### Chapter 3: Pivotal Greenplum 6.1 Release Notes

- Release 6.1.1
- Resolved Issues
- Release 6.1.0
- New Features
- Resolved Issues
- Upgrading to Greenplum 6.1
- Deprecated Features
- Migrating Data to Greenplum 6

### Chapter 4: Installing and Upgrading Greenplum

- Platform Requirements
- Operating Systems
- Hardware and Network
- Storage
- Tools and Extensions Compatibility
- Hadoop Distributions
- Introduction to Greenplum
- The Greenplum Master
- The Segments
- The Interconnect
- ETL Hosts for Data Loading
- Greenplum Performance Monitoring
- Estimating Storage Capacity
- Calculating Usable Disk Capacity
- Calculating User Data Size
- Calculating Space Requirements for Metadata and Logs
- Configuring Your Systems
- Disabling SELinux and Firewall Software
- Recommended OS Parameters Settings
- Synchronizing System Clocks
- Creating the Greenplum Administrative User
- Next Steps
- Installing the Greenplum Database Software
- Installing Greenplum Database
- Enabling Passwordless SSH
- Configuring Your Installation
- About Your Greenplum Database Installation
- Next Steps
- Creating the Data Storage Areas
- Creating Data Storage Areas on the Master and Standby Master Hosts
- Creating Data Storage Areas on Segment Hosts
- Next Steps
- Validating Your Systems
- Validating Network Performance
- Validating Disk I/O and Memory Bandwidth
- Initializing a Greenplum Database System

Pivotal Greenplum 6.1 Release Notes

This document contains pertinent release information about Pivotal Greenplum Database 6.1 releases. For previous versions of the release notes for Greenplum Database, go to Pivotal Greenplum Database Documentation. For information about Greenplum Database end of life, see Pivotal Greenplum Database end of life policy.

Pivotal Greenplum 6 software is available for download from the Pivotal Greenplum page on Pivotal Network.

Pivotal Greenplum 6 is based on the open source Greenplum Database project code.

Important: Pivotal Support does not provide support for open source versions of Greenplum Database. Only Pivotal Greenplum Database is supported by Pivotal Support.
Release 6.1.1

Release Date: 2019-11-15

Pivotal Greenplum 6.1.1 is a maintenance release that resolves several issues.

Resolved Issues

Pivotal Greenplum 6.1.1 resolves these issues:

8590 – Postgres Planner
A query that used the Postgres planner could return incorrect results if it specified a volatile function in a LIMIT clause (for example, LIMIT (random() * 10)). This occurred because Greenplum evaluated the LIMIT clause separately on each segment instance to obtain a preliminary limit, before evaluating it once again as the query was dispatched. The problem was fixed by ensuring that a volatile functions in a LIMIT clause functions are not pushed to segment instances for evaluation.

30083 – Postgres Planner
Fixed a problem in the Postgres planner that could result in the error variable not found in subplan target list for certain queries.

30227 – Server
Greenplum Database with resource groups enabled might generate a PANIC when using an extension with improper debug_query_string settings. The cause was a message context issue and it has been resolved.
Release 6.1.0

Release Date: 2019-11-1

Pivotal Greenplum 6.1.0 is a minor release that includes new features and resolves several issues.

New Features

Greenplum Database 6.1.0 includes these new features:

• Greenplum Stream Server 1.3 is included, which introduces new features and bug fixes. New GPSS features include:
  • GPSS now supports log rotation, utilizing a mechanism that you can easily integrate with the Linux logrotate system. See Managing GPSS Log Files for more information.
  • GPSS has added the new INPUT:FILTER load configuration property. This property enables you to specify a filter that GPSS applies to Kafka input data before loading it into Greenplum Database.
  • GPSS displays job progress by partition when you provide the --partition flag to the gpsscli progress command.
  • GPSS enables you to load Kafka data that was emitted since a specific timestamp into Greenplum Database. To use this feature, you provide the --force-reset-timestamp flag when you run gpsscli load, gpsscli start, or gpkafka load.
  • GPSS now supports update and merge operations on data stored in a Greenplum Database table. The load configuration file accepts MODE, MATCH_COLUMNS, UPDATE_COLUMNS, and UPDATE_CONDITION property values to direct these operations. Example: Merging Data from Kafka into Greenplum Using the Greenplum Stream Server provides an example merge scenario.
  • GPSS supports Kerberos authentication to both Kafka and Greenplum Database.
  • GPSS supports SSL encryption between GPSS and Kafka.
  • GPSS supports SSL encryption on the data channel between GPSS and Greenplum Database.
• The DataDirect JDBC and ODBC drivers were updated to versions 5.1.4.000270 (F000450.U000214) and 07.16.0334 (B0510, U0363), respectively.

The DataDirect JDBC driver introduces support for the prepareThreshold connection parameter, which specifies the number of prepared statement executions that can be performed before the driver switches to using server-side prepared statements. This parameter defaults to 0, which preserves the earlier driver behavior of always using server-side prepare for prepared statements. Set a number greater than 1 to set a threshold after which server-side prepare is used.

Note: ExecuteBatch() always uses server-side prepare for prepared statements. This matches the behavior of the Postgres open source driver.

When the prepareThreshold value is greater than 1, parameterized operations do not send any SQL prepare calls with connection.prepareStatement(). The driver instead sends the query all at once, at execution time. Because of this limitation, the driver must determine the type of every column using the JDBC API before sending the query to the server. This determination works for many data types, but does not work for the following types that could be mapped to multiple Greenplum data types:

- BIT VARYING
- BOOLEAN
- JSON
- TIME WITH TIME ZONE
- UUIDCOL

You must set prepareThreshold to 0 before using parameterized operations with any of the above types. Examine the ResultSetMetaData object in advance to determine if any of the above types...
are used in a query. Also keep in mind that GPORCA does not support prepared statements that have parameterized values, and will fall back to using the Postgres Planner.

**Resolved Issues**

Pivotal Greenplum 6.1.0 is a minor release that resolves these issues:

**8804 - Server**

In some cases, running the `EXPLAIN ANALYZE` command on a sorted query in utility mode would cause the segment to crash. This issue is fixed. Greenplum Database no longer crashes in this situation.

**8636 - Server**

Some users encountered Error: unrecognized parameter "appendoptimized" while creating a partitioned table that specified the `appendoptimized=true` storage parameter. This issue is fixed; the Greenplum Database server now properly recognizes the `appendoptimized` parameter when it is specified on partition table creation.

**26225 - gpcheckcat**

The `gpcheckcat` utility failed to generate a summary report if there was an orphan TOAST table entry in one of the segments. This is fixed. The string “N/A” is reported when there is no relation OID to report.

**29580 - Management and Monitoring**

During Greenplum Database startup, an extra empty log file was produced ahead of the current date while performing time-based rotation of log files. For example, if Greenplum started at midnight September 2nd, two log files were generated, `gpdb-2019-09-02_000000.csv` and `gpdb-2019-09-03_000000.csv`. This issue has now been fixed.

**29984 - Server**

During startup, idle query executor (QE) processes can commit up to 16MB of memory each, but they are not tracked by the Linux virtual memory tracker. In a worst-case scenario, these idle processes could trigger OOM errors that were difficult to diagnose. To prevent these situations, Greenplum now hard-codes a startup memory cost to account for untracked QE processes.

**30112 - Query Optimizer**

For some queries against partitioned tables that contain a large amount of data, GPORCA generated a sub-optimal query plan because of inaccurate cardinality estimation. This issue has been resolved. GPORCA cardinality estimation has been improved.

**30183, 30184 - analyzedb**

When running the `analyzedb` command with the `--skip_root_stats` option, the command could take a long time to finish when analyzing a partitioned table with many partitions due to how the root partition statistics were handled when the partitions were analyzed. This issue has been resolved. Now, only partition statistics are updated.

**Note:** GPORCA uses root partition statistics. If you use `--skip_root_stats` option, you should ensure that root partition statistics are up to date so that GPORCA does not produce inferior query plans due to stale root partition statistics.

**30149 - Query Execution**

A query might fail and return an error with the message invalid seek in sequential BufFile when the server configuration file `gp_workfile_compression` is on and the query spills to temporary workfiles. The error was caused due to an issue working with workfiles that contain compressed data. The issue has been resolved by correctly handling the compressed workfile data.
30150 - Query Execution
A query might fail and return with the message `AssignTransactionId()` called by Segment Reader process when the server configuration parameter `temp_tablespaces` is set. The error was cause by an internal locking and transaction ID issue. This issue has been resolved by removing the requirement to acquire the lock.

30160 - Query Optimizer
GPORCA might return incorrect results when a the query contains a join predicate where one side is distributed on a `citext` column, and the other is not. GPORCA did not use the correct hash when generating a plan that redistributes the `citext` column. Now Greenplum Database falls back to the Postgres Planner for the specified type of query.

30183 - analyzedb
The `analyzedb` command could take a long time to finish when analyzing a table with many partitions. The command's performance has been greatly improved by waiting to update the root partition statistics until all leaf partitions of a table have been analyzed.

164823612 - gpss
GPSS incorrectly treated Kafka jobs that specified the same Kafka topic and Greenplum output schema name and output table name, but different database names, as the same job. This issue has been resolved. GPSS now includes the Greenplum database name when constructing a job definition.

167997441 - gpss
GPSS did not save error data to the external table error log when it encountered an incorrectly-formatted JSON or Avro message. This issue has been fixed; invoking `gp_read_error_log()` on the external table now displays the offending data.

168130147 - gpss
In some situations, specifying the `--force-reset-earliest` flag when loading data failed to read from the correct offset. This problem has been fixed. (Using the `--force-reset-xxx` flags outside of an offset mismatch scenario is discouraged.)

168393571 - Query Optimizer
Certain queries with btree indexes on Append Optimized (AO) tables were unnecessarily slow due to GPORCA selecting a scan with high transformation and cost impact. This issue has been fixed by improving GPORCA handling of btree type indexes.

168393645 - Query Optimizer
In some situations, a query ran slow because GPORCA did not produce an optimal plan when it encountered a null-rejecting predicate where an operand could be false or null, but not true. This issue is fixed; GPORCA now produces a more optimal plan when evaluating null-rejecting predicates for `AND` and `OR` operands.

168705484 - Query Optimizer
For certain queries with a UNION operator over a large number of children, GPORCA query optimization required a long time. This issue has been addressed by adding the ability to derive scalar properties on demand.

168707515 - Query Optimizer
Some queries in GPORCA were consuming more memory than necessary due to suboptimal memory tracking. This has been fixed by optimizing memory accounting inside GPORCA.

169081574 - Interconnect
Greenplum Database might generate a PANIC when the server configuration parameter `gp_interconnect_type` is `TCP` due to an issue with memory management during interconnect setup. The issue has been resolved by properly managing the internal interconnect object memory.
169117536 - Execution
Greenplum Database might generate a PANIC when the server configuration parameter `log_min_messages` is set to `debug5`. Greenplum Database did not properly handle a `debug5` message correctly. The issue is resolved.

169198230 - Plan Cache
A prepared statement might run slow because a cost model issue prevented Greenplum Database from generating a direct dispatch plan for the statement. This issue is fixed. Greenplum Database now introduces non-direct dispatch cost into the cost model only for cached plans, and tries to use direct dispatch for prepared statements when possible.
Upgrading to Greenplum 6.1

Note: Greenplum 6 does not support direct upgrades from Greenplum 4 or Greenplum 5 releases, or from earlier Greenplum 6 Beta releases.

See Upgrading from an Earlier Greenplum 6 Release to upgrade your existing Greenplum 6.x software to Greenplum 6.1.
**Deprecated Features**

Deprecated features will be removed in a future major release of Greenplum Database. Pivotal Greenplum 6.x deprecates:

- The server configuration parameter `gp_ignore_error_table` (deprecated since 6.0).
  
  To avoid a Greenplum Database syntax error, set the value of this parameter to `true` when you run applications that execute `CREATE EXTERNAL TABLE` or `COPY` commands that include the now removed Greenplum Database 4.3.x `INTO ERROR TABLE` clause.

- Specifying `=>` as an operator name in the `CREATE OPERATOR` command (deprecated since 6.0).

- The Greenplum external table C API (deprecated since 6.0).
  
  Any developers using this API are encouraged to use the new Foreign Data Wrapper API in its place.

- Commas placed between a `SUBPARTITION TEMPLATE` clause and its corresponding `SUBPARTITION BY` clause, and between consecutive `SUBPARTITION BY` clauses in a `CREATE TABLE` command (deprecated since 6.0).
  
  Using this undocumented syntax will generate a deprecation warning message.

- The timestamp format `YYYYMMDDHH24MISS` (deprecated since 6.0).
  
  This format could not be parsed unambiguously in previous Greenplum Database releases, and is not supported in PostgreSQL 9.4.

- The `createlang` and `droplang` utilities (deprecated since 6.0).

- The `pg_resqueue_status` system view (deprecated since 6.0).
  
  Use the `gp_toolkit.gp_resqueue_status` view instead.

- The `GLOBAL` and `LOCAL` modifiers when creating a temporary table with the `CREATE TABLE` and `CREATE TABLE AS` commands (deprecated since 6.0).
  
  These keywords are present for SQL standard compatibility, but have no effect in Greenplum Database.

- The Greenplum Platform Extension Framework (PXF) HDFS profile names for the Text, Avro, JSON, Parquet, and SequenceFile data formats (deprecated since 5.16).

  Refer to *Connectors, Data Formats, and Profiles* in the PXF Hadoop documentation for more information.

- Using `WITH OIDS` or `oids=TRUE` to assign an OID system column when creating or altering a table (deprecated since 6.0).

- Allowing superusers to specify the `SQL_ASCII` encoding regardless of the locale settings (deprecated since 6.0).
  
  This choice may result in misbehavior of character-string functions when data that is not encoding-compatible with the locale is stored in the database.

- The `@@@` text search operator (deprecated since 6.0).
  
  This operator is currently a synonym for the `@@` operator.

- The unparenthesized syntax for option lists in the `VACUUM` command (deprecated since 6.0).
  
  This syntax requires that the options to the command be specified in a specific order.

- The `plain pgbouncer` authentication type (`auth_type = plain`) (deprecated since 4.x).
Migrating Data to Greenplum 6

Note: Greenplum 6 does not support direct upgrades from Greenplum 4 or Greenplum 5 releases, or from earlier Greenplum 6 Beta releases.

See Migrating Data from Greenplum 4.3 or 5 for guidelines and considerations for migrating existing Greenplum data to Greenplum 6, using standard backup and restore procedures.
Known Issues and Limitations

Pivotal Greenplum 6 has these limitations:

- Upgrading a Greenplum Database 4 or 5 release, or Greenplum 6 Beta release, to Pivotal Greenplum 6 is not supported.
- MADlib, GPText, and PostGIS are not yet provided for installation on Ubuntu systems.
- `gpcopy` cannot yet copy data from Greenplum 4 or 5 to Greenplum 6.
- Greenplum 6 is not supported for installation on DCA systems.
- Greenplum for Kubernetes is not yet provided with this release.

The following table lists key known issues in Pivotal Greenplum 6.x.

**Table 1: Key Known Issues in Pivotal Greenplum 6.x**

**Workaround:** Use `CREATE EXTENSION` to install PL/R, as described in the documentation. |
Chapter 4

Installing and Upgrading Greenplum

Information about installing, configuring, and upgrading Greenplum Database software and configuring Greenplum Database host machines.
Platform Requirements

This topic describes the Pivotal Greenplum Database 6 platform and operating system software requirements.

**Important:** Pivotal Support does not provide support for open source versions of Greenplum Database. Only Pivotal Greenplum Database is supported by Pivotal Support.

- Operating Systems
  - Software Dependencies
  - Java
  - Hardware and Network
  - Storage
  - Tools and Extensions Compatibility
    - Client Tools
    - Extensions
    - Data Connectors
    - GPText
    - Greenplum Command Center
    - Hadoop Distributions

**Operating Systems**

Pivotal Greenplum 6 runs on the following operating system platforms:

- Red Hat Enterprise Linux 64-bit 7.x (See the following Note.)
- Red Hat Enterprise Linux 64-bit 6.x
- CentOS 64-bit 7.x
- CentOS 64-bit 6.x
- Ubuntu 18.04 LTS

**Important:** Significant Greenplum Database performance degradation has been observed when enabling resource group-based workload management on RedHat 6.x and CentOS 6.x systems. This issue is caused by a Linux cgroup kernel bug. This kernel bug has been fixed in CentOS 7.x and Red Hat 7.x systems.

If you use RedHat 6 and the performance with resource groups is acceptable for your use case, upgrade your kernel to version 2.6.32-696 or higher to benefit from other fixes to the cgroups implementation.

**Note:** For Greenplum Database that is installed on Red Hat Enterprise Linux 7.x or CentOS 7.x prior to 7.3, an operating system issue might cause Greenplum Database that is running large workloads to hang in the workload. The Greenplum Database issue is caused by Linux kernel bugs. RHEL 7.3 and CentOS 7.3 resolves the issue.

Greenplum Database supports TLS V2.

**Software Dependencies**

Greenplum Database 6 requires the following software packages on RHEL/CentOS 6/7 systems which are installed automatically as dependencies when you install the Pivotal Greenplum Database RPM package):

- apr
- apr-util
• bash
• bzip2
• curl
• krb5
• libcurl
• libevent
• libxml2
• libyaml
• zlib
• openldap
• openssh
• openssl
• openssl-libs (RHEL7/Centos7)
• perl
• readline
• rsync
• R
• sed (used by gpinitsystem)
• tar
• zip

Greenplum Database 6 client software requires these operating system packages:
• apr
• apr-util
• libyaml
• libevent

On Ubuntu systems, Greenplum Database 6 requires the following software packages, which are installed automatically as dependencies when you install Greenplum Database with the Debian package installer:
• libapr
• libaprutil1
• bash
• bzip2
• krb5-multidev
• libcurl3-gnutls
• libcurl4
• libevent-2.1-6
• libxml2
• libyaml-0-2
• zlib1g
• libldap-2.4-2
• openssh-client
• openssh-client
• openssl
• perl
• readline
• rsync
• sed
• tar
• zip
• net-tools
Greenplum Database 6 uses Python 2.7.12, which is included with the product installation (and not installed as a package dependency).

**Important:** SSL is supported only on the Greenplum Database master host system. It cannot be used on the segment host systems.

**Important:** For all Greenplum Database host systems, SELinux must be disabled. You should also disable firewall software, although firewall software can be enabled if it is required for security purposes. See [Disabling SELinux and Firewall Software](#).

**Java**

Greenplum 6 supports these Java versions for PL/Java and PXF:

- Open JDK 8 or Open JDK 11, available from [AdoptOpenJDK](#)
- Oracle JDK 8 or Oracle JDK 11

**Hardware and Network**

The following table lists minimum recommended specifications for hardware servers intended to support Greenplum Database on Linux systems in a production environment. All host servers in your Greenplum Database system must have the same hardware and software configuration. Greenplum also provides hardware build guides for its certified hardware platforms. It is recommended that you work with a Greenplum Systems Engineer to review your anticipated environment to ensure an appropriate hardware configuration for Greenplum Database.

**Warning:** Running Pivotal Greenplum Database on hyper-converged infrastructure (HCI) has known issues with performance, scalability, and stability and is not recommended as a scalable solution for Pivotal Greenplum and may not be supported by Pivotal if stability problems appear related to the infrastructure. HCI virtualizes all of the elements of conventional hardware systems and includes, at a minimum, virtualized computing, a virtualised SAN, and virtualized networking.

<table>
<thead>

<td>NIC bonding is recommended when multiple interfaces are present</td>
</tr>
<tr>
<td></td>
<td>Pivotal Greenplum can use either IPV4 or IPV6 protocols.</td>
</tr>
</tbody>
</table>

**Storage**

The only file system supported for running Greenplum Database is the XFS file system. All other file systems are explicitly **not** supported by Pivotal.
Greenplum Database is supported on network or shared storage if the shared storage is presented as a block device to the servers running Greenplum Database and the XFS file system is mounted on the block device. Network file systems are not supported. When using network or shared storage, Greenplum Database mirroring must be used in the same way as with local storage, and no modifications may be made to the mirroring scheme or the recovery scheme of the segments.

Other features of the shared storage such as de-duplication and/or replication are not directly supported by Pivotal Greenplum Database, but may be used with support of the storage vendor as long as they do not interfere with the expected operation of Greenplum Database at the discretion of Pivotal.

Greenplum Database can be deployed to virtualized systems only if the storage is presented as block devices and the XFS file system is mounted for the storage of the segment directories.

**Warning:** Running Greenplum Database on hyper-converged infrastructure (HCI) has known issues with performance, scalability, and stability and is not recommended as a scalable solution for Pivotal Greenplum Database and may not be supported by Pivotal if stability problems appear related to the infrastructure. HCI virtualizes all of the elements of conventional hardware systems and includes, at a minimum, virtualized computing, a virtualised SAN, and virtualized networking.

Greenplum Database is supported on Amazon Web Services (AWS) servers using either Amazon instance store (Amazon uses the volume names `ephemeral[0-20]`) or Amazon Elastic Block Store (Amazon EBS) storage. If using Amazon EBS storage the storage should be RAID of Amazon EBS volumes and mounted with the XFS file system for it to be a supported configuration.

**Data Domain Boost**

Pivotal Greenplum 6.0.0 supports Data Domain Boost for backup on Red Hat Enterprise Linux. This table lists the versions of Data Domain Boost SDK and DDOS supported by Pivotal Greenplum 6.x.

**Table 3: Data Domain Boost Compatibility**

<table>
<thead>
<tr>
<th>Pivotal Greenplum</th>
<th>Data Domain Boost</th>
<th>DDOS</th>
</tr>
</thead>
<tbody>
<tr>
<td>6.x</td>
<td>3.3</td>
<td>6.1 (all versions)</td>
</tr>
<tr>
<td></td>
<td></td>
<td>6.0 (all versions)</td>
</tr>
</tbody>
</table>

**Note:** In addition to the DDOS versions listed in the previous table, Pivotal Greenplum supports all minor patch releases (fourth digit releases) later than the certified version.

**Tools and Extensions Compatibility**

- **Client Tools**
- **Extensions**
- **Data Connectors**
- **GPText**
- **Greenplum Command Center**

**Client Tools**

Greenplum Database 6 releases a Clients tool package on various platforms that can be used to access Greenplum Database from a client system. The Greenplum 6 Clients tool package is supported on the following platforms:

- Red Hat Enterprise Linux x86_64 6.x (RHEL 6)
- Red Hat Enterprise Linux x86_64 7.x (RHEL 7)
- Ubuntu 18.04 LTS
- Windows 10 (32-bit and 64-bit)
Installing and Upgrading Greenplum

- Windows 8 (32-bit and 64-bit)
- Windows Server 2012 (32-bit and 64-bit)
- Windows Server 2012 R2 (32-bit and 64-bit)
- Windows Server 2008 R2 (32-bit and 64-bit)

The Greenplum 6 Clients package includes the client and loader programs provided in the Greenplum 5 packages plus the addition of database/role/language commands and the Greenplum-Kafka Integration and Greenplum Stream Server command utilities. Refer to Greenplum Client and Loader Tools Package for installation and usage details of the Greenplum 6 Client tools.

Extensions

Table 4: Pivotal Greenplum 6.0.0 Extensions Compatibility

</tr>
</tbody>
</table>

**Note:**  
\(^1\)For information about MADlib support and upgrade information, see the MADlib FAQ.  
\(^2\)PL/R supports R 3.5.1. On RHEL and CentOS the PL/R package installs R 3.3.3. See PL/R Language.  
\(^3\)For information about the Python package, including the modules provided, see the Python Data Science Module Package.  
\(^4\)For information about the R package, including the libraries provided, see the R Data Science Library Package.

For information about the Oracle Compatibility Functions, see Oracle Compatibility Functions.

These Greenplum Database extensions are installed with Pivotal Greenplum Database

- Fuzzy String Match Extension
- PL/Python Extension
- pgcrypto Extension

Data Connectors

- Greenplum Platform Extension Framework (PXF) v5.8.1 - PXF, integrated with Greenplum Database 6, provides access to Hadoop, object store, and SQL external data stores. Refer to Accessing External Data with PXF in the Greenplum Database Administrator Guide for PXF configuration and usage information.
- Greenplum-Kafka Integration - The Pivotal Greenplum-Kafka Integration provides high speed, parallel data transfer from a Kafka cluster to a Pivotal Greenplum Database cluster for batch and streaming ETL operations. It requires Kafka version 0.11 or newer for exactly-once delivery assurance. Refer to the Pivotal Greenplum-Kafka Integration Documentation for more information about this feature.
• Greenplum Stream Server v1.2.6 - The Pivotal Greenplum Stream Server is an ETL tool that provides high speed, parallel data transfer from Informatica, Kafka, and custom client data sources to a Pivotal Greenplum Database cluster. Refer to the Performing ETL Operations with the Pivotal Greenplum Stream Server Documentation for more information about this feature.

• Greenplum Informatica Connector v1.0.5 - The Pivotal Greenplum Informatica Connector supports high speed data transfer from an Informatica PowerCenter cluster to a Pivotal Greenplum Database cluster for batch and streaming ETL operations.

• Greenplum Spark Connector v1.6.1 - The Pivotal Greenplum Spark Connector supports high speed, parallel data transfer between Greenplum Database and an Apache Spark cluster using Spark's Scala API.

• Progress DataDirect JDBC Drivers v5.1.4.000223 - The Progress DataDirect JDBC drivers are compliant with the Type 4 architecture, but provide advanced features that define them as Type 5 drivers.

• Progress DataDirect ODBC Drivers v7.1.6 (07.16.0301) - The Progress DataDirect ODBC drivers enable third party applications to connect via a common interface to the Pivotal Greenplum Database system.

  Note: Pivotal Greenplum 6 does not support the ODBC driver for Cognos Analytics V11. Connecting to IBM Cognos software with an ODBC driver is not supported. Greenplum Database supports connecting to IBM Cognos software with the DataDirect JDBC driver for Pivotal Greenplum. This driver is available as a download from Pivotal Network.

GPText

Pivotal Greenplum Database 6 is compatible with Pivotal Greenplum Text version 3.3.1 and later. See the Greenplum Text documentation for additional compatibility information.

Greenplum Command Center

Pivotal Greenplum Database 6 is compatible with Pivotal Greenplum Command Center 6.0.0 and later. See the Greenplum Command Center documentation for additional compatibility information.

Hadoop Distributions

Greenplum Database provides access to HDFS with the Greenplum Platform Extension Framework (PXF). PXF can use Cloudera, Hortonworks Data Platform, MapR, and generic Apache Hadoop distributions. PXF bundles all of the JAR files on which it depends, including the following Hadoop libraries:

• Hadoop version 2.9.2
• Hive version 1.2.2
• HBase version 1.3.2

  Note: If you plan to access JSON format data stored in a Cloudera Hadoop cluster, PXF requires a Cloudera version 5.8 or later Hadoop distribution.
Introduction to Greenplum

High-level overview of the Greenplum Database system architecture.

Greenplum Database stores and processes large amounts of data by distributing the load across several servers or hosts. A logical database in Greenplum is an array of individual PostgreSQL databases working together to present a single database image. The master is the entry point to the Greenplum Database system. It is the database instance to which users connect and submit SQL statements. The master coordinates the workload across the other database instances in the system, called segments, which handle data processing and storage. The segments communicate with each other and the master over the interconnect, the networking layer of Greenplum Database.

Greenplum Database is a software-only solution; the hardware and database software are not coupled. Greenplum Database runs on a variety of commodity server platforms from Greenplum-certified hardware vendors. Performance depends on the hardware on which it is installed. Because the database is distributed across multiple machines in a Greenplum Database system, proper selection and configuration of hardware is vital to achieving the best possible performance.

This chapter describes the major components of a Greenplum Database system and the hardware considerations and concepts associated with each component: The Greenplum Master, The Segments and The Interconnect. Additionally, a system may have optional ETL Hosts for Data Loading and Greenplum Performance Monitoring for monitoring query workload and performance.
The Greenplum Master

The master is the entry point to the Greenplum Database system. It is the database server process that accepts client connections and processes the SQL commands that system users issue. Users connect to Greenplum Database through the master using a PostgreSQL-compatible client program such as psql or ODBC.

