texttt{DO} command). Zero if anonymous blocks are not supported.</td>
</tr>
<tr>
<td>lanvalidator</td>
<td>oid</td>
<td>pg_proc.oid</td>
<td>This references a language validator function that is responsible for checking the syntax and validity of new functions when they are created. Zero if no validator is provided.</td>
</tr>
<tr>
<td>lanacl</td>
<td>aclitem[]</td>
<td></td>
<td>Access privileges for the language.</td>
</tr>
</tbody>
</table>
**pg_largeobject**

*Note:* Greenplum Database does not support the PostgreSQL *large object facility* for streaming user data that is stored in large-object structures.

The `pg_largeobject` system catalog table holds the data making up ‘large objects’. A large object is identified by an OID assigned when it is created. Each large object is broken into segments or ‘pages’ small enough to be conveniently stored as rows in `pg_largeobject`. The amount of data per page is defined to be `LOBLKSIZe` (which is currently `BLCKSZ/4`, or typically 8K).

Each row of `pg_largeobject` holds data for one page of a large object, beginning at byte offset (`pageno * LOBLKSIZe`) within the object. The implementation allows sparse storage: pages may be missing, and may be shorter than `LOBLKSIZe` bytes even if they are not the last page of the object. Missing regions within a large object read as zeroes.

**Table 170: pg_catalog.pg_largeobject**

<table>
<thead>
<tr>
<th>column</th>
<th>type</th>
<th>references</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>
<td>loid</td>
<td>oid</td>
<td></td>
<td>Identifier of the large object that includes this page.</td>
</tr>
<tr>
<td>pageno</td>
<td>int4</td>
<td></td>
<td>Page number of this page within its large object (counting from zero).</td>
</tr>
<tr>
<td>data</td>
<td>bytea</td>
<td></td>
<td>Actual data stored in the large object. This will never be more than <code>LOBLKSIZe</code> bytes and may be less.</td>
</tr>
</tbody>
</table>

**pg_listener**

The `pg_listener` system catalog table supports the `LISTEN` and `NOTIFY` commands. A listener creates an entry in `pg_listener` for each notification name it is listening for. A notifier scans and updates each matching entry to show that a notification has occurred. The notifier also sends a signal (using the PID recorded in the table) to awaken the listener from sleep.

This table is not currently used in Greenplum Database.

**Table 171: pg_catalog.pg_listener**

<table>
<thead>
<tr>
<th>column</th>
<th>type</th>
<th>references</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>
<td>relname</td>
<td>name</td>
<td></td>
<td>Notify condition name. (The name need not match any actual relation in the database.</td>
</tr>
<tr>
<td>listenerpid</td>
<td>int4</td>
<td></td>
<td>PID of the server process that created this entry.</td>
</tr>
</tbody>
</table>
**notification**

<table>
<thead>
<tr>
<th>column</th>
<th>type</th>
<th>references</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>
<td>notification</td>
<td>int4</td>
<td></td>
<td>Zero if no event is pending for this listener. If an event is pending, the PID of the server process that sent the notification.</td>
</tr>
</tbody>
</table>

**pg_locks**

The `pg_locks` view provides access to information about the locks held by open transactions within Greenplum Database.

`pg_locks` contains one row per active lockable object, requested lock mode, and relevant transaction. Thus, the same lockable object may appear many times if multiple transactions are holding or waiting for locks on it. An object with no current locks on it will not appear in the view at all.

There are several distinct types of lockable objects: whole relations (such as tables), individual pages of relations, individual tuples of relations, transaction IDs (both virtual and permanent IDs), and general database objects. Also, the right to extend a relation is represented as a separate lockable object.

**Table 172: pg_catalog.pg_locks**

<table>
<thead>
<tr>
<th>column</th>
<th>type</th>
<th>references</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>
<td>locktype</td>
<td>text</td>
<td></td>
<td>Type of the lockable object: relation, extend, page, tuple, transactionid, object, userlock, resource queue, or advisory</td>

<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>gp_segment_id</td>
<td>integer</td>
<td></td>
<td>The Greenplum segment id (dbid) where the lock is held.</td>
</tr>
</tbody>
</table>

**pg_max_external_files**

The `pg_max_external_files` view shows the maximum number of external table files allowed per segment host when using the external table file protocol.

Table 173: `pg_catalog.pg_max_external_files`

<table>
<thead>
<tr>
<th>column</th>
<th>type</th>
<th>references</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>
<td>hostname</td>
<td>name</td>
<td></td>
<td>The host name used to access a particular segment instance on a segment host.</td>
</tr>
<tr>
<td>maxfiles</td>
<td>bigint</td>
<td></td>
<td>Number of primary segment instances on the host.</td>
</tr>
</tbody>
</table>

**pg_namespace**

The `pg_namespace` system catalog table stores namespaces. A namespace is the structure underlying SQL schemas: each namespace can have a separate collection of relations, types, etc. without name conflicts.

Table 174: `pg_catalog.pg_namespace`

<table>
<thead>
<tr>
<th>column</th>
<th>type</th>
<th>references</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>
<td>oid</td>
<td>oid</td>
<td></td>
<td>Row identifier (hidden attribute; must be explicitly selected)</td>
</tr>
<tr>
<td>nspname</td>
<td>name</td>
<td></td>
<td>Name of the namespace</td>
</tr>
<tr>
<td>nspowner</td>
<td>oid</td>
<td>pg_authid.oid</td>
<td>Owner of the namespace</td>
</tr>
<tr>
<td>nspacl</td>
<td>aclitem[]</td>
<td></td>
<td>Access privileges as given by <code>GRANT</code> and <code>REVOKE</code></td>
</tr>
</tbody>
</table>

**pg_opclass**

The `pg_opclass` system catalog table defines index access method operator classes. Each operator class defines semantics for index columns of a particular data type and a particular index access method. An operator class essentially specifies that a particular operator family is applicable to a particular indexable column data type. The set of operators from the family that are actually usable with the indexed column are those that accept the column's data type as their left-hand input.

An operator class's `opcmethod` must match the `opfmethod` of its containing operator family. Also, there must be no more than one `pg_opclass` row having `opcdefault` true for any given combination of `opcmethod` and `opcintype`. 
Table 175: pg_catalog.pg_opclass

<table>
<thead>
<tr>
<th>column</th>
<th>type</th>
<th>references</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>
<td>oid</td>
<td>oid</td>
<td></td>
<td>Row identifier (hidden attribute; must be explicitly selected)</td>
</tr>
<tr>

<td>oid</td>
<td>pg_am.oid</td>
<td>Index access method operator class is for</td>
</tr>
<tr>
<td>opcname</td>
<td>name</td>
<td></td>
<td>Name of this operator class</td>
</tr>
<tr>
<td>opcnamespace</td>
<td>oid</td>
<td>pg_namespace.oid</td>
<td>Namespace of this operator class</td>
</tr>
<tr>
<td>opcowner</td>
<td>oid</td>
<td>pg_authid.oid</td>
<td>Owner of the operator class</td>
</tr>
<tr>
<td>opcfamily</td>
<td>oid</td>
<td>pg_opfamily.oid</td>
<td>Operator family containing the operator class</td>
</tr>
<tr>
<td>opcintype</td>
<td>oid</td>
<td>pg_type.oid</td>
<td>Data type that the operator class indexes</td>
</tr>
<tr>
<td>opcdefault</td>
<td>boolean</td>
<td></td>
<td>True if this operator class is the default for the data type opcintype</td>
</tr>
<tr>
<td>opckeytype</td>
<td>oid</td>
<td>pg_type.oid</td>
<td>Type of data stored in index, or zero if same as opcintype</td>
</tr>
</tbody>
</table>

pg_operator

The pg_operator system catalog table stores information about operators, both built-in and those defined by CREATE OPERATOR. Unused column contain zeroes. For example, oprleft is zero for a prefix operator.

Table 176: pg_catalog.pg_operator

<table>
<thead>
<tr>
<th>column</th>
<th>type</th>
<th>references</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>
<td>oid</td>
<td>oid</td>
<td></td>
<td>Row identifier (hidden attribute, must be explicitly selected)</td>
</tr>

<tr>
<td>oprkind</td>
<td>char</td>
<td></td>
<td>$b =$ infix (both), $l =$ prefix (left), $r =$ postfix (right)</td>
</tr>
</tbody>
</table>
**column** | **type** | **references** | **description**  
---|---|---|---  
oprcanmerge | boolean | | This operator supports merge joins  
oprcanhash | boolean | | This operator supports hash joins  
oprleft | oid | pg_type.oid | Type of the left operand  
oprright | oid | pg_type.oid | Type of the right operand  
oprresult | oid | pg_type.oid | Type of the result  
oprcom | oid | pg_operator.oid | Commutator of this operator, if any  
oprnegate | oid | pg_operator.oid | Negator of this operator, if any  
oprcode | regproc | pg_proc.oid | Function that implements this operator  
oprest | regproc | pg_proc.oid | Restriction selectivity estimation function for this operator  
oprjoin | regproc | pg_proc.oid | Join selectivity estimation function for this operator  

**pg_opfamily**

The catalog `pg_opfamily` defines operator families. Each operator family is a collection of operators and associated support routines that implement the semantics specified for a particular index access method. Furthermore, the operators in a family are all compatible in a way that is specified by the access method. The operator family concept allows cross-data-type operators to be used with indexes and to be reasoned about using knowledge of access method semantics.

The majority of the information defining an operator family is not in its `pg_opfamily` row, but in the associated rows in `pg_amop`, `pg_amproc`, and `pg_opclass`.

**Table 177: pg_opfamily**

<tr>
<td>opfnamespace</td>
<td>oid</td>
<td>pg_namespace.oid</td>
<td>Namespace of this operator family</td>
</tr>
<tr>
<td>opfowner</td>
<td>oid</td>
<td>pg_authid.oid</td>
<td>Owner of the operator family</td>
</tr>
</tbody>
</table>
**pg_partition**

The `pg_partition` system catalog table is used to track partitioned tables and their inheritance level relationships. Each row of `pg_partition` represents either the level of a partitioned table in the partition hierarchy, or a subpartition template description. The value of the attribute `paristemplate` determines what a particular row represents.

**Table 178: pg_catalog.pg_partition**

<table>
<thead>
<tr>
<th>column</th>
<th>type</th>
<th>references</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>
<td>parrelid</td>
<td>oid</td>
<td>pg_class.oid</td>
<td>The object identifier of the table.</td>
</tr>
<tr>
<td>parkind</td>
<td>char</td>
<td></td>
<td>The partition type - <code>R</code> for range or <code>L</code> for list.</td>
</tr>
<tr>
<td>parlevel</td>
<td>smallint</td>
<td></td>
<td>The partition level of this row: 0 for the top-level parent table, 1 for the first level under the parent table, 2 for the second level, and so on.</td>
</tr>
<tr>
<td>paristemplate</td>
<td>boolean</td>
<td></td>
<td>Whether or not this row represents a subpartition template definition (true) or an actual partitioning level (false).</td>
</tr>
<tr>
<td>parnatts</td>
<td>smallint</td>
<td></td>
<td>The number of attributes that define this level.</td>
</tr>
<tr>
<td>paratts</td>
<td>smallint()</td>
<td>pg_attribute.attnum</td>
<td>An array of the attribute numbers (as in <code>pg_attribute.attnum</code>) of the attributes that participate in defining this level.</td>
</tr>
<tr>
<td>parclass</td>
<td>oidvector</td>
<td>pg_opclass.oid</td>
<td>The operator class identifier(s) of the partition columns.</td>
</tr>
</tbody>
</table>

**pg_partition_columns**

The `pg_partition_columns` system view is used to show the partition key columns of a partitioned table.

**Table 179: pg_catalog.pg_partition_columns**

<table>
<thead>
<tr>
<th>column</th>
<th>type</th>
<th>reference</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>
<td>schemaname</td>
<td>name</td>
<td></td>
<td>The name of the schema the partitioned table is in.</td>
</tr>
<tr>
<td>tablename</td>
<td>name</td>
<td></td>
<td>The table name of the top-level parent table.</td>
</tr>
<tr>
<td>column</td>
<td>type</td>
<td>references</td>
<td>description</td>
</tr>
<tr>
<td>---------------------</td>
<td>----------</td>
<td>------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>columnname</td>
<td>name</td>
<td></td>
<td>The name of the partition key column.</td>
</tr>
<tr>
<td>partitionlevel</td>
<td>smallint</td>
<td></td>
<td>The level of this subpartition in the hierarchy.</td>
</tr>
<tr>
<td>position_in_</td>
<td>integer</td>
<td></td>
<td>For list partitions you can have a composite (multi-column) partition key.</td>
</tr>
<tr>
<td>partition_key</td>
<td></td>
<td></td>
<td>This shows the position of the column in a composite key.</td>
</tr>
</tbody>
</table>

**pg_partition_encoding**

The `pg_partition_encoding` system catalog table describes the available column compression options for a partition template.

**Table 180: pg_catalog.pg_attribute_encoding**

<table>
<thead>
<tr>
<th>column</th>
<th>type</th>
<th>modifiers</th>
<th>storage</th>
<th>description</th>
</tr>
</thead>
<tbody>

</tr>
<tr>
<td>parencatoption</td>
<td>text []</td>
<td></td>
<td>extended</td>
<td></td>
</tr>
</tbody>
</table>

**pg_partition_rule**

The `pg_partition_rule` system catalog table is used to track partitioned tables, their check constraints, and data containment rules. Each row of `pg_partition_rule` represents either a leaf partition (the bottom level partitions that contain data), or a branch partition (a top or mid-level partition that is used to define the partition hierarchy, but does not contain any data).

**Table 181: pg_catalog.pg_partition_rule**

<table>
<thead>
<tr>
<th>column</th>
<th>type</th>
<th>references</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>
<td>paroid</td>
<td>oid</td>
<td>pg_partition.oid</td>
<td>Row identifier of the partitioning level (from <code>pg_partition</code>) to which this partition belongs. In the case of a branch partition, the corresponding table (identified by <code>pg_partition_rule</code>) is an empty container table. In case of a leaf partition, the table contains the rows for that partition containment rule.</td>
</tr>
<tr>
<td>parchildrelid</td>
<td>oid</td>
<td>pg_class.oid</td>
<td>The table identifier of the partition (child table).</td>
</tr>
</tbody>
</table>
### pg_partition_rule

<table>
<thead>

<td></td>
<td>For range partitions, the rank of the partition compared to other partitions of the same level.</td>
</tr>
<tr>
<td>partitionposition</td>
<td>smallint</td>
<td></td>
<td>The rule order position of this partition.</td>
</tr>
</tbody>
</table>
### pg_pltemplate

The `pg_pltemplate` system catalog table stores template information for procedural languages. A template for a language allows the language to be created in a particular database by a simple `CREATE LANGUAGE` command, with no need to specify implementation details. Unlike most system catalogs, `pg_pltemplate` is shared across all databases of Greenplum system: there is only one copy of `pg_pltemplate` per system, not one per database. This allows the information to be accessible in each database as it is needed.

There are not currently any commands that manipulate procedural language templates; to change the built-in information, a superuser must modify the table using ordinary `INSERT`, `DELETE`, or `UPDATE` commands.

#### Table 184: pg_catalog.pg_pltemplate

<table>
<thead>
<tr>
<th>column</th>
<th>type</th>
<th>references</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>
<td>tmplname</td>
<td>name</td>

<td>text</td>
<td></td>
<td>Name of call handler function</td>
</tr>
<tr>
<td>tmplvalidator</td>
<td>text</td>
<td></td>
<td>Name of validator function, or NULL if none</td>
</tr>
</tbody>
</table>
### pg_proc

The `pg_proc` system catalog table stores information about functions (or procedures), both built-in functions and those defined by `CREATE FUNCTION`. The table contains data for aggregate and window functions as well as plain functions. If `proisagg` is true, there should be a matching row in `pg_aggregate`.

For compiled functions, both built-in and dynamically loaded, `prosrc` contains the function's C-language name (link symbol). For all other currently-known language types, `prosrc` contains the function's source text. `probin` is unused except for dynamically-loaded C functions, for which it gives the name of the shared library file containing the function.

#### Table 185: `pg_catalog.pg_proc`

</table>

**pg_resgroupcapability**

*Note:* The `pg_resgroupcapability` system catalog table is valid only when resource group-based resource management is active.

The `pg_resgroupcapability` system catalog table contains information about the capabilities and limits of defined Greenplum Database resource groups. You can join this table to the `pg_resgroup` table by resource group object ID.

The `pg_resgroupcapability` table, defined in the `pg_global` tablespace, is globally shared across all databases in the system.

**Table 187: pg_catalog.pg_resgroupcapability**

<table>

</tbody>
</table>

### pg_resourcetype

The `pg_resourcetype` system catalog table contains information about the extended attributes that can be assigned to Greenplum Database resource queues. Each row details an attribute and inherent qualities such as its default setting, whether it is required, and the value to disable it (when allowed).

This table is populated only on the master. This table is defined in the `pg_global` tablespace, meaning it is globally shared across all databases in the system.

**Table 188: pg_catalog.pg_resourcetype**

<table>
<thead>
<tr>
<th>column</th>

</tbody>
</table>

**pg_resqueue**

*Note:* The `pg_resqueue` system catalog table is valid only when resource queue-based resource management is active.

The `pg_resqueue` system catalog table contains information about Greenplum Database resource queues, which are used for the resource management feature. This table is populated only on the master. This table is defined in the `pg_global` tablespace, meaning it is globally shared across all databases in the system.

**Table 189: pg_catalog.pg_resqueue**

<table>
<thead>
<tr>
<th>column</th>
<th>type</th>
<th>references</th>
<th>description</th>

<td>real</td>
<td></td>
<td>The active query threshold of the resource queue.</td>
</tr>
<tr>
<td>rsqcostlimit</td>
<td>real</td>
<td></td>
<td>The query cost threshold of the resource queue.</td>
</tr>
<tr>
<td>rsqovercommit</td>
<td>boolean</td>
<td></td>
<td>Allows queries that exceed the cost threshold to run when the system is idle.</td>
</tr>
<tr>
<td>rsqignorecostlimit</td>
<td>real</td>
<td></td>
<td>The query cost limit of what is considered a 'small query'. Queries with a cost under this limit will not be queued and run immediately.</td>
</tr>
</tbody>
</table>

**pg_resqueue_attributes**

*Note:* The `pg_resqueue_attributes` view is valid only when resource queue-based resource management is active.

The `pg_resqueue_attributes` view allows administrators to see the attributes set for a resource queue, such as its active statement limit, query cost limits, and priority.
Table 190: pg_catalog.pg_resqueue_attributes

<table>
<thead>
<tr>

</tbody>
</table>

pg_resqueuecapability

Note: The pg_resqueuecapability system catalog table is valid only when resource queue-based resource management is active.

The pg_resqueuecapability system catalog table contains information about the extended attributes, or capabilities, of existing Greenplum Database resource queues. Only resource queues that have been assigned an extended capability, such as a priority setting, are recorded in this table. This table is joined to the pg_resqueue table by resource queue object ID, and to the pg_resourcetype table by resource type ID (restypid).

This table is populated only on the master. This table is defined in the pg_global tablespace, meaning it is globally shared across all databases in the system.

Table 191: pg_catalog.pg_resqueuecapability

<table>
<thead>
<tr>

<td>The specific value set for the capability referenced in this record. Depending on the actual resource type, this value may have different data types.</td>
</tr>
</tbody>
</table>

pg_rewrite

The pg_rewrite system catalog table stores rewrite rules for tables and views. pg_class.relhasrules must be true if a table has any rules in this catalog.
Table 192: pg_catalog.pg_rewrite

<table>
<thead>
<tr>
<th>column</th>
<th>type</th>
<th>references</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>
<td>rulename</td>
<td>name</td>

<td>Query tree (in the form of a nodeToString() representation) for the rule’s action.</td>
</tr>
</tbody>
</table>

pg_roles

The view pg_roles provides access to information about database roles. This is simply a publicly readable view of pg_authid that blanks out the password field. This view explicitly exposes the OID column of the underlying table, since that is needed to do joins to other catalogs.

Table 193: pg_catalog.pg_roles

<table>
<thead>
<tr>

</tr>
</tbody>
</table>

**pg_shdepend**

The **pg_shdepend** system catalog table records the dependency relationships between database objects and shared objects, such as roles. This information allows Greenplum Database to ensure that those objects are unreferenced before attempting to delete them. See also **pg_depend**, which performs
a similar function for dependencies involving objects within a single database. Unlike most system catalogs, `pg_shdepend` is shared across all databases of Greenplum system: there is only one copy of `pg_shdepend` per system, not one per database.

In all cases, a `pg_shdepend` entry indicates that the referenced object may not be dropped without also dropping the dependent object. However, there are several subflavors identified by `deptype`:

- **SHARED_DEPENDENCY_OWNER (o)** — The referenced object (which must be a role) is the owner of the dependent object.
- **SHARED_DEPENDENCY_ACL (a)** — The referenced object (which must be a role) is mentioned in the ACL (access control list) of the dependent object.
- **SHARED_DEPENDENCY_PIN (p)** — There is no dependent object; this type of entry is a signal that the system itself depends on the referenced object, and so that object must never be deleted. Entries of this type are created only by system initialization. The columns for the dependent object contain zeroes.

**Table 194: pg_catalog.pg_shdepend**

<table>
<thead>
<tr>
<th>column</th>
<th>type</th>
<th>references</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dbid</td>
<td>oid</td>

<td>For a table column, this is the referenced column number. For all other object types, this column is zero.</td>
</tr>
<tr>
<td>deptype</td>
<td>char</td>
<td></td>
<td>A code defining the specific semantics of this dependency relationship.</td>
</tr>
</tbody>
</table>

**pg_shdescription**

The `pg_shdescription` system catalog table stores optional descriptions (comments) for shared database objects. Descriptions can be manipulated with the `COMMENT` command and viewed with `psql`'s...
\d meta-commands. See also \texttt{pg\_description}, which performs a similar function for descriptions involving objects within a single database. Unlike most system catalogs, \texttt{pg\_shdescription} is shared across all databases of a Greenplum system: there is only one copy of \texttt{pg\_shdescription} per system, not one per database.

Table 195: \texttt{pg\_catalog.pg\_shdescription}

<table>
<thead>
<tr>
<th>column</th>
<th>type</th>
<th>references</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>
<td>objoid</td>

<td>oid</td>
<td>pg_class.oid</td>
<td>The OID of the system catalog this object appears in</td>
</tr>
<tr>
<td>description</td>
<td>text</td>
<td></td>
<td>Arbitrary text that serves as the description of this object.</td>
</tr>
</tbody>
</table>

\textbf{pg\_stat\_activity}

The view \texttt{pg\_stat\_activity} shows one row per server process with details about the associated user session and query. The columns that report data on the current query are available unless the parameter \texttt{stats\_command\_string} has been turned off. Furthermore, these columns are only visible if the user examining the view is a superuser or the same as the user owning the process being reported on.

The maximum length of the query text string stored in the column \texttt{query} can be controlled with the server configuration parameter \texttt{track\_activity\_query\_size}.

Table 196: \texttt{pg\_catalog.pg\_stat\_activity}

</tbody>
</table>
### pg_statistic

The `pg_statistic` system catalog table stores statistical data about the contents of the database. Entries are created by `ANALYZE` and subsequently used by the query optimizer. There is one entry for each table column that has been analyzed. Note that all the statistical data is inherently approximate, even assuming that it is up-to-date.

`pg_statistic` also stores statistical data about the values of index expressions. These are described as if they were actual data columns; in particular, `starelid` references the index. No entry is made for an ordinary non-expression index column, however, since it would be redundant with the entry for the underlying table column. Currently, entries for index expressions always have `stainherit = false`.