The master maintains the system catalog (a set of system tables that contain metadata about the Greenplum Database system itself), however the master does not contain any user data. Data resides only on the segments. The master authenticates client connections, processes incoming SQL commands, distributes the work load between segments, coordinates the results returned by each segment, and presents the final results to the client program.

Because the master does not contain any user data, it has very little disk load. The master needs a fast, dedicated CPU for data loading, connection handling, and query planning because extra space is often necessary for landing load files and backup files, especially in production environments. Customers may decide to also run ETL and reporting tools on the master, which requires more disk space and processing power.

Master Redundancy

You may optionally deploy a backup or mirror of the master instance. A backup master host serves as a warm standby if the primary master host becomes nonoperational. You can deploy the standby master on a designated redundant master host or on one of the segment hosts.

The standby master is kept up to date by a transaction log replication process, which runs on the standby master host and synchronizes the data between the primary and standby master hosts. If the primary master fails, the log replication process shuts down, and an administrator can activate the standby master in its place. When an the standby master is active, the replicated logs are used to reconstruct the state of the master host at the time of the last successfully committed transaction.

Since the master does not contain any user data, only the system catalog tables need to be synchronized between the primary and backup copies. When these tables are updated, changes automatically copy over to the standby master so it is always synchronized with the primary.

The Segments

In Greenplum Database, the segments are where data is stored and where most query processing occurs. User-defined tables and their indexes are distributed across the available segments in the Greenplum Database system; each segment contains a distinct portion of the data. Segment instances are the
database server processes that serve segments. Users do not interact directly with the segments in a Greenplum Database system, but do so through the master.

In the reference Greenplum Database hardware configurations, the number of segment instances per segment host is determined by the number of effective CPUs or CPU core. For example, if your segment hosts have two dual-core processors, you may have two or four primary segments per host. If your segment hosts have three quad-core processors, you may have three, six or twelve segments per host. Performance testing will help decide the best number of segments for a chosen hardware platform.

**Segment Redundancy**

When you deploy your Greenplum Database system, you have the option to configure mirror segments. Mirror segments allow database queries to fail over to a backup segment if the primary segment becomes unavailable. Mirroring is a requirement for Pivotal-supported production Greenplum Database systems.

A mirror segment must always reside on a different host than its primary segment. Mirror segments can be arranged across the hosts in the system in one of two standard configurations, or in a custom configuration you design. The default configuration, called group mirroring, places the mirror segments for all primary segments on a host on one other host. Another option, called spread mirroring, spreads mirrors for each host's primary segments over the remaining hosts. Spread mirroring requires that there be more hosts in the system than there are primary segments on the host. On hosts with multiple network interfaces, the primary and mirror segments are distributed equally among the interfaces. Figure 2: Data Mirroring in Greenplum Database shows how table data is distributed across the segments when the default group mirroring option is configured.

**Figure 2: Data Mirroring in Greenplum Database**

**Segment Failover and Recovery**

When mirroring is enabled in a Greenplum Database system, the system automatically fails over to the mirror copy if a primary copy becomes unavailable. A Greenplum Database system can remain operational
if a segment instance or host goes down only if all portions of data are available on the remaining active segments.

If the master cannot connect to a segment instance, it marks that segment instance as invalid in the Greenplum Database system catalog. The segment instance remains invalid and out of operation until an administrator brings that segment back online. An administrator can recover a failed segment while the system is up and running. The recovery process copies over only the changes that were missed while the segment was nonoperational.

If you do not have mirroring enabled and a segment becomes invalid, the system automatically shuts down. An administrator must recover all failed segments before operations can continue.

Example Segment Host Hardware Stack

Regardless of the hardware platform you choose, a production Greenplum Database processing node (a segment host) is typically configured as described in this section.

The segment hosts do the majority of database processing, so the segment host servers are configured in order to achieve the best performance possible from your Greenplum Database system. Greenplum Database's performance will be as fast as the slowest segment server in the array. Therefore, it is important to ensure that the underlying hardware and operating systems that are running Greenplum Database are all running at their optimal performance level. It is also advised that all segment hosts in a Greenplum Database array have identical hardware resources and configurations.

Segment hosts should also be dedicated to Greenplum Database operations only. To get the best query performance, you do not want Greenplum Database competing with other applications for machine or network resources.

The following diagram shows an example Greenplum Database segment host hardware stack. The number of effective CPUs on a host is the basis for determining how many primary Greenplum Database segment instances to deploy per segment host. This example shows a host with two effective CPUs (one dual-core CPU). Note that there is one primary segment instance (or primary/mirror pair if using mirroring) per CPU core.
Each CPU is typically mapped to a logical disk. A logical disk consists of one primary file system (and optionally a mirror file system) accessing a pool of physical disks through an I/O channel or disk controller. The logical disk and file system are provided by the operating system. Most operating systems provide the ability for a logical disk drive to use groups of physical disks arranged in RAID arrays.

Depending on the hardware platform you choose, different RAID configurations offer different performance and capacity levels. Greenplum supports and certifies a number of reference hardware platforms and operating systems. Check with your sales account representative for the recommended configuration on your chosen platform.
**The Interconnect**

The *interconnect* is the networking layer of Greenplum Database. When a user connects to a database and issues a query, processes are created on each of the segments to handle the work of that query. The *interconnect* refers to the inter-process communication between the segments, as well as the network infrastructure on which this communication relies. The interconnect uses a standard 10 Gigabit Ethernet switching fabric.

By default, Greenplum Database interconnect uses UDP (User Datagram Protocol) with flow control for interconnect traffic to send messages over the network. The Greenplum software does the additional packet verification and checking not performed by UDP, so the reliability is equivalent to TCP (Transmission Control Protocol), and the performance and scalability exceeds that of TCP. For information about the types of interconnect supported by Greenplum Database, see server configuration parameter `gp_interconnect_type` in the *Greenplum Database Reference Guide*.

**Interconnect Redundancy**

A highly available interconnect can be achieved by deploying dual 10 Gigabit Ethernet switches on your network, and redundant 10 Gigabit connections to the Greenplum Database master and segment host servers.

**Network Interface Configuration**

A segment host typically has multiple network interfaces designated to Greenplum interconnect traffic. The master host typically has additional external network interfaces in addition to the interfaces used for interconnect traffic.

Depending on the number of interfaces available, you will want to distribute interconnect network traffic across the number of available interfaces. This is done by assigning segment instances to a particular network interface and ensuring that the primary segments are evenly balanced over the number of available interfaces.

This is done by creating separate host address names for each network interface. For example, if a host has four network interfaces, then it would have four corresponding host addresses, each of which maps to one or more primary segment instances. The `/etc/hosts` file should be configured to contain not only the host name of each machine, but also all interface host addresses for all of the Greenplum Database hosts (master, standby master, segments, and ETL hosts).

With this configuration, the operating system automatically selects the best path to the destination. Greenplum Database automatically balances the network destinations to maximize parallelism.
When using multiple 10 Gigabit Ethernet switches within your Greenplum Database array, evenly divide the number of subnets between each switch. In this example configuration, if we had two switches, NICs 1 and 2 on each host would use switch 1 and NICs 3 and 4 on each host would use switch 2. For the master host, the host name bound to NIC 1 (and therefore using switch 1) is the effective master host name for the array. Therefore, if deploying a warm standby master for redundancy purposes, the standby master should map to a NIC that uses a different switch than the primary master.
**ETL Hosts for Data Loading**

Greenplum supports fast, parallel data loading with its external tables feature. By using external tables in conjunction with Greenplum Database’s parallel file server (`gpfdist`), administrators can achieve maximum parallelism and load bandwidth from their Greenplum Database system. Many production systems deploy designated ETL servers for data loading purposes. These machines run the Greenplum parallel file server (`gpfdist`), but not Greenplum Database instances.

One advantage of using the `gpfdist` file server program is that it ensures that all of the segments in your Greenplum Database system are fully utilized when reading from external table data files.

The `gpfdist` program can serve data to the segment instances at an average rate of about 350 MB/s for delimited text formatted files and 200 MB/s for CSV formatted files. Therefore, you should consider the following options when running `gpfdist` in order to maximize the network bandwidth of your ETL systems:

- If your ETL machine is configured with multiple network interface cards (NICs) as described in *Network Interface Configuration*, run one instance of `gpfdist` on your ETL host and then define your external table definition so that the host name of each NIC is declared in the `LOCATION` clause (see `CREATE EXTERNAL TABLE` in the *Greenplum Database Reference Guide*). This allows network traffic between your Greenplum segment hosts and your ETL host to use all NICs simultaneously.
Figure 7: External Table Using Single gpfdist Instance with Multiple NICs

- Run multiple gpfdist instances on your ETL host and divide your external data files equally between each instance. For example, if you have an ETL system with two network interface cards (NICs), then you could run two gpfdist instances on that machine to maximize your load performance. You would then divide the external table data files evenly between the two gpfdist programs.

Figure 8: External Tables Using Multiple gpfdist Instances with Multiple NICs

Greenplum Performance Monitoring

Greenplum Database includes a dedicated system monitoring and management database, named gpperfmon, that administrators can install and enable. When this database is enabled, data collection
agents on each segment host collect query status and system metrics. At regular intervals (typically every 15 seconds), an agent on the Greenplum master requests the data from the segment agents and updates the gpperfmon database. Users can query the gpperfmon database to see the stored query and system metrics. For more information see the “gpperfmon Database Reference” in the Greenplum Database Reference Guide.

Greenplum Command Center is an optional web-based performance monitoring and management tool for Greenplum Database, based on the gpperfmon database. Administrators can install Command Center separately from Greenplum Database.

Figure 9: Greenplum Performance Monitoring Architecture
Estimating Storage Capacity

To estimate how much data your Greenplum Database system can accommodate, use these measurements as guidelines. Also keep in mind that you may want to have extra space for landing backup files and data load files on each segment host.

Calculating Usable Disk Capacity

To calculate how much data a Greenplum Database system can hold, you have to calculate the usable disk capacity per segment host and then multiply that by the number of segment hosts in your Greenplum Database array. Start with the raw capacity of the physical disks on a segment host that are available for data storage (raw_capacity), which is:

\[
\text{disk_size} \times \text{number_of_disks}
\]

Account for file system formatting overhead (roughly 10 percent) and the RAID level you are using. For example, if using RAID-10, the calculation would be:

\[
\frac{(\text{raw_capacity} \times 0.9)}{2} = \text{formatted_disk_space}
\]

For optimal performance, do not completely fill your disks to capacity, but run at 70% or lower. So with this in mind, calculate the usable disk space as follows:

\[
\text{formatted_disk_space} \times 0.7 = \text{usable_disk_space}
\]

Using only 70% of your disk space allows Greenplum Database to use the other 30% for temporary and transaction files on the same disks. If your host systems have a separate disk system that can be used for temporary and transaction files, you can specify a tablespace that Greenplum Database uses for the files. Moving the location of the files might improve performance depending on the performance of the disk system.

Once you have formatted RAID disk arrays and accounted for the maximum recommended capacity (usable_disk_space), you will need to calculate how much storage is actually available for user data (U). If using Greenplum Database mirrors for data redundancy, this would then double the size of your user data (2 * U). Greenplum Database also requires some space be reserved as a working area for active queries. The work space should be approximately one third the size of your user data (work space = U/3):

**With mirrors:**

\[
(2 \times U) + \frac{U}{3} = \text{usable_disk_space}
\]

**Without mirrors:**

\[
U + \frac{U}{3} = \text{usable_disk_space}
\]

Guidelines for temporary file space and user data space assume a typical analytic workload. Highly concurrent workloads or workloads with queries that require very large amounts of temporary space can benefit from reserving a larger working area. Typically, overall system throughput can be increased while decreasing work area usage through proper workload management. Additionally, temporary space and user space can be isolated from each other by specifying that they reside on different tablespaces.

In the *Greenplum Database Administrator Guide*, see these topics:

- *Managing Performance* for information about workload management
- *Creating and Managing Tablespaces* for information about moving the location of temporary and transaction files
- *Monitoring System State* for information about monitoring Greenplum Database disk space usage
Calculating User Data Size

As with all databases, the size of your raw data will be slightly larger once it is loaded into the database. On average, raw data will be about 1.4 times larger on disk after it is loaded into the database, but could be smaller or larger depending on the data types you are using, table storage type, in-database compression, and so on.

- **Page Overhead** - When your data is loaded into Greenplum Database, it is divided into pages of 32KB each. Each page has 20 bytes of page overhead.
- **Row Overhead** - In a regular 'heap' storage table, each row of data has 24 bytes of row overhead. An 'append-optimized' storage table has only 4 bytes of row overhead.
- **Attribute Overhead** - For the data values itself, the size associated with each attribute value is dependent upon the data type chosen. As a general rule, you want to use the smallest data type possible to store your data (assuming you know the possible values a column will have).
- **Indexes** - In Greenplum Database, indexes are distributed across the segment hosts as is table data. The default index type in Greenplum Database is B-tree. Because index size depends on the number of unique values in the index and the data to be inserted, precalculating the exact size of an index is impossible. However, you can roughly estimate the size of an index using these formulas.

<table>
<thead>
<tr>
<th>Formula</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>(\text{B-tree: unique_values} \times (\text{data_type_size} + 24 \text{ bytes}))</td>
<td>For B-tree indexes, size depends on unique values and data type size.</td>
</tr>
<tr>
<td>(\text{Bitmap: (unique_values} \times \text{number_of_rows} \times 1 \text{ bit} \times \text{compression_ratio} / 8) + \text{(unique_values} \times 32))</td>
<td>For bitmap indexes, size depends on unique values, number of rows, and compression ratio.</td>
</tr>
</tbody>
</table>

Calculating Space Requirements for Metadata and Logs

On each segment host, you will also want to account for space for Greenplum Database log files and metadata:

- **System Metadata** — For each Greenplum Database segment instance (primary or mirror) or master instance running on a host, estimate approximately 20 MB for the system catalogs and metadata.
- **Write Ahead Log** — For each Greenplum Database segment (primary or mirror) or master instance running on a host, allocate space for the write ahead log (WAL). The WAL is divided into segment files of 64 MB each. At most, the number of WAL files will be:

\[2 \times \text{checkpoint_segments} + 1\]

You can use this to estimate space requirements for WAL. The default \(\text{checkpoint_segments}\) setting for a Greenplum Database instance is 8, meaning 1088 MB WAL space allocated for each segment or master instance on a host.

- **Greenplum Database Log Files** — Each segment instance and the master instance generates database log files, which will grow over time. Sufficient space should be allocated for these log files, and some type of log rotation facility should be used to ensure that log files do not grow too large.
- **Command Center Data** — The data collection agents utilized by Command Center run on the same set of hosts as your Greenplum Database instance and utilize the system resources of those hosts. The resource consumption of the data collection agent processes on these hosts is minimal and should not significantly impact database performance. Historical data collected by the collection agents is stored in its own Command Center database (named `gpperfmon`) within your Greenplum Database system. Collected data is distributed just like regular database data, so you will need to account for disk space in the data directory locations of your Greenplum segment instances. The amount of space required depends on the amount of historical data you would like to keep. Historical data is not automatically truncated. Database administrators must set up a truncation policy to maintain the size of the Command Center database.
Configuring Your Systems

Describes how to prepare your operating system environment for Greenplum Database software installation.

Perform the following tasks in order:

1. Make sure your host systems meet the requirements described in Platform Requirements.
2. Disable SELinux and firewall software.
3. Set the required operating system parameters.
4. Synchronize system clocks.
5. Create the gpadmin account.

Unless noted, these tasks should be performed for all hosts in your Greenplum Database array (master, standby master, and segment hosts).

The Greenplum Database host naming convention for the master host is `mdw` and for the standby master host is `smdw`.

The segment host naming convention is `sdwN` where `sdw` is a prefix and `N` is an integer. For example, segment host names would be `sdw1`, `sdw2` and so on. NIC bonding is recommended for hosts with multiple interfaces, but when the interfaces are not bonded, the convention is to append a dash (-) and number to the host name. For example, `sdw1-1` and `sdw1-2` are the two interface names for host `sdw1`.

For information about running Greenplum Database in the cloud see Cloud Services in the Pivotal Greenplum Partner Marketplace.

**Important:** When data loss is not acceptable for a Pivotal Greenplum Database system, Greenplum Database master and segment mirroring must be enabled in order for the cluster to be supported by Pivotal. Without mirroring, system and data availability is not guaranteed. Pivotal will make best efforts to restore a cluster in this case. For information about master and segment mirroring, see About Redundancy and Failover in the Greenplum Database Administrator Guide.

**Note:** For information about upgrading Pivotal Greenplum Database from a previous version, see the Greenplum Database Release Notes for the release that you are installing.

**Note:** Automating the configuration steps described in this topic and Installing the Greenplum Database Software with a system provisioning tool, such as Ansible, Chef, or Puppet, can save time and ensure a reliable and repeatable Greenplum Database installation.

Disabling SELinux and Firewall Software

For all Greenplum Database host systems running RHEL or CentOS, SELinux must be disabled. Follow these steps:

1. As the root user, check the status of SELinux:

   ```
   # sestatus
   SELinux status: disabled
   ```

2. If SELinux is not disabled, disable it by editing the `/etc/selinux/config` file. As root, change the value of the `SELINUX` parameter in the `config` file as follows:

   ```
   SELINUX=disabled
   ```

3. If the System Security Services Daemon (SSSD) is installed on your systems, edit the SSSD configuration file and set the `selinux_provider` parameter to `none` to prevent SELinux-related issues.
SSH authentication denials that could occur even with SELinux disabled. As root, edit `/etc/sssd/sssd.conf` and add this parameter:

```
    selinux_provider=none
```

4. Reboot the system to apply any changes that you made and verify that SELinux is disabled.

For information about disabling SELinux, see the SELinux documentation.

You should also disable firewall software such as `iptables` (on systems such as RHEL 6.x and CentOS 6.x), `firewalld` (on systems such as RHEL 7.x and CentOS 7.x), or `ufw` (on Ubuntu systems, disabled by default).

If you decide to enable `iptables` with Greenplum Database for security purposes, see `Enabling iptables (Optional)`.

Follow these steps to disable `iptables`:

1. As the root user, check the status of `iptables`:

   ```
   # /sbin/chkconfig --list iptables
   ```

   If `iptables` is disabled, the command output is:

   ```
   iptables 0:off 1:off 2:off 3:off 4:off 5:off 6:off
   ```

2. If necessary, execute this command as root to disable `iptables`:

   ```
   /sbin/chkconfig iptables off
   ```

   You will need to reboot your system after applying the change.

3. For systems with `firewalld`, check the status of `firewalld` with the command:

   ```
   # systemctl status firewalld
   ```

   If `firewalld` is disabled, the command output is:

   ```
   * firewalld.service - firewalld - dynamic firewall daemon
     Loaded: loaded (/usr/lib/systemd/system/firewalld.service; disabled; vendor preset: enabled)
     Active: inactive (dead)
   ```

4. If necessary, execute these commands as root to disable `firewalld`:

   ```
   # systemctl stop firewalld.service
   # systemctl disable firewalld.service
   ```

   For more information about configuring your firewall software, see the documentation for the firewall or your operating system.

**Recommended OS Parameters Settings**

Greenplum requires that certain Linux operating system (OS) parameters be set on all hosts in your Greenplum Database system (masters and segments).

In general, the following categories of system parameters need to be altered:

- **Shared Memory** - A Greenplum Database instance will not work unless the shared memory segment for your kernel is properly sized. Most default OS installations have the shared memory values set too low for Greenplum Database. On Linux systems, you must also disable the OOM (out of memory) killer. For information about Greenplum Database shared memory requirements, see the Greenplum
Database server configuration parameter `shared_buffers` in the *Greenplum Database Reference Guide*.

- **Network** - On high-volume Greenplum Database systems, certain network-related tuning parameters must be set to optimize network connections made by the Greenplum interconnect.

- **User Limits** - User limits control the resources available to processes started by a user’s shell. Greenplum Database requires a higher limit on the allowed number of file descriptors that a single process can have open. The default settings may cause some Greenplum Database queries to fail because they will run out of file descriptors needed to process the query.

More specifically, you need to edit the following Linux configuration settings:

- The `hosts` File
- The `sysctl.conf` File
- System Resources Limits
- XFS Mount Options
- Disk I/O Settings
  - Read ahead values
  - Disk I/O scheduler disk access
- `Transparent Huge Pages (THP)`
- `IPC Object Removal`
- `SSH Connection Threshold`

### The `hosts` File

Edit the `/etc/hosts` file and make sure that it includes the host names and all interface address names for every machine participating in your Greenplum Database system.

### The `sysctl.conf` File

The `sysctl.conf` parameters listed in this topic are for performance, optimization, and consistency in a wide variety of environments. Change these settings according to your specific situation and setup.

Set the parameters in the `/etc/sysctl.conf` file and reload with `sysctl -p`:

```plaintext
# kernel.shmall = _PHYS_PAGES / 2 # See Shared Memory Pages
kernel.shmall = 4000000000
# kernel.shmmmax = kernel.shmall * PAGE_SIZE
kernel.shmmmax = 5000000000
kernel.shmmni = 4096
vm.overcommit_memory = 2 # See Segment Host Memory
vm.overcommit_ratio = 95 # See Segment Host Memory

net.ipv4.ip_local_port_range = 10000 65535 # See Port Settings
kernel.sem = 500 2048000 200 40960
kernel.sysrq = 1
kernel.core_uses_pid = 1
kernel.msgmnb = 65536
kernel.msgmax = 65536
kernel.msgmni = 2048
net.ipv4.tcp_syncookies = 1
net.ipv4.conf.default.accept_source_route = 0
net.ipv4.tcp_max_syn_backlog = 4096
net.ipv4.conf.all.arp_filter = 1
net.core.netdev_max_backlog = 10000
net.core.rmem_max = 2097152
net.core.wmem_max = 2097152
vm.swappiness = 10
vm.zone_reclaim_mode = 0
```
vm.dirty_expire_centisecs = 500
vm.dirty_writeback_centisecs = 100
vm.dirty_background_ratio = 0 # See System Memory
vm.dirty_ratio = 0
vm.dirty_background_bytes = 1610612736
vm.dirty_bytes = 4294967296

Shared Memory Pages

Greenplum Database uses shared memory to communicate between postgres processes that are part of the same postgres instance. kernel.shmall sets the total amount of shared memory, in pages, that can be used system wide. kernel.shmmax sets the maximum size of a single shared memory segment in bytes.

Set kernel.shmall and kernel.shmmax values based on your system's physical memory and page size. In general, the value for both parameters should be one half of the system physical memory.

Use the operating system variables _PHYS_PAGES and PAGE_SIZE to set the parameters.

    kernel.shmall = ( _PHYS_PAGES / 2)
    kernel.shmmax = ( _PHYS_PAGES / 2) * PAGE_SIZE

To calculate the values for kernel.shmall and kernel.shmmax, run the following commands using the getconf command, which returns the value of an operating system variable.

    $ echo $(expr $(getconf _PHYS_PAGES) / 2)
    $ echo $(expr $(getconf _PHYS_PAGES) / 2 \* $(getconf PAGE_SIZE))

As best practice, we recommend you set the following values in the /etc/sysctl.conf file:

    kernel.shmmax = 500000000
    kernel.shmmax = 4096
    kernel.shmall = 4000000000

Segment Host Memory

The vm.overcommit_memory Linux kernel parameter is used by the OS to determine how much memory can be allocated to processes. For Greenplum Database, this parameter should always be set to 2.

vm.overcommit_ratio is the percent of RAM that is used for application processes and the remainder is reserved for the operating system. The default is 50 on Red Hat Enterprise Linux.

For vm.overcommit_ratio tuning and calculation recommendations with resource group-based resource management or resource queue-based resource management, refer to Options for Configuring Segment Host Memory in the Greenplum Database Administrator Guide. Also refer to the Greenplum Database server configuration parameter gp_vmem_protect_limit in the Greenplum Database Reference Guide.

Port Settings

To avoid port conflicts between Greenplum Database and other applications during Greenplum initialization, make a note of the port range specified by the operating system parameter net.ipv4.ip_local_port_range. When initializing Greenplum using the gpinit system cluster configuration file, do not specify Greenplum Database ports in that range. For example, if net.ipv4.ip_local_port_range = 10000 65535, set the Greenplum Database base port numbers to these values.

    PORT_BASE = 6000
    MIRROR_PORT_BASE = 7000

For information about the the gpinit system cluster configuration file, see Initializing a Greenplum Database System.
Installing and Upgrading Greenplum

Release Notes

For Azure deployments with Greenplum Database avoid using port 65330; add the following line to
sysctl.conf:
net.ipv4.ip_local_reserved_ports=65330
For additional requirements and recommendations for cloud deployments, see Greenplum Database Cloud
Technical Recommendations.
System Memory
For host systems with more than 64GB of memory, these settings are recommended:
vm.dirty_background_ratio = 0
vm.dirty_ratio = 0
vm.dirty_background_bytes = 1610612736 # 1.5GB
vm.dirty_bytes = 4294967296 # 4GB
For host systems with 64GB of memory or less, remove vm.dirty_background_bytes and
vm.dirty_bytes and set the two ratio parameters to these values:
vm.dirty_background_ratio = 3
vm.dirty_ratio = 10
Increase vm.min_free_kbytes to ensure PF_MEMALLOC requests from network and storage drivers are
easily satisfied. This is especially critical on systems with large amounts of system memory. The default
value is often far too low on these systems. Use this awk command to set vm.min_free_kbytes to a
recommended 3% of system physical memory:
awk 'BEGIN {OFMT = "%.0f";} /MemTotal/ {print "vm.min_free_kbytes =", $2
* .03;}'
/proc/meminfo >> /etc/sysctl.conf
Do not set vm.min_free_kbytes to higher than 5% of system memory as doing so might cause out of
memory conditions.

System Resources Limits
Set the following parameters in the /etc/security/limits.conf file:
*
*
*
*

soft
hard
soft
hard

nofile 524288
nofile 524288
nproc 131072
nproc 131072

For Red Hat Enterprise Linux (RHEL) and CentOS systems, parameter values in the /etc/security/
limits.d/90-nproc.conf file (RHEL/CentOS 6) or /etc/security/limits.d/20-nproc.conf
file (RHEL/CentOS 7) override the values in the limits.conf file. Ensure that any parameters in the
override file are set to the required value. The Linux module pam_limits sets user limits by reading the
values from the limits.conf file and then from the override file. For information about PAM and user
limits, see the documentation on PAM and pam_limits.
Execute the ulimit -u command on each segment host to display the maximum number of processes
that are available to each user. Validate that the return value is 131072.

47


XFS Mount Options

XFS is the preferred data storage file system on Linux platforms. Use the `mount` command with the following recommended XFS mount options:

```
rw,nodev,noatime,nobarrier,inode64
```

See the `mount` manual page (`man mount` opens the man page) for more information about using this command.

The XFS options can also be set in the `/etc/fstab` file. This example entry from an `fstab` file specifies the XFS options.

```
/dev/data /data xfs nodev,noatime,nobarrier,inode64 0 0
```

Disk I/O Settings

- Read-ahead value

  Each disk device file should have a read-ahead (`blockdev`) value of 16384. To verify the read-ahead value of a disk device:

  ```
  # /sbin/blockdev --getra devname
  ```

  For example:

  ```
  # /sbin/blockdev --getra /dev/sdb
  ```

  To set `blockdev` (read-ahead) on a device:

  ```
  # /sbin/blockdev --setra bytes devname
  ```

  For example:

  ```
  # /sbin/blockdev --setra 16384 /dev/sdb
  ```

  See the manual page (man) for the `blockdev` command for more information about using that command (man `blockdev` opens the man page).

  **Note:** The `blockdev --setra` command is not persistent, it needs to be run every time the system reboots. How to run the command will vary based on your system, but you must ensure that the read ahead setting is set every time the system reboots.

- Disk I/O scheduler

  The Linux disk I/O scheduler for disk access supports different policies, such as CFQ, AS, and deadline.