When `stainherit = false`, there is normally one entry for each table column that has been analyzed. If the table has inheritance children, Greenplum Database creates a second entry with `stainherit = true`. This row represents the column's statistics over the inheritance tree, for example, statistics for the data you would see with `SELECT column FROM table*`, whereas the `stainherit = false` row represents the results of `SELECT column FROM ONLY table`.

Since different kinds of statistics may be appropriate for different kinds of data, `pg_statistic` is designed not to assume very much about what sort of statistics it stores. Only extremely general statistics (such as nullness) are given dedicated columns in `pg_statistic`. Everything else is stored in slots, which are groups of associated columns whose content is identified by a code number in one of the slot's columns.

Statistical information about a table's contents should be considered sensitive (for example: minimum and maximum values of a salary column). `pg_stats` is a publicly readable view on `pg_statistic` that only exposes information about those tables that are readable by the current user.

**Warning:** Diagnostic tools such as `gpsd` and `minirepro` collect sensitive information from `pg_statistic`, such as histogram boundaries, in a clear, readable form. Always review the output files of these utilities to ensure that the contents are acceptable for transport outside of the database in your organization.

### Table 202: `pg_catalog.pg_statistic`

**Table 202: pg_catalog.pg_statistic**
<table>
<thead>
<tr>
<th>column</th>
<th>type</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>
<td>stainherit</td>
<td>bool</td>
<td>If true, the statistics include inheritance child columns, not just the values in the specified relations.</td>
</tr>
<tr>
<td>stanullfrac</td>
<td>float4</td>
<td>The fraction of the column's entries that are null.</td>
</tr>
<tr>
<td>stawidth</td>
<td>int4</td>
<td>The average stored width, in bytes, of nonnull entries.</td>
</tr>
<tr>
<td>stadistinct</td>
<td>float4</td>
<td>The number of distinct nonnull data values in the column. A value greater than zero is the actual number of distinct values. A value less than zero is the negative of a fraction of the number of rows in the table (for example, a column in which values appear about twice on the average could be represented by <code>stadistinct = -0.5</code>). A zero value means the number of distinct values is unknown.</td>
</tr>
<tr>
<td>stakindN</td>
<td>int2</td>
<td>A code number indicating the kind of statistics stored in the Nth slot of the pg_statistic row.</td>
</tr>
<tr>
<td>staopN</td>
<td>oid</td>
<td>An operator used to derive the statistics stored in the Nth slot. For example, a histogram slot would show the &lt; operator that defines the sort order of the data.</td>
</tr>
<tr>
<td>stanumbersN</td>
<td>float4[]</td>
<td>Numerical statistics of the appropriate kind for the Nth slot, or NULL if the slot kind does not involve numerical values.</td>
</tr>
</tbody>
</table>
pg_stat_resqueues

Note: The pg_stat_resqueues view is valid only when resource queue-based resource management is active.

The pg_stat_resqueues view allows administrators to view metrics about a resource queue’s workload over time. To allow statistics to be collected for this view, you must enable the stats_queue_level server configuration parameter on the Greenplum Database master instance. Enabling the collection of these metrics does incur a small performance penalty, as each statement submitted through a resource queue must be logged in the system catalog tables.

Table 203: pg_catalog.pg_stat_resqueues

</tr>
</tbody>
</table>
pg_tablespace

The `pg_tablespace` system catalog table stores information about the available tablespaces. Tables can be placed in particular tablespaces to aid administration of disk layout. Unlike most system catalogs, `pg_tablespace` is shared across all databases of a Greenplum system: there is only one copy of `pg_tablespace` per system, not one per database.

<table>
<thead>

<tr>
<td>tgattr</td>
<td>int2vector</td>
<td></td>
<td>Currently not used.</td>
</tr>
<tr>
<td>tgargs</td>
<td>bytea</td>
<td></td>
<td>Argument strings to pass to trigger, each NULL-terminated.</td>
</tr>
</tbody>
</table>

**pg_type**

The `pg_type` system catalog table stores information about data types. Base types (scalar types) are created with `CREATE TYPE`, and domains with `CREATE DOMAIN`. A composite type is automatically created for each table in the database, to represent the row structure of the table. It is also possible to create composite types with `CREATE TYPE AS`.

**Table 206: pg_catalog.pg_type**

<table>
<thead>
<tr>
<th>column</th>
<th>type</th>
<th>references</th>
<th>description</th>
</tr>
</thead>
<tbody>

</table>
| typalign | char     |            | The alignment required when storing a value of this type. It applies to storage on disk as well as most representations of the value inside Greenplum Database. When multiple values are stored consecutively, such as in the representation of a complete row on disk, padding is inserted before a datum of this type so that it begins on the specified boundary. The alignment reference is the beginning of the first datum in the sequence. Possible values are:  
  c = char alignment (no alignment needed).  
  s = short alignment (2 bytes on most machines).  
  i = int alignment (4 bytes on most machines).  
  d = double alignment (8 bytes on many machines, but not all). |
<table>
<thead>
<tr>
<th>column</th>
<th>type</th>
<th>references</th>
<th>description</th>
</tr>
</thead>
</table>
| typstorage | char    |            | For varlena types (those with `typlen = -1`) tells if the type is prepared for toasting and what the default strategy for attributes of this type should be. Possible values are:  
<p>|            |         |            | <code>p</code>: Value must always be stored plain.                                                                                                         |
|            |         |            | <code>e</code>: Value can be stored in a secondary relation (if relation has one, see <code>pg_class.reltoastrelid</code>).                                             |
|            |         |            | <code>m</code>: Value can be stored compressed inline.                                                                                                     |
|            |         |            | <code>x</code>: Value can be stored compressed inline or stored in secondary storage.                                                                          |
|            |         |            | Note that <code>m</code> columns can also be moved out to secondary storage, but only as a last resort (<code>e</code> and <code>x</code> columns are moved first).               |
| typnotnull | boolean |            | Represents a not-null constraint on a type. Used for domains only.                                                                              |
| typbasetype| oid     | <code>pg_type.oid</code> | Identifies the type that a domain is based on. Zero if this type is not a domain.                                                              |
| typtypmod  | int4    |            | Domains use <code>typtypmod</code> to record the <code>typmod</code> to be applied to their base type (-1 if base type does not use a <code>typmod</code>). <code>-1</code> if this type is not a domain. |</p>

</tbody>
</table>

**pg_type_encoding**

The `pg_type_encoding` system catalog table contains the column storage type information.

Table 208: pg_catalog.pg_type_encoding

<table>
<thead>
<tr>
<th>column</th>
<th>type</th>
<th>modifiers</th>
<th>storage</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>
<td>typeid</td>
<td>oid</td>
<td>not null</td>
<td>plain</td>
<td>Foreign key to <code>pg_</code>attribute</td>
</tr>
<tr>
<td>typoptions</td>
<td>text[]</td>
<td></td>
<td>extended</td>
<td>The actual options</td>
</tr>
</tbody>
</table>

**pg_user_mapping**

The system catalog table `pg_user_mapping` stores the mappings from local user to remote user. You must have administrator privileges to view this catalog. Access to this catalog is restricted from normal users, use the `pg_user_mappings` view instead.

Table 209: pg_catalog.pg_user_mapping

<table>
<thead>
<tr>
<th>column</th>
<th>type</th>
<th>references</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>
<td>umuser</td>
<td>oid</td>
<td>pg_authid.oid</td>
<td>OID of the local role being mapped, 0 if the user mapping is public.</td>
</tr>
<tr>
<td>column</td>
<td>type</td>
<td>references</td>
<td>description</td>
</tr>
<tr>
<td>-----------</td>
<td>----------</td>
<td>--------------------</td>
<td>--------------------------------------------------</td>
</tr>
<tr>
<td>umserver</td>
<td>oid</td>
<td>pg_foreign_server.oid</td>
<td>OID of the foreign server that contains this mapping.</td>
</tr>
<tr>
<td>umoptions</td>
<td>text[]</td>
<td></td>
<td>User mapping-specific options, as “keyword=value” strings.</td>
</tr>
</tbody>
</table>

**pg_user_mappings**

The `pg_user_mappings` view provides access to information about user mappings. This view is essentially a public-readable view of the `pg_user_mapping` system catalog table that omits the options field if the user does not have access rights to view it.

**Table 210: pg_user_mappings**

<table>
<thead>
<tr>
<th>column</th>
<th>type</th>
<th>references</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>
<td>umid</td>
<td>oid</td>
<td>pg_user_mapping.oid</td>
<td>OID of the user mapping.</td>
</tr>
<tr>
<td>srvid</td>
<td>oid</td>
<td>pgForeignServer.oid</td>
<td>OID of the foreign server that contains this mapping.</td>
</tr>
<tr>
<td>srvname</td>
<td>text</td>
<td>pgForeignServer.srvname</td>
<td>Name of the foreign server.</td>
</tr>
<tr>
<td>umuser</td>
<td>oid</td>
<td>pg_authid.oid</td>
<td>OID of the local role being mapped, 0 if the user mapping is public.</td>
</tr>
<tr>
<td>username</td>
<td>name</td>
<td></td>
<td>Name of the local user to be mapped.</td>
</tr>
<tr>
<td>umoptions</td>
<td>text[]</td>
<td></td>
<td>User mapping-specific options, as “keyword=value” strings.</td>
</tr>
</tbody>
</table>

To protect password information stored as a user mapping option, the `umoptions` column reads as null unless one of the following applies:

- The current user is the user being mapped, and owns the server or holds USAGE privilege on it.
- The current user is the server owner and the mapping is for PUBLIC.
- The current user is a superuser.

**user_mapping_options**

The `user_mapping_options` view contains all of the options defined for user mappings in the current database. Greenplum Database displays only those user mappings to which the current user has access (by way of being the owner or having some privilege).
Table 211: user_mapping_options

<table>
<thead>
<tr>
<th>column</th>

</tbody>
</table>
The gp_toolkit Administrative Schema

Greenplum Database provides an administrative schema called gp_toolkit that you can use to query the system catalogs, log files, and operating environment for system status information. The gp_toolkit schema contains a number of views that you can access using SQL commands. The gp_toolkit schema is accessible to all database users, although some objects may require superuser permissions. For convenience, you may want to add the gp_toolkit schema to your schema search path. For example:

```sql
=> ALTER ROLE myrole SET search_path TO myschema,gp_toolkit;
```

This documentation describes the most useful views in gp_toolkit. You may notice other objects (views, functions, and external tables) within the gp_toolkit schema that are not described in this documentation (these are supporting objects to the views described in this section).

**Warning:** Do not change database objects in the gp_toolkit schema. Do not create database objects in the schema. Changes to objects in the schema might affect the accuracy of administrative information returned by schema objects. Any changes made in the gp_toolkit schema are lost when the database is backed up and then restored with the gpbackup and gprestore utilities.

These are the categories for views in the gp_toolkit schema.

### Checking for Tables that Need Routine Maintenance

The following views can help identify tables that need routine table maintenance (VACUUM and/or ANALYZE).

- `gp_bloat_diag`
- `gp_stats_missing`

The VACUUM or VACUUM FULL command recovers disk space occupied by deleted or obsolete rows. Because of the MVCC transaction concurrency model used in Greenplum Database, data rows that are deleted or updated still occupy physical space on disk even though they are not visible to any new transactions. Expired rows increase table size on disk and eventually slow down scans of the table.

The ANALYZE command collects column-level statistics needed by the query optimizer. Greenplum Database uses a cost-based query optimizer that relies on database statistics. Accurate statistics allow the query optimizer to better estimate selectivity and the number of rows retrieved by a query operation in order to choose the most efficient query plan.

**gp_bloat_diag**

This view shows regular heap-storage tables that have bloat (the actual number of pages on disk exceeds the expected number of pages given the table statistics). Tables that are bloated require a VACUUM or a VACUUM FULL in order to reclaim disk space occupied by deleted or obsolete rows. This view is accessible to all users, however non-superusers will only be able to see the tables that they have permission to access.

**Note:** For diagnostic functions that return append-optimized table information, see Checking Append-Optimized Tables.

<table>
<thead>

<td>Does this table have statistics? False if the table does not have row count and row sizing statistics recorded in the system catalog, which may indicate that the table needs to be analyzed. This will also be false if the table does not contain any rows. For example, the parent tables of partitioned tables are always empty and will always return a false result.</td>
</tr>
<tr>
<td>smicols</td>
<td>Number of columns in the table.</td>
</tr>
<tr>
<td>smirecs</td>
<td>Number of rows in the table.</td>
</tr>
</tbody>
</table>

**Checking for Locks**

When a transaction accesses a relation (such as a table), it acquires a lock. Depending on the type of lock acquired, subsequent transactions may have to wait before they can access the same relation. For more information on the types of locks, see "Managing Data" in the Greenplum Database Administrator Guide. Greenplum Database resource queues (used for resource management) also use locks to control the admission of queries into the system.

The `gp_locks_*` family of views can help diagnose queries and sessions that are waiting to access an object due to a lock.

- `gp_locks_on_relation`
- `gp_locks_on_resqueue`

**gp_locks_on_relation**

This view shows any locks currently being held on a relation, and the associated session information about the query associated with the lock. For more information on the types of locks, see "Managing Data" in the Greenplum Database Administrator Guide. This view is accessible to all users, however non-superusers will only be able to see the locks for relations that they have permission to access.
Table 215: gp_locks_on_relation view

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>

</tr>
<tr>
<td>lorgranted</td>
<td>Displays whether the lock is granted (true) or not granted (false).</td>
</tr>
<tr>
<td>lorwaiting</td>
<td>Displays whether or not the session is waiting.</td>
</tr>
</tbody>
</table>

**gp_locks_on_resqueue**

**Note:** The gp_locks_on_resqueue view is valid only when resource queue-based resource management is active.

This view shows any locks currently being held on a resource queue, and the associated session information about the query associated with the lock. This view is accessible to all users, however non-superusers will only be able to see the locks associated with their own sessions.
**Checking Append-Optimized Tables**

The `gp_toolkit` schema includes a set of diagnostic functions you can use to investigate the state of append-optimized tables.

When an append-optimized table (or column-oriented append-optimized table) is created, another table is implicitly created, containing metadata about the current state of the table. The metadata includes information such as the number of records in each of the table’s segments.

Append-optimized tables may have non-visible rows—rows that have been updated or deleted, but remain in storage until the table is compacted using `VACUUM`. The hidden rows are tracked using an auxiliary visibility map table, or visimap.

The following functions let you access the metadata for append-optimized and column-oriented tables and view non-visible rows. Some of the functions have two versions: one that takes the `oid` of the table, and one that takes the name of the table. The latter version has "_name" appended to the function name.

`__gp_aovisimap_compaction_info(oid)`

This function displays compaction information for an append-optimized table. The information is for the on-disk data files on Greenplum Database segments that store the table data. You can use the information to determine the data files that will be compacted by a `VACUUM` operation on an append-optimized table.

**Note:** Until a `VACUUM` operation deletes the row from the data file, deleted or updated data rows occupy physical space on disk even though they are hidden to new transactions. The configuration parameter `gp_appendonly_compaction` controls the functionality of the `VACUUM` command.

This table describes the `__gp_aovisimap_compaction_info` function output table.

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>content</td>
<td>Greenplum Database segment ID.</td>
</tr>
<tr>
<td>datafile</td>
<td>ID of the data file on the segment.</td>
</tr>
<tr>
<td>compaction_possible</td>
<td>The value is either t or f. The value t indicates that the data in data file be compacted when a <code>VACUUM</code> operation is performed.</td>
</tr>
<tr>
<td></td>
<td>The server configuration parameter <code>gp_appendonly_compaction_threshold</code> affects this value.</td>
</tr>
<tr>
<td>hidden_tupcount</td>
<td>In the data file, the number of hidden (deleted or updated) rows.</td>
</tr>
<tr>
<td>total_tupcount</td>
<td>In the data file, the total number of rows.</td>
</tr>
<tr>
<td>percent_hidden</td>
<td>In the data file, the ratio (as a percentage) of hidden (deleted or updated) rows to total rows.</td>
</tr>
</tbody>
</table>

`__gp_aoseg_name('table_name')`

This function returns metadata information contained in the append-optimized table’s on-disk segment file.
Table 218: __gp_aoseg_name output table

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>segno</td>
<td>The file segment number.</td>
</tr>
<tr>
<td>eof</td>
<td>The effective end of file for this file segment.</td>
</tr>
<tr>
<td>tupcount</td>
<td>The total number of tuples in the segment, including invisible tuples.</td>
</tr>
<tr>
<td>varblockcount</td>
<td>The total number of varblocks in the file segment.</td>
</tr>
<tr>
<td>eof_uncompressed</td>
<td>The end of file if the file segment were uncompressed.</td>
</tr>
<tr>
<td>modcount</td>
<td>The number of data modification operations.</td>
</tr>
<tr>
<td>state</td>
<td>The state of the file segment. Indicates if the segment is active or ready to be dropped after compaction.</td>
</tr>
</tbody>
</table>

__gp_aoseg_history(oid)

This function returns metadata information contained in the append-optimized table's on-disk segment file. It displays all different versions (heap tuples) of the aoseg meta information. The data is complex, but users with a deep understanding of the system may find it useful for debugging.

The input argument is the oid of the append-optimized table.

Call __gp_aoseg_history_name('table_name') to get the same result with the table name as an argument.

Table 219: __gp_aoseg_history output table

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>gp_tid</td>
<td>The id of the tuple.</td>
</tr>
<tr>

<td>The id of the latest transaction.</td>
</tr>
<tr>
<td>gp_xmax_status</td>
<td>The status of the latest transaction.</td>
</tr>
<tr>
<td>gp_xmax_commit_</td>
<td>The commit distribution id of the gp_xmax transaction.</td>
</tr>
<tr>
<td>gp_command_id</td>
<td>The id of the query command.</td>
</tr>
<tr>
<td>gp_infomask</td>
<td>A bitmap containing state information.</td>
</tr>
<tr>
<td>gp_update_tid</td>
<td>The ID of the newer tuple if the row is updated.</td>
</tr>
<tr>
<td>gp_visibility</td>
<td>The tuple visibility status.</td>
</tr>
<tr>
<td>segno</td>
<td>The number of the segment in the segment file.</td>
</tr>
<tr>
<td>tupcount</td>
<td>The number of tuples, including hidden tuples.</td>
</tr>
<tr>
<td>eof</td>
<td>The effective end of file for the segment.</td>
</tr>
</tbody>
</table>
Column | Description
--- | ---
eof\_uncompressed | The end of file for the segment if data were uncompressed.
modcount | A count of data modifications.
state | The status of the segment.

___gp\_aocsseg(oid)___

This function returns metadata information contained in a column-oriented append-optimized table’s on-disk segment file, excluding non-visible rows. Each row describes a segment for a column in the table.

The input argument is the oid of a column-oriented append-optimized table. Call as ___gp\_aocsseg\_name('table\_name')___ to get the same result with the table name as an argument.

Table 220: ___gp\_aocsseg(oid)___ output table

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>

</tr>
<tr>
<td>modcount</td>
<td>A count of data modification operations for the segment.</td>
</tr>
<tr>
<td>state</td>
<td>The status of the segment.</td>
</tr>
</tbody>
</table>

___gp\_aocsseg\_history(oid)___

This function returns metadata information contained in a column-oriented append-optimized table’s on-disk segment file. Each row describes a segment for a column in the table. The data is complex, but users with a deep understanding of the system may find it useful for debugging.

The input argument is the oid of a column-oriented append-optimized table. Call as ___gp\_aocsseg\_history\_name('table\_name')___ to get the same result with the table name as argument.

Table 221: ___gp\_aocsseg\_history output table

<table>
<thead>

<tr>
<td>eof_uncompressed</td>
<td>The end of file for the segment if the data were uncompressed.</td>
</tr>
<tr>
<td>modcount</td>
<td>A count of the data modification operations.</td>
</tr>
<tr>
<td>state</td>
<td>The state of the segment.</td>
</tr>
</tbody>
</table>

__gp_aovisimap(oid)__,

This function returns the tuple id, the segment file, and the row number of each non-visible tuple according to the visibility map.

The input argument is the oid of an append-optimized table.

Use __gp_aovisimap_name('table_name') to get the same result with the table name as argument.

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>tid</td>
<td>The tuple id.</td>
</tr>
<tr>
<td>segno</td>
<td>The number of the segment file.</td>
</tr>
<tr>
<td>row_num</td>
<td>The row number of a row that has been deleted or updated.</td>
</tr>
</tbody>
</table>

__gp_aovisimap_hidden_info(oid)__,

This function returns the numbers of hidden and visible tuples in the segment files for an append-optimized table.

The input argument is the oid of the append-optimized table.

Call __gp_aovisimap_hidden_info_name('table_name') to get the same result with a table name argument.

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>segno</td>
<td>The number of the segment file.</td>
</tr>
<tr>
<td>hidden_tupcount</td>
<td>The number of hidden tuples in the segment file.</td>
</tr>
</tbody>
</table>
**Column** | **Description**
---|---
total_tupcount | The total number of tuples in the segment file.

**__gp_aovisimap_entry(oid)**

This function returns information about each visibility map entry for the table.
The input argument is the oid of an append-optimized table.
Call **__gp_aovisimap_entry_name('table_name')** to get the same result with a table name argument.

**Table 222: __gp_aovisimap_entry output table**

<table>
<thead>
<tr>

<tr>
<td>first_row_num</td>
<td>The first row number of the entry.</td>
</tr>
<tr>
<td>hidden_tupcount</td>
<td>The number of hidden tuples in the entry.</td>
</tr>
<tr>
<td>bitmap</td>
<td>A text representation of the visibility bitmap.</td>
</tr>
</tbody>
</table>

**Viewing Greenplum Database Server Log Files**

Each component of a Greenplum Database system (master, standby master, primary segments, and mirror segments) keeps its own server log files. The gp_log_* family of views allows you to issue SQL queries against the server log files to find particular entries of interest. The use of these views require superuser permissions.

- **gp_log_command_timings**
- **gp_log_database**
- **gp_log_master_concise**
- **gp_log_system**

**gp_log_command_timings**

This view uses an external table to read the log files on the master and report the execution time of SQL commands executed in a database session. The use of this view requires superuser permissions.

**Table 223: gp_log_command_timings view**

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>logsession</td>
<td>The session identifier (prefixed with &quot;con&quot;).</td>
</tr>
<tr>
<td>logcmdcount</td>
<td>The command number within a session (prefixed with &quot;cmd&quot;).</td>
</tr>
<tr>
<td>logdatabase</td>
<td>The name of the database.</td>
</tr>
<tr>
<td>loguser</td>
<td>The name of the database user.</td>
</tr>
<tr>
<td>logpid</td>
<td>The process id (prefixed with &quot;p&quot;).</td>
</tr>
<tr>
<td>logtimemin</td>
<td>The time of the first log message for this command.</td>
</tr>
<tr>
<td>logtimemax</td>
<td>The time of the last log message for this command.</td>
</tr>
<tr>
<td>logduration</td>
<td>Statement duration from start to end time.</td>
</tr>
</tbody>
</table>
**gp_log_database**

This view uses an external table to read the server log files of the entire Greenplum system (master, segments, and mirrors) and lists log entries associated with the current database. Associated log entries can be identified by the session id (logsession) and command id (logcmdcount). The use of this view requires superuser permissions.

**Table 224: gp_log_database view**

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>logtime</td>
<td>The timestamp of the log message.</td>

<td>The function in which this message is generated.</td>
</tr>
<tr>
<td>logfile</td>
<td>The log file in which this message is generated.</td>
</tr>
<tr>
<td>logline</td>
<td>The line in the log file in which this message is generated.</td>
</tr>
<tr>
<td>logstack</td>
<td>Full text of the stack trace associated with this message.</td>
</tr>
</tbody>
</table>

**gp_log_master_concise**

This view uses an external table to read a subset of the log fields from the master log file. The use of this view requires superuser permissions.