  The `deadline` scheduler option is recommended. To specify a scheduler until the next system reboot, run the following:

  ```
  # echo schedulename > /sys/block/devname/queue/scheduler
  ```

  For example:

  ```
  # echo deadline > /sys/block/sdb/queue/scheduler
  ```

  **Note:** Using the `echo` command to set the disk I/O scheduler policy is not persistent, therefore you must ensure the command is run whenever the system reboots. How to run the command will vary based on your system.
One method to set the I/O scheduler policy at boot time is with the `elevator` kernel parameter. Add the parameter `elevator=deadline` to the kernel command in the file `/boot/grub/grub.conf`, the GRUB boot loader configuration file. This is an example kernel command from a `grub.conf` file on RHEL 6.x or CentOS 6.x. The command is on multiple lines for readability:

```
kernel /vmlinuz-2.6.18-274.3.1.el5 ro root=LABEL=/
  elevator=deadline crashkernel=128M@16M  quiet
console=tty1
  console=ttyS1,115200 panic=30 transparent_hugepage=never
initrd /initrd-2.6.18-274.3.1.el5.img
```

To specify the I/O scheduler at boot time on systems that use `grub2` such as RHEL 7.x or CentOS 7.x, use the system utility `grubby`. This command adds the parameter when run as root.

```
# grubby --update-kernel=ALL --args="elevator=deadline"
```

After adding the parameter, reboot the system.

This `grubby` command displays kernel parameter settings.

```
# grubby --info=ALL
```

For more information about the `grubby` utility, see your operating system documentation. If the `grubby` command does not update the kernels, see the `Note` at the end of the section.

### Transparent Huge Pages (THP)

Disable Transparent Huge Pages (THP) as it degrades Greenplum Database performance. RHEL 6.0 or higher enables THP by default. One way to disable THP on RHEL 6.x is by adding the parameter `transparent_hugepage=never` to the kernel command in the file `/boot/grub/grub.conf`, the GRUB boot loader configuration file. This is an example kernel command from a `grub.conf` file. The command is on multiple lines for readability:

```
kernel /vmlinuz-2.6.18-274.3.1.el5 ro root=LABEL=/
  elevator=deadline crashkernel=128M@16M  quiet
console=tty1
  console=ttyS1,115200 panic=30 transparent_hugepage=never
initrd /initrd-2.6.18-274.3.1.el5.img
```

On systems that use `grub2` such as RHEL 7.x or CentOS 7.x, use the system utility `grubby`. This command adds the parameter when run as root.

```
# grubby --update-kernel=ALL --args="transparent_hugepage=never"
```

After adding the parameter, reboot the system.

For Ubuntu systems, install the `hugepages` package and execute this command as root:

```
# hugeadm --thp-never
```

This `cat` command checks the state of THP. The output indicates that THP is disabled.

```
$ cat /sys/kernel/mm/*/transparent_hugepage/enabled
always [never]
```

For more information about Transparent Huge Pages or the `grubby` utility, see your operating system documentation. If the `grubby` command does not update the kernels, see the `Note` at the end of the section.
IPC Object Removal

Disable IPC object removal for RHEL 7.2 or CentOS 7.2, or Ubuntu. The default `systemd` setting `RemoveIPC=yes` removes IPC connections when non-system user accounts log out. This causes the Greenplum Database utility `gpinitsystem` to fail with semaphore errors. Perform one of the following to avoid this issue.

- When you add the `gpadmin` operating system user account to the master node in Creating the Greenplum Administrative User, create the user as a system account.
- Disable `RemoveIPC`. Set this parameter in `/etc/systemd/logind.conf` on the Greenplum Database host systems.

```
RemoveIPC=no
```

The setting takes effect after restarting the `systemd-login` service or rebooting the system. To restart the service, run this command as the root user.

```
service systemd-logind restart
```

SSH Connection Threshold

Certain Greenplum Database management utilities including `gpexpand`, `gpinitsystem`, and `gpaddmirrors`, use secure shell (SSH) connections between systems to perform their tasks. In large Greenplum Database deployments, cloud deployments, or deployments with a large number of segments per host, these utilities may exceed the hosts’ maximum threshold for unauthenticated connections. When this occurs, you receive errors such as `ssh_exchange_identification: Connection closed by remote host`.

To increase this connection threshold for your Greenplum Database system, update the SSH `MaxStartups` and `MaxSessions` configuration parameters in one of the `/etc/ssh/sshd_config` or `/etc/sshd_config` SSH daemon configuration files.

If you specify `MaxStartups` and `MaxSessions` using a single integer value, you identify the maximum number of concurrent unauthenticated connections (`MaxStartups`) and maximum number of open shell, login, or subsystem sessions permitted per network connection (`MaxSessions`). For example:

```
MaxStartups 200
MaxSessions 200
```

If you specify `MaxStartups` using the "start:rate:full" syntax, you enable random early connection drop by the SSH daemon. `start` identifies the maximum number of unauthenticated SSH connection attempts allowed. Once `start` number of unauthenticated connection attempts is reached, the SSH daemon refuses `rate` percent of subsequent connection attempts. `full` identifies the maximum number of unauthenticated connection attempts after which all attempts are refused. For example:

```
Max Startups 10:30:200
MaxSessions 200
```

Restart the SSH daemon after you update `MaxStartups` and `MaxSessions`. For example, on a CentOS 6 system, run the following command as the root user:

```
# service sshd restart
```

For detailed information about SSH configuration options, refer to the SSH documentation for your Linux distribution.

**Note:** If the `grubby` command does not update the kernels of a RHEL 7.x or CentOS 7.x system, you can manually update all kernels on the system. For example, to add the parameter `transparent_hugepage=never` to all kernels on a system.
1. Add the parameter to the GRUB_CMDLINE_LINUX line in the file parameter in /etc/default/grub.

   GRUB_TIMEOUT=5
   GRUB_DISTRIBUTOR="$(sed 's, release .*$,,g' /etc/system-release)"
   GRUB_DEFAULT=saved
   GRUB_DISABLE_SUBMENU=true
   GRUB_TERMINAL_OUTPUT="console"
   GRUB_CMDLINE_LINUX="crashkernel=auto rd.lvm.lv=cl/root rd.lvm.lv=cl/swap rhgb quiet transparent_hugepage=never"
   GRUB_DISABLE_RECOVERY="true"

2. As root, run the grub2-mkconfig command to update the kernels.

   # grub2-mkconfig -o /boot/grub2/grub.cfg

3. Reboot the system.

**Synchronizing System Clocks**

You should use NTP (Network Time Protocol) to synchronize the system clocks on all hosts that comprise your Greenplum Database system. See [www.ntp.org](http://www.ntp.org) for more information about NTP.

NTP on the segment hosts should be configured to use the master host as the primary time source, and the standby master as the secondary time source. On the master and standby master hosts, configure NTP to point to your preferred time server.

**To configure NTP**

1. On the master host, log in as root and edit the /etc/ntp.conf file. Set the server parameter to point to your data center's NTP time server. For example (if 10.6.220.20 was the IP address of your data center's NTP server):

   server 10.6.220.20

2. On each segment host, log in as root and edit the /etc/ntp.conf file. Set the first server parameter to point to the master host, and the second server parameter to point to the standby master host. For example:

   server mdw prefer
   server smdw

3. On the standby master host, log in as root and edit the /etc/ntp.conf file. Set the first server parameter to point to the primary master host, and the second server parameter to point to your data center's NTP time server. For example:

   server mdw prefer
   server 10.6.220.20

4. On the master host, use the NTP daemon synchronize the system clocks on all Greenplum hosts. For example, using `gpssh`:

   # gpssh -f hostfile_gpssh_allhosts -v -e 'ntpd'

**Creating the Greenplum Administrative User**

Create a dedicated operating system user account on each node to run and administer Greenplum Database. This user account is named `gpadmin` by convention.

**Important:** You cannot run the Greenplum Database server as `root`. 
The gpadmin user must have permission to access the services and directories required to install and run Greenplum Database.

The gpadmin user on each Greenplum host must have an SSH key pair installed and be able to SSH from any host in the cluster to any other host in the cluster without entering a password or passphrase (called "passwordless SSH"). If you enable passwordless SSH from the master host to every other host in the cluster ("1-n passwordless SSH"), you can use the Greenplum Database gpssh-exkeys command-line utility later to enable passwordless SSH from every host to every other host ("n-n passwordless SSH").

You can optionally give the gpadmin user sudo privilege, so that you can easily administer all hosts in the Greenplum Database cluster as gpadmin using the sudo, ssh/scp, and gpssh/gpscp commands.

The following steps show how to set up the gpadmin user on a host, set a password, create an SSH key pair, and (optionally) enable sudo capability. These steps must be performed as root on every Greenplum Database cluster host. (For a large Greenplum Database cluster you will want to automate these steps using your system provisioning tools.)

Note: See Example Ansible Playbook for an example that shows how to automate the tasks of creating the gpadmin user and installing the Greenplum Database software on all hosts in the cluster.

1. Create the gpadmin group and user.

   Note: If you are installing Greenplum Database on RHEL 7.2 or CentOS 7.2 and want to disable IPC object removal by creating the gpadmin user as a system account, provide both the -r option (create the user as a system account) and the -m option (create a home directory) to the useradd command. On Ubuntu systems, you must use the -m option with the useradd command to create a home directory for a user.

   This example creates the gpadmin group, creates the gpadmin user as a system account with a home directory and as a member of the gpadmin group, and creates a password for the user.

   ```bash
   # groupadd gpadmin
   # useradd gpadmin -r -m -g gpadmin
   # passwd gpadmin
   New password: <changeme>
   Retype new password: <changeme>
   ```
   
   Note: Make sure the gpadmin user has the same user id (uid) and group id (gid) numbers on each host to prevent problems with scripts or services that use them for identity or permissions. For example, backing up Greenplum databases to some networked file systems or storage appliances could fail if the gpadmin user has different uid or gid numbers on different segment hosts. When you create the gpadmin group and user, you can use the groupadd -g option to specify a gid number and the useradd -u option to specify the uid number. Use the command id gpadmin to see the uid and gid for the gpadmin user on the current host.

2. Switch to the gpadmin user and generate an SSH key pair for the gpadmin user.

   ```bash
   $ su gpadmin
   $ ssh-keygen -t rsa -b 4096
   Generating public/private rsa key pair.
   Enter file in which to save the key (/home/gpadmin/.ssh/id_rsa):
   Created directory '/home/gpadmin/.ssh'.
   Enter passphrase (empty for no passphrase):
   Enter same passphrase again:
   ```
   
   At the passphrase prompts, press Enter so that SSH connections will not require entry of a passphrase.

3. (Optional) Grant sudo access to the gpadmin user.

   On Red Hat or CentOS, run visudo and uncomment the %wheel group entry.

   ```bash
   %wheel     ALL=(ALL) NO密码: ALL
   ```
Make sure you uncomment the line that has the `NOPASSWD` keyword.

Add the `gpadmin` user to the `wheel` group with this command.

```bash
# usermod -aG wheel gpadmin
```

**Next Steps**

- *Installing Greenplum Database Software*
- *Validating Your Systems*
- *Initializing a Greenplum Database System*
Installing the Greenplum Database Software

Describes how to install the Greenplum Database software binaries on all of the hosts that will comprise your Greenplum Database system, how to enable passwordless SSH for the `gpadmin` user, and how to verify the installation.

Perform the following tasks in order:

1. **Installing Greenplum Database**
2. **Enabling Passwordless SSH**
3. **Confirm the software installation.**
4. **Next Steps**

## Installing Greenplum Database

You must install Greenplum Database on each host machine of the Greenplum Database system. Pivotal distributes the Greenplum Database software as a downloadable package that you install on each host system with the operating system's package management system. You can download the package from Pivotal Network.

Before you begin installing Greenplum Database, be sure you have completed the steps in **Configuring Your Systems** to configure each of the master, standby master, and segment host machines for Greenplum Database.

**Important:** After installing Greenplum Database, you must set Greenplum Database environment variables. See **Setting Greenplum Environment Variables**.

See **Example Ansible Playbook** for an example script that shows how you can automate creating the `gpadmin` user and installing the Greenplum Database.

Follow these instructions to install Greenplum Database.

**Important:** You will need sudo or root user access to install from a pre-built binary.

1. Download and copy the Greenplum Database package to the `gpadmin` user's home directory on the master, standby master, and every segment host machine. The distribution file name has the format `greenplum-db-<version>-<platform>.rpm` for RHEL and CentOS systems, or `greenplum-db-<version>-<platform>.deb` for Ubuntu systems, where `<platform>` is similar to `rhel7-x86_64` (Red Hat 7 64-bit).
2. With sudo (or as root), install the Greenplum Database package on each host machine using your system's package manager software.
   
   - For RHEL/CentOS systems, execute the `yum` command:
     
     ```
     $ sudo yum install ./greenplum-db-<version>-<platform>.rpm
     ```
   
   - For Ubuntu systems, execute the `apt` command:
     
     ```
     $ sudo apt install ./greenplum-db-<version>-<platform>.deb
     ```

   The `yum` or `apt` command installs software dependencies, copies the Greenplum Database software files into a version-specific directory, `/usr/local/greenplum-db-<version>`, and creates the symbolic link `/usr/local/greenplum-db` to the installation directory.

3. Change the owner and group of the installed files to `gpadmin`:

   ```
   $ sudo chown -R gpadmin:gpadmin /usr/local/greenplum*
   ```
Enabling Passwordless SSH

The `gpadmin` user on each Greenplum host must be able to SSH from any host in the cluster to any other host in the cluster without entering a password or passphrase (called "passwordless SSH"). If you enable passwordless SSH from the master host to every other host in the cluster ("1-n passwordless SSH"), you can use the Greenplum Database `gpssh-exkeys` command-line utility to enable passwordless SSH from every host to every other host ("n-n passwordless SSH").

1. Log in to the master host as the `gpadmin` user.
2. Source the path file in the Greenplum Database installation directory.

   ```bash
   $ source /usr/local/greenplum-db-<version>/greenplum_path.sh
   ```

   **Note:** Add the above `source` command to the `gpadmin` user's `.bashrc` or other shell startup file so that the Greenplum Database path and environment variables are set whenever you log in as `gpadmin`.

3. Use the `ssh-copy-id` command to add the `gpadmin` user's public key to the `authorized_hosts` SSH file on every other host in the cluster.

   ```bash
   $ ssh-copy-id smdw
   $ ssh-copy-id sdw1
   $ ssh-copy-id sdw2
   $ ssh-copy-id sdw3
   . . .
   ```

   This enables 1-n passwordless SSH. You will be prompted to enter the `gpadmin` user's password for each host. If you have the `sshpass` command on your system, you can use a command like the following to avoid the prompt.

   ```bash
   $ SSHPASS=<password> sshpass -e ssh-copy-id smdw
   ```

4. In the `gpadmin` home directory, create a file named `hostfile_exkeys` that has the machine configured host names and host addresses (interface names) for each host in your Greenplum system (master, standby master, and segment hosts). Make sure there are no blank lines or extra spaces. Check the `/etc/hosts` file on your systems for the correct host names to use for your environment. For example, if you have a master, standby master, and three segment hosts with two unbonded network interfaces per host, your file would look something like this:

   ```bash
   mdw
   mdw-1
   mdw-2
   smdw
   smdw-1
   smdw-2
   sdw1
   sdw1-1
   sdw1-2
   sdw2
   sdw2-1
   sdw2-2
   sdw3
   sdw3-1
   sdw3-2
   ```

5. Run the `gpssh-exkeys` utility with your `hostfile_exkeys` file to enable n-n passwordless SSH for the `gpadmin` user.

   ```bash
   $ gpssh-exkeys -f hostfile_exkeys
   ```
## Confirming Your Installation

To make sure the Greenplum software was installed and configured correctly, run the following confirmation steps from your Greenplum master host. If necessary, correct any problems before continuing on to the next task.

1. Log in to the master host as gpadmin:
   
   ```bash
   $ su - gpadmin
   ```

2. Use the `gpssh` utility to see if you can log in to all hosts without a password prompt, and to confirm that the Greenplum software was installed on all hosts. Use the `hostfile_exkeys` file you used to set up passwordless SSH. For example:

   ```bash
   $ gpssh -f hostfile_exkeys -e 'ls -l /usr/local/greenplum-db-<version>'
   ```

   If the installation was successful, you should be able to log in to all hosts without a password prompt. All hosts should show that they have the same contents in their installation directories, and that the directories are owned by the gpadmin user.

   If you are prompted for a password, run the following command to redo the ssh key exchange:

   ```bash
   $ gpssh-exkeys -f hostfile_exkeys
   ```

## About Your Greenplum Database Installation

- `greenplum_path.sh` — This file contains the environment variables for Greenplum Database. See [Setting Greenplum Environment Variables](#).
- `bin` — This directory contains the Greenplum Database management utilities. This directory also contains the PostgreSQL client and server programs, most of which are also used in Greenplum Database.
- `docs/cli_help` — This directory contains help files for Greenplum Database command-line utilities.
- `docs/cli_help/gpconfigs` — This directory contains sample `gpinitsystem` configuration files and host files that can be modified and used when installing and initializing a Greenplum Database system.
- `ext` — Bundled programs (such as Python) used by some Greenplum Database utilities.
- `include` — The C header files for Greenplum Database.
- `lib` — Greenplum Database and PostgreSQL library files.
- `sbin` — Supporting/Internal scripts and programs.
- `share` — Shared files for Greenplum Database.

## Next Steps

- [Creating the Data Storage Areas](#)
- [Validating Your Systems](#)
- [Initializing a Greenplum Database System](#)
Creating the Data Storage Areas

Describes how to create the directory locations where Greenplum Database data is stored for each master, standby, and segment instance.

Creating Data Storage Areas on the Master and Standby Master Hosts

A data storage area is required on the Greenplum Database master and standby master hosts to store Greenplum Database system data such as catalog data and other system metadata.

To create the data directory location on the master

The data directory location on the master is different than those on the segments. The master does not store any user data, only the system catalog tables and system metadata are stored on the master instance, therefore you do not need to designate as much storage space as on the segments.

1. Create or choose a directory that will serve as your master data storage area. This directory should have sufficient disk space for your data and be owned by the gpadmin user and group. For example, run the following commands as root:

   # mkdir -p /data/master

2. Change ownership of this directory to the gpadmin user. For example:

   # chown gpadmin:gpadmin /data/master

3. Using gpssh, create the master data directory location on your standby master as well. For example:

   # source /usr/local/greenplum-db/greenplum_path.sh
   # gpssh -h smdw -e 'mkdir -p /data/master'
   # gpssh -h smdw -e 'chown gpadmin:gpadmin /data/master'

Creating Data Storage Areas on Segment Hosts

Data storage areas are required on the Greenplum Database segment hosts for primary segments. Separate storage areas are required for mirror segments.

To create the data directory locations on all segment hosts

1. On the master host, log in as root:

   # su

2. Create a file called hostfile_gpssh_segonly. This file should have only one machine configured host name for each segment host. For example, if you have three segment hosts:

   sdw1
   sdw2
   sdw3

3. Using gpssh, create the primary and mirror data directory locations on all segment hosts at once using the hostfile_gpssh_segonly file you just created. For example:

   # source /usr/local/greenplum-db/greenplum_path.sh
   # gpssh -f hostfile_gpssh_segonly -e 'mkdir -p /data/primary'
Next Steps

- Validating Your Systems
- Initializing a Greenplum Database System

```bash
# gpssh -f hostfile_gpssh_segonly -e 'mkdir -p /data/mirror'
# gpssh -f hostfile_gpssh_segonly -e 'chown -R gpadmin /data/*'
```
Validating Your Systems

Validate your hardware and network performance.

Greenplum provides a management utility called `gpcheckperf`, which can be used to identify hardware and system-level issues on the machines in your Greenplum Database array. `gpcheckperf` starts a session on the specified hosts and runs the following performance tests:

- Network Performance (`gpnetbench*`)
- Disk I/O Performance (`dd` test)
- Memory Bandwidth (`stream` test)

Before using `gpcheckperf`, you must have a trusted host setup between the hosts involved in the performance test. You can use the utility `gpssh-exkeys` to update the known host files and exchange public keys between hosts if you have not done so already. Note that `gpcheckperf` calls to `gpssh` and `gpscp`, so these Greenplum utilities must be in your `$PATH`.

Validating Network Performance

To test network performance, run `gpcheckperf` with one of the network test run options: parallel pair test (`-r N`), serial pair test (`-r n`), or full matrix test (`-r M`). The utility runs a network benchmark program that transfers a 5 second stream of data from the current host to each remote host included in the test. By default, the data is transferred in parallel to each remote host and the minimum, maximum, average and median network transfer rates are reported in megabytes (MB) per second. If the summary transfer rate is slower than expected (less than 100 MB/s), you can run the network test serially using the `-r n` option to obtain per-host results. To run a full-matrix bandwidth test, you can specify `-r M` which will cause every host to send and receive data from every other host specified. This test is best used to validate if the switch fabric can tolerate a full-matrix workload.

Most systems in a Greenplum Database array are configured with multiple network interface cards (NICs), each NIC on its own subnet. When testing network performance, it is important to test each subnet individually. For example, considering the following network configuration of two NICs per host:

<table>
<thead>
<tr>
<th>Greenplum Host</th>
<th>Subnet1 NICs</th>
<th>Subnet2 NICs</th>
</tr>
</thead>
<tbody>
<tr>
<td>Segment 1</td>
<td>sdw1-1</td>
<td>sdw1-2</td>
</tr>
<tr>
<td>Segment 2</td>
<td>sdw2-1</td>
<td>sdw2-2</td>
</tr>
<tr>
<td>Segment 3</td>
<td>sdw3-1</td>
<td>sdw3-2</td>
</tr>
</tbody>
</table>

You would create four distinct host files for use with the `gpcheckperf` network test:

<table>
<thead>
<tr>
<th>hostfile_gpchecknet_ic1</th>
<th>hostfile_gpchecknet_ic2</th>
</tr>
</thead>
<tbody>
<tr>
<td>sdw1-1</td>
<td>sdw1-2</td>
</tr>
<tr>
<td>sdw2-1</td>
<td>sdw2-2</td>
</tr>
<tr>
<td>sdw3-1</td>
<td>sdw3-2</td>
</tr>
</tbody>
</table>
You would then run `gpcheckperf` once per subnet. For example (if testing an even number of hosts, run in parallel pairs test mode):

```bash
$ gpcheckperf -f hostfile_gpchecknet_ic1 -r N -d /tmp > subnet1.out
$ gpcheckperf -f hostfile_gpchecknet_ic2 -r N -d /tmp > subnet2.out
```

If you have an odd number of hosts to test, you can run in serial test mode (`-r n`).

## Validating Disk I/O and Memory Bandwidth

To test disk and memory bandwidth performance, run `gpcheckperf` with the disk and stream test run options (`-r ds`). The disk test uses the `dd` command (a standard UNIX utility) to test the sequential throughput performance of a logical disk or file system. The memory test uses the STREAM benchmark program to measure sustainable memory bandwidth. Results are reported in MB per second (MB/s).

### To run the disk and stream tests

1. Log in on the master host as the `gpadmin` user.
2. Source the `greenplum_path.sh` path file from your Greenplum installation. For example:

   ```bash
   $ source /usr/local/greenplum-db/greenplum_path.sh
   
   3. Create a host file named `hostfile_gpcheckperf` that has one host name per segment host. Do not include the master host. For example:

   ```bash
   sdw1
ds2
ds3
ds4
   ```

4. Run the `gpcheckperf` utility using the `hostfile_gpcheckperf` file you just created. Use the `-d` option to specify the file systems you want to test on each host (you must have write access to these directories). You will want to test all primary and mirror segment data directory locations. For example:

   ```bash
   $ gpcheckperf -f hostfile_gpcheckperf -r ds -D -d /data1/primary -d /data2/primary -d /data1/mirror -d /data2/mirror
   ```

5. The utility may take a while to perform the tests as it is copying very large files between the hosts. When it is finished you will see the summary results for the Disk Write, Disk Read, and Stream tests.
Initializing a Greenplum Database System

Describes how to initialize a Greenplum Database database system.

The instructions in this chapter assume you have already prepared your hosts as described in Configuring Your Systems and installed the Greenplum Database software on all of the hosts in the system according to the instructions in Installing the Greenplum Database Software.

This chapter contains the following topics:

- Overview
- Initializing Greenplum Database
- Next Steps

Overview

Because Greenplum Database is distributed, the process for initializing a Greenplum Database management system (DBMS) involves initializing several individual PostgreSQL database instances (called segment instances in Greenplum).

Each database instance (the master and all segments) must be initialized across all of the hosts in the system in such a way that they can all work together as a unified DBMS. Greenplum provides its own version of initdb called gpinitsystem, which takes care of initializing the database on the master and on each segment instance, and starting each instance in the correct order.

After the Greenplum Database database system has been initialized and started, you can then create and manage databases as you would in a regular PostgreSQL DBMS by connecting to the Greenplum master.

Initializing Greenplum Database

These are the high-level tasks for initializing Greenplum Database:

1. Make sure you have completed all of the installation tasks described in Configuring Your Systems and Installing the Greenplum Database Software.
2. Create a host file that contains the host addresses of your segments. See Creating the Initialization Host File.
4. By default, Greenplum Database will be initialized using the locale of the master host system. Make sure this is the correct locale you want to use, as some locale options cannot be changed after initialization. See Configuring Timezone and Localization Settings for more information.
5. Run the Greenplum Database initialization utility on the master host. See Running the Initialization Utility.
6. Set the Greenplum Database timezone. See Setting the Greenplum Database Timezone.

Creating the Initialization Host File

The gpinitsystem utility requires a host file that contains the list of addresses for each segment host. The initialization utility determines the number of segment instances per host by the number host addresses listed per host times the number of data directory locations specified in the gpinitsystem_config file.

This file should only contain segment host addresses (not the master or standby master). For segment machines with multiple, unbonded network interfaces, this file should list the host address names for each interface — one per line.
Note: The Greenplum Database segment host naming convention is sdwN where sdw is a prefix and N is an integer. For example, sdw2 and so on. If hosts have multiple unbonded NICs, the convention is to append a dash (-) and number to the host name. For example, sdw1-1 and sdw1-2 are the two interface names for host sdw1. However, NIC bonding is recommended to create a load-balanced, fault-tolerant network.

To create the initialization host file

1. Log in as gpadmin.

   $ su - gpadmin

2. Create a file named hostfile_gpinit_system. In this file add the host address name(s) of your segment host interfaces, one name per line, no extra lines or spaces. For example, if you have four segment hosts with two unbonded network interfaces each:

   sdw1-1
   sdw1-2
   sdw2-1
   sdw2-2
   sdw3-1
   sdw3-2
   sdw4-1
   sdw4-2

3. Save and close the file.

   Note: If you are not sure of the host names and/or interface address names used by your machines, look in the /etc/hosts file.

Creating the Greenplum Database Configuration File

Your Greenplum Database configuration file tells the gpinit_system utility how you want to configure your Greenplum Database system. An example configuration file can be found in $GPHOME/docs/cli_help/gpconfigs/gpinit_system_config.

To create a gpinit_system_config file

1. Log in as gpadmin.

   $ su - gpadmin

2. Make a copy of the gpinit_system_config file to use as a starting point. For example:

   $ cp $GPHOME/docs/cli_help/gpconfigs/gpinit_system_config /
   /home/gpadmin/gpconfigs/gpinit_system_config

3. Open the file you just copied in a text editor.

   Set all of the required parameters according to your environment. See gpinit_system for more information. A Greenplum Database system must contain a master instance and at least two segment instances (even if setting up a single node system).

   The DATA_DIRECTORY parameter is what determines how many segments per host will be created. If your segment hosts have multiple network interfaces, and you used their interface address names in your host file, the number of segments will be evenly spread over the number of available interfaces.

   To specify PORT_BASE, review the port range specified in the net.ipv4.ip_local_port_range parameter in the /etc/sysctl.conf file.
Here is an example of the *required* parameters in the `gpinit system_config` file:

```bash
ARRAY_NAME="Greenplum Data Platform"
SEG_PREFIX=gpseg
PORT_BASE=6000
MASTER_HOSTNAME=mdw
MASTER_DIRECTORY=/data/master
MASTER_PORT=5432
TRUSTED_SHELL=ssh
CHECK_POINT_SEGMENTS=8
ENCODING=UNICODE
```

4. (Optional) If you want to deploy mirror segments, uncomment and set the mirroring parameters according to your environment. To specify `MIRROR_PORT_BASE`, review the port range specified under the `net.ipv4.ip_local_port_range` parameter in the `/etc/sysctl.conf` file. Here is an example of the *optional* mirror parameters in the `gpinit system_config` file:

```bash
MIRROR_PORT_BASE=7000
declare -a MIRROR_DATA_DIRECTORY=(/data1/mirror /data1/mirror /data1/mirror /data2/mirror /data2/mirror /data2/mirror)
```

**Note:** You can initialize your Greenplum system with primary segments only and deploy mirrors later using the `gpaddmirrors` utility.

5. Save and close the file.

**Running the Initialization Utility**

The `gpinit system` utility will create a Greenplum Database system using the values defined in the configuration file.

**To run the initialization utility**

1. Run the following command referencing the path and file name of your initialization configuration file (`gpinit system_config`) and host file (`hostfile_gpinit system`). For example:

```bash
$ cd ~
$ gpinit system -c gpconfigs/gpinit system_config -h gpconfigs/hostfile_gpinit system
```

For a fully redundant system (with a standby master and a spread mirror configuration) include the `-s` and `-S` options. For example:

```bash
$ gpinit system -c gpconfigs/gpinit system_config -h gpconfigs/hostfile_gpinit system \
-s standby_master_hostname -S
```

2. The utility will verify your setup information and make sure it can connect to each host and access the data directories specified in your configuration. If all of the pre-checks are successful, the utility will prompt you to confirm your configuration. For example:

```bash
=> Continue with Greenplum creation? Yy/Nn
```

3. Press `y` to start the initialization.

4. The utility will then begin setup and initialization of the master instance and each segment instance in the system. Each segment instance is set up in parallel. Depending on the number of segments, this process can take a while.
5. At the end of a successful setup, the utility will start your Greenplum Database system. You should see:

```
=> Greenplum Database instance successfully created.
```

**Troubleshooting Initialization Problems**

If the utility encounters any errors while setting up an instance, the entire process will fail, and could possibly leave you with a partially created system. Refer to the error messages and logs to determine the cause of the failure and where in the process the failure occurred. Log files are created in `~/gpAdminLogs`.

Depending on when the error occurred in the process, you may need to clean up and then try the gpinitsystem utility again. For example, if some segment instances were created and some failed, you may need to stop `postgres` processes and remove any utility-created data directories from your data storage area(s). A backout script is created to help with this cleanup if necessary.

**Using the Backout Script**

If the gpinitsystem utility fails, it will create the following backout script if it has left your system in a partially installed state:

```
~/gpAdminLogs/backout_gpinitsystem_<user>_<timestamp>
```

You can use this script to clean up a partially created Greenplum Database system. This backout script will remove any utility-created data directories, `postgres` processes, and log files. After correcting the error that caused gpinitsystem to fail and running the backout script, you should be ready to retry initializing your Greenplum Database array.

The following example shows how to run the backout script:

```
$ sh backout_gpinitsystem_gpadmin_20071031_121053
```

**Setting the Greenplum Database Timezone**

As a best practice, configure Greenplum Database and the host systems to use a known, supported timezone. Greenplum Database uses a timezone from a set of internally stored PostgreSQL timezones. Setting the Greenplum Database timezone prevents Greenplum Database from selecting a timezone each time the cluster is restarted and sets the timezone for the Greenplum Database master and segment instances.

Use the `gpconfig` utility to show and set the Greenplum Database timezone. For example, these commands show the Greenplum Database timezone and set the timezone to `US/Pacific`.