Table 225: gp_log_master_concise view

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>logtime</td>
<td>The timestamp of the log message.</td>

<td>The name of the database user.</td>
</tr>
<tr>
<td>logdatabase</td>
<td>The name of the database.</td>
</tr>
<tr>
<td>logpid</td>
<td>The associated process id (prefixed with &quot;p&quot;).</td>
</tr>
<tr>
<td>logthread</td>
<td>The associated thread count (prefixed with &quot;th&quot;).</td>
</tr>
<tr>
<td>loghost</td>
<td>The segment or master host name.</td>
</tr>
<tr>
<td>logport</td>
<td>The segment or master port.</td>
</tr>
<tr>
<td>logsessiontime</td>
<td>Time session connection was opened.</td>
</tr>
</tbody>
</table>
### Checking Server Configuration Files

Each component of a Greenplum Database system (master, standby master, primary segments, and mirror segments) has its own server configuration file (`postgresql.conf`). The following `gp_toolkit` objects can be used to check parameter settings across all primary `postgresql.conf` files in the system:

- `gp_param_setting('parameter_name')`
- `gp_param_settings_seg_value_diffs`

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>logtransaction</td>
<td>Global transaction id.</td>
</tr>
<tr>
<td>logsession</td>
<td>The session identifier (prefixed with &quot;con&quot;).</td>
</tr>
<tr>
<td>logcmdcount</td>
<td>The command number within a session (prefixed with &quot;cmd&quot;).</td>
</tr>
<tr>
<td>logsegment</td>
<td>The segment content identifier (prefixed with &quot;seg&quot; for primary or &quot;mir&quot; for mirror. The master always has a content id of -1).</td>
</tr>
<tr>
<td>logslice</td>
<td>The slice id (portion of the query plan being executed).</td>
</tr>
<tr>
<td>logdistxact</td>
<td>Distributed transaction id.</td>
</tr>
<tr>
<td>loglocalxact</td>
<td>Local transaction id.</td>
</tr>
<tr>
<td>logsubxact</td>
<td>Subtransaction id.</td>
</tr>
<tr>
<td>logseverity</td>
<td>LOG, ERROR, FATAL, PANIC, DEBUG1 or DEBUG2.</td>
</tr>
<tr>
<td>logstate</td>
<td>SQL state code associated with the log message.</td>
</tr>
<tr>
<td>logmessage</td>
<td>Log or error message text.</td>
</tr>
<tr>
<td>logdetail</td>
<td>Detail message text associated with an error message.</td>
</tr>
<tr>
<td>loghint</td>
<td>Hint message text associated with an error message.</td>
</tr>
<tr>
<td>logquery</td>
<td>The internally-generated query text.</td>
</tr>
<tr>
<td>logquerypos</td>
<td>The cursor index into the internally-generated query text.</td>
</tr>
<tr>
<td>logcontext</td>
<td>The context in which this message gets generated.</td>
</tr>
<tr>
<td>logdebug</td>
<td>Query string with full detail for debugging.</td>
</tr>
<tr>
<td>logcursorpos</td>
<td>The cursor index into the query string.</td>
</tr>
<tr>
<td>logfunction</td>
<td>The function in which this message is generated.</td>
</tr>
<tr>
<td>logfile</td>
<td>The log file in which this message is generated.</td>
</tr>
<tr>
<td>logline</td>
<td>The line in the log file in which this message is generated.</td>
</tr>
<tr>
<td>logstack</td>
<td>Full text of the stack trace associated with this message.</td>
</tr>
</tbody>
</table>
gp_param_setting('parameter_name')

This function takes the name of a server configuration parameter and returns the `postgresql.conf` value for the master and each active segment. This function is accessible to all users.

Table 227: gp_param_setting('parameter_name') function

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>paramsegment</td>
<td>The segment content id (only active segments are shown). The master content id is always -1.</td>
</tr>
<tr>
<td>paramname</td>
<td>The name of the parameter.</td>
</tr>
<tr>
<td>paramvalue</td>
<td>The value of the parameter.</td>
</tr>
</tbody>
</table>

Example:

```sql
SELECT * FROM gp_param_setting('max_connections');
```

gp_param_settings_seg_value_diffs

Server configuration parameters that are classified as `local` parameters (meaning each segment gets the parameter value from its own `postgresql.conf` file), should be set identically on all segments. This view shows local parameter settings that are inconsistent. Parameters that are supposed to have different values (such as `port`) are not included. This view is accessible to all users.

Table 228: gp_param_settings_seg_value_diffs view

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>psdname</td>
<td>The name of the parameter.</td>
</tr>
<tr>
<td>psdvalue</td>
<td>The value of the parameter.</td>
</tr>
<tr>
<td>psdcount</td>
<td>The number of segments that have this value.</td>
</tr>
</tbody>
</table>

Checking for Failed Segments

The `gp_pgdatabase_invalid` view can be used to check for down segments.

gp_pgdatabase_invalid

This view shows information about segments that are marked as down in the system catalog. This view is accessible to all users.

Table 229: gp_pgdatabase_invalid view

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pgdbidbid</td>
<td>The segment dbid. Every segment has a unique dbid.</td>
</tr>
<tr>
<td>pgdbiisprimary</td>
<td>Is the segment currently acting as the primary (active) segment? (t or f)</td>
</tr>
<tr>
<td>pgdbicontent</td>
<td>The content id of this segment. A primary and mirror will have the same content id.</td>
</tr>
</tbody>
</table>
Checking Resource Group Activity and Status

Note: The resource group activity and status views described in this section are valid only when resource group-based resource management is active.

Resource groups manage transactions to avoid exhausting system CPU and memory resources. Every database user is assigned a resource group. Greenplum Database evaluates every transaction submitted by a user against the limits configured for the user's resource group before running the transaction.

You can use the `gp_resgroup_config` view to check the configuration of each resource group. You can use the `gp_resgroup_status*` views to display the current transaction status and resource usage of each resource group.

- `gp_resgroup_config`
- `gp_resgroup_status`
- `gp_resgroup_status_per_host`
- `gp_resgroup_status_per_segment`

### gp_resgroup_config

The `gp_resgroup_config` view allows administrators to see the current CPU, memory, and concurrency limits for a resource group.

This view is accessible to all users.

**Table 230: gp_resgroup_config**

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>groupid</td>
<td>The ID of the resource group.</td>
</tr>
<tr>
<td>groupname</td>
<td>The name of the resource group.</td>
</tr>
<tr>
<td>concurrency</td>
<td>The concurrency (CONCURRENCY) value specified for the resource group.</td>
</tr>
<tr>
<td>cpu_rate_limit</td>
<td>The CPU limit (CPU_RATE_LIMIT) value specified for the resource group, or -1.</td>
</tr>
<tr>
<td>memory_limit</td>
<td>The memory limit (MEMORY_LIMIT) value specified for the resource group.</td>
</tr>
<tr>
<td>memory_shared_quota</td>
<td>The shared memory quota (MEMORY_SHARED_QUOTA) value specified for the resource group.</td>
</tr>
<tr>
<td>memory_spill_ratio</td>
<td>The memory spill ratio (MEMORY_SPILL_RATIO) value specified for the resource group.</td>
</tr>
<tr>
<td>memory_auditor</td>
<td>The memory auditor for the resource group.</td>
</tr>
<tr>
<td>cpuset</td>
<td>The CPU cores reserved for the resource group, or -1.</td>
</tr>
</tbody>
</table>
gp_resgroup_status

The gp_resgroup_status view allows administrators to see status and activity for a resource group. It shows how many queries are waiting to run and how many queries are currently active in the system for each resource group. The view also displays current memory and CPU usage for the resource group.

Note: Resource groups use the Linux control groups (cgroups) configured on the host systems. The cgroups are used to manage host system resources. When resource groups use cgroups that are as part of a nested set of cgroups, resource group limits are relative to the parent cgroup allotment. For information about nested cgroups and Greenplum Database resource group limits, see Understanding Role and Component Resource Groups.

This view is accessible to all users.

Table 231: gp_resgroup_status view

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>rsgname</td>
<td>The name of the resource group.</td>
</tr>
<tr>
<td>groupid</td>
<td>The ID of the resource group.</td>
</tr>
<tr>
<td>num_running</td>
<td>The number of transactions currently executing in the resource group.</td>
</tr>
<tr>
<td>num_queueing</td>
<td>The number of currently queued transactions for the resource group.</td>
</tr>
<tr>
<td>num_queued</td>
<td>The total number of queued transactions for the resource group since the Greenplum Database cluster was last started, excluding the num_queueing.</td>
</tr>
<tr>
<td>num_executed</td>
<td>The total number of executed transactions in the resource group since the Greenplum Database cluster was last started, excluding the num_running.</td>
</tr>
<tr>
<td>total_queue_duration</td>
<td>The total time any transaction was queued since the Greenplum Database cluster was last started.</td>
</tr>
<tr>
<td>cpu_usage</td>
<td>The real-time CPU usage of the resource group on each Greenplum Database segment's host.</td>
</tr>
<tr>
<td>memory_usage</td>
<td>The real-time memory usage of the resource group on each Greenplum Database segment's host.</td>
</tr>
</tbody>
</table>

The cpu_usage field is a JSON-formatted, key:value string that identifies, for each resource group, the per-segment CPU usage percentage. The key is segment id, the value is the percentage of CPU usage by the resource group on the segment host. The total CPU usage of all segments running on a segment host should not exceed the gp_resource_group_cpu_limit. Example cpu_usage column output:

```
{"-1":0.01, "0":0.31, "1":0.31}
```

In this example, segment 0 and segment 1 are running on the same host; their CPU usage is the same.

The memory_usage field is also a JSON-formatted, key:value string. The string contents differ depending upon the type of resource group. For each resource group that you assign to a role (default memory auditor vmtracker), this string identifies the used and available fixed and shared memory quota.
allocations on each segment. The key is segment id. The values are memory values displayed in MB units. The following example shows memory_usage column output for a single segment for a resource group that you assign to a role:

```
"0":{"used":0, "available":76, "quota_used":-1, "quota_available":60, "shared_used":0, "shared_available":16}
```

For each resource group that you assign to an external component, the memory_usage JSON-formatted string identifies the memory used and the memory limit on each segment. The following example shows memory_usage column output for an external component resource group for a single segment:

```
"1":{"used":11, "limit_granted":15}
```

**Note:** See the gp_resgroup_status_per_host and gp_resgroup_status_per_segment views, described below, for more user-friendly display of CPU and memory usage.

### gp_resgroup_status_per_host

The gp_resgroup_status_per_host view displays the real-time CPU and memory usage (MBs) for each resource group on a per-host basis. The view also displays available and granted group fixed and shared memory for each resource group on a host.

#### Table 232: gp_resgroup_status_per_host view

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>rsgname</td>
<td>The name of the resource group.</td>
</tr>
<tr>
<td>groupid</td>
<td>The ID of the resource group.</td>
</tr>
<tr>
<td>hostname</td>
<td>The hostname of the segment host.</td>
</tr>
<tr>
<td>cpu</td>
<td>The real-time CPU usage of the resource group on the host.</td>
</tr>
<tr>
<td>memory_used</td>
<td>The real-time memory usage of the resource group on the host. This total includes resource group fixed and shared memory. It also includes global shared memory used by the resource group.</td>
</tr>
<tr>
<td>memory_available</td>
<td>The unused fixed and shared memory for the resource group that is available on the host. This total does not include available resource group global shared memory.</td>
</tr>
<tr>
<td>memory_quota_used</td>
<td>The real-time fixed memory usage for the resource group on the host.</td>
</tr>
<tr>
<td>memory_quota_available</td>
<td>The fixed memory available to the resource group on the host.</td>
</tr>
<tr>
<td>memory_shared_used</td>
<td>The group shared memory used by the resource group on the host. If any global shared memory is used by the resource group, this amount is included in the total as well.</td>
</tr>
<tr>
<td>memory_shared_available</td>
<td>The amount of group shared memory available to the resource group on the host. Resource group global shared memory is not included in this total.</td>
</tr>
</tbody>
</table>
Sample output for the `gp_resgroup_status_per_host` view:

```
grpname      | groupid | hostname   | cpu  | memory_used | memory_available | memory_quota_used | memory_quota_available |
--------------+---------+------------+------|-------------|------------------|-------------------|-----------------------|
admin_group   | 6438    | my-desktop | 0.84 | 1           | 271              |                    |                       |
| 68          | 68      |            | 0    | 136         |                  |                   |                       |
default_group | 6437    | my-desktop | 0.00 | 0           | 816              |                    |                       |
| 0           | 400     |            | 0    | 416         |                  |                   |                       |
(2 rows)
```

**gp_resgroup_status_per_segment**

The `gp_resgroup_status_per_segment` view displays the real-time CPU and memory usage (MBs) for each resource group on a per-segment-instance and per-host basis. The view also displays available and granted group fixed and shared memory for each resource group and segment instance combination on the host.

**Table 233: gp_resgroup_status_per_segment view**

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>rsgname</td>
<td>The name of the resource group.</td>
</tr>
<tr>
<td>groupid</td>
<td>The ID of the resource group.</td>
</tr>
<tr>
<td>hostname</td>
<td>The hostname of the segment host.</td>
</tr>
<tr>
<td>segment_id</td>
<td>The content ID for a segment instance on the segment host.</td>
</tr>
<tr>
<td>cpu</td>
<td>The real-time CPU usage of the resource group for the segment instance on the host.</td>
</tr>
<tr>
<td>memory_used</td>
<td>The real-time memory usage of the resource group for the segment instance on the host. This total includes resource group fixed and shared memory. It also includes global shared memory used by the resource group.</td>
</tr>
<tr>
<td>memory_available</td>
<td>The unused fixed and shared memory for the resource group for the segment instance on the host.</td>
</tr>
<tr>
<td>memory_quota_used</td>
<td>The real-time fixed memory usage for the resource group for the segment instance on the host.</td>
</tr>
<tr>
<td>memory_quota_available</td>
<td>The fixed memory available to the resource group for the segment instance on the host.</td>
</tr>
<tr>
<td>memory_shared_used</td>
<td>The group shared memory used by the resource group for the segment instance on the host.</td>
</tr>
<tr>
<td>memory_shared_available</td>
<td>The amount of group shared memory available for the segment instance on the host. Resource group global shared memory is not included in this total.</td>
</tr>
</tbody>
</table>
Query output for this view is similar to that of the `gp_resgroup_status_per_host` view, and breaks out the CPU and memory (used and available) for each segment instance on each host.

**Checking Resource Queue Activity and Status**

**Note:** The resource queue activity and status views described in this section are valid only when resource queue-based resource management is active.

The purpose of resource queues is to limit the number of active queries in the system at any given time in order to avoid exhausting system resources such as memory, CPU, and disk I/O. All database users are assigned to a resource queue, and every statement submitted by a user is first evaluated against the resource queue limits before it can run. The `gp_resq_` * family of views can be used to check the status of statements currently submitted to the system through their respective resource queue. Note that statements issued by superusers are exempt from resource queuing.

- `gp_resq_activity`
- `gp_resq_activity_by_queue`
- `gp_resq_priority_statement`
- `gp_resq_role`
- `gp_resqueue_status`

**gp_resq_activity**

For the resource queues that have active workload, this view shows one row for each active statement submitted through a resource queue. This view is accessible to all users.

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>resqprocpid</td>
<td>Process ID assigned to this statement (on the master).</td>
</tr>
<tr>
<td>resqrole</td>
<td>User name.</td>
</tr>
<tr>
<td>resqoid</td>
<td>Resource queue object id.</td>
</tr>
<tr>
<td>resqname</td>
<td>Resource queue name.</td>
</tr>
<tr>
<td>resqstart</td>
<td>Time statement was issued to the system.</td>
</tr>
<tr>
<td>resqstatus</td>
<td>Status of statement: running, waiting or cancelled.</td>
</tr>
</tbody>
</table>

**gp_resq_activity_by_queue**

For the resource queues that have active workload, this view shows a summary of queue activity. This view is accessible to all users.

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>resqoid</td>
<td>Resource queue object id.</td>
</tr>
<tr>
<td>resqname</td>
<td>Resource queue name.</td>
</tr>
<tr>
<td>resqlast</td>
<td>Time of the last statement issued to the queue.</td>
</tr>
<tr>
<td>resqstatus</td>
<td>Status of last statement: running, waiting or cancelled.</td>
</tr>
<tr>
<td>Column</td>
<td>Description</td>
</tr>
<tr>
<td>------------</td>
<td>---------------------------------------</td>
</tr>
<tr>
<td>resqtotal</td>
<td>Total statements in this queue.</td>
</tr>
</tbody>
</table>

**gp_resq_priority_statement**

This view shows the resource queue priority, session ID, and other information for all statements currently running in the Greenplum Database system. This view is accessible to all users.

**Table 236: gp_resq_priority_statement view**

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>rqpdatname</td>
<td>The database name that the session is connected to.</td>
</tr>
<tr>
<td>rqpusename</td>
<td>The user who issued the statement.</td>
</tr>
<tr>
<td>rqpsession</td>
<td>The session ID.</td>
</tr>
<tr>
<td>rpcommand</td>
<td>The number of the statement within this session (the command id and session id uniquely identify a statement).</td>
</tr>
<tr>
<td>rpwpriority</td>
<td>The resource queue priority for this statement (MAX, HIGH, MEDIUM, LOW).</td>
</tr>
<tr>
<td>rqpweight</td>
<td>An integer value associated with the priority of this statement.</td>
</tr>
<tr>
<td>rqpquery</td>
<td>The query text of the statement.</td>
</tr>
</tbody>
</table>

**gp_resq_role**

This view shows the resource queues associated with a role. This view is accessible to all users.

**Table 237: gp_resq_role view**

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>rrolrname</td>
<td>Role (user) name.</td>
</tr>
<tr>
<td>rrresqname</td>
<td>The resource queue name assigned to this role. If a role has not been explicitly assigned to a resource queue, it will be in the default resource queue (pg_default).</td>
</tr>
</tbody>
</table>

**gp_resqueue_status**

This view allows administrators to see status and activity for a resource queue. It shows how many queries are waiting to run and how many queries are currently active in the system from a particular resource queue.

**Table 238: gp_resqueue_status view**

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>queueid</td>
<td>The ID of the resource queue.</td>
</tr>
<tr>
<td>rsqname</td>
<td>The name of the resource queue.</td>
</tr>
</tbody>
</table>
### Checking Query Disk Spill Space Usage

The **gp_workfile_*** views show information about all the queries that are currently using disk spill space. Greenplum Database creates work files on disk if it does not have sufficient memory to execute the query in memory. This information can be used for troubleshooting and tuning queries. The information in the views can also be used to specify the values for the Greenplum Database configuration parameters `gp_workfile_limit_per_query` and `gp_workfile_limit_per_segment`.

- **gp_workfile_entries**
- **gp_workfile_usage_per_query**
- **gp_workfile_usage_per_segment**

#### gp_workfile_entries

This view contains one row for each operator using disk space for workfiles on a segment at the current time. The view is accessible to all users, however non-superusers only to see information for the databases that they have permission to access.

<table>
<thead>
<tr>
<th>Column</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>datname</td>
<td>name</td>
<td></td>
<td>Greenplum database name.</td>

<td>Segment ID.</td>
</tr>
<tr>
<td>size</td>
<td>numeric</td>
<td></td>
<td>The size of the work file in bytes.</td>
</tr>
<tr>
<td>numfiles</td>
<td>bigint</td>
<td></td>
<td>The number of files created.</td>
</tr>
</tbody>
</table>
**gp_workfile_usage_per_segment**

This view contains one row for each segment. Each row displays the total amount of disk space used for workfiles on the segment at the current time. The view is accessible to all users, however non-superusers only to see information for the databases that they have permission to access.

<table>
<thead>
<tr>
<th>Column</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>segid</td>
<td>smallint</td>
<td></td>
<td>Segment ID.</td>
</tr>
<tr>

<td>numeric</td>
<td></td>
<td>The total size of the workfiles on a segment.</td>
</tr>
<tr>
<td>numfiles</td>
<td>bigint</td>
<td></td>
<td>The number of files created.</td>
</tr>
</tbody>
</table>

**Viewing Users and Groups (Roles)**

It is frequently convenient to group users (roles) together to ease management of object privileges: that way, privileges can be granted to, or revoked from, a group as a whole. In Greenplum Database this is done by creating a role that represents the group, and then granting membership in the group role to individual user roles.

The *gp_roles_assigned* view can be used to see all of the roles in the system, and their assigned members (if the role is also a group role).

**gp_roles_assigned**

This view shows all of the roles in the system, and their assigned members (if the role is also a group role). This view is accessible to all users.

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>raroleid</td>
<td>The role object ID. If this role has members (users), it is considered a group role.</td>
</tr>
<tr>
<td>rarolename</td>
<td>The role (user or group) name.</td>
</tr>
<tr>
<td>ramemberid</td>
<td>The role object ID of the role that is a member of this role.</td>
</tr>
<tr>
<td>ramembername</td>
<td>Name of the role that is a member of this role.</td>
</tr>
</tbody>
</table>

**Checking Database Object Sizes and Disk Space**

The *gp_size_* family of views can be used to determine the disk space usage for a distributed Greenplum Database, schema, table, or index. The following views calculate the total size of an object across all primary segments (mirrors are not included in the size calculations).

- *gp_size_of_all_table_indexes*
- *gp_size_of_database*
- *gp_size_of_index*
- *gp_size_of_partition_and_indexes_disk*
- *gp_size_of_schema_disk*
- `gp_size_of_table_and_indexes_disk`
- `gp_size_of_table_and_indexes_licensing`
- `gp_size_of_table_disk`
- `gp_size_of_table_uncompressed`
- `gp_disk_free`

The table and index sizing views list the relation by object ID (not by name). To check the size of a table or index by name, you must look up the relation name (`relname`) in the `pg_class` table. For example:

```sql
SELECT relname as name, sotdsize as size, sotdtoastsize as toast, sotdadditionalsize as other
FROM gp_size_of_table_disk as sotd, pg_class
WHERE sotd.sotdoid=pg_class.oid ORDER BY relname;
```

**gp_size_of_all_table_indexes**

This view shows the total size of all indexes for a table. This view is accessible to all users, however non-superusers will only be able to see relations that they have permission to access.

Table 243: gp_size_of_all_table_indexes view

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>soatioid</td>
<td>The object ID of the table</td>
</tr>
<tr>
<td>soatisize</td>
<td>The total size of all table indexes in bytes</td>
</tr>
<tr>
<td>soatischemaname</td>
<td>The schema name</td>
</tr>
<tr>
<td>soatitablename</td>
<td>The table name</td>
</tr>
</tbody>
</table>

**gp_size_of_database**

This view shows the total size of a database. This view is accessible to all users, however non-superusers will only be able to see databases that they have permission to access.

Table 244: gp_size_of_database view

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sodddatname</td>
<td>The name of the database</td>
</tr>
<tr>
<td>sodddatsize</td>
<td>The size of the database in bytes</td>
</tr>
</tbody>
</table>

**gp_size_of_index**

This view shows the total size of an index. This view is accessible to all users, however non-superusers will only be able to see relations that they have permission to access.

Table 245: gp_size_of_index view

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>soioid</td>
<td>The object ID of the index</td>
</tr>
<tr>
<td>soitableoid</td>
<td>The object ID of the table to which the index belongs</td>
</tr>
<tr>
<td>soisize</td>
<td>The size of the index in bytes</td>
</tr>
<tr>
<td>Column</td>
<td>Description</td>
</tr>
<tr>
<td>---------------------</td>
<td>--------------------------------------</td>
</tr>
<tr>
<td>soiindexschemaname</td>
<td>The name of the index schema</td>
</tr>
<tr>
<td>soiindexname</td>
<td>The name of the index</td>
</tr>
<tr>
<td>soitableschemaname</td>
<td>The name of the table schema</td>
</tr>
<tr>
<td>soitablename</td>
<td>The name of the table</td>
</tr>
</tbody>
</table>

**gp_size_of_partition_and_indexes_disk**

This view shows the size on disk of partitioned child tables and their indexes. This view is accessible to all users, however non-superusers will only be able to see relations that they have permission to access.