```
# gpconfig -s TimeZone
# gpconfig -c TimeZone -v 'US/Pacific'
```

You must restart Greenplum Database after changing the timezone. The command `gpstop -ra` restarts Greenplum Database. The catalog view `pg_timezone_names` provides Greenplum Database timezone information.

For more information about the Greenplum Database timezone, see *Configuring Timezone and Localization Settings*.

**Setting Greenplum Environment Variables**

You must configure your environment on the Greenplum Database master (and standby master). A `greenplum_path.sh` file is provided in your `$GPHOME` directory with environment variable settings for Greenplum Database. You can source this file in the `gpadmin` user’s startup shell profile (such as `.bashrc`).
The Greenplum Database management utilities also require that the `MASTER_DATA_DIRECTORY` environment variable be set. This should point to the directory created by the `gpinitsystem` utility in the master data directory location.

**Note:** The `greenplum_path.sh` script changes the operating environment in order to support running the Greenplum Database-specific utilities. These same changes to the environment can negatively affect the operation of other system-level utilities, such as `ps` or `yum`. Use separate accounts for performing system administration and database administration, instead of attempting to perform both functions as `gpadmin`.

**To set up your user environment for Greenplum**

1. Make sure you are logged in as `gpadmin`:

   ```bash
   $ su - gpadmin
   ```

2. Open your profile file (such as `.bashrc`) in a text editor. For example:

   ```bash
   $ vi ~/.bashrc
   ```

3. Add lines to this file to source the `greenplum_path.sh` file and set the `MASTER_DATA_DIRECTORY` environment variable. For example:

   ```bash
   source /usr/local/greenplum-db/greenplum_path.sh
   export MASTER_DATA_DIRECTORY=/data/master/gpseg-1
   ```

4. (Optional) You may also want to set some client session environment variables such as `PGPORT`, `PGUSER` and `PGDATABASE` for convenience. For example:

   ```bash
   export PGPORT=5432
   export PGUSER=gpadmin export PGDATABASE=default_login_database_name
   ```

5. (Optional) If you use RHEL 7 or CentOS 7, add the following line to the end of the `.bashrc` file to enable using the `ps` command in the `greenplum_path.sh` environment:

   ```bash
   export LD_PRELOAD=/lib64/libz.so.1 ps
   ```

6. Save and close the file.

7. After editing the profile file, source it to make the changes active. For example:

   ```bash
   $ source ~/.bashrc
   ```

8. If you have a standby master host, copy your environment file to the standby master as well. For example:

   ```bash
   $ cd ~
   $ scp ~/.bashrc standby_hostname:`pwd`
   ```

**Note:** The `.bashrc` file should not produce any output. If you wish to have a message display to users upon logging in, use the `.profile` file instead.

**Next Steps**

After your system is up and running, the next steps are:

- **Allowing Client Connections**
- **Creating Databases and Loading Data**
Allowing Client Connections

After a Greenplum Database is first initialized it will only allow local connections to the database from the gpadmin role (or whatever system user ran gpinitsystem). If you would like other users or client machines to be able to connect to Greenplum Database, you must give them access. See the Greenplum Database Administrator Guide for more information.

Creating Databases and Loading Data

After verifying your installation, you may want to begin creating databases and loading data. See Defining Database Objects and Loading and Unloading Data in the Greenplum Database Administrator Guide for more information about creating databases, schemas, tables, and other database objects in Greenplum Database and loading your data.
Installing Optional Extensions

Information about installing optional Greenplum Database extensions and packages, such as the Procedural Language extensions and the Python and R Data Science Packages.

Procedural Language, Machine Learning, and Geospatial Extensions

Optional. Use the Greenplum package manager (\texttt{gppkg}) to install Greenplum Database extensions such as PL/Java, PL/R, PostGIS, and MADlib, along with their dependencies, across an entire cluster. The package manager also integrates with existing scripts so that any packages are automatically installed on any new hosts introduced into the system following cluster expansion or segment host recovery.

See \texttt{gppkg} for more information, including usage.

Extension packages can be downloaded from the Greenplum Database page on Pivotal Network. The extension documentation in the Greenplum Database Reference Guide contains information about installing extension packages and using extensions.

- Greenplum PL/R Language Extension
- Greenplum PL/Java Language Extension
- Greenplum MADlib Extension for Analytics
- Greenplum PostGIS Extension

\textbf{Important:} If you intend to use an extension package with Greenplum Database 6 you must install and use a Greenplum Database extension package (gppkg files and contrib modules) that is built for Greenplum Database 6. Any custom modules that were used with earlier versions must be rebuilt for use with Greenplum Database 6.

Python Data Science Module Package

Greenplum Database provides a collection of data science-related Python modules that can be used with the Greenplum Database PL/Python language. You can download these modules in \texttt{.gppkg} format from Pivotal Network.

This section contains the following information:

- Python Data Science Modules
- Installing the Python Data Science Module Package
- Uninstalling the Python Data Science Module Package

For information about the Greenplum Database PL/Python Language, see Greenplum PL/Python Language Extension.

Python Data Science Modules

Modules provided in the Python Data Science package include:

\textbf{Table 7: Data Science Modules}

<table>
<thead>
<tr>
<th>Module Name</th>
<th>Description/Used For</th>
</tr>
</thead>
<tbody>
<tr>
<td>atomicwrites</td>
<td>Atomic file writes</td>
</tr>
<tr>
<td>attrs</td>
<td>Declarative approach for defining class attributes</td>
</tr>
<tr>
<td>Autograd</td>
<td>Gradient-based optimization</td>
</tr>
<tr>
<td>Module Name</td>
<td>Description/Used For</td>
</tr>
<tr>
<td>-------------------------------</td>

### Installing the Python Data Science Module Package

Before you install the Python Data Science Module package, make sure that your Greenplum Database is running, you have sourced `greenplum_path.sh`, and that the `$MASTER_DATA_DIRECTORY` and `$GPHOME` environment variables are set.

**Note:** The PyMC3 module depends on Tk. If you want to use PyMC3, you must install the `tk` OS package on every node in your cluster. For example:

```
$ yum install tk
```

1. Locate the Python Data Science module package that you built or downloaded.
   The file name format of the package is `DataSciencePython-<version>-relhel<N>-x86_64.gppkg`.
2. Copy the package to the Greenplum Database master host.
3. Use the `gppkg` command to install the package. For example:

   ```
   $ gppkg -i DataSciencePython-<version>-relhel<N>_x86_64.gppkg
   ```

   `gppkg` installs the Python Data Science modules on all nodes in your Greenplum Database cluster. The command also updates the `PYTHONPATH`, `PATH`, and `LD_LIBRARY_PATH` environment variables in your `greenplum_path.sh` file.
4. Restart Greenplum Database. You must re-source `greenplum_path.sh` before restarting your Greenplum cluster:

   ```
   $ source /usr/local/greenplum-db/greenplum_path.sh
   ```
$ gpstop -r

The Greenplum Database Python Data Science Modules are installed in the following directory:

$GP HOME/ext/DataSciencePython/lib/python2.7/site-packages/

Uninstalling the Python Data Science Module Package

Use the gppkg utility to uninstall the Python Data Science Module package. You must include the version number in the package name you provide to gppkg.

To determine your Python Data Science Module package version number and remove this package:

$ gppkg -q --all | grep DataSciencePython
DataSciencePython-<version>
$ gppkg -r DataSciencePython-<version>

The command removes the Python Data Science modules from your Greenplum Database cluster. It also updates the PYTHONPATH, PATH, and LD_LIBRARY_PATH environment variables in your greenplum_path.sh file to their pre-installation values.

Re-source greenplum_path.sh and restart Greenplum Database after you remove the Python Data Science Module package:

$ . /usr/local/greenplum-db/greenplum_path.sh
$ gpstop -r

**Note:** When you uninstall the Python Data Science Module package from your Greenplum Database cluster, any UDFs that you have created that import Python modules installed with this package will return an error.

R Data Science Library Package

R packages are modules that contain R functions and data sets. Greenplum Database provides a collection of data science-related R libraries that can be used with the Greenplum Database PL/R language. You can download these libraries in .gppkg format from Pivotal Network.

This chapter contains the following information:

- **R Data Science Libraries**
- **Installing the R Data Science Library Package**
- **Uninstalling the R Data Science Library Package**

For information about the Greenplum Database PL/R Language, see Greenplum PL/R Language Extension.

R Data Science Libraries

Libraries provided in the R Data Science package include:

</tbody>
</table>
Installing the R Data Science Library Package

Before you install the R Data Science Library package, make sure that your Greenplum Database is running, you have sourced `greenplum_path.sh`, and that the $MASTER_DATA_DIRECTORY and $GPHOME environment variables are set.

1. Locate the R Data Science library package that you built or downloaded.
   The file name format of the package is `DataScienceR-<version>-relhel<N>_x86_64.gppkg`.
2. Copy the package to the Greenplum Database master host.
3. Use the `gppkg` command to install the package. For example:

   ```bash
   $ gppkg -i DataScienceR-<version>-relhel<N>_x86_64.gppkg
   ```
   
   `gppkg` installs the R Data Science libraries on all nodes in your Greenplum Database cluster. The command also sets the `R_LIBS_USER` environment variable and updates the `PATH` and `LD_LIBRARY_PATH` environment variables in your `greenplum_path.sh` file.

4. Restart Greenplum Database. You must re-source `greenplum_path.sh` before restarting your Greenplum cluster:

   ```bash
   $ source /usr/local/greenplum-db/greenplum_path.sh
   $ gpstop -r
   ```

   The Greenplum Database R Data Science Modules are installed in the following directory:

   `$$GPHOME/ext/DataScienceR/library`

   **Note:** `rjags` libraries are installed in the `$$GPHOME/ext/DataScienceR/extlib/lib` directory. If you want to use `rjags` and your `$GPHOME` is not `/usr/local/greenplum-db`, you must perform additional configuration steps to create a symbolic link from `$GPHOME` to `/usr/local/greenplum-db` on each node in your Greenplum Database cluster. For example:

   ```bash
   $ gpssh -f all_hosts -e 'ln -s $$GPHOME /usr/local/greenplum-db'
   $ gpssh -f all_hosts -e 'chown -h gpadmin /usr/local/greenplum-db'
   ```

Uninstalling the R Data Science Library Package

Use the `gppkg` utility to uninstall the R Data Science Library package. You must include the version number in the package name you provide to `gppkg`.

To determine your R Data Science Library package version number and remove this package:

```bash
$ gppkg -q --all | grep DataScienceR
DataScienceR-<version>
$ gppkg -r DataScienceR-<version>
```

The command removes the R Data Science libraries from your Greenplum Database cluster. It also removes the `R_LIBS_USER` environment variable and updates the `PATH` and `LD_LIBRARY_PATH` environment variables in your `greenplum_path.sh` file to their pre-installation values.

Re-source `greenplum_path.sh` and restart Greenplum Database after you remove the R Data Science Library package:

```bash
$ . /usr/local/greenplum-db/greenplum_path.sh
$ gpstop -r
```
Note: When you uninstall the R Data Science Library package from your Greenplum Database cluster, any UDFs that you have created that use R libraries installed with this package will return an error.

**Greenplum Platform Extension Framework (PXF)**

Optional. If you do not plan to use PXF, no action is necessary.

If you plan to use PXF, refer to *Configuring PXF* for instructions.
Installing Additional Supplied Modules

The Greenplum Database distribution includes several PostgreSQL- and Greenplum-sourced contrib modules that you have the option to install.

Each module is typically packaged as a Greenplum Database extension. You must register these modules in each database in which you want to use it. For example, to register the dblink module in the database named testdb, use the command:

```bash
$ psql -d testdb -c 'CREATE EXTENSION dblink;'
```

To remove a module from a database, drop the associated extension. For example, to remove the dblink module from the testdb database:

```bash
$ psql -d testdb -c 'DROP EXTENSION dblink;'
```

**Note:** When you drop a module extension from a database, any user-defined function that you created in the database that references functions defined in the module will no longer work. If you created any database objects that use data types defined in the module, Greenplum Database will notify you of these dependencies when you attempt to drop the module extension.

You can register the following modules in this manner:

For additional information about the modules supplied with Greenplum Database, refer to Additional Supplied Modules in the Greenplum Database Reference Guide.
Configuring Timezone and Localization Settings

Describes the available timezone and localization features of Greenplum Database.

Configuring the Timezone

Greenplum Database selects a timezone to use from a set of internally stored PostgreSQL timezones. The available PostgreSQL timezones are taken from the Internet Assigned Numbers Authority (IANA) Time Zone Database, and Greenplum Database updates its list of available timezones as necessary when the IANA database changes for PostgreSQL.

Greenplum Database selects the timezone by matching a PostgreSQL timezone with the value of the `TimeZone` server configuration parameter, or the host system time zone if `TimeZone` is not set. For example, when selecting a default timezone from the host system time zone, Greenplum Database uses an algorithm to select a PostgreSQL timezone based on the host system timezone files. If the system timezone includes leap second information, Greenplum Database cannot match the system timezone with a PostgreSQL timezone. In this case, Greenplum Database calculates a "best match" with a PostgreSQL timezone based on information from the host system.

As a best practice, configure Greenplum Database and the host systems to use a known, supported timezone. This sets the timezone for the Greenplum Database master and segment instances, and prevents Greenplum Database from selecting a best match timezone each time the cluster is restarted, using the current system timezone and Greenplum Database timezone files (which may have been updated from the IANA database since the last restart). Use the `gpconfig` utility to show and set the Greenplum Database timezone. For example, these commands show the Greenplum Database timezone and set the timezone to `US/Pacific`.

```
# gpconfig -s TimeZone
# gpconfig -c TimeZone -v 'US/Pacific'
```

You must restart Greenplum Database after changing the timezone. The command `gpstop -ra` restarts Greenplum Database. The catalog view `pg_timezone_names` provides Greenplum Database timezone information.

About Locale Support in Greenplum Database

Greenplum Database supports localization with two approaches:

- Using the locale features of the operating system to provide locale-specific collation order, number formatting, and so on.
- Providing a number of different character sets defined in the Greenplum Database server, including multiple-byte character sets, to support storing text in all kinds of languages, and providing character set translation between client and server.

Locale support refers to an application respecting cultural preferences regarding alphabets, sorting, number formatting, etc. Greenplum Database uses the standard ISO C and POSIX locale facilities provided by the server operating system. For additional information refer to the documentation of your operating system.

Locale support is automatically initialized when a Greenplum Database system is initialized. The initialization utility, `gpinitsystem`, will initialize the Greenplum array with the locale setting of its execution environment by default, so if your system is already set to use the locale that you want in your Greenplum Database system then there is nothing else you need to do.
When you are ready to initiate Greenplum Database and you want to use a different locale (or you are not sure which locale your system is set to), you can instruct `gpinitsystem` exactly which locale to use by specifying the `-n locale` option. For example:

```bash
$ gpinitsystem -c gp_init_config -n sv_SE
```

See *Initializing a Greenplum Database System* for information about the database initialization process.

The example above sets the locale to Swedish (sv) as spoken in Sweden (SE). Other possibilities might be `en_US` (U.S. English) and `fr_CA` (French Canadian). If more than one character set can be useful for a locale then the specifications look like this: `cs_CZ.ISO8859-2`. What locales are available under what names on your system depends on what was provided by the operating system vendor and what was installed. On most systems, the command `locale -a` will provide a list of available locales.

Occasionally it is useful to mix rules from several locales, for example use English collation rules but Spanish messages. To support that, a set of locale subcategories exist that control only a certain aspect of the localization rules:

- **LC_COLLATE** — String sort order
- **LC_CTYPE** — Character classification (What is a letter? Its upper-case equivalent?)
- **LC_MESSAGES** — Language of messages
- **LC_MONETARY** — Formatting of currency amounts
- **LC_NUMERIC** — Formatting of numbers
- **LC_TIME** — Formatting of dates and times

If you want the system to behave as if it had no locale support, use the special locale `C` or `POSIX`.

The nature of some locale categories is that their value has to be fixed for the lifetime of a Greenplum Database system. That is, once `gpinitsystem` has run, you cannot change them anymore. `LC_COLLATE` and `LC_CTYPE` are those categories. They affect the sort order of indexes, so they must be kept fixed, or indexes on text columns will become corrupt. Greenplum Database enforces this by recording the values of `LC_COLLATE` and `LC_CTYPE` that are seen by `gpinitsystem`. The server automatically adopts those two values based on the locale that was chosen at initialization time.

The other locale categories can be changed as desired whenever the server is running by setting the server configuration parameters that have the same name as the locale categories (see the *Greenplum Database Reference Guide* for more information on setting server configuration parameters). The defaults that are chosen by `gpinitsetup` are written into the master and segment `postgresql.conf` configuration files to serve as defaults when the Greenplum Database system is started. If you delete these assignments from the master and each segment `postgresql.conf` files then the server will inherit the settings from its execution environment.

Note that the locale behavior of the server is determined by the environment variables seen by the server, not by the environment of any client. Therefore, be careful to configure the correct locale settings on each Greenplum Database host (master and segments) before starting the system. A consequence of this is that if client and server are set up in different locales, messages may appear in different languages depending on where they originated.

Inheriting the locale from the execution environment means the following on most operating systems: For a given locale category, say the collation, the following environment variables are consulted in this order until one is found to be set: `LC_ALL`, `LC_COLLATE` (the variable corresponding to the respective category), `LANG`. If none of these environment variables are set then the locale defaults to `C`.

Some message localization libraries also look at the environment variable `LANGUAGE` which overrides all other locale settings for the purpose of setting the language of messages. If in doubt, please refer to the documentation for your operating system, in particular the documentation about `gettext`, for more information.

Native language support (NLS), which enables messages to be translated to the user's preferred language, is not enabled in Greenplum Database for languages other than English. This is independent of the other locale support.
Locale Behavior

The locale settings influence the following SQL features:

- Sort order in queries using ORDER BY on textual data
- The ability to use indexes with LIKE clauses
- The upper, lower, and initcap functions
- The to_char family of functions

The drawback of using locales other than C or POSIX in Greenplum Database is its performance impact. It slows character handling and prevents ordinary indexes from being used by LIKE. For this reason use locales only if you actually need them.

Troubleshooting Locales

If locale support does not work as expected, check that the locale support in your operating system is correctly configured. To check what locales are installed on your system, you may use the command locale -a if your operating system provides it.

Check that Greenplum Database is actually using the locale that you think it is. LC_COLLATE and LC_CTYPE settings are determined at initialization time and cannot be changed without redoing gpinitsystem. Other locale settings including LC_MESSAGES and LC_MONETARY are initially determined by the operating system environment of the master and/or segment host, but can be changed after initialization by editing the postgresql.conf file of each Greenplum master and segment instance. You can check the active locale settings of the master host using the SHOW command. Note that every host in your Greenplum Database array should be using identical locale settings.

Character Set Support

The character set support in Greenplum Database allows you to store text in a variety of character sets, including single-byte character sets such as the ISO 8859 series and multiple-byte character sets such as EUC (Extended Unix Code), UTF-8, and Mule internal code. All supported character sets can be used transparently by clients, but a few are not supported for use within the server (that is, as a server-side encoding). The default character set is selected while initializing your Greenplum Database array using gpinitsystem. It can be overridden when you create a database, so you can have multiple databases each with a different character set.

Table 8: Greenplum Database Character Sets

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Language</th>
<th>Server?</th>
<th>Bytes/Char</th>
<th>Aliases</th>
</tr>
</thead>
<tbody>
<tr>
<td>BIG5</td>
<td>Big Five</td>
<td>Traditional Chinese</td>
<td>No</td>
<td>1-2</td>
<td>WIN950, Windows950</td>
</tr>
<tr>
<td>EUC_CN</td>
<td>Extended UNIX Code-CN</td>
<td>Simplified Chinese</td>
<td>Yes</td>
<td>1-3</td>
<td></td>
</tr>
</tbody>
</table>

1 Not all APIs support all the listed character sets. For example, the JDBC driver does not support MULE_INTERNAL, LATIN6, LATIN8, and LATIN10.

Setting the Character Set

gpinitsystem defines the default character set for a Greenplum Database system by reading the setting of the `ENCODING` parameter in the `gp_init_config` file at initialization time. The default character set is `UNICODE` or `UTF8`.

---

2 The SQL_ASCII setting behaves considerably differently from the other settings. Byte values 0-127 are interpreted according to the ASCII standard, while byte values 128-255 are taken as uninterpreted characters. If you are working with any non-ASCII data, it is unwise to use the SQL_ASCII setting as a client encoding. SQL_ASCII is not supported as a server encoding.
You can create a database with a different character set besides what is used as the system-wide default. For example:

```
=> CREATE DATABASE korean WITH ENCODING 'EUC_KR';
```

**Important:** Although you can specify any encoding you want for a database, it is unwise to choose an encoding that is not what is expected by the locale you have selected. The `LC_COLLATE` and `LC_CTYPE` settings imply a particular encoding, and locale-dependent operations (such as sorting) are likely to misinterpret data that is in an incompatible encoding.

Since these locale settings are frozen by `gpinitsystem`, the apparent flexibility to use different encodings in different databases is more theoretical than real.

One way to use multiple encodings safely is to set the locale to `C` or `POSIX` during initialization time, thus disabling any real locale awareness.

### Character Set Conversion Between Server and Client

Greenplum Database supports automatic character set conversion between server and client for certain character set combinations. The conversion information is stored in the master `pg_conversion` system catalog table. Greenplum Database comes with some predefined conversions or you can create a new conversion using the SQL command `CREATE CONVERSION`.

#### Table 9: Client/Server Character Set Conversions

<table>
<thead>
<tr>
<th>Server Character Set</th>
<th>Available Client Character Sets</th>
</tr>
</thead>
<tbody>
<tr>
<td>BIG5</td>
<td>not supported as a server encoding</td>
</tr>
<tr>
<td>EUC_CN</td>
<td>EUC_CN, MULE_INTERNAL, UTF8</td>
</tr>
<tr>

<tr>
<td>WIN1258</td>
<td>WIN1258, UTF8</td>
</tr>
</tbody>
</table>

To enable automatic character set conversion, you have to tell Greenplum Database the character set (encoding) you would like to use in the client. There are several ways to accomplish this:

- Using the `\encoding` command in `psql`, which allows you to change client encoding on the fly.
- Using `SET client_encoding TO`. Setting the client encoding can be done with this SQL command:
  
  ```
  => SET CLIENT_ENCODING TO 'value';
  ```

To query the current client encoding:

  ```
  => SHOW client_encoding;
  ```

To return to the default encoding:

  ```
  => RESET client_encoding;
  ```
• Using the PGCLIENTENCODING environment variable. When PGCLIENTENCODING is defined in the client’s environment, that client encoding is automatically selected when a connection to the server is made. (This can subsequently be overridden using any of the other methods mentioned above.)

• Setting the configuration parameter client_encoding. If client_encoding is set in the master postgresql.conf file, that client encoding is automatically selected when a connection to Greenplum Database is made. (This can subsequently be overridden using any of the other methods mentioned above.)

If the conversion of a particular character is not possible — suppose you chose EUC_JP for the server and LATIN1 for the client, then some Japanese characters do not have a representation in LATIN1 — then an error is reported.

If the client character set is defined as SQL_ASCII, encoding conversion is disabled, regardless of the server’s character set. The use of SQL_ASCII is unwise unless you are working with all-ASCII data. SQL_ASCII is not supported as a server encoding.
Upgrading from an Earlier Greenplum 6 Release

The upgrade path supported for this release is Greenplum Database 6.x to a newer Greenplum Database 6.x release. Direct upgrade from Greenplum Database 4 or 5 to Greenplum 6 is not supported.

Important: Set the Greenplum Database timezone to a value that is compatible with your host systems. Setting the Greenplum Database timezone prevents Greenplum Database from selecting a timezone each time the cluster is restarted and sets the timezone for the Greenplum Database master and segment instances. After you upgrade to this release and if you have not set a Greenplum Database timezone value, verify that the selected Greenplum Database timezone is acceptable for your deployment. See Configuring Timezone and Localization Settings for more information.

Prerequisites

Before starting the upgrade process, perform the following checks.

• Verify the health of the Greenplum Database host hardware, and verify that the hosts meet the requirements for running Greenplum Database. The Greenplum Database gpcheckperf utility can assist you in confirming the host requirements.

Note: If you need to run the gpcheckcat utility, run it a few weeks before the upgrade during a maintenance period. If necessary, you can resolve any issues found by the utility before the scheduled upgrade.

The utility is in S$GPHOME/bin. Place Greenplum Database in restricted mode when you run the gpcheckcat utility. See the Greenplum Database Utility Guide for information about the gpcheckcat utility.

If gpcheckcat reports catalog inconsistencies, you can run gpcheckcat with the -g option to generate SQL scripts to fix the inconsistencies.

After you run the SQL scripts, run gpcheckcat again. You might need to repeat the process of running gpcheckcat and creating SQL scripts to ensure that there are no inconsistencies. Run the SQL scripts generated by gpcheckcat on a quiescent system. The utility might report false alerts if there is activity on the system.

Important: If the gpcheckcat utility reports errors, but does not generate a SQL script to fix the errors, contact Pivotal Support. Information for contacting Pivotal Support is at https://support.pivotal.io.

• During the migration process from Greenplum Database 6, a backup is made of some files and directories in $MASTER_DATA_DIRECTORY. Manually back up and remove any remaining files and directories from the $MASTER_DATA_DIRECTORY before migration. For information about the Greenplum Database migration utilities, see the Release Notes.

If you have configured the Greenplum Platform Extension Framework (PXF) in your previous Greenplum Database installation, you must stop the PXF service, and you might need to back up PXF configuration files before upgrading to a new version of Greenplum Database. Refer to PXF Pre-Upgrade Actions for instructions.

If you have not yet configured PXF, no action is necessary.

Upgrading from 6.x to a Newer 6.x Release

An upgrade from Greenplum Database 6.x to a newer 6.x release involves stopping Greenplum Database, updating the Greenplum Database software binaries, and restarting Greenplum Database. If you are using Greenplum Database extension packages there are additional requirements. See Prerequisites in the previous section.
1. Log in to your Greenplum Database master host as the Greenplum administrative user:

   $ su - gpadmin

2. Perform a smart shutdown of your Greenplum Database 6.x system (there can be no active connections to the database). This example uses the -a option to disable confirmation prompts:

   $ gpstop -a

3. Copy the new Greenplum Database software installation package to the gpadmin user’s home directory on each master, standby, and segment host.

4. As root, install the new Greenplum Database software release on each host. For example, on RHEL/CentOS systems:

   $ sudo yum install greenplum-db-<version>-<platform>.rpm

   On Ubuntu systems:

   # apt install ./greenplum-db-<version>-<platform>.deb

5. Update the permissions for the new installation. For example, run this command as root to change the user and group of the installed files to gpadmin.

   $ sudo chown -R gpadmin:gpadmin /usr/local/greenplum* 

6. If needed, update the greenplum_path.sh file on the master and standby master hosts for use with your specific installation. These are some examples.

   - If Greenplum Database uses LDAP authentication, edit the greenplum_path.sh file to add the line:

     ```bash
     export LDAPCONF=/etc/openldap/ldap.conf
     ```

   - If Greenplum Database uses PL/Java, you might need to set or update the environment variables JAVA_HOME and LD_LIBRARY_PATH in greenplum_path.sh.

     **Note:** When comparing the previous and new greenplum_path.sh files, be aware that installing some Greenplum Database extensions also updates the greenplum_path.sh file. The greenplum_path.sh from the previous release might contain updates that were the result of installing those extensions.

7. Edit the environment of the Greenplum Database superuser (gpadmin) and make sure you are sourcing the greenplum_path.sh file for the new installation. For example change the following line in the .bashrc or your chosen profile file:

   ```bash
   source /usr/local/greenplum-db-<current_version>/greenplum_path.sh
   ```

   to:

   ```bash
   source /usr/local/greenplum-db-<new_version>/greenplum_path.sh
   ```

   Or if you are sourcing a symbolic link (/usr/local/greenplum-db) in your profile files, update the link to point to the newly installed version. For example:

   ```bash
   $ rm /usr/local/greenplum-db
   $ ln -s /usr/local/greenplum-db-<new_version> /usr/local/greenplum-db
   ```

8. Source the environment file you just edited. For example:

   $ source ~/.bashrc
9. Use the Greenplum Database gppkg utility to re-install Greenplum Database extensions. If you were previously using any Greenplum Database extensions such as pgcrypto, PL/R, PL/Java, or PostGIS, download the corresponding packages from Pivotal Network, and install using this utility. See the extension documentation for details.

Also copy any files that are used by the extensions (such as JAR files, shared object files, and libraries) from the previous version installation directory to the new version installation directory on the master and segment host systems.

10. After all segment hosts have been upgraded, log in as the gpadmin user and restart your Greenplum Database system:

```
# su - gpadmin
$ gpstart
```

11. If you configured PXF in your previous Greenplum Database installation, you must re-initialize the PXF service after you upgrade Greenplum Database. Refer to Upgrading PXF for instructions.

After upgrading Greenplum Database, ensure that all features work as expected. For example, test that backup and restore perform as expected, and Greenplum Database features such as user-defined functions, and extensions such as MADlib and PostGIS perform as expected.

**Troubleshooting a Failed Upgrade**

If you experience issues during the migration process and have active entitlements for Greenplum Database that were purchased through Pivotal, contact Pivotal Support. Information for contacting Pivotal Support is at [https://support.pivotal.io](https://support.pivotal.io).

**Be prepared to provide the following information:**

- A completed Upgrade Procedure
- Log output from gpcheckcat (located in ~/gpAdminLogs)
Migrating Data from Greenplum 4.3 or 5

You can migrate data from Greenplum Database 4.3 or 5 to Greenplum 6 using the standard backup and restore procedures, gpbackup and gprestore, or by using gpcopy.

**Note:** Currently, you cannot upgrade a Greenplum Database 4.3 or 5 system directly to Greenplum Database 6.

This topic identifies known issues you may encounter when moving data from Greenplum 4.3 to Greenplum 6. You can work around these problems by making needed changes to your Greenplum 4.3 databases so that you can create backups that can be restored successfully to Greenplum 6.

- Preparing the Greenplum 6 Cluster
- Preparing Greenplum 4.3 and 5 Databases for Backup
- Backing Up and Restoring a Database
- Completing the Migration

**Preparing the Greenplum 6 Cluster**

- Install and initialize a new Greenplum Database 6 cluster using the version 6 gpinit system utility.

  **Note:** gprestore only supports restoring data to a cluster that has an identical number of hosts and an identical number of segments per host, with each segment having the same content_id as the segment in the original cluster. Use gpcopy if you need to migrate data to a different-sized Greenplum 6 cluster.

  **Note:** Set the Greenplum Database 6 timezone to a value that is compatible with your host systems. Setting the Greenplum Database timezone prevents Greenplum Database from selecting a timezone each time the cluster is restarted. See Configuring Timezone and Localization Settings for more information.

- Install the latest release of the Greenplum Backup and Restore utilities, available to download from Pivotal Network.

- If you intend to install Greenplum Database 6 on the same hardware as your 4.3 system, you will need enough disk space to accommodate over five times the original data set (two full copies of the primary and mirror data sets, plus the original backup data in ASCII format) in order to migrate data with gpbackup and gprestore. Keep in mind that the ASCII backup data will require more disk space than the original data, which may be stored in compressed binary format. Offline backup solutions such as Dell EMC Data Domain can reduce the required disk space on each host.

  If you want to migrate your data on the same hardware but do not have enough free disk space on your host systems, gpcopy provides the --truncate-source-after option to truncate each source table after copying the table to the destination cluster and validating that the copy succeeded. This reduces the amount of free space needed to migrate clusters that reside on the same hardware. See Migrating Data with gpcopy for more information.

- Install any external modules used in your Greenplum 4.3 system in the Greenplum 6 system before you restore the backup, for example MADlib or PostGIS. If versions of the external modules are not compatible, you may need to exclude tables that reference them when restoring the Greenplum 4.3 backup to Greenplum 6.

- The Greenplum 4.3 Oracle Compatibility Functions module is not compatible with Greenplum 6. Uninstall the module from Greenplum 4.3 by running the uninstall_orafunc.sql script before you back up your databases:

  ```bash
  $ $GPHOME/share/postgresql/contrib/uninstall_orafunc.sql
  ```

  You will also need to drop any dependent database objects that reference compatibility functions.
Install the Oracle Compatibility Functions in Greenplum 6 by creating the `orafce` module in each database where you require the functions:

```
$ psql -d dbname 'CREATE EXTENSION orafce'
```

See [Installing Additional Supplied Modules](#) for information about installing `orafce` and other modules.

- When restoring language-based user-defined functions, the shared object file must be in the location specified in the `CREATE FUNCTION` SQL command and must have been recompiled on the Greenplum 6 system. This applies to user-defined functions, user-defined types, and any other objects that use custom functions, such as aggregates created with the `CREATE AGGREGATE` command.
- Greenplum 6 provides resource groups, an alternative to managing resources using resource queues. Setting the `gp_resource_manager` server configuration parameter to `queue` or `group` selects the resource management scheme the Greenplum Database system will use. The default is `queue`, so no action is required when you move from Greenplum version 4.3 to version 6. To more easily transition from resource queues to resource groups, you can set resource groups to allocate and manage memory in a way that is similar to resource queue memory management. To select this feature, set the `MEMORY_LIMIT` and `MEMORY_SPILL_RATIO` attributes of your resource groups to 0. See [Using Resource Groups](#) for information about enabling and configuring resource groups.

### Preparing Greenplum 4.3 and 5 Databases for Backup

**Note:** A Greenplum 4 system must be at least version 4.3.22 to use the `gpbackup` and `gprestore` utilities. A Greenplum 5 system must be at least version 5.5. Be sure to use the latest release of the backup and restore utilities, available for download from [Pivotal Network](#).

**Important:** Make sure that you have a complete backup of all data in the Greenplum Database 4.3 or 5 cluster, and that you can successfully restore the Greenplum Database cluster if necessary.

Following are some issues that are known to cause errors when restoring a Greenplum 4.3 or 5 backup to Greenplum 6. Keep a list of any changes you make to the Greenplum 4.3 or 5 database to enable migration so that you can fix them in Greenplum 6 after restoring the backup.

- If you have configured PXF in your Greenplum Database 5 installation, review [Migrating PXF from Greenplum 5](#) to plan for the PXF migration.
- Greenplum Database version 6 removes support for the `gphdfs` protocol. If you have created external tables that use `gphdfs`, remove the external table definitions and (optionally) recreate them to use Pivotal Extension Framework (PXF) before you migrate the data to Greenplum 6. Refer to [Migrating gphdfs External Tables to PXF](#) in the PXF documentation for the migration procedure.
- References to catalog tables or their attributes can cause a restore to fail due to catalog changes from Greenplum 4.3 or 5 to Greenplum 6. Here are some catalog issues to be aware of when migrating to Greenplum 6:

  - In the `pg_class` system table, the `reltoastidxid` column has been removed.
  - In the `pg_stat_replication` system table, the `procpid` column is renamed to `pid`.
  - In the `pg_stat_activity` system table, the `procpid` column is renamed to `pid`. The `current_query` column is replaced by two columns `state`: the state of the backend, and `query`: the last run query, or currently running query if `state` is `active`.
  - In the `gp_distribution_policy` system table, the `attrnums` column is renamed to `distkey` and its data type is changed to `int2vector`. A backend function `pg_get_table_distributedby()` was added to get the distribution policy for a table as a string.
  - The `__gp_localid` and `__gp_masterid` columns are removed from the `session_level_memory_consumption` system view in Greenplum 6. The underlying external tables and functions are removed from the `gp_toolkit` schema.
  - Filespaces are removed in Greenplum 6. The `pg_filespace` and `pg_filespace_entry` system tables are removed. Any reference to `pg_filespace` or `pg_filespace_entry` will fail in Greenplum 6.
Installing and Upgrading Greenplum

• Restoring a Greenplum 4 backup can fail due to lack of dependency checking in Greenplum 4 catalog tables. For example, restoring a UDF can fail if it references a custom data type that is created later in the backup file.

• The `INTO error_table` clause of the CREATE EXTERNAL TABLE and COPY commands was deprecated in Greenplum 4.3 and is unsupported in Greenplum 5 and 6. Remove this clause from any external table definitions before you create a backup of your Greenplum 4.3 system. The ERROR_TABLE parameter of the `gpload` utility load control YAML file must also be removed from any `gpload` YAML files before you run `gpload`.

• The `int4_avg_accum()` function signature changed in Greenplum 6 from `int4_avg_accum(bytea, integer)` to `int4_avg_accum(bigint[], integer)`. This function is the state transition function (`sfunc`) called when calculating the average of a series of 4-byte integers. If you have created a custom aggregate in a previous Greenplum release that called the built-in `int4_avg_accum()` function, you will need to revise your aggregate for the new signature.

• The `string_agg(expression)` function has been removed from Greenplum 6. The function concatenates text values into a string. You can replace the single argument function with the function `string_agg(expression, delimiter)` and specify an empty string as the delimiter, for example `string_agg(txt_col1, '')`.

• The `offset` argument of the `lag(expr, offset[, default])` window function has changed from `int8` in Greenplum 4.3 to `int4` in Greenplum 5 and 6.

• `gpbackup` saves the distribution policy and distribution key for each table in the backup so that data can be restored to the same segment. If a table's distribution key in the Greenplum 4.3 or 5 database is incompatible with Greenplum 6, `gprestore` cannot restore the table to the correct segment in the Greenplum 6 database. This can happen if the distribution key in the older Greenplum release has columns with data types not allowed in Greenplum 6 distribution keys, or if the data representation for data types has changed or is insufficient for Greenplum 6 to generate the same hash value for a distribution key. You should correct these kinds of problems by altering distribution keys in the tables before you back up the Greenplum database.

• Greenplum 6 requires primary keys and unique index keys to match a table's distribution key. The leaf partitions of partitioned tables must have the same distribution policy as the root partition. These known issues should be corrected in the source Greenplum database before you back up the database:

  • If the primary key is different than the distribution key for a table, alter the table to either remove the primary key or change the primary key to match the distribution key.
  • If the key columns for a unique index are not a subset of the distribution key columns, before you back up the source database, drop the index and, optionally, recreate it with a compatible key.
  • If a partitioned table in the source database has a `DISTRIBUTED BY` distribution policy, but has leaf partitions that are `DISTRIBUTED RANDOMLY`, alter the leaf tables to match the root table distribution policy before you back up the source database.

• In Greenplum 4.3, the name provided for a constraint in a CREATE TABLE command was the name of the index created to enforce the constraint, which could lead to indexes having the same name. In Greenplum 6, duplicate index names are not allowed; restoring from a Greenplum 4.3 backup that has duplicate index names will generate errors.

• Columns of type `abstime`, `reltime`, `tinterval`, `money`, or `anyarray` are not supported as distribution keys in Greenplum 6.

If you have tables distributed on columns of type `abstime`, `reltime`, `tinterval`, `money`, or `anyarray`, use the ALTER TABLE command to set the distribution to `RANDOM` before you back up the database. After the data is restored, you can set a new distribution policy.

• In Greenplum 4.3 and 5, it was possible to ALTER a table that has a primary key or unique index to be `DISTRIBUTED RANDOMLY`. Greenplum 6 does not permit tables `DISTRIBUTED RANDOMLY` to have primary keys or unique indexes. Restoring such a table from a Greenplum 4.3 or 5 backup will cause an error.

• Greenplum 6 no longer automatically converts from the deprecated timestamp format `YYYYMMDHH24MISS`. The format could not be parsed unambiguously in previous Greenplum Database releases. You can still specify the `YYYYMMDHH24MISS` format in conversion functions.
such as to_timestamp and to_char for compatibility with other database systems. You can use input formats for converting text to date or timestamp values to avoid unexpected results or query execution failures.

- Creating a table using the CREATE TABLE AS command in Greenplum 4.3 or 5 could create a table with a duplicate distribution key. The gpbackup utility saves the table to the backup using a CREATE TABLE command that lists the duplicate keys in the DISTRIBUTED BY clause. Restoring this backup will cause a duplicate distribution key error. The CREATE TABLE AS command was fixed in Greenplum 5.10 to disallow duplicate distribution keys.

- Greenplum 4.3 supports foreign key constraints on columns of different types, for example, numeric and bigint, with implicit type conversion. Greenplum 5 and 6 do not support implicit type conversion. Restoring a table with a foreign key on columns with different data types causes an error.

- Only Boolean operators can use Boolean negators. In Greenplum Database 4.3 and 5 it was possible to create a non-Boolean operator that specifies a Boolean negator function. For example, this CREATE OPERATOR command creates an integer @@ operator with a Boolean negator:

```sql
CREATE OPERATOR public.@@ (
    PROCEDURE = int4pl,
    LEFTARG = integer,
    RIGHTARG = integer,
    NEGATOR = OPERATOR(public.!!)
);
```

If you restore a backup containing an operator like this to a Greenplum 6 system, gprestore produces an error: **ERROR: only boolean operators can have negators (SQLSTATE 42P13).**

- In Greenplum Database 4.3 and 5, the undocumented server configuration parameter allow_system_table_mods could have a value of none, ddl, dml, or all. In Greenplum 6, this parameter has changed to a Boolean value, with a default value of false. If there are any references to this parameter in the source database, remove them to prevent errors during the restore.

## Backing Up and Restoring a Database

First use gpbackup to create a --metadata-only backup from the source Greenplum database and restore it to the Greenplum 6 system. This helps find any additional problems that are not identified in Preparing Greenplum 4.3 and 5 Databases for Backup. Refer to the Greenplum Backup and Restore documentation for syntax and examples for the gpbackup and gprestore utilities.

Review the gprestore log file for error messages and correct any remaining problems in the source Greenplum database.

When you are able to restore a metadata backup successfully, create the full backup and then restore it to the Greenplum 6 system, or use gpcopy to transfer the data. If needed, use the gpbackup or gprestore filter options to omit schemas or tables that cannot be restored without error.

If you use gpcopy to migrate data, initiate the gpcopy operation from the Greenplum 4.3 or 5 cluster. See Migrating Data with gpcopy for more information.

**Important:** When you restore a backup taken from a Greenplum Database 4.3 or 5 system, gprestore warns that the restore will use legacy hash operators when loading the data. This is because Greenplum 6 has new hash algorithms that map distribution keys to segments, but the data in the backup set must be restored to the same segments as the cluster from which the backup was taken. The gprestore utility sets the gp_use_legacy_hashops server configuration parameter to on when restoring to Greenplum 6 from an earlier version so that the restored tables are created using the legacy operator classes instead of the new default operator classes.

After restoring, you can redistribute these tables with the gp_use_legacy_hashops parameter set to off so that the tables use the new Greenplum 6 hash operators. See Working With Hash Operator Classes in Greenplum 6 for more information and examples.
Completing the Migration

Migrate any tables you skipped during the restore using other methods, for example using the \texttt{COPY TO} command to create an external file and then loading the data from the external file into Greenplum 6 with the \texttt{COPY FROM} command.

Recreate any objects you dropped in the Greenplum 4.3 or 5 database to enable migration, such as external tables, indexes, user-defined functions, or user-defined aggregates.

Here are some additional items to consider to complete your migration to Greenplum 6.

- If you are migrating from Greenplum Database 4.3.27 or an earlier 4.3.x release and have configured PgBouncer in your Greenplum Database installation, you must migrate to the new PgBouncer when you upgrade Greenplum Database. Refer to Migrating PgBouncer for specific migration instructions.

- Greenplum Database 5 and 6 remove automatic casts between the text type and other data types. After you migrate from Greenplum Database version 4.3 to version 6, this changed behavior may impact existing applications and queries. Refer to About Implicit Text Casting in Greenplum Database for information, including a discussion about supported and unsupported workarounds.

- After migrating data you may need to modify SQL scripts, administration scripts, and user-defined functions as necessary to account for changes in Greenplum Database version 6. Review the Pivotal Greenplum 6.0.0 Release Notes for features and changes that may necessitate post-migration tasks.

- To use the new Greenplum 6 default hash operator classes, use the command \texttt{ALTER TABLE <table> SET DISTRIBUTED BY (<key>)} to redistribute tables restored from Greenplum 4.3 or 5 backups. The \texttt{gp\_use\_legacy\_hashops} parameter must be set to \texttt{off} when you execute the command. See Working With Hash Operator Classes in Greenplum 6 for more information about hash operator classes.

Working With Hash Operator Classes in Greenplum 6

Greenplum 6 has new \textit{jump consistent} hash operators that map distribution keys for distributed tables to the segments. The new hash operators enable faster database expansion because they don’t require redistributing rows unless they map to a different segment. The hash operators used in Greenplum 4.3 and 5 are present in Greenplum 6 as non-default legacy hash operator classes. For example, for integer columns, the new hash operator class is named \texttt{int\_ops} and the legacy operator class is named \texttt{cdbhash\_int\_ops}.

This example creates a table using the legacy hash operator class \texttt{cdbhash\_int\_ops}.

```
test=# SET gp\_use\_legacy\_hashops=on;
SET
test=# CREATE TABLE t1 (  
    c1 integer,  
    c2 integer,  
    p integer  
  ) DISTRIBUTED BY (c1);  
CREATE TABLE  

Test=# \texttt{\textbackslash d+ t1}  

| Column | Type    | Modifiers | Storage | Stats target | Description |
|--------+---------+-----------+---------+--------------+-------------|
| c1     | integer |           | plain   |              |             |
| c2     | integer |           | plain   |              |             |
| p      | integer |           | plain   |              |             |
Distributed by: (c1)
```
Notice that the distribution key is `c1`. If the `gp_use_legacy_hashops` parameter is on and the operator class is a legacy operator class, the operator class name is not shown. However, if `gp_use_legacy_hashops` is off, the legacy operator class name is reported with the distribution key.

```
SET gp_use_legacy_hashops=off;
```

```
test=# \d+ t1
Table "public.t1"

| Column | Type   | Modifiers | Storage | Stats target | Description          |
|--------+---------+-----------+---------+--------------+----------------------|
| c1     | integer |           | plain   |              |                      |
| c2     | integer |           | plain   |              |                      |
| p      | integer |           | plain   |              |                      |
Distributed by: (c1 cdbhash_int4_ops)
```

The operator class name is reported only when it does not match the setting of the `gp_use_legacy_hashops` parameter.

To change the table to use the new jump consistent operator class, use the `ALTER TABLE` command to redistribute the table with the `gp_use_legacy_hashops` parameter set to off.

**Note:** Redistributing tables with a large amount of data can take a long time.

```
SHOW gp_use_legacy_hashops;
```

```
gp_use_legacy_hashops
-----------------------
off
(1 row)
```

```
ALTER TABLE t1 SET DISTRIBUTED BY (c1);
```

```
test=# \d+ t1
Table "public.t1"

| Column | Type   | Modifiers | Storage | Stats target | Description          |
|--------+---------+-----------+---------+--------------+----------------------|
| c1     | integer |           | plain   |              |                      |
| c2     | integer |           | plain   |              |                      |
| p      | integer |           | plain   |              |                      |
Distributed by: (c1)
```

To verify the default jump consistent operator class has been used, set `gp_use_legacy_hashops` to on before you show the table definition.

```
SET gp_use_legacy_hashops=on;
```

```
test=# \d+ t1
Table "public.t1"

| Column | Type   | Modifiers | Storage | Stats target | Description          |
|--------+---------+-----------+---------+--------------+----------------------|
| c1     | integer |           | plain   |              |                      |
| c2     | integer |           | plain   |              |                      |

```
Enabling iptables (Optional)

On Linux systems, you can configure and enable the `iptables` firewall to work with Greenplum Database.

**Note:** Greenplum Database performance might be impacted when `iptables` is enabled. You should test the performance of your application with `iptables` enabled to ensure that performance is acceptable.

For more information about `iptables` see the `iptables` and firewall documentation for your operating system. See also *Disabling SELinux and Firewall Software*.

### How to Enable iptables

1. As `gpadmin`, run this command on the Greenplum Database master host to stop Greenplum Database:
   
   ```
   $ gpstop -a
   ```

2. On the Greenplum Database hosts:
   
   a. Update the file `/etc/sysconfig/iptables` based on the *Example iptables Rules*.
   
   b. As root user, run these commands to enable `iptables`:
      
      ```
      # chkconfig iptables on
      # service iptables start
      ```

3. As `gpadmin`, run this command on the Greenplum Database master host to start Greenplum Database:
   
   ```
   $ gpstart -a
   ```

   **Warning:** After enabling `iptables`, this error in the `/var/log/messages` file indicates that the setting for the `iptables` table is too low and needs to be increased.

   ```
   ip_conntrack: table full, dropping packet.
   ```

   As root, run this command to view the `iptables` table value:

   ```
   # sysctl net.ipv4.netfilter.ip_conntrack_max
   ```

   To ensure that the Greenplum Database workload does not overflow the `iptables` table, as root, set it to the following value:

   ```
   # sysctl net.ipv4.netfilter.ip_conntrack_max=6553600
   ```

   The value might need to be adjusted for your hosts. To maintain the value after reboot, you can update the `/etc/sysctl.conf` file as discussed in *Setting the Greenplum Recommended OS Parameters*.

### Example iptables Rules

When `iptables` is enabled, `iptables` manages the IP communication on the host system based on configuration settings (rules). The example rules are used to configure `iptables` for Greenplum Database master host, standby master host, and segment hosts.

- *Example Master and Standby Master iptables Rules*
- *Example Segment Host iptables Rules*
The two sets of rules account for the different types of communication Greenplum Database expects on the master (primary and standby) and segment hosts. The rules should be added to the `/etc/sysconfig/iptables` file of the Greenplum Database hosts. For Greenplum Database, `iptables` rules should allow the following communication:

- For customer facing communication with the Greenplum Database master, allow at least `postgres` and 28080 (eth1 interface in the example).
- For Greenplum Database system interconnect, allow communication using `tcp`, `udp`, and `icmp` protocols (eth4 and eth5 interfaces in the example).

The network interfaces that you specify in the `iptables` settings are the interfaces for the Greenplum Database hosts that you list in the `hostfile_gpinitsystem` file. You specify the file when you run the `gpinitsystem` command to initialize a Greenplum Database system. See `Initializing a Greenplum Database System` for information about the `hostfile_gpinitsystem` file and the `gpinitsystem` command.

- For the administration network on a Greenplum DCA, allow communication using `ssh`, `ntp`, and `icmp` protocols. (eth0 interface in the example).

In the `iptables` file, each append rule command (lines starting with `-A`) is a single line.

The example rules should be adjusted for your configuration. For example:

- The append command, the `-A` lines and connection parameter `-i` should match the connectors for your hosts.
- the CIDR network mask information for the source parameter `-s` should match the IP addresses for your network.

**Example Master and Standby Master iptables Rules**

Example `iptables` rules with comments for the `/etc/sysconfig/iptables` file on the Greenplum Database master host and standby master host.