Table 246: gp_size_of_partition_and_indexes_disk view

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sopaidparentoid</td>
<td>The object ID of the parent table</td>

<tr>
<td>sopaidpartitionoid</td>
<td>The object ID of the partition table</td>
</tr>
<tr>
<td>sopaidpartitiontablesizel</td>
<td>The partition table size in bytes</td>
</tr>
<tr>
<td>sopaidpartitionindexesizel</td>
<td>The total size of all indexes on this partition</td>
</tr>
<tr>
<td>Sopaidparentschemaname</td>
<td>The name of the parent schema</td>
</tr>
<tr>
<td>Sopaidparenttablename</td>
<td>The name of the parent table</td>
</tr>
<tr>
<td>Sopaid_partitionschemaname</td>
<td>The name of the partition schema</td>
</tr>
<tr>
<td>sopaidpartitiontablename</td>
<td>The name of the partition table</td>
</tr>
</tbody>
</table>

**gp_size_of_schema_disk**

This view shows schema sizes for the public schema and the user-created schemas in the current database. This view is accessible to all users, however non-superusers will be able to see only the schemas that they have permission to access.

Table 247: gp_size_of_schema_disk view

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sosdsnsp</td>
<td>The name of the schema</td>
</tr>
<tr>
<td>sosdschematablesizel</td>
<td>The total size of tables in the schema in bytes</td>
</tr>
<tr>
<td>sosdschemaidxsize</td>
<td>The total size of indexes in the schema in bytes</td>
</tr>
</tbody>
</table>

**gp_size_of_table_and_indexes_disk**

This view shows the size on disk of tables and their indexes. This view is accessible to all users, however non-superusers will only be able to see relations that they have permission to access.

Table 248: gp_size_of_table_and_indexes_disk view

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sotaidoid</td>
<td>The object ID of the parent table</td>
</tr>
<tr>
<td>Column</td>
<td>Description</td>
</tr>
<tr>
<td>------------------------</td>
<td>-------------------------------------------------</td>
</tr>
<tr>
<td>sotaidtablesizetablesize</td>
<td>The disk size of the table</td>
</tr>
<tr>
<td>sotaididxsize</td>
<td>The total size of all indexes on the table</td>
</tr>
<tr>
<td>sotaidschemaname</td>
<td>The name of the schema</td>
</tr>
<tr>
<td>sotaidtablename</td>
<td>The name of the table</td>
</tr>
</tbody>
</table>

**gp_size_of_table_and_indexes_licensing**

This view shows the total size of tables and their indexes for licensing purposes. The use of this view requires superuser permissions.

**Table 249: gp_size_of_table_and_indexes_licensing view**

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sotailoid</td>
<td>The object ID of the table</td>
</tr>
<tr>
<td>sotailtablesizetabledisk</td>
<td>The total disk size of the table</td>
</tr>
<tr>
<td>sotailtablesizeuncompressed</td>
<td>If the table is a compressed append-optimized table, shows the uncompressed table size in bytes.</td>
</tr>
<tr>
<td>sotaindexessize</td>
<td>The total size of all indexes in the table</td>
</tr>
<tr>
<td>sotailschemename</td>
<td>The schema name</td>
</tr>
<tr>
<td>sotailtablename</td>
<td>The table name</td>
</tr>
</tbody>
</table>

**gp_size_of_table_disk**

This view shows the size of a table on disk. This view is accessible to all users, however non-superusers will only be able to see tables that they have permission to access.

**Table 250: gp_size_of_table_disk view**

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sotdoid</td>
<td>The object ID of the table</td>
</tr>
<tr>
<td>sotdsizetable</td>
<td>The size of the table in bytes. The size is only the main table size. The size does not include auxiliary objects such as oversized (toast) attributes, or additional storage objects for AO tables.</td>
</tr>
<tr>
<td>sotdtoastsize</td>
<td>The size of the TOAST table (oversized attribute storage), if there is one.</td>
</tr>
<tr>
<td>sotddoadditionalsize</td>
<td>Reflects the segment and block directory table sizes for append-optimized (AO) tables.</td>
</tr>
<tr>
<td>sotdschemename</td>
<td>The schema name</td>
</tr>
<tr>
<td>sotdtablename</td>
<td>The table name</td>
</tr>
</tbody>
</table>

**gp_size_of_table_uncompressed**

This view shows the uncompressed table size for append-optimized (AO) tables. Otherwise, the table size on disk is shown. The use of this view requires superuser permissions.
Table 251: gp_size_of_table_uncompressed view

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sotuoid</td>
<td>The object ID of the table</td>
</tr>
<tr>
<td>sotusize</td>
<td>The uncompressed size of the table in bytes if it is a compressed AO table. Otherwise, the table size on disk.</td>
</tr>
<tr>
<td>sotuschemaname</td>
<td>The schema name</td>
</tr>
<tr>
<td>sotutablename</td>
<td>The table name</td>
</tr>
</tbody>
</table>

gp_disk_free
This external table runs the `df` (disk free) command on the active segment hosts and reports back the results. Inactive mirrors are not included in the calculation. The use of this external table requires superuser permissions.

Table 252: gp_disk_free external table

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dfsegment</td>
<td>The content id of the segment (only active segments are shown)</td>
</tr>
<tr>
<td>dfhostname</td>
<td>The hostname of the segment host</td>
</tr>
<tr>
<td>dfdevice</td>
<td>The device name</td>
</tr>
<tr>
<td>dfspace</td>
<td>Free disk space in the segment file system in kilobytes</td>
</tr>
</tbody>
</table>

Checking for Uneven Data Distribution

All tables in Greenplum Database are distributed, meaning their data is divided across all of the segments in the system. If the data is not distributed evenly, then query processing performance may suffer. The following views can help diagnose if a table has uneven data distribution:

- `gp_skew_coefficients`
- `gp_skew_idle_fractions`

gp_skew_coefficients
This view shows data distribution skew by calculating the coefficient of variation (CV) for the data stored on each segment. This view is accessible to all users, however non-superusers will only be able to see tables that they have permission to access.

Table 253: gp_skew_coefficients view

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>skcoid</td>
<td>The object id of the table.</td>
</tr>
<tr>
<td>skcnamespace</td>
<td>The namespace where the table is defined.</td>
</tr>
<tr>
<td>skcrelename</td>
<td>The table name.</td>
</tr>
</tbody>
</table>
### Column Description

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>skccoeff</td>
<td>The coefficient of variation (CV) is calculated as the standard deviation divided by the average. It takes into account both the average and variability around the average of a data series. The lower the value, the better. Higher values indicate greater data skew.</td>
</tr>
</tbody>
</table>

#### gp_skew_idle_fractions

This view shows data distribution skew by calculating the percentage of the system that is idle during a table scan, which is an indicator of processing data skew. This view is accessible to all users, however non-superusers will only be able to see tables that they have permission to access.

**Table 254: gp_skew_idle_fractions view**

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>

<td>The percentage of the system that is idle during a table scan, which is an indicator of uneven data distribution or query processing skew. For example, a value of 0.1 indicates 10% skew, a value of 0.5 indicates 50% skew, and so on. Tables that have more than 10% skew should have their distribution policies evaluated.</td>
</tr>
</tbody>
</table>
The gpperfmon Database

The gpperfmon database is a dedicated database where data collection agents on Greenplum segment hosts save query and system statistics.

The gpperfmon database is created using the gpperfmon_install command-line utility. The utility creates the database and the gpmon database role and enables the data collection agents on the master and segment hosts. See the gpperfmon_install reference in the Greenplum Database Utility Guide for information about using the utility and configuring the data collection agents.

The gpperfmon database consists of three sets of tables that capture query and system status information at different stages.

- **_now** tables store current system metrics such as active queries.
- **_tail** tables are used to stage data before it is saved to the _history tables. The _tail tables are for internal use only and not to be queried by users.
- **_history** tables store historical metrics.

The data for _now and _tail tables are stored as text files on the master host file system, and are accessed in the gpperfmon database via external tables. The history tables are regular heap database tables in the gpperfmon database. History is saved only for queries that run for a minimum number of seconds, 20 by default. You can set this threshold to another value by setting the min_query_time parameter in the $MASTER_DATA_DIRECTORY/gpperfmon/conf/gpperfmon.conf configuration file. Setting the value to 0 saves history for all queries.

**Note:** gpperfmon does not support SQL ALTER commands. ALTER queries are not recorded in the gpperfmon query history tables.

The history tables are partitioned by month. See History Table Partition Retention for information about removing old partitions.

The database contains the following categories of tables:

- The database_* tables store query workload information for a Greenplum Database instance.
- The diskspace_* tables store diskspace metrics.
- The log_alert_* tables store error and warning messages from pg_log.
- The queries_* tables store high-level query status information.
- The segment_* tables store memory allocation statistics for the Greenplum Database segment instances.
- The socket_stats_* tables store statistical metrics about socket usage for a Greenplum Database instance. Note: These tables are in place for future use and are not currently populated.
- The system_* tables store system utilization metrics.

The gpperfmon database also contains the following views:

- The dynamic_memory_info view shows an aggregate of all the segments per host and the amount of dynamic memory used per host.
- The memory_info view shows per-host memory information from the system_history and segment_history tables.

History Table Partition Retention

The history tables in the gpperfmon database are partitioned by month. Partitions are automatically added in two month increments as needed.

The partition_age parameter in the $MASTER_DATA_DIRECTORY/gpperfmon/conf/gpperfmon.conf file can be set to the maximum number of monthly partitions to keep. Partitions older than the specified value are removed automatically when new partitions are added.
The default value for `partition_age` is 0, which means that administrators must manually remove unneeded partitions.

**Alert Log Processing and Log Rotation**

When the `gp_enable_gpperfmon` server configuration parameter is set to true, the Greenplum Database syslogger writes alert messages to a `.csv` file in the `$MASTER_DATA_DIRECTORY/gpperfmon/logs` directory.

The level of messages written to the log can be set to `none`, `warning`, `error`, `fatal`, or `panic` by setting the `gpperfmon_log_alert_level` server configuration parameter in `postgresql.conf`. The default message level is `warning`.

The directory where the log is written can be changed by setting the `log_location` configuration variable in the `$MASTER_DATA_DIRECTORY/gpperfmon/conf/gpperfmon.conf` configuration file.

The syslogger rotates the alert log every 24 hours or when the current log file reaches or exceeds 1MB.

A rotated log file can exceed 1MB if a single error message contains a large SQL statement or a large stack trace. Also, the syslogger processes error messages in chunks, with a separate chunk for each logging process. The size of a chunk is OS-dependent; on Red Hat Enterprise Linux, for example, it is 4096 bytes. If many Greenplum Database sessions generate error messages at the same time, the log file can grow significantly before its size is checked and log rotation is triggered.

**gpperfmon Data Collection Process**

When Greenplum Database starts up with gpperfmon support enabled, it forks a `gpmmon` agent process. `gpmmon` then starts a `gpsmon` agent process on the master host and every segment host in the Greenplum Database cluster. The Greenplum Database postmaster process monitors the `gpmmon` process and restarts it if needed, and the `gpmmon` process monitors and restarts `gpsmon` processes as needed.

The `gpmmon` process runs in a loop and at configurable intervals retrieves data accumulated by the `gpsmon` processes, adds it to the data files for the `_now` and `_tail` external database tables, and then into the `_history` regular heap database tables.

**Note:** The `log_alert` tables in the `gpperfmon` database follow a different process, since alert messages are delivered by the Greenplum Database system logger instead of through `gpsmon`. See *Alert Log Processing and Log Rotation* for more information.

Two configuration parameters in the `$MASTER_DATA_DIRECTORY/gpperfmon/conf/gpperfmon.conf` configuration file control how often `gpmmon` activities are triggered:

- The `quantum` parameter is how frequently, in seconds, `gpmmon` requests data from the `gpsmon` agents on the segment hosts and adds retrieved data to the `_now` and `_tail` external table data files. Valid values for the `quantum` parameter are 10, 15, 20, 30, and 60. The default is 15.
- The `harvest_interval` parameter is how frequently, in seconds, data in the `_tail` tables is moved to the `_history` tables. The `harvest_interval` must be at least 30. The default is 120.

See the `gpperfmon_install` management utility reference in the *Greenplum Database Utility Guide* for the complete list of gpperfmon configuration parameters.

The following steps describe the flow of data from Greenplum Database into the `gpperfmon` database when gpperfmon support is enabled.

1. While executing queries, the Greenplum Database query dispatcher and query executor processes send out query status messages in UDP datagrams. The `gp_gpperfmon_send_interval` server configuration variable determines how frequently the database sends these messages. The default is every second.
2. The `gpsmon` process on each host receives the UDP packets, consolidates and summarizes the data they contain, and adds additional host metrics, such as CPU and memory usage.
3. The `gpsmon` processes continue to accumulate data until they receive a dump command from `gpmmon`. 
4. The `gpsmon` processes respond to a dump command by sending their accumulated status data and log alerts to a listening `gpmmon` event handler thread.

5. The `gpmmon` event handler saves the metrics to `.txt` files in the `$MASTER_DATA_DIRECTORY/gpperfmon/data` directory on the master host.

At each quantum interval (15 seconds by default), `gpmmon` performs the following steps:

1. Sends a dump command to the `gpsmon` processes.
2. Gathers and converts the `.txt` files saved in the `$MASTER_DATA_DIRECTORY/gpperfmon/data` directory into `.dat` external data files for the `_now` and `_tail` external tables in the `gpperfmon` database.
   
   For example, disk space metrics are added to the `diskspace_now.dat` and `diskspace_tail.dat` delimited text files. These text files are accessed via the `diskspace_now` and `diskspace_tail` external tables in the `gpperfmon` database.

At each harvest_interval (120 seconds by default), `gpmmon` performs the following steps for each `_tail` file:

1. Renames the `_tail` file to a `_stage` file.
3. Appends data from the `_stage` file into the `_tail` file.
4. Runs a SQL command to insert the data from the `_tail` external table into the corresponding `_history` table.
   
   For example, the contents of the `_database_tail` external table is inserted into the `database_history` regular (heap) table.

5. Deletes the `_tail` file after its contents have been loaded into the database table.
6. Gathers all of the `gpdb-alert-*.csv` files in the `$MASTER_DATA_DIRECTORY/gpperfmon/logs` directory (except the most recent, which the syslogger has open and is writing to) into a single file, `alert_log_stage`.
7. Loads the `alert_log_stage` file into the `log_alert_history` table in the `gpperfmon` database.
8. Truncates the `alert_log_stage` file.

The following topics describe the contents of the tables in the `gpperfmon` database.

**database_***

The `database_*` tables store query workload information for a Greenplum Database instance. There are three database tables, all having the same columns:

- `database_now` is an external table whose data files are stored in `$MASTER_DATA_DIRECTORY/gpperfmon/data`. Current query workload data is stored in `database_now` during the period between data collection from the data collection agents and automatic commitment to the `database_history` table.

- `database_tail` is an external table whose data files are stored in `$MASTER_DATA_DIRECTORY/gpperfmon/data`. This is a transitional table for query workload data that has been cleared from `database_now` but has not yet been committed to `database_history`. It typically only contains a few minutes worth of data.

- `database_history` is a regular table that stores historical database-wide query workload data. It is pre-partitioned into monthly partitions. Partitions are automatically added in two month increments as needed.

<td>int</td>
<td>The number of active queries running at data collection time.</td>
</tr>
<tr>
<td>queries_queued</td>
<td>int</td>
<td>The number of queries waiting in a resource group or resource queue, depending upon which resource management scheme is active, at data collection time.</td>
</tr>
</tbody>
</table>

#### diskspace_*  

The diskspace_* tables store diskspace metrics.  

- diskspace_now is an external table whose data files are stored in $MASTER_DATA_DIRECTORY/gpperfmon/data. Current diskspace metrics are stored in database_now during the period between data collection from the gpperfmon agents and automatic commitment to the diskspace_history table.  
- diskspace_tail is an external table whose data files are stored in $MASTER_DATA_DIRECTORY/gpperfmon/data. This is a transitional table for diskspace metrics that have been cleared from diskspace_now but has not yet been committed to diskspace_history. It typically only contains a few minutes worth of data.  
- diskspace_history is a regular table that stores historical diskspace metrics. It is pre-partitioned into monthly partitions. Partitions are automatically added in two month increments as needed.  

<table>
<thead>
<tr>
<th>Column</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ctime</td>
<td>timestamp(0) without time zone</td>
<td>Time of diskspace measurement.</td>
</tr>
<tr>
<td>hostname</td>
<td>varchar(64)</td>
<td>The hostname associated with the diskspace measurement.</td>
</tr>
<tr>
<td>Filesystem</td>
<td>text</td>
<td>Name of the filesystem for the diskspace measurement.</td>
</tr>
<tr>
<td>total_bytes</td>
<td>bigint</td>
<td>Total bytes in the file system.</td>
</tr>
<tr>
<td>bytes_used</td>
<td>bigint</td>
<td>Total bytes used in the file system.</td>
</tr>
<tr>
<td>bytes_available</td>
<td>bigint</td>
<td>Total bytes available in file system.</td>
</tr>
</tbody>
</table>

#### interface_stats_*  

The interface_stats_* tables store statistical metrics about communications over each active interface for a Greenplum Database instance.  

These tables are in place for future use and are not currently populated.  

There are three interface_stats tables, all having the same columns:  

- interface_stats_now is an external table whose data files are stored in $MASTER_DATA_DIRECTORY/gpperfmon/data.  
- interface_stats_tail is an external table whose data files are stored in $MASTER_DATA_DIRECTORY/gpperfmon/data. This is a transitional table for statistical interface communications.
metrics that has been cleared from `interface_stats_now` but has not yet been committed to `interface_stats_history`. It typically only contains a few minutes worth of data.

- `interface_stats_history` is a regular table that stores statistical interface metrics. It is pre-partitioned into monthly partitions. Partitions are automatically added in one month increments as needed.

<table>
<thead>
<tr>

<td>Number of packets transmitted in compressed format.</td>
</tr>
</tbody>
</table>

**log_alert_***

The log_alert_* tables store pg_log errors and warnings. See Alert Log Processing and Log Rotation for information about configuring the system logger for gpperfmon.

There are three log_alert tables, all having the same columns:

- **log_alert_now** is an external table whose data is stored in .csv files in the $MASTER_DATA_DIRECTORY/gpperfmon/logs directory. Current pg_log errors and warnings data are available in log_alert_now during the period between data collection from the gpperfmon agents and automatic commitment to the log_alert_history table.

- **log_alert_tail** is an external table with data stored in $MASTER_DATA_DIRECTORY/gpperfmon/logs/alert_log_stage. This is a transitional table for data that has been cleared from log_alert_now but has not yet been committed to log_alert_history. The table includes records from all alert logs except the most recent. It typically contains only a few minutes' worth of data.

- **log_alert_history** is a regular table that stores historical database-wide errors and warnings data. It is pre-partitioned into monthly partitions. Partitions are automatically added in two month increments as needed.

</tbody>
</table>
The `queries_*` tables store high-level query status information. The `tmid`, `ssid` and `ccnt` columns are the composite key that uniquely identifies a particular query.

There are three queries tables, all having the same columns:

- `queries_now` is an external table whose data files are stored in $MASTER_DATA_DIRECTORY/gpperfmon/data. Current query status is stored in `queries_now` during the period between data collection from the gpperfmon agents and automatic commitment to the `queries_history` table.
- `queries_tail` is an external table whose data files are stored in $MASTER_DATA_DIRECTORY/gpperfmon/data. This is a transitional table for query status data that has been cleared from `queries_now` but has not yet been committed to `queries_history`. It typically only contains a few minutes worth of data.
- `queries_history` is a regular table that stores historical query status data. It is pre-partitioned into monthly partitions. Partitions are automatically added in two month increments as needed.

<table>

<td>rsqname</td>
<td>varchar(64)</td>
<td>If the resource queue-based resource management scheme is active, this column specifies the name of the resource queue.</td>
</tr>
<tr>
<td>rqppriority</td>
<td>varchar(64)</td>
<td>If the resource queue-based resource management scheme is active, this column specifies the priority of the query -- max, high, med, low, or min.</td>
</tr>
</tbody>
</table>

**segment_**

The `segment_` tables contain memory allocation statistics for the Greenplum Database segment instances. This tracks the amount of memory consumed by all postgres processes of a particular segment instance, and the remaining amount of memory available to a segment as per the settings configured by the currently active resource management scheme (resource group-based or resource queue-based). See the *Greenplum Database Administrator Guide* for more information about resource management schemes.

There are three segment tables, all having the same columns:

- `segment_now` is an external table whose data files are stored in `$MASTER_DATA_DIRECTORY/gpperfmon/data`. Current memory allocation data is stored in `segment_now` during the
period between data collection from the gpperfmon agents and automatic commitment to the segment_history table.

- **segment_tail** is an external table whose data files are stored in $MASTER_DATA_DIRECTORY/gpperfmon/data. This is a transitional table for memory allocation data that has been cleared from segment_now but has not yet been committed to segment_history. It typically only contains a few minutes worth of data.

- **segment_history** is a regular table that stores historical memory allocation metrics. It is pre-partitioned into monthly partitions. Partitions are automatically added in two month increments as needed.

A particular segment instance is identified by its hostname and dbid (the unique segment identifier as per the gp_segment_configuration system catalog table).

<table>
<thead>
<tr>
<th>Column</th>
<th>Type</th>
<th>Description</th>

<td>The segment ID (dbid from gp_segment_configuration).</td>
</tr>
<tr>
<td>hostname</td>
<td>charvar(64)</td>
<td>The segment hostname.</td>
</tr>
<tr>
<td>dynamic_memory_used</td>
<td>bigint</td>
<td>The amount of dynamic memory (in bytes) allocated to query processes running on this segment.</td>
</tr>
<tr>
<td>dynamic_memory_available</td>
<td>bigint</td>
<td>The amount of additional dynamic memory (in bytes) that the segment can request before reaching the limit set by the currently active resource management scheme (resource group-based or resource queue-based).</td>
</tr>
</tbody>
</table>

See also the views memory_info and dynamic_memory_info for aggregated memory allocation and utilization by host.

**socket_stats_***

The socket_stats_* tables store statistical metrics about socket usage for a Greenplum Database instance. There are three system tables, all having the same columns:

These tables are in place for future use and are not currently populated.

- **socket_stats_now** is an external table whose data files are stored in $MASTER_DATA_DIRECTORY/gpperfmon/data.

- **socket_stats_tail** is an external table whose data files are stored in $MASTER_DATA_DIRECTORY/gpperfmon/data. This is a transitional table for socket statistical metrics that has been cleared from socket_stats_now but has not yet been committed to socket_stats_history. It typically only contains a few minutes worth of data.

- **socket_stats_history** is a regular table that stores historical socket statistical metrics. It is pre-partitioned into monthly partitions. Partitions are automatically added in two month increments as needed.
### Column

<table>

</table>

### system_*

The `system_*` tables store system utilization metrics. There are three system tables, all having the same columns:

- **system_now** is an external table whose data files are stored in `MASTER_DATA_DIRECTORY/gpperfmon/data`. Current system utilization data is stored in `system_now` during the period between data collection from the `gpperfmon` agents and automatic commitment to the `system_history` table.
- **system_tail** is an external table whose data files are stored in `MASTER_DATA_DIRECTORY/gpperfmon/data`. This is a transitional table for system utilization data that has been cleared from `system_now` but has not yet been committed to `system_history`. It typically only contains a few minutes worth of data.
- **system_history** is a regular table that stores historical system utilization metrics. It is pre-partitioned into monthly partitions. Partitions are automatically added in two month increments as needed.