```sh
*filter
# Following 3 are default rules. If the packet passes through
# the rule set it gets these rule.
# Drop all inbound packets by default.
# Drop all forwarded (routed) packets.
# Let anything outbound go through.
:INPUT DROP [0:0]
:FORWARD DROP [0:0]
:OUTPUT ACCEPT [0:0]
# Accept anything on the loopback interface.
-A INPUT -i lo -j ACCEPT
# If a connection has already been established allow the
# remote host packets for the connection to pass through.
-A INPUT -m state --state ESTABLISHED,RELATED -j ACCEPT
# These rules let all tcp and udp through on the standard
# interconnect IP addresses and on the interconnect interfaces.
# NOTE: gpsyncmaster uses random tcp ports in the range 1025 to 65535
# and Greenplum Database uses random udp ports in the range 1025 to 65535.
-A INPUT -i eth4 -p udp -s 192.0.2.0/22 -j ACCEPT
-A INPUT -i eth5 -p udp -s 198.51.100.0/22 -j ACCEPT
-A INPUT -i eth4 -p tcp -s 192.0.2.0/22 -j ACCEPT --syn --state NEW
-A INPUT -i eth5 -p tcp -s 198.51.100.0/22 -j ACCEPT --syn --state NEW
-A INPUT -i eth0 -p udp --dport ntp -s 203.0.113.0/21 -j ACCEPT
-A INPUT -i eth0 -p tcp --dport ntp -s 203.0.113.0/21 -j ACCEPT --syn --state NEW
-A INPUT -i eth0 -p tcp --dport ssh -s 203.0.113.0/21 -j ACCEPT --syn --state NEW
-A INPUT -p tcp --dport ssh -j ACCEPT --syn --state NEW
-A INPUT -p tcp --dport ntp -j ACCEPT
-A INPUT -p tcp --dport ssh -j ACCEPT --syn --state NEW
-A INPUT -p tcp --dport ssh -j ACCEPT --syn --state NEW
-A INPUT -p tcp --dport ssh -j ACCEPT --syn --state NEW
-A INPUT -p tcp --dport ssh -j ACCEPT --syn --state NEW
-A INPUT -p tcp --dport ssh -j ACCEPT --syn --state NEW
-A INPUT -p tcp --dport ssh -j ACCEPT --syn --state NEW
-A INPUT -p tcp --dport ssh -j ACCEPT --syn --state NEW
-A INPUT -p tcp --dport ssh -j ACCEPT --syn --state NEW
-A INPUT -p tcp --dport ssh -j ACCEPT --syn --state NEW
-A INPUT -p tcp --dport ssh -j ACCEPT --syn --state NEW
-A INPUT -p tcp --dport ssh -j ACCEPT --syn --state NEW
-A INPUT -p tcp --dport ssh -j ACCEPT --syn --state NEW
-A INPUT -p tcp --dport ssh -j ACCEPT --syn --state NEW
-A INPUT -p tcp --dport ssh -j ACCEPT --syn --state NEW
-A INPUT -p tcp --dport ssh -j ACCEPT --syn --state NEW
-A INPUT -p tcp --dport ssh -j ACCEPT --syn --state NEW
-A INPUT -p tcp --dport ssh -j ACCEPT --syn --state NEW
-A INPUT -p tcp --dport ssh -j ACCEPT --syn --state NEW
-A INPUT -p tcp --dport ssh -j ACCEPT --syn --state NEW
-A INPUT -p tcp --dport ssh -j ACCEPT --syn --state NEW
-A INPUT -p tcp --dport ssh -j ACCEPT --syn --state NEW
-A INPUT -p tcp --dport ssh -j ACCEPT --syn --state NEW
-A INPUT -p tcp --dport ssh -j ACCEPT --syn --state NEW
-A INPUT -p tcp --dport ssh -j ACCEPT --syn --state NEW
-A INPUT -p tcp --dport ssh -j ACCEPT --syn --state NEW
-A INPUT -p tcp --dport ssh -j ACCEPT --syn --state NEW
-A INPUT -p tcp --dport ssh -j ACCEPT --syn --state NEW
-A INPUT -p tcp --dport ssh -j ACCEPT --syn --state NEW
-A INPUT -p tcp --dport ssh -j ACCEPT --syn --state NEW
-A INPUT -p tcp --dport ssh -j ACCEPT --syn --state NEW
-A INPUT -p tcp --dport ssh -j ACCEPT --syn --state NEW
-A INPUT -p tcp --dport ssh -j ACCEPT --syn --state NEW
-A INPUT -p tcp --dport ssh -j ACCEPT --syn --state NEW
-A INPUT -p tcp --dport ssh -j ACCEPT --syn --state NEW
-A INPUT -p tcp --dport ssh -j ACCEPT --syn --state NEW
-A INPUT -p tcp --dport ssh -j ACCEPT --syn --state NEW
-A INPUT -p tcp --dport ssh -j ACCEPT --syn --state NEW
```
Example Segment Host iptables Rules

Example iptables rules for the /etc/sysconfig/iptables file on the Greenplum Database segment hosts. The rules for segment hosts are similar to the master rules with fewer interfaces and fewer udp and tcp services.

```bash
*filter
:INPUT DROP
:FORWARD DROP
:OUTPUT ACCEPT
-A INPUT -i lo -j ACCEPT
-A INPUT -i eth3 -p udp -s 192.0.2.0/22 -j ACCEPT
-A INPUT -i eth2 -p tcp -s 192.0.2.0/22 -j ACCEPT
-A INPUT -p tcp --dport ssh -j ACCEPT --syn -m state --state NEW
-A INPUT -i eth3 -p icmp --icmp-type echo-request -s 198.51.100.0/22 -j ACCEPT
-A INPUT -i eth3 -p tcp -s 198.51.100.0/22 -j ACCEPT --syn -m state --state NEW
-A INPUT -i eth2 -p tcp -s 198.51.100.0/22 -j ACCEPT --syn -m state --state NEW
-A INPUT -i eth0 -p icmp --icmp-type echo-request -s 203.0.113.0/21 -j ACCEPT
-A INPUT -m limit --limit 5/min -j LOG --log-prefix "iptables denied: " --log-level 7
COMMIT
```
Installation Management Utilities

References for the command-line management utilities used to install and initialize a Greenplum Database system.

For a full reference of all Greenplum Database utilities, see the *Greenplum Database Utility Guide*.

The following Greenplum Database management utilities are located in `$GPHOME/bin`.

- gpactivatestandby
- gpaddmirrors
- gpcheckperf
- gpcopy
- gpdeletefilesystem
- gpinitstandby
- gpinstsystem
- gppkg
- gpscp
- gpssh
- gpssh-exkeys
- gpstart
- gpstop
Greenplum Environment Variables

Reference of the environment variables to set for Greenplum Database.

Set these in your user's startup shell profile (such as ~/.bashrc or ~/.bash_profile), or in /etc/profile if you want to set them for all users.

Required Environment Variables

Note: GPHOME, PATH and LD_LIBRARY_PATH can be set by sourcing the greenplum_path.sh file from your Greenplum Database installation directory

GPHOME

This is the installed location of your Greenplum Database software. For example:

```
GPHOME=/usr/local/greenplum-db-6.x.x
export GPHOME
```

PATH

Your PATH environment variable should point to the location of the Greenplum Database bin directory. For example:

```
PATH=$GPHOME/bin:$PATH
export PATH
```

LD_LIBRARY_PATH

The LD_LIBRARY_PATH environment variable should point to the location of the Greenplum Database/PostgreSQL library files. For example:

```
LD_LIBRARY_PATH=$GPHOME/lib
export LD_LIBRARY_PATH
```

MASTER_DATA_DIRECTORY

This should point to the directory created by the gpinitsystem utility in the master data directory location. For example:

```
MASTER_DATA_DIRECTORY=/data/master/gpseg-1
export MASTER_DATA_DIRECTORY
```

Optional Environment Variables

The following are standard PostgreSQL environment variables, which are also recognized in Greenplum Database. You may want to add the connection-related environment variables to your profile for convenience, so you do not have to type so many options on the command line for client connections. Note that these environment variables should be set on the Greenplum Database master host only.
**PGAPPNAME**

The name of the application that is usually set by an application when it connects to the server. This name is displayed in the activity view and in log entries. The `PGAPPNAME` environmental variable behaves the same as the `application_name` connection parameter. The default value for `application_name` is `psql`. The name cannot be longer than 63 characters.

**PGDATABASE**

The name of the default database to use when connecting.

**PGHOST**

The Greenplum Database master host name.

**PGHOSTADDR**

The numeric IP address of the master host. This can be set instead of or in addition to `PGHOST` to avoid DNS lookup overhead.

**PGPASSWORD**

The password used if the server demands password authentication. Use of this environment variable is not recommended for security reasons (some operating systems allow non-root users to see process environment variables via `ps`). Instead consider using the `~/.pgpass` file.

**PGPASSFILE**

The name of the password file to use for lookups. If not set, it defaults to `~/.pgpass`. See the topic about *The Password File* in the PostgreSQL documentation for more information.

**PGOPTIONS**

Sets additional configuration parameters for the Greenplum Database master server.

**PGPORT**

The port number of the Greenplum Database server on the master host. The default port is 5432.

**PGUSER**

The Greenplum Database user name used to connect.

**PGDATESTYLE**

Sets the default style of date/time representation for a session. (Equivalent to `SET datestyle TO...`)

**PGTZ**

Sets the default time zone for a session. (Equivalent to `SET timezone TO...`)

**PGCLIENTENCODING**

Sets the default client character set encoding for a session. (Equivalent to `SET client_encoding TO...`)
Example Ansible Playbook

A sample Ansible playbook to install a Greenplum Database software release onto the hosts that will comprise a Greenplum Database system.

This Ansible playbook shows how tasks described in *Installing the Greenplum Database Software* might be automated using Ansible.

**Important:** This playbook is provided as an example only to illustrate how Greenplum Database cluster configuration and software installation tasks can be automated using provisioning tools such as Ansible, Chef, or Puppet. Pivotal does not provide support for Ansible or for the playbook presented in this example.

The example playbook is designed for use with CentOS 7. It creates the `gpadmin` user, installs the Greenplum Database software release, sets the owner and group of the installed software to `gpadmin`, and sets the Pam security limits for the `gpadmin` user.

You can revise the script to work with your operating system platform and to perform additional host configuration tasks.

Following are steps to use this Ansible playbook.

1. Install Ansible on the control node using your package manager. See the Ansible documentation for help with installation.
2. Set up passwordless SSH from the control node to all hosts that will be a part of the Greenplum Database cluster. You can use the `ssh-copy-id` command to install your public SSH key on each host in the cluster. Alternatively, your provisioning software may provide more convenient ways to securely install public keys on multiple hosts.
3. Create an Ansible inventory by creating a file called `hosts` with a list of the hosts that will comprise your Greenplum Database cluster. For example:

   ```
   mdw
   sdw1
   sdw2
   ...
   ```

   This file can be edited and used with the Greenplum Database `gpssh-exkeys` and `gpinitsystem` utilities later on.

4. Copy the playbook code below to a file `ansible-playbook.yml` on your Ansible control node.
5. Edit the playbook variables at the top of the playbook, such as the `gpadmin` administrative user and password to create, and the version of Greenplum Database you are installing.
6. Run the playbook, passing the package to be installed to the `package_path` parameter.

   ```bash
   ansible-playbook ansible-playbook.yml -i hosts -e package_path=./
   greenplum-db-6.0.0-rhel7-x86_64.rpm
   ```

Ansible Playbook - Greenplum Database Installation for CentOS 7

```
---
- hosts: all
  vars:
    - version: "6.0.0"
    - greenplum_admin_user: "gpadmin"
    - greenplum_admin_password: "changeme"
```
When the playbook has executed successfully, you can proceed with Creating the Data Storage Areas and Initializing a Greenplum Database System.
Chapter 6

Greenplum Database Administrator Guide

Information about configuring, managing and monitoring Greenplum Database installations, and administering, monitoring, and working with databases. The guide also contains information about Greenplum Database architecture and concepts such as parallel processing.
Greenplum Database Concepts

This section provides an overview of Greenplum Database components and features such as high availability, parallel data loading features, and management utilities.

This section contains the following topics:

- About the Greenplum Architecture
- About Management and Monitoring Utilities
- About Parallel Data Loading
- About Redundancy and Failover in Greenplum Database
- About Database Statistics in Greenplum Database

About the Greenplum Architecture

Greenplum Database is a massively parallel processing (MPP) database server with an architecture specially designed to manage large-scale analytic data warehouses and business intelligence workloads.

MPP (also known as a shared nothing architecture) refers to systems with two or more processors that cooperate to carry out an operation, each processor with its own memory, operating system and disks. Greenplum uses this high-performance system architecture to distribute the load of multi-terabyte data warehouses, and can use all of a system's resources in parallel to process a query.

Greenplum Database is based on PostgreSQL open-source technology. It is essentially several PostgreSQL disk-oriented database instances acting together as one cohesive database management system (DBMS). It is based on PostgreSQL 9.4, and in most cases is very similar to PostgreSQL with regard to SQL support, features, configuration options, and end-user functionality. Database users interact with Greenplum Database as they would with a regular PostgreSQL DBMS.

Greenplum Database can use the append-optimized (AO) storage format for bulk loading and reading of data, and provides performance advantages over HEAP tables. Append-optimized storage provides checksums for data protection, compression and row/column orientation. Both row-oriented or column-oriented append-optimized tables can be compressed.

The main differences between Greenplum Database and PostgreSQL are as follows:

- GPORCA is leveraged for query planning, in addition to the Postgres Planner.
- Greenplum Database can use append-optimized storage.
- Greenplum Database has the option to use column storage, data that is logically organized as a table, using rows and columns that are physically stored in a column-oriented format, rather than as rows. Column storage can only be used with append-optimized tables. Column storage is compressible. It also can provide performance improvements as you only need to return the columns of interest to you. All compression algorithms can be used with either row or column-oriented tables, but Run-Length Encoded (RLE) compression can only be used with column-oriented tables. Greenplum Database provides compression on all Append-Optimized tables that use column storage.

The internals of PostgreSQL have been modified or supplemented to support the parallel structure of Greenplum Database. For example, the system catalog, optimizer, query executor, and transaction manager components have been modified and enhanced to be able to execute queries simultaneously across all of the parallel PostgreSQL database instances. The Greenplum interconnect (the networking layer) enables communication between the distinct PostgreSQL instances and allows the system to behave as one logical database.

Greenplum Database also can use declarative partitions and sub-partitions to implicitly generate partition constraints.

Greenplum Database also includes features designed to optimize PostgreSQL for business intelligence (BI) workloads. For example, Greenplum has added parallel data loading (external tables), resource
management, query optimizations, and storage enhancements, which are not found in standard PostgreSQL. Many features and optimizations developed by Greenplum make their way into the PostgreSQL community. For example, table partitioning is a feature first developed by Greenplum, and it is now in standard PostgreSQL.

Greenplum Database queries use a Volcano-style query engine model, where the execution engine takes an execution plan and uses it to generate a tree of physical operators, evaluates tables through physical operators, and delivers results in a query response.

Greenplum Database stores and processes large amounts of data by distributing the data and processing workload across several servers or hosts. Greenplum Database is an array of individual databases based upon PostgreSQL 9.4 working together to present a single database image. The master is the entry point to the Greenplum Database system. It is the database instance to which clients connect and submit SQL statements. The master coordinates its work with the other database instances in the system, called segments, which store and process the data.

![Figure 10: High-Level Greenplum Database Architecture](image)

The following topics describe the components that make up a Greenplum Database system and how they work together.

**About the Greenplum Master**

The Greenplum Database master is the entry to the Greenplum Database system, accepting client connections and SQL queries, and distributing work to the segment instances.

Greenplum Database end-users interact with Greenplum Database (through the master) as they would with a typical PostgreSQL database. They connect to the database using client programs such as `psql` or application programming interfaces (APIs) such as JDBC, ODBC or `libpq` (the PostgreSQL C API).

The master is where the global system catalog resides. The global system catalog is the set of system tables that contain metadata about the Greenplum Database system itself. The master does not contain
any user data; data resides only on the segments. The master authenticates client connections, processes incoming SQL commands, distributes workloads among segments, coordinates the results returned by each segment, and presents the final results to the client program.

Greenplum Database uses Write-Ahead Logging (WAL) for master/standby master mirroring. In WAL-based logging, all modifications are written to the log before being applied, to ensure data integrity for any in-process operations.

**Note:** WAL logging is not yet available for segment mirroring.

### About the Greenplum Segments

Greenplum Database segment instances are independent PostgreSQL databases that each store a portion of the data and perform the majority of query processing.

When a user connects to the database via the Greenplum master and issues a query, processes are created in each segment database to handle the work of that query. For more information about query processes, see *About Greenplum Query Processing*.

User-defined tables and their indexes are distributed across the available segments in a Greenplum Database system; each segment contains a distinct portion of data. The database server processes that serve segment data run under the corresponding segment instances. Users interact with segments in a Greenplum Database system through the master.

Segments run on servers called *segment hosts*. A segment host typically executes from two to eight Greenplum segments, depending on the CPU cores, RAM, storage, network interfaces, and workloads. Segment hosts are expected to be identically configured. The key to obtaining the best performance from Greenplum Database is to distribute data and workloads evenly across a large number of equally capable segments so that all segments begin working on a task simultaneously and complete their work at the same time.

### About the Greenplum Interconnect

The interconnect is the networking layer of the Greenplum Database architecture.

The interconnect refers to the inter-process communication between segments and the network infrastructure on which this communication relies. The Greenplum interconnect uses a standard Ethernet switching fabric. For performance reasons, a 10-Gigabit system, or faster, is recommended.

By default, the interconnect uses User Datagram Protocol with flow control (UDPIFC) for interconnect traffic to send messages over the network. The Greenplum software performs packet verification beyond what is provided by UDP. This means the reliability is equivalent to Transmission Control Protocol (TCP), and the performance and scalability exceeds TCP. If the interconnect is changed to TCP, Greenplum Database has a scalability limit of 1000 segment instances. With UDPIFC as the default protocol for the interconnect, this limit is not applicable.

### About Management and Monitoring Utilities

Greenplum Database provides standard command-line utilities for performing common monitoring and administration tasks.

Greenplum command-line utilities are located in the `$GPHOME/bin` directory and are executed on the master host. Greenplum provides utilities for the following administration tasks:

- Installing Greenplum Database on an array
- Initializing a Greenplum Database System
- Starting and stopping Greenplum Database
- Adding or removing a host
- Expanding the array and redistributing tables among new segments
- Managing recovery for failed segment instances
- Managing failover and recovery for a failed master instance
• Backing up and restoring a database (in parallel)
• Loading data in parallel
• Transferring data between Greenplum databases
• System state reporting

Greenplum Database includes an optional performance management database that contains query status information and system metrics. The `gpperfmon_install` management utility creates the database, named `gpperfmon`, and enables data collection agents that execute on the Greenplum Database master and segment hosts. Data collection agents on the segment hosts collect query status from the segments, as well as system metrics such as CPU and memory utilization. An agent on the master host periodically (typically every 15 seconds) retrieves the data from the segment host agents and updates the `gpperfmon` database. Users can query the `gpperfmon` database to see the query and system metrics.

Pivotal provides an optional system monitoring and management tool, Greenplum Command Center, which administrators can install and enable with Greenplum Database. Greenplum Command Center provides a web-based user interface for viewing system metrics and allows administrators to perform additional system management tasks. For more information about Greenplum Command Center, see the Greenplum Command Center documentation.

![Greenplum Command Center Architecture](image)

**Figure 11: Greenplum Command Center Architecture**

### About Concurrency Control in Greenplum Database

Greenplum Database uses the PostgreSQL Multiversion Concurrency Control (MVCC) model to manage concurrent transactions for heap tables.

Concurrency control in a database management system allows concurrent queries to complete with correct results while ensuring the integrity of the database. Traditional databases use a two-phase locking protocol that prevents a transaction from modifying data that has been read by another concurrent transaction and prevents any concurrent transaction from reading or writing data that another transaction has updated. The locks required to coordinate transactions add contention to the database, reducing overall transaction throughput.
Greenplum Database uses the PostgreSQL Multiversion Concurrency Control (MVCC) model to manage concurrency for heap tables. With MVCC, each query operates on a snapshot of the database when the query starts. While it executes, a query cannot see changes made by other concurrent transactions. This ensures that a query sees a consistent view of the database. Queries that read rows can never block waiting for transactions that write rows. Conversely, queries that write rows cannot be blocked by transactions that read rows. This allows much greater concurrency than traditional database systems that employ locks to coordinate access between transactions that read and write data.

**Note:** Append-optimized tables are managed with a different concurrency control model than the MVCC model discussed in this topic. They are intended for "write-once, read-many" applications that never, or only very rarely, perform row-level updates.

**Snapshots**

The MVCC model depends on the system's ability to manage multiple versions of data rows. A query operates on a snapshot of the database at the start of the query. A snapshot is the set of rows that are visible at the beginning of a statement or transaction. The snapshot ensures the query has a consistent and valid view of the database for the duration of its execution.

Each transaction is assigned a unique transaction ID (XID), an incrementing 32-bit value. When a new transaction starts, it is assigned the next XID. An SQL statement that is not enclosed in a transaction is treated as a single-statement transaction—the BEGIN and COMMIT are added implicitly. This is similar to autocommit in some database systems.

**Note:** Greenplum Database assigns XID values only to transactions that involve DDL or DML operations, which are typically the only transactions that require an XID.

When a transaction inserts a row, the XID is saved with the row in the xmin system column. When a transaction deletes a row, the XID is saved in the xmax system column. Updating a row is treated as a delete and an insert, so the XID is saved to the xmax of the current row and the xmin of the newly inserted row. The xmin and xmax columns, together with the transaction completion status, specify a range of transactions for which the version of the row is visible. A transaction can see the effects of all transactions less than xmin, which are guaranteed to be committed, but it cannot see the effects of any transaction greater than or equal to xmax.

Multi-statement transactions must also record which command within a transaction inserted a row (cmin) or deleted a row (cmax) so that the transaction can see changes made by previous commands in the transaction. The command sequence is only relevant during the transaction, so the sequence is reset to 0 at the beginning of a transaction.

XID is a property of the database. Each segment database has its own XID sequence that cannot be compared to the XIDs of other segment databases. The master coordinates distributed transactions with the segments using a cluster-wide session ID number, called gp_session_id. The segments maintain a mapping of distributed transaction IDs with their local XIDs. The master coordinates distributed transactions across all of the segment with the two-phase commit protocol. If a transaction fails on any one segment, it is rolled back on all segments.

You can see the xmin, xmax, cmin, and cmax columns for any row with a SELECT statement:

```sql
SELECT xmin, xmax, cmin, cmax, * FROM tablename;
```

Because you run the SELECT command on the master, the XIDs are the distributed transactions IDs. If you could execute the command in an individual segment database, the xmin and xmax values would be the segment's local XIDs.

**Note:** Greenplum Database distributes all of a replicated table's rows to every segment, so each row is duplicated on every segment. Each segment instance maintains its own values for the system columns xmin, xmax, cmin, and cmax, as well as for the gp_segment_id and ctid system columns. Greenplum Database does not permit user queries to access these system...
columns for replicated tables because they have no single, unambiguous value to evaluate in a query.

Transaction ID Wraparound

The MVCC model uses transaction IDs (XIDs) to determine which rows are visible at the beginning of a query or transaction. The XID is a 32-bit value, so a database could theoretically execute over four billion transactions before the value overflows and wraps to zero. However, Greenplum Database uses modulo $2^{32}$ arithmetic with XIDs, which allows the transaction IDs to wrap around, much as a clock wraps at twelve o'clock. For any given XID, there could be about two billion past XIDs and two billion future XIDs. This works until a version of a row persists through about two billion transactions, when it suddenly appears to be a new row. To prevent this, Greenplum has a special XID, called FrozenXID, which is always considered older than any regular XID it is compared with. The xmin of a row must be replaced with FrozenXID within two billion transactions, and this is one of the functions the VACUUM command performs.

Vacuuming the database at least every two billion transactions prevents XID wraparound. Greenplum Database monitors the transaction ID and warns if a VACUUM operation is required.

A warning is issued when a significant portion of the transaction IDs are no longer available and before transaction ID wraparound occurs:

```
WARNING: database "database_name" must be vacuumed within number_of_transactions transactions
```

When the warning is issued, a VACUUM operation is required. If a VACUUM operation is not performed, Greenplum Database stops creating transactions to avoid possible data loss when it reaches a limit prior to when transaction ID wraparound occurs and issues this error:

```
FATAL: database is not accepting commands to avoid wraparound data loss in database "database_name"
```

See *Recovering from a Transaction ID Limit Error* for the procedure to recover from this error.

The server configuration parameters `xid_warn_limit` and `xid_stop_limit` control when the warning and error are displayed. The `xid_warn_limit` parameter specifies the number of transaction IDs before the `xid_stop_limit` when the warning is issued. The `xid_stop_limit` parameter specifies the number of transaction IDs before wraparound would occur when the error is issued and new transactions cannot be created.

Transaction Isolation Modes

The SQL standard describes three phenomena that can occur when database transactions run concurrently:

- **Dirty read** – a transaction can read uncommitted data from another concurrent transaction.
- **Non-repeatable read** – a row read twice in a transaction can change because another concurrent transaction committed changes after the transaction began.
- **Phantom read** – a query executed twice in the same transaction can return two different sets of rows because another concurrent transaction added rows.

The SQL standard defines four transaction isolation levels that database systems can support, with the phenomena that are allowed when transactions execute concurrently for each level.

<table>
<thead>
<tr>
<th>Table 10: SQL Transaction Isolation Modes</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Level</strong></td>
</tr>
<tr>
<td>Read Uncommitted</td>
</tr>
<tr>
<td>Read Committed</td>
</tr>
<tr>
<td>Level</td>
</tr>
<tr>
<td>--------------------</td>
</tr>
<tr>
<td>Repeatable Read</td>
</tr>
<tr>
<td>Serializable</td>
</tr>
</tbody>
</table>

Greenplum Database `READ UNCOMMITTED` and `READ COMMITTED` isolation modes behave like the SQL standard `READ COMMITTED` mode. Greenplum Database `SERIALIZABLE` and `REPEATABLE` `READ` isolation modes behave like the SQL standard `READ COMMITTED` mode, except that Greenplum Database also prevents phantom reads.

The difference between `READ COMMITTED` and `REPEATABLE` `READ` is that with `READ COMMITTED`, each statement in a transaction sees only rows committed before the `statement` started, while in `READ COMMITTED` mode, statements in a transaction see only rows committed before the `transaction` started.

With `READ COMMITTED` isolation mode the values in a row retrieved twice in a transaction can differ if another concurrent transaction has committed changes since the transaction began. `READ COMMITTED` mode also permits phantom reads, where a query executed twice in the same transaction can return two different sets of rows.

The `REPEATABLE` `READ` isolation mode prevents non-repeatable reads and phantom reads, although the latter is not required by the standard. A transaction that attempts to modify data modified by another concurrent transaction is rolled back. Applications that execute transactions in `REPEATABLE` `READ` mode must be prepared to handle transactions that fail due to serialization errors. If `REPEATABLE` `READ` isolation mode is not required by the application, it is better to use `READ COMMITTED` mode.

`SERIALIZABLE` mode, which Greenplum Database does not fully support, guarantees that a set of transactions executed concurrently produces the same result as if the transactions executed sequentially one after the other. If `SERIALIZABLE` is specified, Greenplum Database falls back to `REPEATABLE` `READ`. The MVCC Snapshot Isolation (SI) model prevents dirty reads, non-repeatable reads, and phantom reads without expensive locking, but there are other interactions that can occur between some `SERIALIZABLE` transactions in Greenplum Database that prevent them from being truly serializable. These anomalies can often be attributed to the fact that Greenplum Database does not perform predicate locking, which means that a write in one transaction can affect the result of a previous read in another concurrent transaction.

**Note:** The PostgreSQL 9.1 `SERIALIZABLE` isolation level introduces a new Serializable Snapshot Isolation (SSI) model, which is fully compliant with the SQL standard definition of serializable transactions. This model is not available in Greenplum Database. SSI monitors concurrent transactions for conditions that could cause serialization anomalies. When potential serialization problems are found, one transaction is allowed to commit and others are rolled back and must be retried.

Greenplum Database transactions that run concurrently should be examined to identify interactions that may update the same data concurrently. Problems identified can be prevented by using explicit table locks or by requiring the conflicting transactions to update a dummy row introduced to represent the conflict.

The SQL `SET TRANSACTION ISOLATION LEVEL` statement sets the isolation mode for the current transaction. The mode must be set before any `SELECT`, `INSERT`, `DELETE`, `UPDATE`, or `COPY` statements:

```
BEGIN;
SET TRANSACTION ISOLATION LEVEL REPEATABLE READ;
...
COMMIT;
```

The isolation mode can also be specified as part of the `BEGIN` statement:

```
BEGIN TRANSACTION ISOLATION LEVEL REPEATABLE READ;
```

The default transaction isolation mode can be changed for a session by setting the `default_transaction_isolation` configuration property.
Removing Dead Rows from Tables

Updating or deleting a row leaves an expired version of the row in the table. When an expired row is no longer referenced by any active transactions, it can be removed and the space it occupied can be reused. The VACUUM command marks the space used by expired rows for reuse.

When expired rows accumulate in a table, the disk files must be extended to accommodate new rows. Performance suffers due to the increased disk I/O required to execute queries. This condition is called bloat and it should be managed by regularly vacuuming tables.

The VACUUM command (without FULL) can run concurrently with other queries. It marks the space previously used by the expired rows as free, and updates the free space map. When Greenplum Database later needs space for new rows, it first consults the table’s free space map to find pages with available space. If none are found, new pages will be appended to the file.

VACUUM (without FULL) does not consolidate pages or reduce the size of the table on disk. The space it recovers is only available through the free space map. To prevent disk files from growing, it is important to run VACUUM often enough. The frequency of required VACUUM runs depends on the frequency of updates and deletes in the table (inserts only ever add new rows). Heavily updated tables might require several VACUUM runs per day, to ensure that the available free space can be found through the free space map. It is also important to run VACUUM after running a transaction that updates or deletes a large number of rows.

The VACUUM FULL command rewrites the table without expired rows, reducing the table to its minimum size. Every page in the table is checked, and visible rows are moved up into pages which are not yet fully packed. Empty pages are discarded. The table is locked until VACUUM FULL completes. This is very expensive compared to the regular VACUUM command, and can be avoided or postponed by vacuuming regularly. It is best to run VACUUM FULL during a maintenance period. An alternative to VACUUM FULL is to recreate the table with a CREATE TABLE AS statement and then drop the old table.

You can run VACUUM VERBOSE tablename to get a report, by segment, of the number of dead rows removed, the number of pages affected, and the number of pages with usable free space.

Query the pg_class system table to find out how many pages a table is using across all segments. Be sure to ANALYZE the table first to get accurate data.