**dynamic_memory_info**

The `dynamic_memory_info` view shows a sum of the used and available dynamic memory for all segment instances on a segment host. Dynamic memory refers to the maximum amount of memory that Greenplum Database instance will allow the query processes of a single segment instance to consume before it starts cancelling processes. This limit, determined by the currently active resource management scheme (resource group-based or resource queue-based), is evaluated on a per-segment basis.

<table>
<thead>
<tr>
<th>Column</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ctime</td>
<td>timestamp(0) without time zone</td>
<td>Time this row was created in the <code>segment_history</code> table.</td>
</tr>
<tr>
<td>hostname</td>
<td>varchar(64)</td>
<td>Segment or master hostname associated with these system memory metrics.</td>
</tr>
<tr>
<td>dynamic_memory_used_mb</td>
<td>numeric</td>
<td>The amount of dynamic memory in MB allocated to query processes running on this segment.</td>
</tr>
<tr>
<td>dynamic_memory_available_mb</td>
<td>numeric</td>
<td>The amount of additional dynamic memory (in MB) available to the query processes running on this segment host. Note that this value is a sum of the available memory for all segments on a host. Even though this value reports available memory, it is possible that one or more segments on the host have exceeded their memory limit.</td>
</tr>
</tbody>
</table>

**memory_info**

The `memory_info` view shows per-host memory information from the `system_history` and `segment_history` tables. This allows administrators to compare the total memory available on a segment host, total memory used on a segment host, and dynamic memory used by query processes.

<table>
<thead>
<tr>
<th>Column</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ctime</td>
<td>timestamp(0) without time zone</td>
<td>Time this row was created in the <code>segment_history</code> table.</td>
</tr>
<tr>
<td>hostname</td>
<td>varchar(64)</td>
<td>Segment or master hostname associated with these system memory metrics.</td>
</tr>
<tr>
<td>mem_total_mb</td>
<td>numeric</td>
<td>Total system memory in MB for this segment host.</td>
</tr>
<tr>
<td>mem_used_mb</td>
<td>numeric</td>
<td>Total system memory used in MB for this segment host.</td>
</tr>
<tr>

Even though this value reports available memory, it is possible that one or more segments on the host have exceeded their memory limit.</td>
</tr>
</tbody>
</table>
Server Programmatic Interfaces

This section describes programmatic interfaces to the Greenplum Database server.

- Greenplum Partner Connector API
- Background Worker Processes

Greenplum Partner Connector API

With the Greenplum Partner Connector API (GPPC API), you can write portable Greenplum Database user-defined functions (UDFs) in the C and C++ programming languages. Functions that you develop with the GPPC API require no recompilation or modification to work with older or newer Greenplum Database versions.

Functions that you write to the GPPC API can be invoked using SQL in Greenplum Database. The API provides a set of functions and macros that you can use to issue SQL commands through the Server Programming Interface (SPI), manipulate simple and composite data type function arguments and return values, manage memory, and handle data.

You compile the C/C++ functions that you develop with the GPPC API into a shared library. The GPPC functions are available to Greenplum Database users after the shared library is installed in the Greenplum Database cluster and the GPPC functions are registered as SQL UDFs.

Note: The Greenplum Partner Connector is supported for Greenplum Database versions 4.3.5.0 and later.

This topic contains the following information:

- Registering a GPPC Function with Greenplum Database
- Packaging and Deployment Considerations
- GPPC Text Function Example
- GPPC Set-Returning Function Example

Using the GPPC API

The GPPC API shares some concepts with C language functions as defined by PostgreSQL. Refer to C-Language Functions in the PostgreSQL documentation for detailed information about developing C language functions.
The GPPC API is a wrapper that makes a C/C++ function SQL-invokable in Greenplum Database. This wrapper shields GPPC functions that you write from Greenplum Database library changes by normalizing table and data manipulation and SPI operations through functions and macros defined by the API.

The GPPC API includes functions and macros to:

- Operate on base and composite data types.
- Process function arguments and return values.
- Allocate and free memory.
- Log and report errors to the client.
- Issue SPI queries.
- Return a table or set of rows.
- Process tables as function input arguments.

**Requirements**

When you develop with the GPPC API:

- You must develop your code on a system with the same hardware and software architecture as that of your Greenplum Database hosts.
- You must write the GPPC function(s) in the C or C++ programming languages.
- The function code must use the GPPC API, data types, and macros.
- The function code must not use the PostgreSQL C-Language Function API, header files, functions, or macros.
- The function code must not include the postgres.h header file or use PG_MODULE_MAGIC.
- You must use only the GPPC-wrapped memory functions to allocate and free memory. See Memory Handling.
- Symbol names in your object files must not conflict with each other nor with symbols defined in the Greenplum Database server. You must rename your functions or variables if you get error messages to this effect.

**Header and Library Files**

The GPPC header files and libraries are installed in `$GPHOME`:

- `$GPHOME/include/gppc.h` - the main GPPC header file
- `$GPHOME/include/gppc_config.h` - header file defining the GPPC version
- `$GPHOME/lib/libgppc.[a, so, so.1, so.1.2]` - GPPC archive and shared libraries

**Data Types**

The GPPC functions that you create will operate on data residing in Greenplum Database. The GPPC API includes data type definitions for equivalent Greenplum Database SQL data types. You must use these types in your GPPC functions.

The GPPC API defines a generic data type that you can use to represent any GPPC type. This data type is named `GppcDatum`, and is defined as follows:

```
typedef int64_t GppcDatum;
```

The following table identifies each GPPC data type and the SQL type to which it maps.

<table>
<thead>
<tr>
<th>SQL Type</th>
<th>GPPC Type</th>
<th>GPPC Oid for Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>boolean</td>
<td>GppcBool</td>
<td>GppcOidBool</td>
</tr>
<tr>
<td>char (single byte)</td>
<td>GppcChar</td>
<td>GppcOidChar</td>
</tr>
<tr>
<td>int2/smallint</td>
<td>GppcInt2</td>
<td>GppcOidInt2</td>
</tr>
<tr>
<td>SQL Type</td>
<td>GPPC Type</td>
<td>GPPC Oid for Type</td>
</tr>
<tr>
<td>------------</td>
<td>--------------</td>
<td>-------------------</td>
</tr>
<tr>
<td>int4/integer</td>
<td>GppcInt4</td>
<td>GppcOidInt4</td>
</tr>
<tr>
<td>int8/bigint</td>
<td>GppcInt8</td>
<td>GppcOidInt8</td>
</tr>
<tr>
<td>float4/real</td>
<td>GppcFloat4</td>
<td>GppcOidFloat4</td>
</tr>
<tr>
<td>float8/double</td>
<td>GppcFloat8</td>
<td>GppcOidFloat8</td>
</tr>
<tr>
<td>text</td>
<td>*GppcText</td>
<td>GppcOidText</td>
</tr>
<tr>
<td>varchar</td>
<td>*GppcVarChar</td>
<td>GppcOidVarChar</td>
</tr>
<tr>
<td>char</td>
<td>*GppcBpChar</td>
<td>GppcOidBpChar</td>
</tr>
<tr>
<td>bytea</td>
<td>*GppcBytea</td>
<td>GppcOidBytea</td>
</tr>
<tr>
<td>numeric</td>
<td>*GppcNumeric</td>
<td>GppcOidNumeric</td>
</tr>
<tr>
<td>date</td>
<td>GppcDate</td>
<td>GppcOidDate</td>
</tr>
<tr>
<td>time</td>
<td>GppcDate</td>
<td>GppcOidTime</td>
</tr>
<tr>
<td>timetz</td>
<td>*GppcTimeTz</td>
<td>GppcOidTimeTz</td>
</tr>
<tr>
<td>timestamp</td>
<td>GppcTimestamp</td>
<td>GppcOidTimestamp</td>
</tr>
<tr>
<td>timestampTz</td>
<td>GppcTimestampTz</td>
<td>GppcOidTimestampTz</td>
</tr>
<tr>
<td>anytable</td>
<td>GppcAnyTable</td>
<td>GppcOidAnyTable</td>
</tr>
<tr>
<td>oid</td>
<td>GppcOid</td>
<td></td>
</tr>
</tbody>
</table>

The GPPC API treats text, numeric, and timestamp data types specially, providing functions to operate on these types.

Example GPPC base data type declarations:

```
GppcText  message;
GppcInt4  arg1;
GppcNumeric  total_sales;
```

The GPPC API defines functions to convert between the generic `GppcDatum` type and the GPPC specific types. For example, to convert from an integer to a datum:

```
GppcInt4  num = 13;
GppcDatum  num_dat = GppcInt4GetDatum(num);
```

**Composite Types**

A composite data type represents the structure of a row or record, and is comprised of a list of field names and their data types. This structure information is typically referred to as a tuple descriptor. An instance of a composite type is typically referred to as a tuple or row. A tuple does not have a fixed layout and can contain null fields.

The GPPC API provides an interface that you can use to define the structure of, to access, and to set tuples. You will use this interface when your GPPC function takes a table as an input argument or returns table or set of record types. Using tuples in table and set returning functions is covered later in this topic.
**Function Declaration, Arguments, and Results**

The GPPC API relies on macros to declare functions and to simplify the passing of function arguments and results. These macros include:

<table>
<thead>
<tr>
<th>Task</th>
<th>Macro Signature</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Make a function SQL-invokable</td>
<td>GPPC_FUNCTION_INFO(function_name)</td>
<td>Glue to make function function_name SQL-invokable.</td>
</tr>
<tr>
<td>Declare a function</td>
<td>GppcDatum function_name(GPPC_FUNCTION_ARGS)</td>
<td>Declare a GPPC function named function_name; every function must have this same signature.</td>
</tr>
<tr>
<td>Return the number of arguments</td>
<td>GPPC_NARGS()</td>
<td>Return the number of arguments passed to the function.</td>
</tr>
<tr>
<td>Fetch an argument</td>
<td>GPPC_GETARG_&lt;ARGTYPE&gt;(arg_num)</td>
<td>Fetch the value of argument number arg_num (starts at 0), where &lt;ARGTYPE&gt; identifies the data type of the argument. For example, GPPC_GETARG_FLOAT8(0).</td>
</tr>
<tr>
<td>Fetch and make a copy of a text-type argument</td>
<td>GPPC_GETARG_&lt;ARGTYPE&gt;_COPY(arg_num)</td>
<td>Fetch and make a copy of the value of argument number arg_num (starts at 0). &lt;ARGTYPE&gt; identifies the text type (text, varchar, bpchar, bytea). For example, GPPC_GETARG_BYTEA_COPY(1).</td>
</tr>
<tr>
<td>Determine if an argument is NULL</td>
<td>GPPC_ARGISNULL(arg_num)</td>
<td>Return whether or not argument number arg_num is NULL.</td>
</tr>
<tr>
<td>Return a result</td>
<td>GPPC_RETURN_&lt;ARGTYPE&gt;(return_val)</td>
<td>Return the value return_val, where &lt;ARGTYPE&gt; identifies the data type of the return value. For example, GPPC_RETURN_INT4(131).</td>
</tr>
</tbody>
</table>

When you define and implement your GPPC function, you must declare it with the GPPC API using the two declarations identified above. For example, to declare a GPPC function named add_int4s():

```c
GPPC_FUNCTION_INFO(add_int4s);
GppcDatum add_int4s(GPPC_FUNCTION_ARGS);

GppcDatum
add_int4s(GPPC_FUNCTION_ARGS)
{
    // code here
}
```

If the add_int4s() function takes two input arguments of type int4, you use the GPPC_GETARG_INT4(arg_num) macro to access the argument values. The argument index starts at 0. For example:

```c
GppcInt4 first_int = GPPC_GETARG_INT4(0);
GppcInt4 second_int = GPPC_GETARG_INT4(1);
```

If add_int4s() returns the sum of the two input arguments, you use the GPPC_RETURN_INT8(return_val) macro to return this sum. For example:

```c
GppcInt8 sum = first_int + second_int;
```
GPPC_RETURN_INT8(sum);

The complete GPPC function:

```c
GPPC_FUNCTION_INFO(add_int4s);
GppcDatum add_int4s(GPPC_FUNCTION_ARGS);

GppcDatum
add_int4s(GPPC_FUNCTION_ARGS)
{
    // get input arguments
    GppcInt4    first_int = GPPC_GETARG_INT4(0);
    GppcInt4    second_int = GPPC_GETARG_INT4(1);

    // add the arguments
    GppcInt8    sum = first_int + second_int;

    // return the sum
    GPPC_RETURN_INT8(sum);
}
```

### Memory Handling

The GPPC API provides functions that you use to allocate and free memory, including text memory. You must use these functions for all memory operations.

<table>
<thead>
<tr>
<th>Function Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void *GppcAlloc( size_t num )</td>
<td>Allocate num bytes of uninitialized memory.</td>
</tr>
<tr>
<td>void *GppcAlloc0( size_t num )</td>
<td>Allocate num bytes of 0-initialized memory.</td>
</tr>
<tr>
<td>void *GppcRealloc( void *ptr, size_t num )</td>
<td>Resize pre-allocated memory.</td>
</tr>
<tr>
<td>void GppcFree( void *ptr )</td>
<td>Free allocated memory.</td>
</tr>
</tbody>
</table>

After you allocate memory, you can use system functions such as `memcpy()` to set the data.

The following example allocates an array of `GppcDatum`s and sets the array to datum versions of the function input arguments:

```c
GppcDatum  *values;
int attnum = GPPC_NARGS();
// allocate memory for attnum values
values = GppcAlloc( sizeof(GppcDatum) * attnum );
// set the values
for( int i=0; i<attnum; i++ ) {
    GppcDatum d = GPPC_GETARG_DATUM(i);
    values[i] = d;
}
```

When you allocate memory for a GPPC function, you allocate it in the current context. The GPPC API includes functions to return, create, switch, and reset memory contexts.

<table>
<thead>
<tr>
<th>Function Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>GppcMemoryContext GppcGetCurrentMemoryContext( void)</td>
<td>Return the current memory context.</td>
</tr>
<tr>
<td>GppcMemoryContext GppcMemoryContextCreate( GppcMemoryContext parent )</td>
<td>Create a new memory context under parent.</td>
</tr>
</tbody>
</table>
Function Name | Description  
--- | ---  
GppcMemoryContext |  
GppcMemoryContextSwitchTo(GppcMemoryContext context) | Switch to the memory context context.  
void GppcMemoryContextReset(GppcMemoryContext context) | Reset (free) the memory in memory context context.  

Greenplum Database typically calls a SQL-invoked function in a per-tuple context that it creates and deletes every time the server backend processes a table row. Do not assume that memory allocated in the current memory context is available across multiple function calls.

**Working With Variable-Length Text Types**

The GPPC API supports the variable length text, varchar, blank padded, and byte array types. You must use the GPPC API-provided functions when you operate on these data types. Variable text manipulation functions provided in the GPPC API include those to allocate memory for, determine string length of, get string pointers for, and access these types:

| Function Name | Description  
--- | ---  
GppcText GppcAllocText( size_t len ) | Allocate len bytes of memory for the varying length type.  
GppcVarChar GppcAllocVarChar( size_t len ) |  
GppcBpChar GppcAllocBpChar( size_t len ) |  
GppcBytea GppcAllocBytea( size_t len ) |  
size_t GppcGetTextLength( GppcText s ) | Return the number of bytes in the memory chunk.  
size_t GppcGetVarCharLength( GppcVarChar s ) |  
size_t GppcGetBpCharLength( GppcBpChar s ) |  
size_t GppcGetByteaLength( GppcBytea b ) |  
char *GppcGetTextPointer( GppcText s ) | Return a string pointer to the head of the memory chunk. The string is not null-terminated.  
char *GppcGetVarCharPointer( GppcVarChar s ) |  
char *GppcGetBpCharPointer( GppcBpChar s ) |  
char *GppcGetByteaPointer( GppcBytea b ) |  
char *GppcTextGetCString( GppcText s ) | Return a string pointer to the head of the memory chunk. The string is null-terminated.  
char *GppcVarCharGetCString( GppcVarChar s ) |  
char *GppcBpCharGetCString( GppcBpChar s ) |  
GppcText *GppcCStringGetText( const char *s ) | Build a varying-length type from a character string.  
GppcVarChar *GppcCStringGetVarChar( const char *s ) |  
GppcBpChar *GppcCStringGetBpChar( const char *s ) |  

Memory returned by the GppcGet< VLEN_ARGTYPE >Pointer() functions may point to actual database content. Do not modify the memory content. The GPPC API provides functions to allocate memory for these types should you require it. After you allocate memory, you can use system functions such as memcpy() to set the data.
The following example manipulates text input arguments and allocates and sets result memory for a text string concatenation operation:

```c
GppcText first_textstr = GPPC_GETARG_TEXT(0);
GppcText second_textstr = GPPC_GETARG_TEXT(1);

// determine the size of the concatenated string and allocate
// text memory of this size
size_t arg0_len = GppcGetTextLength(first_textstr);
size_t arg1_len = GppcGetTextLength(second_textstr);
GppcText retstring = GppcAllocText(arg0_len + arg1_len);

// construct the concatenated return string; copying each string
// individually
memcpy(GppcGetTextPointer(retstring), GppcGetTextPointer(first_textstr), arg0_len);
memcpy(GppcGetTextPointer(retstring) + arg0_len,
       GppcGetTextPointer(second_textstr), arg1_len);
```

### Error Reporting and Logging

The GPPC API provides error reporting and logging functions. The API defines reporting levels equivalent to those in Greenplum Database:

```c
typedef enum GppcReportLevel
{
    GPPC_DEBUG1                             = 10,
    GPPC_DEBUG2                             = 11,
    GPPC_DEBUG3                             = 12,
    GPPC_DEBUG4                             = 13,
    GPPC_DEBUG                              = 14,
    GPPC_LOG                                = 15,
    GPPC_INFO                               = 17,
    GPPC_NOTICE                             = 18,
    GPPC_WARNING                     = 19,
    GPPC_ERROR                              = 20,
} GppcReportLevel;
```

(The Greenplum Database `client_min_messages` server configuration parameter governs the current client logging level. The `log_min_messages` configuration parameter governs the current log-to-logfile level.)

A GPPC report includes the report level, a report message, and an optional report callback function. Reporting and handling functions provide by the GPPC API include:

<table>
<thead>
<tr>
<th>Function Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>GppcReport()</td>
<td>Format and print/log a string of the specified report level.</td>
</tr>
<tr>
<td>GppcInstallReportCallback()</td>
<td>Register/install a report callback function.</td>
</tr>
<tr>
<td>GppcUninstallReportCallback()</td>
<td>Uninstall a report callback function.</td>
</tr>
<tr>
<td>GppcGetReportLevel()</td>
<td>Retrieve the level from an error report.</td>
</tr>
<tr>
<td>GppcGetReportMessage()</td>
<td>Retrieve the message from an error report.</td>
</tr>
<tr>
<td>GppcCheckForInterrupts()</td>
<td>Error out if an interrupt is pending.</td>
</tr>
</tbody>
</table>
The `GppcReport()` function signature is:

```c
void GppcReport(GppcReportLevel elevel, const char *fmt, ...);
```

`GppcReport()` takes a format string input argument similar to `printf()`. The following example generates an error level report message that formats a GPPC text argument:

```c
GppcText  uname = GPPC_GETARG_TEXT(1);
GppcReport(GPPC_ERROR, "Unknown user name: %s", GppcTextGetCString(uname));
```

Refer to the GPPC example code for example report callback handlers.

### SPI Functions

The Greenplum Database Server Programming Interface (SPI) provides writers of C/C++ functions the ability to run SQL commands within a GPPC function. For additional information on SPI functions, refer to Server Programming Interface in the PostgreSQL documentation.

The GPPC API exposes a subset of PostgreSQL SPI functions. This subset enables you to issue SPI queries and retrieve SPI result values in your GPPC function. The GPPC SPI wrapper functions are:

<table>
<thead>
<tr>
<th>SPI Function Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SPI_connect()</td>
<td>GppcSPIConnect(), connect to the Greenplum Database server programming interface.</td>
</tr>
<tr>
<td>SPI_finish()</td>
<td>GppcSPIFinish(), disconnect from the Greenplum Database server programming interface.</td>
</tr>
<tr>
<td>SPI_exec()</td>
<td>GppcSPIExec(), execute a SQL statement, returning the number of rows.</td>
</tr>
<tr>
<td>SPI_getvalue()</td>
<td>GppcSPIGetValue(), retrieve the value of a specific attribute by number from a SQL result as a character string.</td>
</tr>
<tr>
<td></td>
<td>GppcSPIGetDatum(), retrieve the value of a specific attribute by number from a SQL result as a GppcDatum.</td>
</tr>
<tr>
<td></td>
<td>GppcSPIGetValueByName(), retrieve the value of a specific attribute by name from a SQL result as a character string.</td>
</tr>
<tr>
<td></td>
<td>GppcSPIGetDatumByName(), retrieve the value of a specific attribute by name from a SQL result as a GppcDatum.</td>
</tr>
</tbody>
</table>

When you create a GPPC function that accesses the server programming interface, your function should comply with the following flow:

```c
GppcSPIConnect();
GppcSPIExec(...)
// process the results - GppcSPIGetValue(...), GppcSPIGetDatum(...)
GppcSPIFinish()
```

You use `GppcSPIExec()` to execute SQL statements in your GPPC function. When you call this function, you also identify the maximum number of rows to return. The function signature of `GppcSPIExec()` is:

```c
GppcSPIResult GppcSPIExec(const char *sql_statement, long rcount);
```
GppcSPIExec() returns a GppcSPIResult structure. This structure represents SPI result data. It includes a pointer to the data, information about the number of rows processed, a counter, and a result code. The GPPC API defines this structure as follows:

```c
typedef struct GppcSPIResultData
{
    struct GppcSPITupleTableData   *tuptable;
    uint32_t                       processed;
    uint32_t                       current;
    int                            rescode;
} GppcSPIResultData;

typedef GppcSPIResultData *GppcSPIResult;
```

You can set and use the `current` field in the GppcSPIResult structure to examine each row of the tuptable result data.

The following code excerpt uses the GPPC API to connect to SPI, execute a simple query, loop through query results, and finish processing:

```c
GppcSPIResult   result;
char            *attname = "id";
char            *query = "SELECT i, 'foo' || i AS val FROM generate_series(1, 10) i ORDER BY 1";
bool            isnull = true;

// connect to SPI
if( GppcSPIConnect() < 0 ) {
    GppcReport(GPPC_ERROR, "cannot connect to SPI");
}

// execute the query, returning all rows
result = GppcSPIExec(query, 0);

// process result
while( result->current < result->processed ) {
    // get the value of attname column as a datum, making a copy
    datum = GppcSPIGetDatumByName(result, attname, &isnull, true);

    // do something with value

    // move on to next row
    result->current++;
}

// complete processing
GppcSPIFinish();
```

About Tuple Descriptors and Tuples

A table or a set of records contains one or more tuples (rows). The structure of each attribute of a tuple is defined by a tuple descriptor. A tuple descriptor defines the following for each attribute in the tuple:

- attribute name
- object identifier of the attribute data type
- byte length of the attribute data type
- object identifier of the attribute modifier

The GPPC API defines an abstract type, GppcTupleDesc, to represent a tuple/row descriptor. The API also provides functions that you can use to create, access, and set tuple descriptors:
### Function Name | Description
--- | ---
GppcCreateTemplateTupleDesc() | Create an empty tuple descriptor with a specified number of attributes.
GppcTupleDescInitEntry() | Add an attribute to the tuple descriptor at a specified position.
GppcTupleDescNattrs() | Fetch the number of attributes in the tuple descriptor.
GppcTupleDescAttrName() | Fetch the name of the attribute in a specific position (starts at 0) in the tuple descriptor.
GppcTupleDescAttrType() | Fetch the type object identifier of the attribute in a specific position (starts at 0) in the tuple descriptor.
GppcTupleDescAttrLen() | Fetch the type length of an attribute in a specific position (starts at 0) in the tuple descriptor.
GppcTupleDescAttrTypmod() | Fetch the type modifier object identifier of an attribute in a specific position (starts at 0) in the tuple descriptor.

To construct a tuple descriptor, you first create a template, and then fill in the descriptor fields for each attribute. The signatures for these functions are:

```c
GppcTupleDesc GppcCreateTemplateTupleDesc(int natts);
void GppcTupleDescInitEntry(GppcTupleDesc desc, uint16_t attno, const char *attname, GppcOid typid, int32_t typmod);
```

In some cases, you may want to initialize a tuple descriptor entry from an attribute definition in an existing tuple. The following functions fetch the number of attributes in a tuple descriptor, as well as the definition of a specific attribute (by number) in the descriptor:

```c
int GppcTupleDescNattrs(GppcTupleDesc tupdesc);
const char *GppcTupleDescAttrName(GppcTupleDesc tupdesc, int16_t attno);
GppcOid GppcTupleDescAttrType(GppcTupleDesc tupdesc, int16_t attno);
int16_t GppcTupleDescAttrLen(GppcTupleDesc tupdesc, int16_t attno);
int32_t GppcTupleDescAttrTypmod(GppcTupleDesc tupdesc, int16_t attno);
```

The following example initializes a two attribute tuple descriptor. The first attribute is initialized with the definition of an attribute from a different descriptor, and the second attribute is initialized to a boolean type attribute:

```c
GppcTupleDesc tdesc;
GppcTupleDesc indesc = some_input_descriptor;

// initialize the tuple descriptor with 2 attributes
tdesc = GppcCreateTemplateTupleDesc(2);

// use third attribute from the input descriptor
GppcTupleDescInitEntry(tdesc, 1, GppcTupleDescAttrName(indesc, 2), GppcTupleDescAttrType(indesc, 2), GppcTupleDescAttrTypmod(indesc, 2));

// create the boolean attribute
GppcTupleDescInitEntry(tdesc, 2, "is_active", GppcOidBool, 0);
```

The GPPC API defines an abstract type, GppcHeapTuple, to represent a tuple/record/row. A tuple is defined by its tuple descriptor, the value for each tuple attribute, and an indicator of whether or not each value is NULL.
The GPPC API provides functions that you can use to set and access a tuple and its attributes:

<table>
<thead>
<tr>
<th>Function Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>GppcHeapFormTuple()</td>
<td>Form a tuple from an array of GppcDatum.s.</td>
</tr>
<tr>
<td>GppcBuildHeapTupleDatum()</td>
<td>Form a GppcDatum tuple from an array of GppcDatum.s.</td>
</tr>
<tr>
<td>GppcGetAttributeByName()</td>
<td>Fetch an attribute from the tuple by name.</td>
</tr>
<tr>
<td>GppcGetAttributeByNum()</td>
<td>Fetch an attribute from the tuple by number (starts at 1).</td>
</tr>
</tbody>
</table>

The signatures for the tuple-building GPPC functions are:

```c
GppcHeapTuple GppcHeapFormTuple(GppcTupleDesc tupdesc, GppcDatum *values, bool *nulls);
GppcDatum    GppcBuildHeapTupleDatum(GppcTupleDesc tupdesc, GppcDatum *values, bool *nulls);
```

The following code excerpt constructs a GppcDatum tuple from the tuple descriptor in the above code example, and from integer and boolean input arguments to a function:

```c
GppcDatum intarg = GPPC_GETARG_INT4(0);
GppcDatum boolarg = GPPC_GETARG_BOOL(1);
GppcDatum result, values[2];
bool nulls[2] = { false, false };

// construct the values array
values[0] = intarg;
values[1] = boolarg;
result = GppcBuildHeapTupleDatum( tdesc, values, nulls );
```

**Set-Returning Functions**

Greenplum Database UDFs whose signatures include `RETURNS SETOF RECORD` or `RETURNS TABLE( ... )` are set-returning functions.

The GPPC API provides support for returning sets (for example, multiple rows/tuples) from a GPPC function. Greenplum Database calls a set-returning function (SRF) once for each row or item. The function must save enough state to remember what it was doing and to return the next row on each call. Memory that you allocate in the SRF context must survive across multiple function calls.

The GPPC API provides macros and functions to help keep track of and set this context, and to allocate SRF memory. They include:

<table>
<thead>
<tr>
<th>Function/Macro Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>GPPC_SRF_RESULT_DESC()</td>
<td>Get the output row tuple descriptor for this SRF. The result tuple descriptor is determined by an output table definition or a DESCRIBE function.</td>
</tr>
<tr>
<td>GPPC_SRF_IS_FIRSTCALL()</td>
<td>Determine if this is the first call to the SRF.</td>
</tr>
<tr>
<td>GPPC_SRF_FIRSTCALL_INIT()</td>
<td>Initialize the SRF context.</td>
</tr>
<tr>
<td>GPPC_SRF_PERCALL_SETUP()</td>
<td>Restore the context on each call to the SRF.</td>
</tr>
<tr>
<td>GPPC_SRF_RETURN_NEXT()</td>
<td>Return a value from the SRF and continue processing.</td>
</tr>
<tr>
<td>GPPC_SRF_RETURN_DONE()</td>
<td>Signal that SRF processing is complete.</td>
</tr>
<tr>
<td>GppSRFAlloc()</td>
<td>Allocate memory in this SRF context.</td>
</tr>
</tbody>
</table>
### Function/Macro Name

<table>
<thead>
<tr>
<th>Function/Macro Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>GppSRFAlloc0()</td>
<td>Allocate memory in this SRF context and initialize it to zero.</td>
</tr>
<tr>
<td>GppSRFSave()</td>
<td>Save user state in this SRF context.</td>
</tr>
<tr>
<td>GppSRFRestore()</td>
<td>Restore user state in this SRF context.</td>
</tr>
</tbody>
</table>

The `GppcFuncCallContext` structure provides the context for an SRF. You create this context on the first call to your SRF. Your set-returning GPPC function must retrieve the function context on each invocation. For example:

```c
// set function context
GppcFuncCallContext fctx;
if (GPPC_SRF_IS_FIRSTCALL()) {
    fctx = GPPC_SRF_FIRSTCALL_INIT();
}
fctx = GPPC_SRF_PERCALL_SETUP();
// process the tuple
```

The GPPC function must provide the context when it returns a tuple result or to indicate that processing is complete. For example:

```c
GPPC_SRF_RETURN_NEXT(fctx, result_tuple);
// or
GPPC_SRF_RETURN_DONE(fctx);
```

Use a `DESCRIBE` function to define the output tuple descriptor of a function that uses the `RETURNS SETOF RECORD` clause. Use the `GPPC_SRF_RESULT_DESC()` macro to get the output tuple descriptor of a function that uses the `RETURNS TABLE( ... )` clause.

Refer to the [GPPC Set-Returning Function Example](#) for a set-returning function code and deployment example.

### Table Functions

The GPPC API provides the `GppcAnyTable` type to pass a table to a function as an input argument, or to return a table as a function result.

Table-related functions and macros provided in the GPPC API include:

<table>
<thead>
<tr>
<th>Function/Macro Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>GPPC_GETARG_ANYTABLE()</td>
<td>Fetch an anytable function argument.</td>
</tr>
<tr>
<td>GPPC_RETURN_ANYTABLE()</td>
<td>Return the table.</td>
</tr>
<tr>
<td>GppcAnyTableGetTupleDesc()</td>
<td>Fetch the tuple descriptor for the table.</td>
</tr>
<tr>
<td>GppcAnyTableGetNextTuple()</td>
<td>Fetch the next row in the table.</td>
</tr>
</tbody>
</table>

You can use the `GPPC_GETARG_ANYTABLE()` macro to retrieve a table input argument. When you have access to the table, you can examine the tuple descriptor for the table using the `GppcAnyTableGetTupleDesc()` function. The signature of this function is:

```c
GppcTupleDesc GppcAnyTableGetTupleDesc(GppcAnyTable t);
```

For example, to retrieve the tuple descriptor of a table that is the first input argument to a function:

```c
GppcAnyTable intbl;
```
GppcTupleDesc in_desc;

intbl = GPPC_GETARG_ANYTABLE(0);
in_desc = GppcAnyTableGetTupleDesc(intbl);

The GppcAnyTableGetNextTuple() function fetches the next row from the table. Similarly, to retrieve the next tuple from the table above:

GppcHeapTuple ntuple;
ntuple = GppcAnyTableGetNextTuple(intbl);

Limitations
The GPPC API does not support the following operators with Greenplum Database version 5.0.x:

- integer || integer
- integer = text
- text < integer

Sample Code
The gppc test directory in the Greenplum Database github repository includes sample GPPC code:

- gppc_demo/ - sample code exercising GPPC SPI functions, error reporting, data type argument and return macros, set-returning functions, and encoding functions
- tabfunc_gppc_demo/ - sample code exercising GPPC table and set-returning functions

Building a GPPC Shared Library with PGXS
You compile functions that you write with the GPPC API into one or more shared libraries that the Greenplum Database server loads on demand.

You can use the PostgreSQL build extension infrastructure (PGXS) to build the source code for your GPPC functions against a Greenplum Database installation. This framework automates common build rules for simple modules. If you have a more complicated use case, you will need to write your own build system.

To use the PGXS infrastructure to generate a shared library for functions that you create with the GPPC API, create a simple Makefile that sets PGXS-specific variables.

Note: Refer to Extension Building Infrastructure in the PostgreSQL documentation for information about the Makefile variables supported by PGXS.

For example, the following Makefile generates a shared library named sharedlib_name.so from two C source files named src1.c and src2.c:

```
MODULE_big = sharedlib_name
OBJS = src1.o src2.o
PG_CPPFLAGS = -I$(shell $(PG_CONFIG) --includedir)
SHLIB_LINK = -L$(shell $(PG_CONFIG) --libdir) -lgppc
PG_CONFIG = pg_config
PGXS := $(shell $(PG_CONFIG) --pgxs)
include $(PGXS)
```

MODULE_big identifies the base name of the shared library generated by the Makefile.

PG_CPPFLAGS adds the Greenplum Database installation include directory to the compiler header file search path.
SHLIB_LINK adds the Greenplum Database installation library directory to the linker search path. This variable also adds the GPPC library (-lgppc) to the link command.

The PG_CONFIG and PGXS variable settings and the include statement are required and typically reside in the last three lines of the Makefile.

## Registering a GPPC Function with Greenplum Database

Before users can invoke a GPPC function from SQL, you must register the function with Greenplum Database.

Registering a GPPC function involves mapping the GPPC function signature to a SQL user-defined function. You define this mapping with the `CREATE FUNCTION .. AS` command specifying the GPPC shared library name. You may choose to use the same name or differing names for the GPPC and SQL functions.

Sample `CREATE FUNCTION ... AS` syntax follows:

```sql
CREATE FUNCTION sql_function_name(arg[, ...]) RETURNS return_type
  AS 'shared_library_path'[,'gppc_function_name'] LANGUAGE C STRICT [WITH (DESCRIBE=describe_function)];
```

You may omit the shared library `.so` extension when you specify `shared_library_path`.

The following command registers the example `add_int4s()` function referenced earlier in this topic to a SQL UDF named `add_two_int4s_gppc()` if the GPPC function was compiled and linked in a shared library named `gppc_try.so`:

```sql
CREATE FUNCTION add_two_int4s_gppc(int4, int4) RETURNS int8
  AS 'gppc_try.so', 'add_int4s'
  LANGUAGE C STRICT;
```

## About Dynamic Loading

You specify the name of the GPPC shared library in the SQL `CREATE FUNCTION ... AS` command to register a GPPC function in the shared library with Greenplum Database. The Greenplum Database dynamic loader loads a GPPC shared library file into memory the first time that a user invokes a user-defined function linked in that shared library. If you do not provide an absolute path to the shared library in the `CREATE FUNCTION ... AS` command, Greenplum Database attempts to locate the library using these ordered steps:

1. If the shared library file path begins with the string `$libdir`, Greenplum Database looks for the file in the PostgreSQL package library directory. Run the `pg_config --pkglibdir` command to determine the location of this directory.
2. If the shared library file name is specified without a directory prefix, Greenplum Database searches for the file in the directory identified by the `dynamic_library_path` server configuration parameter value.
3. The current working directory.

## Packaging and Deployment Considerations

You must package the GPPC shared library and SQL function registration script in a form suitable for deployment by the Greenplum Database administrator in the Greenplum cluster. Provide specific deployment instructions for your GPPC package.

When you construct the package and deployment instructions, take into account the following:

- Consider providing a shell script or program that the Greenplum Database administrator runs to both install the shared library to the desired file system location and register the GPPC functions.
• The GPPC shared library must be installed to the same file system location on the master host and on every segment host in the Greenplum Database cluster.
• The gpadmin user must have permission to traverse the complete file system path to the GPPC shared library file.
• The file system location of your GPPC shared library after it is installed in the Greenplum Database deployment determines how you reference the shared library when you register a function in the library with the CREATE FUNCTION ... AS command.
• Create a .sql script file that registers a SQL UDF for each GPPC function in your GPPC shared library. The functions that you create in the .sql registration script must reference the deployment location of the GPPC shared library. Include this script in your GPPC deployment package.
• Document the instructions for running your GPPC package deployment script, if you provide one.
• Document the instructions for installing the GPPC shared library if you do not include this task in a package deployment script.
• Document the instructions for installing and running the function registration script if you do not include this task in a package deployment script.

GPPC Text Function Example

In this example, you develop, build, and deploy a GPPC shared library and register and run a GPPC function named concat_two_strings. This function uses the GPPC API to concatenate two string arguments and return the result.

You will develop the GPPC function on your Greenplum Database master host. Deploying the GPPC shared library that you create in this example requires administrative access to your Greenplum Database cluster.

Perform the following procedure to run the example:

1. Log in to the Greenplum Database master host and set up your environment. For example:

   ```
   $ ssh gpadmin@<gpmaster>
   gpadmin@gpmaster$ . /usr/local/greenplum-db/greenplum_path.sh
   ```

2. Create a work directory and navigate to the new directory. For example:

   ```
   gpadmin@gpmaster$ mkdir gppc_work
   gpadmin@gpmaster$ cd gppc_work
   ```

3. Prepare a file for GPPC source code by opening the file in the editor of your choice. For example, to open a file named gppc_concat.c using vi:

   ```
   gpadmin@gpmaster$ vi gppc_concat.c
   ```

4. Copy/paste the following code into the file:

   ```
#include <stdio.h>
#include <string.h>
#include "gppc.h"

// make the function SQL-invokable
GPPC_FUNCTION_INFO(concat_two_strings);

// declare the function
GppcDatum concat_two_strings(GPPC_FUNCTION_ARGS);

GppcDatum
concat_two_strings(GPPC_FUNCTION_ARGS)
{
    // retrieve the text input arguments
    GppcText arg0 = GPPC_GETARG_TEXT(0);
    ```
GppcText arg1 = GPPC_GETARG_TEXT(1);

    // determine the size of the concatenated string and allocate
    // text memory of this size
    size_t arg0_len = GppcGetTextLength(arg0);
    size_t arg1_len = GppcGetTextLength(arg1);
    GppcText retstring = GppcAllocText(arg0_len + arg1_len);

    // construct the concatenated return string
    memcpy(GppcGetTextPointer(retstring), GppcGetTextPointer(arg0),
           arg0_len);
    memcpy(GppcGetTextPointer(retstring) + arg0_len,
             GppcGetTextPointer(arg1), arg1_len);
    GPPC_RETURN_TEXT( retstring );
}

The code declares and implements the concat_two_strings() function. It uses GPPC data types, macros, and functions to get the function arguments, allocate memory for the concatenated string, copy the arguments into the new string, and return the result.

5. Save the file and exit the editor.

6. Open a file named Makefile in the editor of your choice. Copy/paste the following text into the file:

    MODULE_big = gppc_concat
    OBJS = gppc_concat.o

    PG_CONFIG = pg_config
    PGXS := $(shell $(PG_CONFIG) --pgxs)

    PG_CPPFLAGS = -I$(shell $(PG_CONFIG) --includedir)
    SHLIB_LINK = -L$(shell $(PG_CONFIG) --libdir) -lgppc
    include $(PGXS)

7. Save the file and exit the editor.

8. Build a GPPC shared library for the concat_two_strings() function. For example:

    gpadmin@gpmaster$ make all

    The make command generates a shared library file named gppc_concat.so in the current working directory.

9. Copy the shared library to your Greenplum Database installation. You must have Greenplum Database administrative privileges to copy the file. For example:

    gpadmin@gpmaster$ cp gppc_concat.so /usr/local/greenplum-db/lib/postgresql/

10. Copy the shared library to every host in your Greenplum Database installation. For example, if seghostfile contains a list, one-host-per-line, of the segment hosts in your Greenplum Database cluster:

    gpadmin@gpmaster$ gpscp -v -f seghostfile /usr/local/greenplum-db/lib/postgresql/gppc_concat.so =:/usr/local/greenplum-db/lib/postgresql/gppc_concat.so

11. Open a psql session. For example:

    gpadmin@gpmaster$ psql -d testdb
12. Register the GPPC function named `concat_two_strings()` with Greenplum Database, for example, to map the Greenplum Database function `concat_with_gppc()` to the GPPC `concat_two_strings()` function:

```sql
testdb=# CREATE FUNCTION concat_with_gppc(text, text) RETURNS text AS 'gppc_concat', 'concat_two_strings' LANGUAGE C STRICT;
```

13. Run the `concat_with_gppc()` function. For example:

```sql
testdb=# SELECT concat_with_gppc( 'happy', 'monday' );
<table>
<thead>
<tr>
<th>concat_with_gppc</th>
</tr>
</thead>
<tbody>
<tr>
<td>happymonday</td>
</tr>
</tbody>
</table>
(1 row)
```

### GPPC Set-Returning Function Example

In this example, you develop, build, and deploy a GPPC shared library. You also create and run a `.sql` registration script for a GPPC function named `return_tbl()`. This function uses the GPPC API to take an input table with an integer and a text column, determine if the integer column is greater than 13, and returns a result table with the input integer column and a boolean column identifying whether or not the integer is greater than 13. `return_tbl()` utilizes GPPC API reporting and SRF functions and macros.

You will develop the GPPC function on your Greenplum Database master host. Deploying the GPPC shared library that you create in this example requires administrative access to your Greenplum Database cluster.

Perform the following procedure to run the example:

1. Log in to the Greenplum Database master host and set up your environment. For example:

   ```bash
   $ ssh gpadmin@<gpmaster>
gadmin@gpmaster$ . /usr/local/greenplum-db/greenplum_path.sh
   ```

2. Create a work directory and navigate to the new directory. For example:

   ```bash
gadmin@gpmaster$ mkdir gppc_work
gadmin@gpmaster$ cd gppc_work
   ```

3. Prepare a source file for GPPC code by opening the file in the editor of your choice. For example, to open a file named `gppc_concat.c` using `vi`:

   ```bash
gadmin@gpmaster$ vi gppc_rettbl.c
   ```

4. Copy/paste the following code into the file:

   ```c
#include <stdio.h>
#include <string.h>
#include "gppc.h"

// initialize the logging level
GppcReportLevel level = GPPC_INFO;

// make the function SQL-invokable and declare the function
GPPC_FUNCTION_INFO(return_tbl);
GppcDatum return_tbl(GPPC_FUNCTION_ARGS);

GppcDatum
return_tbl(GPPC_FUNCTION_ARGS)
{
    GppcFuncCallContext fctx;
```
GppcAnyTable intbl;
GppcHeapTuple intuple;
GppcTupleDesc in_tupdesc, out_tupdesc;
GppcBool resbool = false;
GppcDatum result, boolres, values[2];
bool nulls[2] = {false, false};

// single input argument - the table
intbl = GPPC_GETARG_ANYTABLE(0);

// set the function context
if (GPPC_SRF_IS_FIRSTCALL()) {
    fctx = GPPC_SRF_FIRSTCALL_INIT();
}

fctx = GPPC_SRF_PERCALL_SETUP();

// get the tuple descriptor for the input table
in_tupdesc = GppcAnyTableGetTupleDesc(intbl);

// retrieve the next tuple
intuple = GppcAnyTableGetNextTuple(intbl);
if( intuple == NULL ) {
    // no more tuples, conclude
    GPPC_SRF_RETURN_DONE(fctx);
}

// get the output tuple descriptor and verify that it is
// defined as we expect
out_tupdesc = GPPC_SRF_RESULT_DESC();
if (GppcTupleDescNattrs(out_tupdesc) != 2          
    || GppcTupleDescAttrType(out_tupdesc, 0) != GppcOidInt4 
    || GppcTupleDescAttrType(out_tupdesc, 1) != GppcOidBool) {
    GppcReport(GPPC_ERROR, "INVALID out_tupdesc tuple");
}

// log the attribute names of the output tuple descriptor
GppcReport(level, "output tuple descriptor attr0 name: %s", 
            GppcTupleDescAttrName(out_tupdesc, 0));
GppcReport(level, "output tuple descriptor attr1 name: %s", 
            GppcTupleDescAttrName(out_tupdesc, 1));

// retrieve the attribute values by name from the tuple
bool text_isnull, int_isnull;
GppcDatum intdat = GppcGetAttributeByName(intuple, "id", &int_isnull);
GppcDatum textdat = GppcGetAttributeByName(intuple, "msg", 
                          &text_isnull);

// convert datum to specific type
GppcInt4 intarg = GppcDatumGetInt4(intdat);
GppcReport(level, "id: %d", intarg);
GppcReport(level, "msg: %s", 
            GppcTextGetCString(GppcDatumGetText(textdat)));

// perform the >13 check on the integer
if( !int_isnull && (intarg > 13) ) {
    // greater than 13?
    resbool = true;
    GppcReport(level, "id is greater than 13!");
}

// values are datums; use integer from the tuple and
// construct the datum for the boolean return
values[0] = intdat;
boolres = GppcBoolGetDatum(resbool);
The code declares and implements the `return_tbl()` function. It uses GPPC data types, macros, and functions to fetch the function arguments, examine tuple descriptors, build the return tuple, and return the result. The function also uses the SRF macros to keep track of the tuple context across function calls.

5. Save the file and exit the editor.

6. Open a file named `Makefile` in the editor of your choice. Copy/paste the following text into the file:

   ```
   MODULE_big = gppc_rettbl
   OBJJS = gppc_rettbl.o
   
   PG_CONFIG = pg_config
   PGXS := $(shell $(PG_CONFIG) --pgxs)
   
   PG_CPPFLAGS = -I$(shell $(PG_CONFIG) --includedir)
   SHLIB_LINK = -L$(shell $(PG_CONFIG) --libdir) -lgppc
   include $(PGXS)
   ```

7. Save the file and exit the editor.

8. Build a GPPC shared library for the `return_tbl()` function. For example:

   ```
   gpadmin@gpmaster$ make all
   ```

   The `make` command generates a shared library file named `gppc_rettbl.so` in the current working directory.

9. Copy the shared library to your Greenplum Database installation. You must have Greenplum Database administrative privileges to copy the file. For example:

   ```
   gpadmin@gpmaster$ cp gppc_rettbl.so /usr/local/greenplum-db/lib/postgresql/
   ```

   This command copies the shared library to `$libdir`

10. Copy the shared library to every host in your Greenplum Database installation. For example, if `seghostfile` contains a list, one-host-per-line, of the segment hosts in your Greenplum Database cluster:

   ```
   gpadmin@gpmaster$ gpscp -v -f seghostfile /usr/local/greenplum-db/lib/postgresql/gppc_rettbl.so =:/usr/local/greenplum-db/lib/postgresql/gppc_rettbl.so
   ```

11. Create a `.sql` file to register the GPPC `return_tbl()` function. Open a file named `gppc_rettbl_reg.sql` in the editor of your choice.

12. Copy/paste the following text into the file:

   ```
   CREATE FUNCTION rettbl_gppc(anytable) RETURNS TABLE(id int4, thirteen bool)
     AS 'gppc_rettbl', 'return_tbl'
   LANGUAGE C STRICT;
   ```
13. Register the GPPC function by running the script you just created. For example, to register the function in a database named testdb:

   gpadmin@gpmaster$ psql -d testdb -f gppc_rettbl_reg.sql

14. Open a psql session. For example:

   gpadmin@gpmaster$ psql -d testdb

15. Create a table with some test data. For example:

   CREATE TABLE gppc_testtbl(id int, msg text);
   INSERT INTO gppc_testtbl VALUES (1, 'f1');
   INSERT INTO gppc_testtbl VALUES (7, 'f7');
   INSERT INTO gppc_testtbl VALUES (10, 'f10');
   INSERT INTO gppc_testtbl VALUES (13, 'f13');
   INSERT INTO gppc_testtbl VALUES (15, 'f15');
   INSERT INTO gppc_testtbl VALUES (17, 'f17');

16. Run the rettbl_gppc() function. For example:

   testdb=# SELECT * FROM rettbl_gppc(TABLE(SELECT * FROM gppc_testtbl));
   id  | thirteen
  ----+----------
   1   | f
   7   | f
   13  | f
   15  | t
   17  | t
   10  | f
   (6 rows)

**Developing a Background Worker Process**

Greenplum Database can be extended to run user-supplied code in separate processes. Such processes are started, stopped, and monitored by postgres, which permits them to have a lifetime closely linked to the server's status. These processes have the option to attach to Greenplum Database's shared memory area and to connect to databases internally; they can also run multiple transactions serially, just like a regular client-connected server process. Also, by linking to libpq they can connect to the server and behave like a regular client application.

**Warning:** There are considerable robustness and security risks in using background worker processes because, being written in the C language, they have unrestricted access to data. Administrators wishing to enable modules that include background worker processes should exercise extreme caution. Only carefully audited modules should be permitted to run background worker processes.

Background workers can be initialized at the time that Greenplum Database is started by including the module name in the shared_preload_libraries server configuration parameter. A module wishing to run a background worker can register it by calling RegisterBackgroundWorker(BackgroundWorker *worker) from its _PG_init(). Background workers can also be started after the system is up and running by calling the function RegisterDynamicBackgroundWorker(BackgroundWorker *worker, BackgroundWorkerHandle **handle). Unlike RegisterBackgroundWorker, which can only be called from within the postmaster, RegisterDynamicBackgroundWorker must be called from a regular backend.

The structure BackgroundWorker is defined thus:

```c
typedef void (*bgworker_main_type)(Datum main_arg);
typedef struct BackgroundWorker
```
bgw_name is a string to be used in log messages, process listings and similar contexts.

bgw_flags is a bitwise-or'd bit mask indicating the capabilities that the module wants. Possible values are BGWORKER_SHMEM_ACCESS (requesting shared memory access) and BGWORKER_BACKEND_DATABASE_CONNECTION (requesting the ability to establish a database connection, through which it can later run transactions and queries). A background worker using BGWORKER_BACKEND_DATABASE_CONNECTION to connect to a database must also attach shared memory using BGWORKER_SHMEM_ACCESS, or worker start-up will fail.

bgw_start_time is the server state during which postgres should start the process; it can be one of BgWorkerStart_PostmasterStart (start as soon as postgres itself has finished its own initialization; processes requesting this are not eligible for database connections), BgWorkerStart_ConsistentState (start as soon as a consistent state has been reached in a hot standby, allowing processes to connect to databases and run read-only queries), and BgWorkerStart_RecoveryFinished (start as soon as the system has entered normal read-write state). Note the last two values are equivalent in a server that's not a hot standby. Note that this setting only indicates when the processes are to be started; they do not stop when a different state is reached.

bgw_restart_time is the interval, in seconds, that postgres should wait before restarting the process, in case it crashes. It can be any positive value, or BGW_NEVER_RESTART, indicating not to restart the process in case of a crash.

bgw_main is a pointer to the function to run when the process is started. This function must take a single argument of type Datum and return void. bgw_main_arg will be passed to it as its only argument. Note that the global variable MyBgworkerEntry points to a copy of the BackgroundWorker structure passed at registration time. bgw_main may be NULL; in that case, bgw_library_name and bgw_function_name will be used to determine the entry point. This is useful for background workers launched after postmaster startup, where the postmaster does not have the requisite library loaded.

bgw_library_name is the name of a library in which the initial entry point for the background worker should be sought. It is ignored unless bgw_main is NULL. But if bgw_main is NULL, then the named library will be dynamically loaded by the worker process and bgw_function_name will be used to identify the function to be called.

bgw_function_name is the name of a function in a dynamically loaded library which should be used as the initial entry point for a new background worker. It is ignored unless bgw_main is NULL.

bgw_notify_pid is the PID of a Greenplum Database backend process to which the postmaster should send SIGUSR1 when the process is started or exits. It should be 0 for workers registered at postmaster startup time, or when the backend registering the worker does not wish to wait for the worker to start up. Otherwise, it should be initialized to MyProcPid.

Once running, the process can connect to a database by calling
BackgroundWorkerInitializeConnection(char *dbname, char *username). This allows the process to run transactions and queries using the SPI interface. If dbname is NULL, the session is not connected to any particular database, but shared catalogs can be accessed. If username is NULL, the
process will run as the superuser created during initdb. BackgroundWorkerInitializeConnection can only be called once per background process, it is not possible to switch databases.

Signals are initially blocked when control reaches the bgw_main function, and must be unblocked by it; this is to allow the process to customize its signal handlers, if necessary. Signals can be unblocked in the new process by calling BackgroundWorkerUnblockSignals and blocked by calling BackgroundWorkerBlockSignals.

If bgw_restart_time for a background worker is configured as BGW_NEVER_RESTART, or if it exits with an exit code of 0 or is terminated by TerminateBackgroundWorker, it will be automatically unregistered by the postmaster on exit. Otherwise, it will be restarted after the time period configured via bgw_restart_time, or immediately if the postmaster reinitializes the cluster due to a backend failure. Backends which need to suspend execution only temporarily should use an interruptible sleep rather than exiting; this can be achieved by calling WaitLatch(). Make sure the WL_POSTMASTER_DEATH flag is set when calling that function, and verify the return code for a prompt exit in the emergency case that postgres itself has terminated.

When a background worker is registered using the RegisterDynamicBackgroundWorker function, it is possible for the backend performing the registration to obtain information regarding the status of the worker. Backends wishing to do this should pass the address of a BackgroundWorkerHandle * as the second argument to RegisterDynamicBackgroundWorker. If the worker is successfully registered, this pointer will be initialized with an opaque handle that can subsequently be passed to GetBackgroundWorkerPid(BackgroundWorkerHandle *, pid_t *) or TerminateBackgroundWorker(BackgroundWorkerHandle *). GetBackgroundWorkerPid can be used to poll the status of the worker: a return value of BGWH_NOT_YET_STARTED indicates that the worker has not yet been started by the postmaster; BGWH_STOPPED indicates that it has been started but is no longer running; and BGWH_STARTED indicates that it is currently running. In this last case, the PID will also be returned via the second argument. TerminateBackgroundWorker causes the postmaster to send SIGTERM to the worker if it is running, and to unregister it as soon as it is not.

In some cases, a process which registers a background worker may wish to wait for the worker to start up. This can be accomplished by initializing bgw_notify_pid to MyProcPid and then passing the BackgroundWorkerHandle * obtained at registration time to WaitForBackgroundWorkerStartup(BackgroundWorkerHandle *handle, pid_t *) function. This function will block until the postmaster has attempted to start the background worker, or until the postmaster dies. If the background runner is running, the return value will be BGWH_STARTED, and the PID will be written to the provided address. Otherwise, the return value will be BGWH_STOPPED or BGWH_POSTMASTER_DIED.

The worker_spi contrib module contains a working example, which demonstrates some useful techniques.

The maximum number of registered background workers is limited by max-worker-processes.
SQL Features, Reserved and Key Words, and Compliance

This section includes topics that identify SQL features and compliance in Greenplum Database:

- Summary of Greenplum Features
- Reserved Identifiers and SQL Key Words
- SQL 2008 Optional Feature Compliance

Summary of Greenplum Features

This section provides a high-level overview of the system requirements and feature set of Greenplum Database. It contains the following topics:

- Greenplum SQL Standard Conformance
- Greenplum and PostgreSQL Compatibility

Greenplum SQL Standard Conformance

The SQL language was first formally standardized in 1986 by the American National Standards Institute (ANSI) as SQL 1986. Subsequent versions of the SQL standard have been released by ANSI and as International Organization for Standardization (ISO) standards: SQL 1989, SQL 1992, SQL 1999, SQL 2003, SQL 2006, and finally SQL 2008, which is the current SQL standard. The official name of the standard is ISO/IEC 9075-14:2008. In general, each new version adds more features, although occasionally features are deprecated or removed.

It is important to note that there are no commercial database systems that are fully compliant with the SQL standard. Greenplum Database is almost fully compliant with the SQL 1992 standard, with most of the features from SQL 1999. Several features from SQL 2003 have also been implemented (most notably the SQL OLAP features).

This section addresses the important conformance issues of Greenplum Database as they relate to the SQL standards. For a feature-by-feature list of Greenplum's support of the latest SQL standard, see SQL 2008 Optional Feature Compliance.

Core SQL Conformance

In the process of building a parallel, shared-nothing database system and query optimizer, certain common SQL constructs are not currently implemented in Greenplum Database. The following SQL constructs are not supported:

1. Some set returning subqueries in EXISTS or NOT EXISTS clauses that Greenplum's parallel optimizer cannot rewrite into joins.
2. Backwards scrolling cursors, including the use of FETCH PRIOR, FETCH FIRST, FETCH ABSOLUTE, and FETCH RELATIVE.
3. In CREATE TABLE statements (on hash-distributed tables): a UNIQUE or PRIMARY KEY clause must include all of (or a superset of) the distribution key columns. Because of this restriction, only one UNIQUE clause or PRIMARY KEY clause is allowed in a CREATE TABLE statement. UNIQUE or PRIMARY KEY clauses are not allowed on randomly-distributed tables.
4. CREATE UNIQUE INDEX statements that do not contain all of (or a superset of) the distribution key columns. CREATE UNIQUE INDEX is not allowed on randomly-distributed tables.

Note that UNIQUE INDEXES (but not UNIQUE CONSTRAINTS) are enforced on a part basis within a partitioned table. They guarantee the uniqueness of the key within each part or sub-part.

5. VOLATILE or STABLE functions cannot execute on the segments, and so are generally limited to being passed literal values as the arguments to their parameters.
6. Triggers are not supported since they typically rely on the use of VOLATILE functions.
7. Referential integrity constraints (foreign keys) are not enforced in Greenplum Database. Users can declare foreign keys and this information is kept in the system catalog, however.
8. Sequence manipulation functions CURRVAL and LASTVAL.

**SQL 1992 Conformance**

The following features of SQL 1992 are not supported in Greenplum Database:

1. NATIONAL CHARACTER (NCHAR) and NATIONAL CHARACTER VARYING (NVARCHAR). Users can declare the NCHAR and NVARCHAR types, however they are just synonyms for CHAR and VARCHAR in Greenplum Database.
2. CREATE ASSERTION statement.
3. INTERVAL literals are supported in Greenplum Database, but do not conform to the standard.
4. GET DIAGNOSTICS statement.
5. GLOBAL TEMPORARY TABLES and LOCAL TEMPORARY TABLES. Greenplum TEMPORARY TABLES do not conform to the SQL standard, but many commercial database systems have implemented temporary tables in the same way. Greenplum temporary tables are the same as VOLATILE TABLES in Teradata.
6. UNIQUE predicate.
7. MATCH PARTIAL for referential integrity checks (most likely will not be implemented in Greenplum Database).

**SQL 1999 Conformance**

The following features of SQL 1999 are not supported in Greenplum Database:

1. Large Object data types: BLOB, CLOB, NCLOB. However, the BYTEA and TEXT columns can store very large amounts of data in Greenplum Database (hundreds of megabytes).
2. MODULE (SQL client modules).
3. CREATE PROCEDURE (SQL/PSM). This can be worked around in Greenplum Database by creating a FUNCTION that returns void, and invoking the function as follows:
   
   ```sql
   SELECT myfunc(args);
   ```

4. The PostgreSQL/Greenplum function definition language (PL/PGSQL) is a subset of Oracle's PL/SQL, rather than being compatible with the SQL/PSM function definition language. Greenplum Database also supports function definitions written in Python, Perl, Java, and R.
5. BIT and BIT VARYING data types (intentionally omitted). These were deprecated in SQL 2003, and replaced in SQL 2008.
6. Greenplum supports identifiers up to 63 characters long. The SQL standard requires support for identifiers up to 128 characters long.
7. Prepared transactions (PREPARE TRANSACTION, COMMIT PREPARED, ROLLBACK PREPARED). This also means Greenplum does not support XA Transactions (2 phase commit coordination of database transactions with external transactions).
8. CHARACTER SET option on the definition of CHAR() or VARCHAR() columns.
9. Specification of CHARACTERS or OCTETS (BYTES) on the length of a CHAR() or VARCHAR() column. For example, VARCHAR(15 CHARACTERS) or VARCHAR(15 OCTETS) or VARCHAR(15 BYTES).
10. CURRENT_SCHEMA function.
11. CREATE DISTINCT TYPE statement. CREATE DOMAIN can be used as a work-around in Greenplum.
12. The explicit table construct.

**SQL 2003 Conformance**

The following features of SQL 2003 are not supported in Greenplum Database:

1. MERGE statements.
2. **IDENTITY** columns and the associated **GENERATED ALWAYS/GENERATED BY DEFAULT** clause. The **SERIAL** or **BIGSERIAL** data types are very similar to **INT** or **BIGINT** GENERATED BY DEFAULT AS **IDENTITY**.

3. **MULTISET** modifiers on data types.

4. **ROW** data type.

5. Greenplum Database syntax for using sequences is non-standard. For example, `nextval('seq')` is used in Greenplum instead of the standard `NEXT VALUE FOR seq`.

6. **GENERATED ALWAYS AS** columns. Views can be used as a work-around.

7. The sample clause (**TABLESAMPLE**) on **SELECT** statements. The `random()` function can be used as a work-around to get random samples from tables.

8. The **partitioned join tables** construct (**PARTITION BY** in a join).

9. For **CREATE TABLE x (LIKE(y))** statements, Greenplum does not support the `[INCLUDING|EXCLUDING] [DEFAULTS|CONSTRAINTS|INDEXES]` clauses.

10. Greenplum array data types are almost SQL standard compliant with some exceptions. Generally customers should not encounter any problems using them.

**SQL 2008 Conformance**

The following features of SQL 2008 are not supported in Greenplum Database:

1. **BINARY** and **VARBINARY** data types. **BYTEA** can be used in place of **VARBINARY** in Greenplum Database.

2. **FETCH FIRST** or **FETCH NEXT** clause for **SELECT**, for example:

   ```
   SELECT id, name FROM tab1 ORDER BY id OFFSET 20 ROWS FETCH NEXT 10 ROWS ONLY;
   ```

   Greenplum has **LIMIT** and **LIMIT OFFSET** clauses instead.

3. The **ORDER BY** clause is ignored in views and subqueries unless a **LIMIT** clause is also used. This is intentional, as the Greenplum optimizer cannot determine when it is safe to avoid the sort, causing an unexpected performance impact for such ORDER BY clauses. To work around, you can specify a really large **LIMIT**. For example: `SELECT * FROM mytable ORDER BY 1 LIMIT 9999999999`

4. The **row subquery** construct is not supported.

5. **TRUNCATE TABLE** does not accept the **CONTINUE IDENTITY** and **RESTART IDENTITY** clauses.

**Greenplum and PostgreSQL Compatibility**

Greenplum Database is based on PostgreSQL 9.4. To support the distributed nature and typical workload of a Greenplum Database system, some SQL commands have been added or modified, and there are a few PostgreSQL features that are not supported. Greenplum has also added features not found in PostgreSQL, such as physical data distribution, parallel query optimization, external tables, resource queues, and enhanced table partitioning. For full SQL syntax and references, see the **SQL Commands**.

**Note**: Greenplum Database does not support the PostgreSQL **large object facility** for streaming user data that is stored in large-object structures.

**Note**: Pivotal does not support using `WITH OIDS` or `oids=TRUE` to assign an OID system column when creating or altering a table. This syntax is deprecated and will be removed in a future Greenplum release.

**Reserved Identifiers and SQL Key Words**

This topic describes Greenplum Database reserved identifiers and object names, and SQL key words recognized by the Greenplum Database and PostgreSQL command parsers.

**Reserved Identifiers**

In the Greenplum Database system, names beginning with `gp_` and `pg_` are reserved and should not be used as names for user-created objects, such as tables, views, and functions.

The resource group names `admin_group`, `default_group`, and `none` are reserved. The resource queue name `pg_default` is reserved.

The tablespace names `pg_default` and `pg_global` are reserved.

The role names `gpadmin` and `gpmon` are reserved. `gpadmin` is the default Greenplum Database superuser role. The `gpmon` role owns the `gpperfmon` database and is also used by Greenplum Command Center.

In data files, the characters that delimit fields (columns) and rows have a special meaning. If they appear within the data you must escape them so that Greenplum Database treats them as data and not as delimiters. The backslash character (`\`) is the default escape character. See *Escaping* for details.

See *SQL Syntax* in the PostgreSQL documentation for more information about SQL identifiers, constants, operators, and expressions.

**SQL Key Words**

*Table 256: SQL Key Words* lists all tokens that are key words in Greenplum Database 6 and PostgreSQL 9.4.

ANSI SQL distinguishes between *reserved* and *unreserved* key words. According to the standard, reserved key words are the only real key words; they are never allowed as identifiers. Unreserved key words only have a special meaning in particular contexts and can be used as identifiers in other contexts. Most unreserved key words are actually the names of built-in tables and functions specified by SQL. The concept of unreserved key words essentially only exists to declare that some predefined meaning is attached to a word in some contexts.

In the Greenplum Database and PostgreSQL parsers there are several different classes of tokens ranging from those that can never be used as an identifier to those that have absolutely no special status in the parser as compared to an ordinary identifier. (The latter is usually the case for functions specified by SQL.) Even reserved key words are not completely reserved, but can be used as column labels (for example, `SELECT 55 AS CHECK`, even though `CHECK` is a reserved key word).

*Table 256: SQL Key Words* classifies as "unreserved" those key words that are explicitly known to the parser but are allowed as column or table names. Some key words that are otherwise unreserved cannot be used as function or data type names and are marked accordingly. (Most of these words represent built-in functions or data types with special syntax. The function or type is still available but it cannot be redefined by the user.) Key words labeled "reserved" are not allowed as column or table names. Some
reserved key words are allowable as names for functions or data types; this is also shown in the table. If not so marked, a reserved key word is only allowed as an "AS" column label name.

If you get spurious parser errors for commands that contain any of the listed key words as an identifier you should try to quote the identifier to see if the problem goes away.

Before studying the table, note the fact that a key word is not reserved does not mean that the feature related to the word is not implemented. Conversely, the presence of a key word does not indicate the existence of a feature.

SQL 2008 Optional Feature Compliance

The following table lists the features described in the 2008 SQL standard. Features that are supported in
Greenplum Database are marked as YES in the “Supported” column, features that are not implemented are
marked as NO.

For information about Greenplum features and SQL compliance, see the Greenplum Database
Administrator Guide.

Table 257: SQL 2008 Optional Feature Compliance Details

Chapter 16

Greenplum Client and Loader Tools Package

This documentation describes the contents of, and how to install, configure, and use the Greenplum client and loader utility programs for UNIX and Windows systems.

Key topics in the documentation include:

• About the Tools Package
• Installing the Client and Loader Tools Package
• Configuring Greenplum Database for Remote Client Access
• Configuring a Client System for Kerberos Authentication
• Using the Client and Loader Tools
• Client and Loader Utility Reference
Chapter 17

About the Tools Package

The Greenplum client and loader tools package provides utility programs that you can install and run on a host outside of your Greenplum Database cluster. The package is available on Pivotal Network.

Greenplum utility programs provided in the client and loader tools package include:

Table 258: Client and Loader Programs

<table>
<thead>
<tr>
<th>Program</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>createdb</td>
<td>Create a Greenplum database. Requires superuser or specially-granted Greenplum Database privileges.</td>
</tr>
<tr>
<td>createlang</td>
<td>Register a language in a Greenplum database. Requires superuser or specially-granted Greenplum Database privileges.</td>
</tr>
<tr>
<td>createuser</td>
<td>Register a Greenplum user. Requires superuser or specially-granted Greenplum Database privileges.</td>
</tr>
<tr>
<td>dropdb</td>
<td>Drop a Greenplum database. Requires superuser or specially-granted Greenplum Database privileges.</td>
</tr>
<tr>
<td>droplang</td>
<td>Remove support for a language from a Greenplum database. Requires superuser or specially-granted Greenplum Database privileges.</td>
</tr>
<tr>
<td>dropuser</td>
<td>Remove a Greenplum user. Requires superuser or specially-granted Greenplum Database privileges.</td>
</tr>
<tr>
<td>gpfdist</td>
<td>Greenplum parallel file distribution program.</td>
</tr>
<tr>
<td>gpkafka</td>
<td>Load Kafka data into Greenplum Database using the Pivotal Greenplum-Kafka Integration.</td>
</tr>
<tr>
<td>gpload</td>
<td>Greenplum data loading utility.</td>
</tr>
<tr>
<td>gpss</td>
<td>Start a Pivotal Greenplum Stream Server instance.</td>
</tr>
<tr>
<td>gpsscli</td>
<td>Pivotal Greenplum Stream Server client program.</td>
</tr>
<tr>
<td>pg_dump</td>
<td>Dump the contents of a Greenplum database to a file.</td>
</tr>
<tr>
<td>pg_dumpall</td>
<td>Dump the contents of all Greenplum databases to a file.</td>
</tr>
<tr>
<td>psql</td>
<td>PostgreSQL interactive command-line interface for Greenplum Database.</td>
</tr>
</tbody>
</table>

**Note:** The Windows Greenplum client and loader tools package provides additional libraries and programs, including kinit, kdestroy, and klist. The Windows package does **not** include the gpkafka, gpsscli, and gpss programs.

The gpload program provided in the Windows package is backwards-compatible with Greenplum Database 5.
Chapter 18

Installing the Client and Loader Tools Package

You can install the client and loader tools package on CentOS 6.x, CentOS 7.x, Ubuntu 18.04, and Windows systems. This section provides the information required to download and install the tools on your client machine.
Installation Procedure

Perform the following procedure to install the Greenplum Database client tools on your system:

1. Download the appropriate installer package for your platform from Pivotal Network. For example, to download the CentOS 7.x package, click to select the Greenplum Clients->Clients for RHEL 7 directory.

   The naming format of a UNIX package file is `greenplum-db-clients-<version>-<platform>.<filetype>`.

   The naming format of a Windows package file is `greenplum-db-clients-<version>-x86_64.msi`.

2. **Note the file system location of the downloaded file.**

3. If you are installing the package on a system running the CentOS or Ubuntu operating system, follow the instructions in *Running the UNIX Tools Installer*.

4. If you are installing the package on a Windows system, follow the instructions in *Running the Windows Tools Installer*. 

# About Your Installation

Your Greenplum Database client and loader tools installation includes the following files and directories:

<table>
<thead>
<tr>
<th>File/Directory</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>bin/</td>
<td>client and loader tool utility programs</td>
</tr>
<tr>
<td>ext/ (UNIX only)</td>
<td>Python runtime components required by the UNIX utilities</td>
</tr>
<tr>
<td>greenplum_clients_path.&lt;ext&gt;</td>
<td>environment set up script or batch file; the file extension (&lt;ext&gt;) is operating system- or shell-dependent</td>
</tr>
<tr>
<td>lib/</td>
<td>libraries required by the utilities</td>
</tr>
<tr>
<td>LICENSE (UNIX)</td>
<td>license notices for the utilities</td>
</tr>
<tr>
<td>‘Pivotal License’ (Windows)</td>
<td>license notices for the utilities</td>
</tr>
<tr>
<td>NOTICE (UNIX)</td>
<td>attribution notices for the utilities</td>
</tr>
<tr>
<td>‘Thirdparty Notice’ (Windows)</td>
<td>attribution notices for the utilities</td>
</tr>
<tr>
<td>‘GPDB Clients Version’ (Windows only)</td>
<td>file identifying the Windows package version</td>
</tr>
</tbody>
</table>
Running the UNIX Tools Installer

This section describes the client and loader tool package installation procedure for CentOS and Ubuntu systems.

Prerequisites

You must have operating system superuser privileges to install the tools package.

Note: Installing the client tools package automatically installs dependent packages not already installed on the system.

Procedure

Perform the following procedure to install the client and loader tools package on a CentOS or Ubuntu system.

1. Locate the installer file that you downloaded from Pivotal Network. The naming format of the file is greenplum-db-clients-<version>-<platform>.<file_type>.
2. Install the package using your package management utility. You must be the superuser or have sudo access to install packages. For example:

   - To install the tools on a host running CentOS 7.x:
     ```
     root@clientsys$ yum install greenplum-db-clients-6.1.0-rhel7-x86_64.rpm
     ```
   - To install the tools on a host running Ubuntu 18.04:
     ```
     root@clientsys$ apt install greenplum-db-clients-6.1.0-ubuntu18.04-amd64.deb
     ```

The client tools are installed into the /usr/local/greenplum-db-clients-<version>/ directory. The installation process creates a symbolic link from /usr/local/greenplum-db-clients to the install directory.
Running the Windows Tools Installer

This section describes the client and loader tool package installation procedure for Windows systems.

Prerequisites

You must have operating system superuser privileges to install the tools package.

Procedure

Perform the following procedure to install the client and loader tools package on a Windows system.

1. The Greenplum Database client and loader tools for Windows require a recent Microsoft Visual C++
   Redistributable for Visual Studio 2017. You must download and install an update as described in the
   Microsoft support article titled The latest supported Visual C++ downloads.
2. If you plan to use the gpload.bat Greenplum Database loader program for Windows:
   a. Ensure that a 64-bit version of Python 2.7 is installed on your system. Refer to Python 2.7.16 or the
      source of your choice for Python download and install instructions.
   b. You must also add the Python directory to your PATH.
3. Locate the installer .msi file that you downloaded from Pivotal Network in a previous step. The naming
   format of the Windows installer file is greenplum-db-clients-<version>-x86_64.msi.
4. Double-click on the greenplum-db-clients-<version>-x86_64.msi file to launch the installer.
5. Click Next on the Greenplum Clients Setup Wizard Welcome screen.
6. Read through the End-User License Agreement, and click I Agree to accept the terms of the license.
7. By default, the Greenplum Database client and load tools are installed into the following directory:

   C:\Program Files\Greenplum\greenplum-clients\

   Click Browse on the Custom Setup screen to choose another location.
8. Click Next when you have chosen the desired install path.
9. Click Install to begin the installation.
10. Click Finish to exit the Windows client and load tools installer.
Greenplum Database does not, by default, accept remote client connections. You must configure Greenplum Database to accept remote connections. This configuration involves identifying each client host system and Greenplum Database role combination to which you want to provide access, and then adding access rules to the `pg_hba.conf` client authentication configuration file. Refer to *Allowing Connections to Greenplum Database* for detailed information about configuring remote client access.

**Note:** Ensure that the authentication method that you configure for a role is supported by the Greenplum Database client program(s) that the role will execute.

In addition to configuring remote client access, you must also ensure that each Greenplum role that you are allowing to connect to the master exists in the cluster, and that the role has the correct privileges to database objects. *Managing Roles and Privileges* describes configuring Greenplum Database users and granting privileges.
Chapter 20

Configuring a Client System for Kerberos Authentication

If your Greenplum Database cluster employs Kerberos user authentication, your client host must be configured to access Greenplum with Kerberos. Refer to the following documentation for instructions on configuring Kerberos authentication on a client system:

- UNIX client hosts - Configuring Kerberos for Linux Clients
- Windows client hosts - Configuring Kerberos for Windows Clients

*If your Greenplum Database cluster is not using Kerberos for user authentication, then this configuration is not required.*
Chapter 21

Using the Client and Loader Tools

This section provides the information required to set up your Greenplum Database client runtime environment and use the client and loader tools. Topics include:

- Prerequisites
- Setting Up Your Greenplum Database Clients Runtime Environment
- Running the Client and Loader Programs
- Greenplum Database Documentation References
- Windows Considerations
Prerequisites

Before using the client and loader tools, ensure that:

- Your Greenplum Database cluster is up and running, and you can identify the master host and port number, if the master server process is not running on the default port (5432).
- Network connectivity exists between the client machine and the Greenplum Database master host. If you are using the `gpfdist`, `gpload`, or `gпss` utility programs, network connectivity must also exist between the client machine and all Greenplum Database segment hosts.
- You have installed and configured the tools and any dependent components on your client machine as described in Installing the Client and Loader Tools Package.
- You can identify your Greenplum Database user/role name and password.
- You have created or can identify the Greenplum database, schema, and table objects of interest.

Contact your Greenplum Database administrator if you do not meet the prerequisites mentioned above.
Setting Up Your Greenplum Database Clients Runtime Environment

The client and loader tools package installs a file that you use to set up your Greenplum Database client and loader environment. This script or batch file, named greenplum_clients_path.<ext> (where the file extension <ext> is operating system- or shell-dependent) is located in the client tools root install directory.

`greenplum_clients_path.<ext>`:

- Sets the runtime environment variables that are required by the utilities.
- Sets the `$GPHOME_CLIENTS` environment variable to point to the root directory of the client and loader tools installation.
- Updates your `$PATH` to include `$GPHOME_CLIENTS/bin`.

You must source or run `greenplum_clients_path.<ext>` before you invoke any of the client or loader programs. For example, run the following command on a CentOS or Ubuntu system to source the file:

```
user@clientsys$ . /usr/local/greenplum-db-clients/greenplum_clients_path.sh
```

**Note**: Consider adding the command to source or run `greenplum_clients_path.<ext>` to your shell or equivalent initialization file.
Running the Client and Loader Programs

Clients always connect to Greenplum Database through the master host. In order for the client or loader program to establish a connection to the master host, you provide the following connection parameters to the program via options, a configuration file, or environment variables:

Table 260: Connection Parameters

<table>
<thead>
<tr>
<th>Connection Parameter</th>
<th>Description</th>
<th>Environment Variable Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Database name</td>
<td>The name of the database to which you want to connect.</td>
<td>PGDATABASE</td>
</tr>
<tr>
<td>Host name</td>
<td>The host name of the Greenplum Database master. The default host is the local host.</td>
<td>PGHOST</td>
</tr>
<tr>
<td>Port</td>
<td>The port number on which the Greenplum Database master server instance is running. The default port is 5432.</td>
<td>PGPORT</td>
</tr>
<tr>
<td>User name</td>
<td>The Greenplum Database user (role) name. This name may not necessarily be the same as your operating system user name.</td>
<td>PGUSER</td>
</tr>
</tbody>
</table>

**Note:** Refer to the *Client and Loader Utility Reference* for the client or load command to determine tool support for specifying these connection parameters via options, configuration property names, and/or environment variables.
Greenplum Database Documentation References

The following Greenplum Database documentation topics provide additional information about using selected client and loader tools:

- gpfdist - Using the Greenplum Parallel File Server (gpfdist)
- gpkafka - Pivotal Greenplum-Kafka Integration documentation
- gpload - Loading Data with gpload
- gpss, gpsscli - Pivotal Greenplum Stream Server documentation
- psql - Connecting with psql
Windows Considerations

Keep in mind these additional considerations when you use the Windows client and load programs:

- You must ensure that any ports that you identify in a gpload control file are unblocked by any firewall running on the Windows client system.
- By default, gpload.bat attempts to create a directory named gpAdminLog in the directory from which you execute the program, and writes its log files there. This operation will fail if you do not have write permission to the current working directory. Run gpload.bat with the -l option to direct the log output to a different location.
- Review the Greenplum Character Encoding and Formatting Rows documentation for Windows-specific considerations for the tools.
Chapter 22

Client and Loader Utility Reference

The Greenplum client and loader tools package includes the following utilities:

Note: The Windows Greenplum client and loader tools package provides additional libraries and programs, including kinit, kdestroy, and klist. The Windows package does not include the gpkafka, gpsscli, and gpss programs.

The gpload program provided in the Windows package is backwards-compatible with Greenplum Database 5.
Chapter 23

DataDirect ODBC Drivers for Pivotal Greenplum

ODBC drivers enable third party applications to connect via a common interface to the Pivotal Greenplum Database system. This document describes how to install DataDirect Connect XE for ODBC drivers for Pivotal Greenplum on either a Linux or Windows system. Unless specified otherwise, references to DataDirect Connect XE for ODBC refer to DataDirect Connect XE for ODBC and DataDirect Connect64 XE for ODBC.

The DataDirect ODBC Drivers for Pivotal Greenplum are available for download from Pivotal Network.
Prerequisites

- Install KornShell (ksh) on your system if it is not available.
- Note the appropriate serial number and license key (use the same number for both the serial number and license key during the installation):

<table>
<thead>
<tr>
<th>Driver</th>
<th>Serial Number / License Key</th>
</tr>
</thead>
<tbody>
<tr>
<td>DataDirect Connect XE for ODBC 7.1 drivers (32-bit drivers)</td>
<td>1076681728</td>
</tr>
<tr>
<td>DataDirect Connect64 XE for ODBC 7.1 drivers (64-bit drivers)</td>
<td>1076681984</td>
</tr>
</tbody>
</table>
**Supported Client Platforms**

DataDirect Connect64 XE for ODBC drivers for Greenplum support the following 64-bit client platforms:

- AIX 64: 7.1, 6.1, 5.3 Fixpack 5 or higher
- HP-UX IPF: 11i v3.0 (B.11.3X), 11i v2.0 (B.11.23)
- Linux Itanium: Red Hat Enterprise Linux (RHEL) 7.x, 6.x, RHEL 5.x, RHEL 4.x
- Linux x64: RHEL 7.x, RHEL 6.x, RHEL 5.x, RHEL 4.x, SUSE Linux Enterprise Server (SLES) 12, SLES 11, SLES 10, Ubuntu 16.04
- Solaris on SPARC: 11 and 11 Express (Solaris 5.11), 10 (Solaris 5.10), 9 (Solaris 5.9), 8 (Solaris 5.8)
- Solaris x64: 11 (Solaris 5.11), 10 (Solaris 5.10)
- Windows x64: Windows 8, Windows 10, Windows Server 20016

DataDirect Connect XE for ODBC drivers for Greenplum support the following 32-bit client platforms:

- AIX 32: 7.1, 6.1, 5.3 Fixpack 5 or higher
- HP-UX IPF: 11i v3.0 (B.11.3X), 11i v2.0 (B.11.23)
- HP-UX PA-RISC: 11i v3 (B.11.3X), 11i v2 (B.11.23) 11i v1 (B.11.11), 11
- Linux x86: Red Hat Enterprise Linux (RHEL) 6.x, RHEL 5.x, RHEL 4.x, SUSE Linux Enterprise Server (SLES) 11, SLES 10, Ubuntu 16.04, Ubuntu 14.04
- Solaris on SPARC: 11 and 11 Express (Solaris 5.11), 10 (Solaris 5.10), 9 (Solaris 5.9), 8 (Solaris 5.8)
- Windows: Windows 8, Windows 10, Windows Server 20016
Installing on Linux Systems

To install ODBC drivers on your client:

1. Log into Pivotal Network and download the correct ODBC driver for your operating system. The following Linux and UNIX files are available:
   - PROGRESS_DATADIRECT_CONNECT64_ODBC_7.1.6.HOTFIX_LINUX_64.tar.gz
   - PROGRESS_DATADIRECT_CONNECT_ODBC_7.1.6.HOTFIX_LINUX_32.tar.gz
   - PROGRESS_DATADIRECT_CONNECT64_ODBC_7.1.6.HOTFIX_AIX_64.tar.gz
   - PROGRESS_DATADIRECT_CONNECT_ODBC_7.1.6.HOTFIX_AIX_32.tar.gz

2. Unpack the files. For example:

   ```
   $ tar -zxvf PROGRESS_DATADIRECT_CONNECT64_ODBC_7.1.6.HOTFIX_LINUX_64.tar.gz
   ```

   The files are extracted to the current directory.

3. Execute the installer as the root user:

   ```
   $ ksh unixmi.ksh
   ```

   Progress DataDirect Connect for ODBC Setup is preparing....

   English has been set as the installation language.

   Log file : /tmp/logfile.492.1

   The following operating system has been detected:

   LinuxX64

   Is this the current operating system on your machine (Y/N) ?

4. Press Y to confirm your operating system. The installer displays the license agreement.

5. Enter YES to accept the End User License Agreement. The installer prompts you for registration information:

   Enter YES to accept the above agreement : YES

   Please enter the following information for proper registration.

   In the Key field, enter either EVAL or the Key provided.

   Name          :

6. Enter the required registration information at each prompt:

<table>
<thead>
<tr>
<th>Prompt</th>
<th>Enter</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name:</td>
<td>Name to associate with the registration.</td>
</tr>
<tr>
<td>Company:</td>
<td>Your company name.</td>
</tr>
<tr>
<td>Serial Number:</td>
<td>• 1076681984 for 64-bit driver, or</td>
</tr>
<tr>
<td></td>
<td>• 1076681728 for 32-bit driver.</td>
</tr>
</tbody>
</table>
### Prompt | Enter
---|---
**Key:** | • 1076681984 for 64-bit driver, or  
• 1076681728 for 32-bit driver.

The installation program displays the registered driver information. For example:

You have chosen the Greenplum Wire Protocol driver.

Server Unlimited
Unlimited Connections

To change this information, enter C. Otherwise, press Enter to continue. :

7. **Press** Enter to continue with the installation. The installer prompts you for a temporary directory:

DataDirect Connect for ODBC Setup is preparing the installation.
Choose a temporary directory.
Enter the full path to the temporary install directory. [/tmp]:

8. **Press** Enter to accept the default /tmp directory or enter a custom directory to store temporary files. The installer extracts temporary files and prompts you for an installation directory:

Checking for available space...
There is enough space.
Extracting files...
Choose a destination directory.
Enter the full path to the install directory. [/opt/Progress/DataDirect/Connect64_for_ODBC_71]:

9. **Press** Enter to accept the default directory or enter a custom destination directory. The installer checks for available space and installs the software:

Checking for available space...
There is enough space.
Extracting files...
Creating license file......

DataDirect Connect for ODBC Setup successfully removed all of the temporary files.

Thank you for using Progress DataDirect products under OEM license to Greenplum Inc.

Would you like to install another product (Y/N) ? [Y]

10. **Enter N** to exit the installer.

### Configuring the Driver on Linux

After you install the driver software, perform these steps to configure the driver.
1. Change to the installation directory for your driver. For example:

```
$ cd /opt/Progress/DataDirect/Connect64_for_ODBC_71/
```

2. Set the `LD_LIBRARY_PATH`, `ODBCINI` and `ODBCINST` environment variables with the command:

```
$ source odbc.sh
```

3. Open the `odbc.ini` file and create a new DSN entry. You can use the existing “Greenplum Wire Protocol” entry as a template.

```
$ vi $ODBCINI
```

You must edit the following entries to add values that match your system:

<table>
<thead>
<tr>
<th>Entry</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Database</td>
<td>Pivotal Greenplum database name.</td>
</tr>
<tr>
<td>HostName</td>
<td>Master host name.</td>
</tr>
<tr>
<td>PortNumber</td>
<td>Master host port number.</td>
</tr>
<tr>
<td>LogonID</td>
<td>Greenplum Database user.</td>
</tr>
<tr>
<td>Password</td>
<td>Password.</td>
</tr>
</tbody>
</table>

4. Verify the driver version:

```
$ cd /opt/Progress/DataDirect/Connect64_for_ODBC_71/bin
$ ./ddtestlib ddgplm27.so
Load of ddgplm27.so successful, qehandle is 0x15C9EC0
File version: 07.16.0301 (B0459, U0308)
```

**Testing the Driver Connection on Linux**

To test the DSN connection:

1. Execute the example utility to test the DSN connection, entering the Greenplum Wire Protocol data source name and the credentials of a Pivotal Greenplum user. For example:

```
$ cd /opt/Progress/DataDirect/Connect64_for_ODBC_71/samples/example
$ ./example
/example DataDirect Technologies, Inc. ODBC Example Application.
Enter the data source name : Greenplum Wire Protocol
Enter the user name        : gpadmin
Enter the password         : gpadmin

Enter SQL statements (Press ENTER to QUIT)
SQL>
```

2. Enter the following select statement to confirm database connectivity:

```
Enter SQL statements (Press ENTER to QUIT)
SQL> select version();
```

```
version
PostgreSQL 8.3.23 (Greenplum Database 5.0.0 build
commit:8c709516061cfff5476c03d6e2da99aae42722ae1) on x86_64-pc-linux-gnu,
compiled by GCC gcc (GCC) 6.2.0 compiled on Sep 1 2017 22:39:53

Enter SQL statements (Press ENTER to QUIT)
```
3. Press the ENTER key to exit the example application.
Installing on Windows Systems

To install ODBC drivers on your client:

1. Log into Pivotal Network and download the correct ODBC driver for your operating system (32-bit or 64-bit). The following Windows files are available:
   - PROGRESS_DATADIRECT_CONNECT64_ODBC_7.1.6.HOTFIX_WIN_64.zip
   - PROGRESS_DATADIRECT_CONNECT_ODBC_7.1.6.HOTFIX_WIN_32.zip
2. Uncompress the installer.
3. Double-click setup.exe to launch the install wizard.
4. If necessary, permit the InstallAnywhere installer to run.
5. Click Next at the Introduction screen to begin the installation.
6. Accept the End User License Agreement and click Next.
7. Select OEM or Licensed Installation as the installation type and click Next.
8. Enter your licensing information: Division name, Company Name, and serial number/license key found in Prerequisites.
9. Select Add. You should see this driver in the License dialog box: ODBC Greenplum Wire Protocol Third Party All Platform Server Unlimited Cores
10. Select Next.
11. Choose options appropriate for your installation. For example, select to replace the existing drivers and/or to create the default data sources. Click Next.
12. Accept the default installation directory or choose a custom directory. Click Next.
13. Verify the selected installation options, and click Install to begin installation. The installation process may take several minutes.
14. Select Done to complete installing the driver package.

Verifying the Version on Windows

To verify your driver version:

1. Select Start > All Programs > DataDirect > ODBC Administrator to open the Windows ODBC Administrator.
2. Click the Drivers tab, and scroll down to DataDirect <version> Greenplum Wire Protocol. Ensure that you see the expected version number.

Configuring and Testing the Driver on Windows

To configure and test a DSN connection to a Greenplum Database:

1. Open the ODBC Administrator.
2. Select the System DSN tab.
3. Select Add.
5. Enter the details for your chosen Greenplum Database instance. For example:

   Recommended: Set the Max Long Varchar size.
   Select the Advanced tab.
   In Max Long Varchar Size, enter 8192 then select Apply.
6. Select Test Connect.
7. Enter your user name and password, then select OK.
8. You should see the confirmation message Connection Established!

If your connection fails, check the following for accuracy:

- Host Name
- Port Number
- Database Name
- User Name
- Password
- Greenplum instance is active
DataDirect Driver Documentation

For more information on working with Data Direct, see documentation that is installed with the driver. By default, you can access the installed documentation by using a Web browser to open the file `/opt/Progress/DataDirect/Connect64_for_ODBC_71/help/index.html`. Documentation is also available online at https://www.progress.com/documentation/datadirect-connectors. Titles include:

- User's Guide
- Reference
- Troubleshooting Guide
- Installation Help
- Windows Readme
- UNIX/Linux Readme
Chapter 24

DataDirect JDBC Driver for Pivotal Greenplum

DataDirect JDBC drivers are compliant with the Type 4 architecture, but provide advanced features that define them as Type 5 drivers. Additionally, the drivers consistently support the latest database features and are fully compliant with Java™ SE 8 and JDBC 4.0 functionality.

The DataDirect JDBC Driver for Pivotal Greenplum is available for download from Pivotal Network.
Prerequisites

- The DataDirect JDBC Driver requires Java SE 5 or higher. See *System and Product Requirements* in the DataDirect documentation for information and requirements associated with specific features of the JDBC driver.
- The license key is embedded in the *greenplum.jar* file itself. You do not need to apply a specific license key to the driver to activate it.
Downloading the DataDirect JDBC Driver

To install the JDBC driver on your client:

1. Log into Pivotal Network and download the DataDirect JDBC driver file:
   PROGRESS_DATADIRECT_JDBC_DRIVER_PIVOTAL_GREENPLUM_5.1.4.zip.
2. Extract the downloaded ZIP file.
3. Add the full path to the PROGRESS_DATADIRECT_JDBC_DRIVER_PIVOTAL_GREENPLUM_5.1.4.jar file to your Java CLASSPATH environment variable, or add it to your classpath with the -classpath option when executing a Java application.
Obtaining Version Details for the Driver

To view the JDBC driver version information:

1. Change to the directory that contains the downloaded
   PROGRESS_DATADIRECT_JDBC_DRIVER_PIVOTAL_GREENPLUM_5.1.4.jar driver file. For example:

   `$ cd /opt/Progress/DataDirect/Connect_for_JDBC_51/lib`

2. Execute the data source class to display the version information.

   For Linux/Unix systems:

   ```
   $ java -classpath PROGRESS_DATADIRECT_JDBC_DRIVER_PIVOTAL_GREENPLUM_5.1.4.jar
   com.pivotal.jdbc.GreenplumDriver
   [Pivotal][Greenplum JDBC Driver]Driver Version: 5.1.4.000223
   (F000432.U000208)
   ```

   For Windows systems:

   ```
   java -classpath .;\greenplum.jar com.pivotal.jdbc.GreenplumDriver
   [Pivotal][Greenplum JDBC Driver]Driver Version: 5.1.4.000223
   (F000432.U000208)
   ```
## Usage Information

The JDBC driver is provided in the `greenplum.jar` file. Use the following data source class and connection URL information with the driver.

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Driver File Name</td>
<td><code>greenplum.jar</code></td>
</tr>
<tr>
<td>Data Source Class</td>
<td><code>com.pivotal.jdbc.GreenplumDriver</code></td>
</tr>
<tr>
<td>Connection URL</td>
<td><code>jdbc:pivotal:greenplum://host:port;DatabaseName=&lt;name&gt;</code></td>
</tr>
<tr>
<td>Driver Defaults</td>
<td><code>ResultSetMetadataOptions=1</code></td>
</tr>
<tr>
<td></td>
<td><code>FetchTWFSasTime=true</code></td>
</tr>
<tr>
<td></td>
<td><code>SupportsCatalogs=true</code></td>
</tr>
<tr>
<td></td>
<td><code>MaxLongVarcharSize=8190</code></td>
</tr>
<tr>
<td></td>
<td><code>MaxNumericPrecision=28</code></td>
</tr>
<tr>
<td></td>
<td><code>MaxNumericScale=6</code></td>
</tr>
</tbody>
</table>
DataDirect Driver Documentation