```
SELECT relname, relpages, reltuples FROM pg_class WHERE relname='tablename';
```

Another useful tool is the gp_bloat_diag view in the gp_toolkit schema, which identifies bloat in tables by comparing the actual number of pages used by a table to the expected number. See "The gp_toolkit Administrative Schema" in the Greenplum Database Reference Guide for more about gp_bloat_diag.

Example of Managing Transaction IDs

For Greenplum Database, the transaction ID (XID) value an incrementing 32-bit \(2^{32}\) value. The maximum unsigned 32-bit value is 4,294,967,295, or about four billion. The XID values restart at 3 after the maximum is reached. Greenplum Database handles the limit of XID values with two features:

- Calculations on XID values using modulo-\(2^{32}\) arithmetic that allow Greenplum Database to reuse XID values. The modulo calculations determine the order of transactions, whether one transaction has occurred before or after another, based on the XID.

  Every XID value can have up to two billion \(2^{31}\) XID values that are considered previous transactions and two billion \(2^{31} - 1\) XID values that are considered newer transactions. The XID values can be considered a circular set of values with no endpoint similar to a 24 hour clock.

  Using the Greenplum Database modulo calculations, as long as two XIDs are within \(2^{31}\) transactions of each other, comparing them yields the correct result.

- A frozen XID value that Greenplum Database uses as the XID for current (visible) data rows. Setting a row's XID to the frozen XID performs two functions.
• When Greenplum Database compares XIDs using the modulo calculations, the frozen XID is always smaller, earlier, when compared to any other XID. If a row's XID is not set to the frozen XID and $2^{31}$ new transactions are executed, the row appears to be executed in the future based on the modulo calculation.

• When the row's XID is set to the frozen XID, the original XID can be used, without duplicating the XID. This keeps the number of data rows on disk with assigned XIDs below $(2^{32})$.

**Note:** Greenplum Database assigns XID values only to transactions that involve DDL or DML operations, which are typically the only transactions that require an XID.

**Simple MVCC Example**

This is a simple example of the concepts of a MVCC database and how it manages data and transactions with transaction IDs. This simple MVCC database example consists of a single table:

• The table is a simple table with 2 columns and 4 rows of data.
• The valid transaction ID (XID) values are from 0 up to 9, after 9 the XID restarts at 0.
• The frozen XID is -2. This is different than the Greenplum Database frozen XID.
• Transactions are performed on a single row.
• Only insert and update operations are performed.
• All updated rows remain on disk, no operations are performed to remove obsolete rows.

The example only updates the amount values. No other changes to the table.

The example shows these concepts.

• *How transaction IDs are used to manage multiple, simultaneous transactions on a table.*
• *How transaction IDs are managed with the frozen XID*
• *How the modulo calculation determines the order of transactions based on transaction IDs*

**Managing Simultaneous Transactions**

This table is the initial table data on disk with no updates. The table contains two database columns for transaction IDs, $\text{xmin}$ (transaction that created the row) and $\text{xmax}$ (transaction that updated the row). In the table, changes are added, in order, to the bottom of the table.

**Table 11: Example Table**

<table>
<thead>
<tr>
<th>item</th>
<th>amount</th>
<th>xmin</th>
<th>xmax</th>
</tr>
</thead>
<tbody>
<tr>
<td>widget</td>
<td>100</td>
<td>0</td>
<td>null</td>
</tr>
<tr>
<td>giblet</td>
<td>200</td>
<td>1</td>
<td>null</td>
</tr>
<tr>
<td>sprocket</td>
<td>300</td>
<td>2</td>
<td>null</td>
</tr>
<tr>
<td>gizmo</td>
<td>400</td>
<td>3</td>
<td>null</td>
</tr>
</tbody>
</table>

The next table shows the table data on disk after some updates on the amount values have been performed.

- $\text{xid} = 4$: update tbl set amount=208 where item = 'widget'
- $\text{xid} = 5$: update tbl set amount=133 where item = 'sprocket'
- $\text{xid} = 6$: update tbl set amount=16 where item = 'widget'

In the next table, the bold items are the current rows for the table. The other rows are obsolete rows, table data that on disk but is no longer current. Using the $\text{xmax}$ value, you can determine the current rows of the table by selecting the rows with **null** value. Greenplum Database uses a slightly different method to determine current table rows.
Table 12: Example Table with Updates

<table>
<thead>
<tr>
<th>item</th>
<th>amount</th>
<th>xmin</th>
<th>xmax</th>
</tr>
</thead>
<tbody>
<tr>
<td>widget</td>
<td>100</td>
<td>0</td>
<td>4</td>
</tr>
<tr>
<td>giblet</td>
<td>200</td>
<td>1</td>
<td>null</td>
</tr>
<tr>
<td>sprocket</td>
<td>300</td>
<td>2</td>
<td>5</td>
</tr>
<tr>
<td>gizmo</td>
<td>400</td>
<td>3</td>
<td>null</td>
</tr>
<tr>
<td>widget</td>
<td>208</td>
<td>4</td>
<td>6</td>
</tr>
<tr>
<td>sprocket</td>
<td>133</td>
<td>5</td>
<td>null</td>
</tr>
<tr>
<td>widget</td>
<td>16</td>
<td>6</td>
<td>null</td>
</tr>
</tbody>
</table>

The simple MVCC database works with XID values to determine the state of the table. For example, both these independent transactions execute concurrently.

- **UPDATE** command changes the sprocket amount value to 133 (xmin value 5)
- **SELECT** command returns the value of sprocket.

During the **UPDATE** transaction, the database returns the value of sprocket 300, until the **UPDATE** transaction completes.

### Managing XIDs and the Frozen XID

For this simple example, the database is close to running out of available XID values. When Greenplum Database is close to running out of available XID values, Greenplum Database takes these actions.

- Greenplum Database issues a warning stating that the database is running out of XID values.

```
WARNING: database "database_name" must be vacuumed within number_of_transactions transactions
```

- Before the last XID is assigned, Greenplum Database stops accepting transactions to prevent assigning an XID value twice and issues this message.

```
FATAL: database is not accepting commands to avoid wraparound data loss in database "database_name"
```

To manage transaction IDs and table data that is stored on disk, Greenplum Database provides the **VACUUM** command.

- A **VACUUM** operation frees up XID values so that a table can have more than 10 rows by changing the xmin values to the frozen XID.
- A **VACUUM** operation manages obsolete or deleted table rows on disk. This database’s **VACUUM** command changes the XID values obsolete to indicate obsolete rows. A Greenplum Database **VACUUM** operation, without the **FULL** option, deletes the data opportunistically to remove rows on disk with minimal impact to performance and data availability.

For the example table, a **VACUUM** operation has been performed on the table. The command updated table data on disk. This version of the **VACUUM** command performs slightly differently than the Greenplum Database command, but the concepts are the same.

- For the widget and sprocket rows on disk that are no longer current, the rows have been marked as obsolete.
- For the giblet and gizmo rows that are current, the xmin has been changed to the frozen XID.
The values are still current table values (the row's xmax value is null). However, the table row is visible to all transactions because the xmin value is frozen XID value that is older than all other XID values when modulo calculations are performed.

After the VACUUM operation, the XID values 0, 1, 2, and 3 available for use.

**Table 13: Example Table after VACUUM**

<table>
<thead>
<tr>
<th>item</th>
<th>amount</th>
<th>xmin</th>
<th>xmax</th>
</tr>
</thead>
<tbody>
<tr>
<td>widget</td>
<td>100</td>
<td>obsolete</td>
<td>obsolete</td>
</tr>
<tr>
<td>giblet</td>
<td>200</td>
<td>-2</td>
<td>null</td>
</tr>
<tr>
<td>sprocket</td>
<td>300</td>
<td>obsolete</td>
<td>obsolete</td>
</tr>
<tr>
<td>gizmo</td>
<td>400</td>
<td>-2</td>
<td>null</td>
</tr>
<tr>
<td>widget</td>
<td>208</td>
<td>4</td>
<td>6</td>
</tr>
<tr>
<td>sproket</td>
<td>133</td>
<td>5</td>
<td>null</td>
</tr>
<tr>
<td>widget</td>
<td>16</td>
<td>6</td>
<td>null</td>
</tr>
</tbody>
</table>

When a row disk with the xmin value of -2 is updated, the xmax value is replaced with the transaction XID as usual, and the row on disk is considered obsolete after any concurrent transactions that access the row have completed.

Obsolete rows can be deleted from disk. For Greenplum Database, the VACUUM command, with FULL option, does more extensive processing to reclaim disk space.

**Example of XID Modulo Calculations**

The next table shows the table data on disk after more UPDATE transactions. The XID values have rolled over and start over at 0. No additional VACUUM operations have been performed.

**Table 14: Example Table with Wrapping XID**

<table>
<thead>
<tr>
<th>item</th>
<th>amount</th>
<th>xmin</th>
<th>xmax</th>
</tr>
</thead>
<tbody>
<tr>
<td>widget</td>
<td>100</td>
<td>obsolete</td>
<td>obsolete</td>
</tr>
<tr>
<td>giblet</td>
<td>200</td>
<td>-2</td>
<td>1</td>
</tr>
<tr>
<td>sprocket</td>
<td>300</td>
<td>obsolete</td>
<td>obsolete</td>
</tr>
<tr>
<td>gizmo</td>
<td>400</td>
<td>-2</td>
<td>9</td>
</tr>
<tr>
<td>widget</td>
<td>208</td>
<td>4</td>
<td>6</td>
</tr>
<tr>
<td>sproket</td>
<td>133</td>
<td>5</td>
<td>null</td>
</tr>
<tr>
<td>widget</td>
<td>16</td>
<td>6</td>
<td>7</td>
</tr>
<tr>
<td>widget</td>
<td>222</td>
<td>7</td>
<td>null</td>
</tr>
<tr>
<td>giblet</td>
<td>233</td>
<td>8</td>
<td>0</td>
</tr>
<tr>
<td>gizmo</td>
<td>18</td>
<td>9</td>
<td>null</td>
</tr>
<tr>
<td>giblet</td>
<td>88</td>
<td>0</td>
<td>1</td>
</tr>
<tr>
<td>giblet</td>
<td>44</td>
<td>1</td>
<td>null</td>
</tr>
</tbody>
</table>
When performing the modulo calculations that compare XIDs, Greenplum Database, considers the XIDs of the rows and the current range of available XIDs to determine if XID wrapping has occurred between row XIDs.

For the example table XID wrapping has occurred. The XID 1 for giblet row is a later transaction than the XID 7 for widget row based on the modulo calculations for XID values even though the XID value 7 is larger than 1.

For the widget and sprocket rows, XID wrapping has not occurred and XID 7 is a later transaction than XID 5.

**About Parallel Data Loading**

This topic provides a short introduction to Greenplum Database data loading features.

In a large scale, multi-terabyte data warehouse, large amounts of data must be loaded within a relatively small maintenance window. Greenplum supports fast, parallel data loading with its external tables feature. Administrators can also load external tables in single row error isolation mode to filter bad rows into a separate error log while continuing to load properly formatted rows. Administrators can specify an error threshold for a load operation to control how many improperly formatted rows cause Greenplum to abort the load operation.

By using external tables in conjunction with Greenplum Database's parallel file server (`gpfdist`), administrators can achieve maximum parallelism and load bandwidth from their Greenplum Database system.

![Figure 12: External Tables Using Greenplum Parallel File Server (gpfdist)](image)

Another Greenplum utility, `gpload`, runs a load task that you specify in a YAML-formatted control file. You describe the source data locations, format, transformations required, participating hosts, database destinations, and other particulars in the control file and `gpload` executes the load. This allows you to describe a complex task and execute it in a controlled, repeatable fashion.
About Redundancy and Failover in Greenplum Database

This topic provides a high-level overview of Greenplum Database high availability features.

You can deploy Greenplum Database without a single point of failure by mirroring components. The following sections describe the strategies for mirroring the main components of a Greenplum system. For a more detailed overview of Greenplum high availability features, see Overview of Greenplum Database High Availability.

Important: When data loss is not acceptable for a Pivotal Greenplum Database cluster, master and segment mirroring must be enabled in order for the cluster to be supported by Pivotal. Without mirroring, system and data availability is not guaranteed, Pivotal will make best efforts to restore a cluster in this case.

About Segment Mirroring

When you deploy your Greenplum Database system, you can configure mirror segment instances. Mirror segments allow database queries to fail over to a backup segment if the primary segment becomes unavailable. The mirror segment is kept current by a transaction log replication process, which synchronizes the data between the primary and mirror instances. Mirroring is strongly recommended for production systems and required for Pivotal support.

As a best practice, the secondary (mirror) segment instance must always reside on a different host than its primary segment instance to protect against a single host failure. In virtualized environments, the secondary (mirror) segment must always reside on a different storage system than the primary. Mirror segments can be arranged over the remaining hosts in the cluster in configurations designed to maximize availability, or minimize the performance degradation when hosts or multiple primary segments fail.

Two standard mirroring configurations are available when you initialize or expand a Greenplum system. The default configuration, called group mirroring, places all the mirrors for a host's primary segments on one other host in the cluster. The other standard configuration, spread mirroring, can be selected with a command-line option. Spread mirroring spreads each host's mirrors over the remaining hosts and requires that there are more hosts in the cluster than primary segments per host.

Figure 13: Spread Mirroring in Greenplum Database shows how table data is distributed across segments when spread mirroring is configured.
Figure 13: Spread Mirroring in Greenplum Database

Segment Failover and Recovery

When segment mirroring is enabled in a Greenplum Database system, the system will automatically fail over to the mirror segment instance if a primary segment instance becomes unavailable. A Greenplum Database system can remain operational if a segment instance or host goes down as long as all the data is available on the remaining active segment instances.

If the master cannot connect to a segment instance, it marks that segment instance as down in the Greenplum Database system catalog and brings up the mirror segment in its place. A failed segment instance will remain out of operation until an administrator takes steps to bring that segment back online. An administrator can recover a failed segment while the system is up and running. The recovery process copies over only the changes that were missed while the segment was out of operation.

If you do not have mirroring enabled, the system will automatically shut down if a segment instance becomes invalid. You must recover all failed segments before operations can continue.

About Master Mirroring

You can also optionally deploy a backup or mirror of the master instance on a separate host from the master host. The backup master instance (the standby master) serves as a warm standby in the event that the primary master host becomes non-operational. The standby master is kept current by a transaction log replication process, which synchronizes the data between the primary and standby master.

If the primary master fails, the log replication process stops, and the standby master can be activated in its place. The switchover does not happen automatically, but must be triggered externally. Upon activation of the standby master, the replicated logs are used to reconstruct the state of the master host at the time of the last successfully committed transaction. The activated standby master effectively becomes the Greenplum Database master, accepting client connections on the master port (which must be set to the same port number on the master host and the backup master host).
Since the master does not contain any user data, only the system catalog tables need to be synchronized between the primary and backup copies. When these tables are updated, changes are automatically copied over to the standby master to ensure synchronization with the primary master.

![Master Mirroring in Greenplum Database](image)

**Figure 14: Master Mirroring in Greenplum Database**

**About Interconnect Redundancy**

The interconnect refers to the inter-process communication between the segments and the network infrastructure on which this communication relies. You can achieve a highly available interconnect using by deploying dual Gigabit Ethernet switches on your network and redundant Gigabit connections to the Greenplum Database host (master and segment) servers. For performance reasons, 10-Gb Ethernet, or faster, is recommended.

**About Database Statistics in Greenplum Database**

An overview of statistics gathered by the `ANALYZE` command in Greenplum Database.

Statistics are metadata that describe the data stored in the database. The query optimizer needs up-to-date statistics to choose the best execution plan for a query. For example, if a query joins two tables and one of them must be broadcast to all segments, the optimizer can choose the smaller of the two tables to minimize network traffic.

The statistics used by the optimizer are calculated and saved in the system catalog by the `ANALYZE` command. There are three ways to initiate an analyze operation:

- You can run the `ANALYZE` command directly.
- You can run the `analyzedb` management utility outside of the database, at the command line.
- An automatic analyze operation can be triggered when DML operations are performed on tables that have no statistics or when a DML operation modifies a number of rows greater than a specified threshold.

These methods are described in the following sections. The `VACUUM ANALYZE` command is another way to initiate an analyze operation, but its use is discouraged because vacuum and analyze are different operations with different purposes.

Calculating statistics consumes time and resources, so Greenplum Database produces estimates by calculating statistics on samples of large tables. In most cases, the default settings provide the information needed to generate correct execution plans for queries. If the statistics produced are not producing optimal query execution plans, the administrator can tune configuration parameters to produce more accurate statistics by increasing the sample size or the granularity of statistics saved in the system catalog.

Producing more accurate statistics has CPU and storage costs and may not produce better plans, so it is important to view explain plans and test query performance to ensure that the additional statistics-related costs result in better query performance.
System Statistics

Table Size
The query planner seeks to minimize the disk I/O and network traffic required to execute a query, using estimates of the number of rows that must be processed and the number of disk pages the query must access. The data from which these estimates are derived are the `pg_class` system table columns `reltuples` and `relpages`, which contain the number of rows and pages at the time a VACUUM or ANALYZE command was last run. As rows are added or deleted, the numbers become less accurate. However, an accurate count of disk pages is always available from the operating system, so as long as the ratio of `reltuples` to `relpages` does not change significantly, the optimizer can produce an estimate of the number of rows that is sufficiently accurate to choose the correct query execution plan.

When the `reltuples` column differs significantly from the row count returned by `SELECT COUNT(*)`, an analyze should be performed to update the statistics.

When a REINDEX command finishes recreating an index, the `relpages` and `reltuples` columns are set to zero. The ANALYZE command should be run on the base table to update these columns.

The `pg_statistic` System Table and `pg_stats` View
The `pg_statistic` system table holds the results of the last ANALYZE operation on each database table. There is a row for each column of every table. It has the following columns:

- **starelid**: The object ID of the table or index the column belongs to.
- **staattnum**: The number of the described column, beginning with 1.
- **stainherit**: If true, the statistics include inheritance child columns, not just the values in the specified relation.
- **stanullfrac**: The fraction of the column's entries that are null.
- **stawidth**: The average stored width, in bytes, of non-null entries.
- **stadistinct**: A positive number is an estimate of the number of distinct values in the column; the number is not expected to vary with the number of rows. A negative value is the number of distinct values divided by the number of rows, that is, the ratio of rows with distinct values for the column, negated. This form is used when the number of distinct values increases with the number of rows. A unique column, for example, has an `n_distinct` value of -1.0. Columns with an average width greater than 1024 are considered unique.
- **stakindN**: A code number indicating the kind of statistics stored in the Nth slot of the `pg_statistic` row.
- **staopN**: An operator used to derive the statistics stored in the Nth slot. For example, a histogram slot would show the < operator that defines the sort order of the data.
- **stanumbersN**: `float4` array containing numerical statistics of the appropriate kind for the Nth slot, or NULL if the slot kind does not involve numerical values.
Column data values of the appropriate kind for the \( N \)th slot, or \texttt{NULL} if the slot kind does not store any data values. Each array's element values are actually of the specific column's data type, so there is no way to define these columns' types more specifically than \texttt{anyarray}.

The statistics collected for a column vary for different data types, so the \texttt{pg_statistic} table stores statistics that are appropriate for the data type in four \texttt{slots}, consisting of four columns per slot. For example, the first slot, which normally contains the most common values for a column, consists of the columns \texttt{stakind1}, \texttt{staop1}, \texttt{stanumbers1}, and \texttt{stavalues1}.

The \texttt{stakindN} columns each contain a numeric code to describe the type of statistics stored in their slot. The \texttt{stakind} code numbers from 1 to 99 are reserved for core PostgreSQL data types. Greenplum Database uses code numbers 1, 2, 3, 4, 5, and 99. A value of 0 means the slot is unused. The following table describes the kinds of statistics stored for the three codes.

### Table 15: Contents of pg\_statistic "slots"

<table>
<thead>
<tr>
<th>stakind Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Most CommonValues (MCV) Slot</td>
</tr>
<tr>
<td></td>
<td>( \cdot ) \texttt{staop} contains the object ID of the &quot;=&quot; operator, used to decide whether values are the same or not.</td>
</tr>
<tr>
<td></td>
<td>( \cdot ) \texttt{stavalues} contains an array of the ( K ) most common non-null values appearing in the column.</td>
</tr>
<tr>
<td></td>
<td>( \cdot ) \texttt{stanumbers} contains the frequencies (fractions of total row count) of the values in the \texttt{stavalues} array.</td>
</tr>
<tr>
<td></td>
<td>The values are ordered in decreasing frequency. Since the arrays are variable-size, ( K ) can be chosen by the statistics collector. Values must occur more than once to be added to the \texttt{stavalues} array; a unique column has no MCV slot.</td>
</tr>
<tr>
<td>2</td>
<td>Histogram Slot – describes the distribution of scalar data.</td>
</tr>
<tr>
<td></td>
<td>( \cdot ) \texttt{staop} is the object ID of the &quot;&lt;&quot; operator, which describes the sort ordering.</td>
</tr>
<tr>
<td></td>
<td>( \cdot ) \texttt{stavalues} contains ( M ) (where ( M \geq 2 )) non-null values that divide the non-null column data values into ( M-1 ) bins of approximately equal population. The first \texttt{stavalues} item is the minimum value and the last is the maximum value.</td>
</tr>
<tr>
<td></td>
<td>( \cdot ) \texttt{stanumbers} is not used and should be \texttt{NULL}.</td>
</tr>
<tr>
<td></td>
<td>If a Most Common Values slot is also provided, then the histogram describes the data distribution after removing the values listed in the MCV array. (It is a compressed histogram in the technical parlance). This allows a more accurate representation of the distribution of a column with some very common values. In a column with only a few distinct values, it is possible that the MCV list describes the entire data population; in this case the histogram reduces to empty and should be omitted.</td>
</tr>
<tr>
<td>3</td>
<td>Correlation Slot – describes the correlation between the physical order of table tuples and the ordering of data values of this column.</td>
</tr>
<tr>
<td></td>
<td>( \cdot ) \texttt{staop} is the object ID of the &quot;&lt;&quot; operator. As with the histogram, more than one entry could theoretically appear.</td>
</tr>
<tr>
<td></td>
<td>( \cdot ) \texttt{stavalues} is not used and should be \texttt{NULL}.</td>
</tr>
<tr>
<td></td>
<td>( \cdot ) \texttt{stanumbers} contains a single entry, the correlation coefficient between the sequence of data values and the sequence of their actual tuple positions. The coefficient ranges from +1 to -1.</td>
</tr>
<tr>
<td>stakind Code</td>
<td>Description</td>
</tr>
<tr>
<td>--------------</td>
<td>-------------</td>
</tr>
</tbody>
</table>
| 4            | **Most Common Elements Slot** - is similar to a Most Common Values (MCV) Slot, except that it stores the most common non-null **elements** of the column values. This is useful when the column datatype is an array or some other type with identifiable elements (for instance, tsvector).  

- **staop** contains the equality operator appropriate to the element type.  
- **stavalues** contains the most common element values.  
- **stanumbers** contains common element frequencies.  

Frequencies are measured as the fraction of non-null rows the element value appears in, not the frequency of all rows. Also, the values are sorted into the element type's default order (to support binary search for a particular value). Since this puts the minimum and maximum frequencies at unpredictable spots in **stanumbers**, there are two extra members of **stanumbers** that hold copies of the minimum and maximum frequencies. Optionally, there can be a third extra member that holds the frequency of null elements (the frequency is expressed in the same terms: the fraction of non-null rows that contain at least one null element). If this member is omitted, the column is presumed to contain no NULL elements.  

**Note:** For tsvector columns, the **stavalues** elements are of type text, even though their representation within tsvector is not exactly text. |
| 5            | **Distinct Elements Count Histogram Slot** - describes the distribution of the number of distinct element values present in each row of an array-type column. Only non-null rows are considered, and only non-null elements.  

- **staop** contains the equality operator appropriate to the element type.  
- **stavalues** is **not used** and should be **NULL**.  
- **stanumbers** contains information about distinct elements. The last member of **stanumbers** is the average count of distinct element values over all non-null rows. The preceding **M** (where **M** >=2) members form a histogram that divides the population of distinct-elements counts into **M**–1 bins of approximately equal population. The first of these is the minimum observed count, and the last the maximum. |
| 99           | **Hyperloglog Slot** - for child leaf partitions of a partitioned table, stores the hyperloglog_counter created for the sampled data. The hyperloglog_counter data structure is converted into a bytea and stored in a stavalues5 slot of the pg_statistic catalog table. |

The pg_stats view presents the contents of pg_statistic in a friendlier format. The pg_stats view has the following columns:

- **schemaname**
  - The name of the schema containing the table.
- **tablename**
  - The name of the table.
- **attname**
  - The name of the column this row describes.
- **inherited**
  - If true, the statistics include inheritance child columns.
- **null_frac**
  - The fraction of column entries that are null.
- **avg_width**
  - The average storage width in bytes of the column’s entries, calculated as \( \text{avg(pg_column_size(column_name))} \).
n_distinct
A positive number is an estimate of the number of distinct values in the column; the number is not expected to vary with the number of rows. A negative value is the number of distinct values divided by the number of rows, that is, the ratio of rows with distinct values for the column, negated. This form is used when the number of distinct values increases with the number of rows. A unique column, for example, has an n_distinct value of -1.0. Columns with an average width greater than 1024 are considered unique.

most_common_vals
An array containing the most common values in the column, or null if no values seem to be more common. If the n_distinct column is -1, most_common_vals is null. The length of the array is the lesser of the number of actual distinct column values or the value of the default_statistics_target configuration parameter. The number of values can be overridden for a column using ALTER TABLE table SET COLUMN column SET STATISTICS N.

most_common_freqs
An array containing the frequencies of the values in the most_common_vals array. This is the number of occurrences of the value divided by the total number of rows. The array is the same length as the most_common_vals array. It is null if most_common_vals is null.

histogram_bounds
An array of values that divide the column values into groups of approximately the same size. A histogram can be defined only if there is a max() aggregate function for the column. The number of groups in the histogram is the same as the most_common_vals array size.

correlation
Greenplum Database does not calculate the correlation statistic.

most_common elems
An array that contains the most common element values.

most_common_elem_freqs
An array that contains common element frequencies.

elem_count_histogram
An array that describes the distribution of the number of distinct element values present in each row of an array-type column.

Newly created tables and indexes have no statistics. You can check for tables with missing statistics using the gp_stats_missing view, which is in the gp_toolkit schema:

```
SELECT * from gp_toolkit.gp_stats_missing;
```

**Sampling**
When calculating statistics for large tables, Greenplum Database creates a smaller table by sampling the base table. If the table is partitioned, samples are taken from all partitions.
**Updating Statistics**

Running **ANALYZE** with no arguments updates statistics for all tables in the database. This could take a very long time, so it is better to analyze tables selectively after data has changed. You can also analyze a subset of the columns in a table, for example columns used in joins, **WHERE** clauses, **SORT** clauses, **GROUP BY** clauses, or **HAVING** clauses.

Analyzing a severely bloated table can generate poor statistics if the sample contains empty pages, so it is good practice to vacuum a bloated table before analyzing it.

See the *SQL Command Reference* in the *Greenplum Database Reference Guide* for details of running the **ANALYZE** command.

Refer to the *Greenplum Database Management Utility Reference* for details of running the **analyzedb** command.

**Analyzing Partitioned Tables**

When the **ANALYZE** command is run on a partitioned table, it analyzes each child leaf partition table, one at a time. You can run **ANALYZE** on just new or changed partition files to avoid analyzing partitions that have not changed.

The **analyzedb** command-line utility skips unchanged partitions automatically. It also runs concurrent sessions so it can analyze several partitions concurrently. It runs five sessions by default, but the number of sessions can be set from 1 to 10 with the **-p** command-line option. Each time **analyzedb** runs, it saves state information for append-optimized tables and partitions in the **db_analyze** directory in the master data directory. The next time it runs, **analyzedb** compares the current state of each table with the saved state and skips analyzing a table or partition if it is unchanged. Heap tables are always analyzed.

If **GPORCA** is enabled (the default), you also need to run **ANALYZE** or **ANALYZE ROOTPARTITION** to refresh the root partition statistics. **GPORCA** requires statistics at the root level for partitioned tables. The Postgres Planner does not use these statistics.

The time to analyze a partitioned table is similar to the time to analyze a non-partitioned table with the same data since **ANALYZE ROOTPARTITION** does not collect statistics on the leaf partitions (the data is only sampled). The **analyzedb** utility updates root partition statistics by default but you can add the **--skip_root_stats** option to leave root partition statistics empty if you do not use **GPORCA**.

The Greenplum Database server configuration parameter **optimizer_analyze_root_partition** affects when statistics are collected on the root partition of a partitioned table. If the parameter is **on** (the default), the **ROOTPARTITION** keyword is not required to collect statistics on the root partition when you run **ANALYZE**. Root partition statistics are collected when you run **ANALYZE** on the root partition, or when you run **ANALYZE** on a child leaf partition of the partitioned table and the other child leaf partitions have statistics. If the parameter is **off**, you must run **ANALYZE ROOTPARTITION** to collect root partition statistics.

If you do not intend to execute queries on partitioned tables with **GPORCA** (setting the server configuration parameter **optimizer** to **off**), you can also set the server configuration parameter **optimizer_analyze_root_partition** to **off** to limit when **ANALYZE** updates the root partition statistics.

**Configuring Statistics**

There are several options for configuring Greenplum Database statistics collection.

**Statistics Target**

The statistics target is the size of the **most_common_vals**, **most_common_freqs**, and **histogram_bounds** arrays for an individual column. By default, the target is 25. The default target can be changed by setting a server configuration parameter and the target can be set for any column using the
ALTER TABLE command. Larger values increase the time needed to do ANALYZE, but may improve the quality of the Postgres Planner estimates.

Set the system default statistics target to a different value by setting the default_statistics_target server configuration parameter. The default value is usually sufficient, and you should only raise or lower it if your tests demonstrate that query plans improve with the new target. For example, to raise the default statistics target from 100 to 150 you can use the \texttt{gpconfig} utility:

\begin{verbatim}
gpconfig -c default_statistics_target -v 150
\end{verbatim}

The statistics target for individual columns can be set with the ALTER TABLE command. For example, some queries can be improved by increasing the target for certain columns, especially columns that have irregular distributions. You can set the target to zero for columns that never contribute to query optimization. When the target is 0, ANALYZE ignores the column. For example, the following ALTER TABLE command sets the statistics target for the \texttt{notes} column in the \texttt{emp} table to zero:

\begin{verbatim}
ALTER TABLE emp ALTER COLUMN notes SET STATISTICS 0;
\end{verbatim}

The statistics target can be set in the range 0 to 1000, or set it to -1 to revert to using the system default statistics target.

Setting the statistics target on a parent partition table affects the child partitions. If you set statistics to 0 on some columns on the parent table, the statistics for the same columns are set to 0 for all children partitions. However, if you later add or exchange another child partition, the new child partition will use either the default statistics target or, in the case of an exchange, the previous statistics target. Therefore, if you add or exchange child partitions, you should set the statistics targets on the new child table.

**Automatic Statistics Collection**

Greenplum Database can be set to automatically run ANALYZE on a table that either has no statistics or has changed significantly when certain operations are performed on the table. For partitioned tables, automatic statistics collection is only triggered when the operation is run directly on a leaf table, and then only the leaf table is analyzed.

Automatic statistics collection has three modes:

- \texttt{none} disables automatic statistics collection.
- \texttt{on_no_stats} triggers an analyze operation for a table with no existing statistics when any of the commands CREATE TABLE AS SELECT, INSERT, or COPY are executed on the table.
- \texttt{on_change} triggers an analyze operation when any of the commands CREATE TABLE AS SELECT, UPDATE, DELETE, INSERT, or COPY are executed on the table and the number of rows affected exceeds the threshold defined by the gp_autostats_on_change_threshold configuration parameter.

The automatic statistics collection mode is set separately for commands that occur within a procedural language function and commands that execute outside of a function:

- The \texttt{gp_autostats_mode} configuration parameter controls automatic statistics collection behavior outside of functions and is set to \texttt{on_no_stats} by default.
- The \texttt{gp_autostats_mode_in_functions} parameter controls the behavior when table operations are performed within a procedural language function and is set to \texttt{none} by default.

With the \texttt{on_change} mode, ANALYZE is triggered only if the number of rows affected exceeds the threshold defined by the gp_autostats_on_change_threshold configuration parameter. The default value for this parameter is a very high value, 2147483647, which effectively disables automatic statistics collection; you must set the threshold to a lower number to enable it. The \texttt{on_change} mode could trigger large, unexpected analyze operations that could disrupt the system, so it is not recommended to set it globally. It could be useful in a session, for example to automatically analyze a table following a load.
To disable automatic statistics collection outside of functions, set the `gp_autostats_mode` parameter to `none`:

```
  gpconfigure -c gp_autostats_mode -v none
```

To enable automatic statistics collection in functions for tables that have no statistics, change `gp_autostats_mode_in_functions` to `on_no_stats`:

```
  gpconfigure -c gp_autostats_mode_in_functions -v on_no_stats
```

Set the `log_autostats` system configuration parameter to `on` if you want to log automatic statistics collection operations.
Managing a Greenplum System

This section describes basic system administration tasks performed by a Greenplum Database system administrator.

This section contains the following topics:

- About the Greenplum Database Release Version Number
- Starting and Stopping Greenplum Database
- Accessing the Database
- Configuring the Greenplum Database System
- Enabling High Availability and Data Consistency Features
- Backing Up and Restoring Databases
- Expanding a Greenplum System
- Migrating Data with gpcopy
- Defining Database Objects
- Routine System Maintenance Tasks

About the Greenplum Database Release Version Number

Greenplum Database version numbers and they way they change identify what has been modified from one Greenplum Database release to the next.

A Greenplum Database release version number takes the format x.y.z, where:

- x identifies the Major version number
- y identifies the Minor version number
- z identifies the Patch version number

Greenplum Database releases that have the same Major release number are guaranteed to be backwards compatible. Greenplum Database increments the Major release number when the catalog changes or when incompatible feature changes or new features are introduced. Previously deprecated functionality may be removed in a major release.

The Minor release number for a given Major release increments when backwards compatible new features are introduced or when a Greenplum Database feature is deprecated. (Previously deprecated functionality will never be removed in a minor release.)

Greenplum Database increments the Patch release number for a given Minor release for backwards-compatible bug fixes.

Starting and Stopping Greenplum Database

In a Greenplum Database DBMS, the database server instances (the master and all segments) are started or stopped across all of the hosts in the system in such a way that they can work together as a unified DBMS.

Because a Greenplum Database system is distributed across many machines, the process for starting and stopping a Greenplum Database system is different than the process for starting and stopping a regular PostgreSQL DBMS.

Use the gpstart and gpstop utilities to start and stop Greenplum Database, respectively. These utilities are located in the $GPHOME/bin directory on your Greenplum Database master host.

**Important:** Do not issue a kill command to end any Postgres process. Instead, use the database command pg_cancel_backend().
Issuing a kill -9 or kill -11 can introduce database corruption and prevent root cause analysis from being performed.

For information about `gpstart` and `gpstop`, see the *Greenplum Database Utility Guide*.

**Starting Greenplum Database**

Start an initialized Greenplum Database system by running the `gpstart` utility on the master instance.

Use the `gpstart` utility to start a Greenplum Database system that has already been initialized by the `gpinitsystem` utility, but has been stopped by the `gpstop` utility. The `gpstart` utility starts Greenplum Database by starting all the Postgres database instances on the Greenplum Database cluster. `gpstart` orchestrates this process and performs the process in parallel.

- Run `gpstart` on the master host to start Greenplum Database:

  ```
  $ gpstart
  ```

**Restarting Greenplum Database**

Stop the Greenplum Database system and then restart it.

The `gpstop` utility with the `-r` option can stop and then restart Greenplum Database after the shutdown completes.

- To restart Greenplum Database, enter the following command on the master host:

  ```
  $ gpstop -r
  ```

**Reloading Configuration File Changes Only**

Reload changes to Greenplum Database configuration files without interrupting the system.

The `gpstop` utility can reload changes to the `pg_hba.conf` configuration file and to runtime parameters in the master `postgresql.conf` file and `pg_hba.conf` file without service interruption. Active sessions pick up changes when they reconnect to the database. Many server configuration parameters require a full system restart (`gpstop -r`) to activate. For information about server configuration parameters, see the *Greenplum Database Reference Guide*.

- Reload configuration file changes without shutting down the system using the `gpstop` utility:

  ```
  $ gpstop -u
  ```

**Starting the Master in Maintenance Mode**

Start only the master to perform maintenance or administrative tasks without affecting data on the segments.

Maintenance mode should only be used with direction from Pivotal Technical Support. For example, you could connect to a database only on the master instance in maintenance mode and edit system catalog settings. For more information about system catalog tables, see the *Greenplum Database Reference Guide*.

1. Run `gpstart` using the `-m` option:

   ```
   $ gpstart -m
   ```

2. Connect to the master in maintenance mode to do catalog maintenance. For example:

   ```
   $ PGOPTIONS='-c gp_session_role=utility' psql postgres
   ```
3. After completing your administrative tasks, stop the master in utility mode. Then, restart it in production mode.

```bash
$ gpstop -mr
```

**Warning:**
Incorrect use of maintenance mode connections can result in an inconsistent system state. Only Technical Support should perform this operation.

### Stopping Greenplum Database

The `gpstop` utility stops or restarts your Greenplum Database system and always runs on the master host. When activated, `gpstop` stops all `postgres` processes in the system, including the master and all segment instances. The `gpstop` utility uses a default of up to 64 parallel worker threads to bring down the Postgres instances that make up the Greenplum Database cluster. The system waits for any active transactions to finish before shutting down. To stop Greenplum Database immediately, use fast mode.

- **To stop Greenplum Database:**
  ```bash
  $ gpstop
  ```

- **To stop Greenplum Database in fast mode:**
  ```bash
  $ gpstop -M fast
  ```

By default, you are not allowed to shut down Greenplum Database if there are any client connections to the database. Use the `-M fast` option to roll back all in progress transactions and terminate any connections before shutting down.

### Stopping Client Processes

Greenplum Database launches a new backend process for each client connection. A Greenplum Database user with `SUPERUSER` privileges can cancel and terminate these client backend processes.

Canceling a backend process with the `pg_cancel_backend()` function ends a specific queued or active client query. Terminating a backend process with the `pg_terminate_backend()` function terminates a client connection to a database.

The `pg_cancel_backend()` function has two signatures:

- `pg_cancel_backend( pid int4 )`
- `pg_cancel_backend( pid int4, msg text )`

The `pg_terminate_backend()` function has two similar signatures:

- `pg_terminate_backend( pid int4 )`
- `pg_terminate_backend( pid int4, msg text )`

If you provide a `msg`, Greenplum Database includes the text in the cancel message returned to the client. `msg` is limited to 128 bytes; Greenplum Database truncates anything longer.

The `pg_cancel_backend()` and `pg_terminate_backend()` functions return `true` if successful, and `false` otherwise.

To cancel or terminate a backend process, you must first identify the process ID of the backend. You can obtain the process ID from the `pid` column of the `pg_stat_activity` view. For example, to view the process information associated with all running and queued queries:

```sql
=# SELECT usename, pid, waiting, state, query, datname FROM pg_stat_activity;
```
Sample partial query output:

<table>
<thead>
<tr>
<th>username</th>
<th>pid</th>
<th>waiting</th>
<th>state</th>
<th>query</th>
<th>datname</th>
</tr>
</thead>
<tbody>
<tr>
<td>sammy</td>
<td>31861</td>
<td>f</td>
<td>idle</td>
<td>SELECT * FROM testtbl;</td>
<td>testdb</td>
</tr>
<tr>
<td>billy</td>
<td>31905</td>
<td>t</td>
<td>active</td>
<td>SELECT * FROM topten;</td>
<td>testdb</td>
</tr>
</tbody>
</table>

Use the output to identify the process id (pid) of the query or client connection.

For example, to cancel the waiting query identified in the sample output above and include 'Admin canceled long-running query.' as the message returned to the client:

```sql
=# SELECT pg_cancel_backend(31905 , 'Admin canceled long-running query.');
ERROR:  canceling statement due to user request: "Admin canceled long-running query."
```

### Accessing the Database

This topic describes the various client tools you can use to connect to Greenplum Database, and how to establish a database session.

#### Establishing a Database Session

Users can connect to Greenplum Database using a PostgreSQL-compatible client program, such as `psql`. Users and administrators always connect to Greenplum Database through the master; the segments cannot accept client connections.

In order to establish a connection to the Greenplum Database master, you will need to know the following connection information and configure your client program accordingly.

#### Table 16: Connection Parameters

<table>
<thead>
<tr>
<th>Connection Parameter</th>
<th>Description</th>
<th>Environment Variable</th>
</tr>
</thead>
<tbody>
<tr>
<td>Application name</td>
<td>The application name that is connecting to the database. The default value, held in the application_name connection parameter is <code>psql</code>.</td>
<td>$PGAPPNAME</td>
</tr>
<tr>
<td>Database name</td>
<td>The name of the database to which you want to connect. For a newly initialized system, use the postgres database to connect for the first time.</td>
<td>$PGDATABASE</td>
</tr>
<tr>
<td>Host name</td>
<td>The host name of the Greenplum Database master. The default host is the local host.</td>
<td>$PGHOST</td>
</tr>
<tr>
<td>Port</td>
<td>The port number that the Greenplum Database master instance is running on. The default is 5432.</td>
<td>$PGPORT</td>
</tr>
<tr>
<td>User name</td>
<td>The database user (role) name to connect as. This is not necessarily the same as your OS user name. Check with your Greenplum administrator if you are not sure what you database user name is. Note that every Greenplum Database system has one superuser account that is created automatically at initialization time. This account has the same name as the OS name of the user who initialized the Greenplum system (typically <code>gpadmin</code>).</td>
<td>$PGUSER</td>
</tr>
</tbody>
</table>

Connecting with `psql` provides example commands for connecting to Greenplum Database.
Supported Client Applications

Users can connect to Greenplum Database using various client applications:

- A number of Greenplum Database Client Applications are provided with your Greenplum installation. The `psql` client application provides an interactive command-line interface to Greenplum Database.
- Using standard Database Application Interfaces, such as ODBC and JDBC, users can create their own client applications that interface to Greenplum Database.
- Most client tools that use standard database interfaces, such as ODBC and JDBC, can be configured to connect to Greenplum Database.

Greenplum Database Client Applications

Greenplum Database comes installed with a number of client utility applications located in the `$GPHOME/bin` directory of your Greenplum Database master host installation. The following are the most commonly used client utility applications:

Table 17: Commonly used client applications

<table>
<thead>
<tr>
<th>Name</th>
<th>Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td>createdb</td>
<td>create a new database</td>
</tr>
<tr>
<td>createlang</td>
<td>define a new procedural language</td>
</tr>
<tr>
<td>createuser</td>
<td>define a new database role</td>
</tr>
<tr>
<td>dropdb</td>
<td>remove a database</td>
</tr>
<tr>
<td>droplang</td>
<td>remove a procedural language</td>
</tr>
<tr>
<td>dropuser</td>
<td>remove a role</td>
</tr>
<tr>
<td>psql</td>
<td>PostgreSQL interactive terminal</td>
</tr>
<tr>
<td>reindexdb</td>
<td>reindex a database</td>
</tr>
<tr>
<td>vacuumdb</td>
<td>garbage-collect and analyze a database</td>
</tr>
</tbody>
</table>

Note: `createlang` and `droplang` are deprecated and might be removed in a future release. These utilities are no longer used in Pivotal Greenplum Database, and they will display an error if you attempt to use them to install a Greenplum procedural language. Use the `CREATE EXTENSION` or `DROP EXTENSION` command instead.

When using these client applications, you must connect to a database through the Greenplum master instance. You will need to know the name of your target database, the host name and port number of the master, and what database user name to connect as. This information can be provided on the command-line using the options `-d`, `-h`, `-p`, and `-U` respectively. If an argument is found that does not belong to any option, it will be interpreted as the database name first.

All of these options have default values which will be used if the option is not specified. The default host is the local host. The default port number is 5432. The default user name is your OS system user name, as is the default database name. Note that OS user names and Greenplum Database user names are not necessarily the same.

If the default values are not correct, you can set the environment variables `PGDATABASE`, `PGHOST`, `PGPORT`, and `PGUSER` to the appropriate values, or use a `psql ~/.pgpass` file to contain frequently-used passwords.

For information about Greenplum Database environment variables, see the Greenplum Database Reference Guide. For information about `psql`, see the Greenplum Database Utility Guide.
Connecting with psql

Depending on the default values used or the environment variables you have set, the following examples show how to access a database via psql:

```
$ psql -d gpdatabase -h master_host -p 5432 -U gpadmin

$ psql gpdatabase

$ psql
```

If a user-defined database has not yet been created, you can access the system by connecting to the `postgres` database. For example:

```
$ psql postgres
```

After connecting to a database, `psql` provides a prompt with the name of the database to which `psql` is currently connected, followed by the string `=>` (or `=#` if you are the database superuser). For example:

```
gpdatabase=>
```

At the prompt, you may type in SQL commands. A SQL command must end with a `;` (semicolon) in order to be sent to the server and executed. For example:

```
=> SELECT * FROM mytable;
```

See the Greenplum Reference Guide for information about using the `psql` client application and SQL commands and syntax.

Using the PgBouncer Connection Pooler

The PgBouncer utility manages connection pools for PostgreSQL and Greenplum Database connections.

The following topics describe how to set up and use PgBouncer with Greenplum Database. Refer to the PgBouncer web site for information about using PgBouncer with PostgreSQL.

- Overview
- Migrating PgBouncer
- Configuring PgBouncer
- Starting PgBouncer
- Managing PgBouncer

Overview

A database connection pool is a cache of database connections. Once a pool of connections is established, connection pooling eliminates the overhead of creating new database connections, so clients connect much faster and the server load is reduced.

The PgBouncer connection pooler, from the PostgreSQL community, is included in your Greenplum Database installation. PgBouncer is a light-weight connection pool manager for Greenplum and PostgreSQL. PgBouncer maintains a pool for connections for each database and user combination. PgBouncer either creates a new database connection for a client or reuses an existing connection for the same user and database. When the client disconnects, PgBouncer returns the connection to the pool for re-use.

PgBouncer shares connections in one of three pool modes:
• **Session pooling** – When a client connects, a connection is assigned to it as long as it remains connected. When the client disconnects, the connection is placed back into the pool.

• **Transaction pooling** – A connection is assigned to a client for the duration of a transaction. When PgBouncer notices the transaction is done, the connection is placed back into the pool. This mode can be used only with applications that do not use features that depend upon a session.

• **Statement pooling** – Statement pooling is like transaction pooling, but multi-statement transactions are not allowed. This mode is intended to enforce autocommit mode on the client and is targeted for PL/Proxy on PostgreSQL.

You can set a default pool mode for the PgBouncer instance. You can override this mode for individual databases and users.

PgBouncer supports the standard connection interface shared by PostgreSQL and Greenplum Database. The Greenplum Database client application (for example, psql) connects to the host and port on which PgBouncer is running rather than the Greenplum Database master host and port.

PgBouncer includes a psql-like administration console. Authorized users can connect to a virtual database to monitor and manage PgBouncer. You can manage a PgBouncer daemon process via the admin console. You can also use the console to update and reload PgBouncer configuration at runtime without stopping and restarting the process.

PgBouncer natively supports TLS.

**Migrating PgBouncer**

When you migrate to a new Greenplum Database version, you must migrate your PgBouncer instance to that in the new Greenplum Database installation.

• **If you are migrating to a Greenplum Database version 5.8.x or earlier**, you can migrate PgBouncer without dropping connections. Launch the new PgBouncer process with the `-R` option and the configuration file that you started the process with:

```
$ pgbouncer -R -d pgbouncer.ini
```

The `-R` (reboot) option causes the new process to connect to the console of the old process through a Unix socket and issue the following commands:

```
SUSPEND;
SHOW FDS;
SHUTDOWN;
```

When the new process detects that the old process is gone, it resumes the work with the old connections. This is possible because the `SHOW FDS` command sends actual file descriptors to the new process. If the transition fails for any reason, kill the new process and the old process will resume.

• **If you are migrating to a Greenplum Database version 5.9.0 or later**, you must shut down the PgBouncer instance in your old installation and reconfigure and restart PgBouncer in your new installation.

• If you used stunnel to secure PgBouncer connections in your old installation, you must configure SSL/TLS in your new installation using the built-in TLS capabilities of PgBouncer 1.8.1 and later.

• If you used LDAP authentication in your old installation, you must configure LDAP in your new installation using the built-in PAM integration capabilities of PgBouncer 1.8.1 and later. You must also remove or replace any ldap://-prefixed password strings in the auth_file.

**Configuring PgBouncer**

You configure PgBouncer and its access to Greenplum Database via a configuration file. This configuration file, commonly named `pgbouncer.ini`, provides location information for Greenplum databases. The
The *pgbouncer.ini* file also specifies process, connection pool, authorized users, and authentication configuration for PgBouncer.

**Sample pgbouncer.ini file contents:**

```ini
[databases]
postgres = host=127.0.0.1 port=5432 dbname=postgres
pgb_mydb = host=127.0.0.1 port=5432 dbname=mydb

[pgbouncer]
pool_mode = session
listen_port = 6543
listen_addr = 127.0.0.1
auth_type = md5
auth_file = users.txt
logfile = pgbouncer.log
pidfile = pgbouncer.pid
admin_users = gpadmin
```

Refer to the *pgbouncer.ini* reference page for the PgBouncer configuration file format and the list of configuration properties it supports.

When a client connects to PgBouncer, the connection pooler looks up the configuration for the requested database (which may be an alias for the actual database) that was specified in the *pgbouncer.ini* configuration file to find the host name, port, and database name for the database connection. The configuration file also identifies the authentication mode in effect for the database.

PgBouncer requires an authentication file, a text file that contains a list of Greenplum Database users and passwords. The contents of the file are dependent on the `auth_type` you configure in the *pgbouncer.ini* file. Passwords may be either clear text or MD5-encoded strings. You can also configure PgBouncer to query the destination database to obtain password information for users that are not in the authentication file.

### PgBouncer Authentication File Format

PgBouncer requires its own user authentication file. You specify the name of this file in the `auth_file` property of the *pgbouncer.ini* configuration file. `auth_file` is a text file in the following format:

```
"username1" "password" ...
"username2" "md5abcdef012342345" ...
```

`auth_file` contains one line per user. Each line must have at least two fields, both of which are enclosed in double quotes (" "). The first field identifies the Greenplum Database user name. The second field is either a plain-text or an MD5-encoded password. PgBouncer ignores the remainder of the line.

(The format of `auth_file` is similar to that of the *pg_auth* text file that Greenplum Database uses for authentication information. PgBouncer can work directly with this Greenplum Database authentication file.)

Use an MD5 encoded password. The format of an MD5 encoded password is:

```
"md5" + MD5_encoded(<password><username>)
```

You can also obtain the MD5-encoded passwords of all Greenplum Database users from the *pg_shadow* view.

### Configuring HBA-based Authentication for PgBouncer

PgBouncer supports HBA-based authentication. To configure HBA-based authentication for PgBouncer, you set `auth_type=hba` in the *pgbouncer.ini* configuration file. You also provide the filename of the HBA-format file in the `auth_hba_file` parameter of the *pgbouncer.ini* file.
Contents of an example PgBouncer HBA file named `hba_bouncer.conf`:

<table>
<thead>
<tr>
<th>local</th>
<th>all</th>
<th>bouncer</th>
<th>trust</th>
</tr>
</thead>
<tbody>
<tr>
<td>host</td>
<td>all</td>
<td>bouncer</td>
<td>127.0.0.1/32</td>
</tr>
</tbody>
</table>

Example excerpt from the related `pgbouncer.ini` configuration file:

```ini
[databases]
p0 = port=15432 host=127.0.0.1 dbname=p0 user=bouncer pool_size=2
p1 = port=15432 host=127.0.0.1 dbname=p1 user=bouncer
...

[pgbouncer]
... auth_type = hba
auth_file = userlist.txt
auth_hba_file = hba_bouncer.conf
...
```

Refer to the [HBA file format](https://www.postgresql.org/docs/current/libpq-hbafile-format.html) discussion in the PgBouncer documentation for information about PgBouncer support of the HBA authentication file format.

**Starting PgBouncer**

You can run PgBouncer on the Greenplum Database master or on another server. If you install PgBouncer on a separate server, you can easily switch clients to the standby master by updating the PgBouncer configuration file and reloading the configuration using the PgBouncer Administration Console.

Follow these steps to set up PgBouncer.

1. Create a PgBouncer configuration file. For example, add the following text to a file named `pgbouncer.ini`:

   ```ini
   [databases]
   postgres = host=127.0.0.1 port=5432 dbname=postgres
   pgb_mydb = host=127.0.0.1 port=5432 dbname=mydb
   
   [pgbouncer]
   pool_mode = session
   listen_port = 6543
   listen_addr = 127.0.0.1
   auth_type = md5
   auth_file = users.txt
   logfile = pgbouncer.log
   pidfile = pgbouncer.pid
   admin_users = gpadmin
   
   The file lists databases and their connection details. The file also configures the PgBouncer instance. Refer to the `pgbouncer.ini` reference page for information about the format and content of a PgBouncer configuration file.

2. Create an authentication file. The filename should be the name you specified for the `auth_file` parameter of the `pgbouncer.ini` file, `users.txt`. Each line contains a user name and password. The format of the password string matches the `auth_type` you configured in the PgBouncer configuration file. If the `auth_type` parameter is `plain`, the password string is a clear text password, for example:

   "gpadmin" "gpadmin1234"
If the `auth_type` in the following example is `md5`, the authentication field must be MD5-encoded. The format for an MD5-encoded password is:

```
"md5" + MD5_encoded(<password><username>)
```

3. Launch `pgbouncer`:

```
$ $GPHOME/bin/pgbouncer -d pgbouncer.ini
```

The `-d` option runs PgBouncer as a background (daemon) process. Refer to the `pgbouncer` reference page for the `pgbouncer` command syntax and options.

4. Update your client applications to connect to `pgbouncer` instead of directly to Greenplum Database server. For example, to connect to the Greenplum database named `mydb` configured above, run `psql` as follows:

```
$ psql -p 6543 -U someuser pgb_mydb
```

The `-p` option value is the `listen_port` that you configured for the PgBouncer instance.

### Managing PgBouncer

PgBouncer provides a `psql`-like administration console. You log in to the PgBouncer Administration Console by specifying the PgBouncer port number and a virtual database named `pgbouncer`. The console accepts SQL-like commands that you can use to monitor, reconfigure, and manage PgBouncer.

For complete documentation of PgBouncer Administration Console commands, refer to the `PgBouncer Administration Console` command reference.

Follow these steps to get started with the PgBouncer Administration Console.

1. Use `psql` to log in to the `pgbouncer` virtual database:

```
$ psql -p 6543 -U username pgbouncer
```

The `username` that you specify must be listed in the `admin_users` parameter in the `pgbouncer.ini` configuration file. You can also log in to the PgBouncer Administration Console with the current Unix `username` if the `pgbouncer` process is running under that user's UID.

2. To view the available PgBouncer Administration Console commands, run the `SHOW help` command:

```
pgbouncer=# SHOW help;
NOTICE: Console usage
DETAIL:  
SHOW HELP|CONFIG|DATABASES|POOLS|CLIENTS|SERVERS|VERSION
SHOW FDS|SOCKETS|ACTIVE_SOCKETS|LISTS|MEM
SHOW DNS_HOSTS|DNS_ZONES
SHOW STATS|STATS_TOTALS|STATS_AVERAGES
SET key = arg
RELOAD
PAUSE [<db>]
RESUME [<db>]
DISABLE <db>
ENABLE <db>
KILL <db>
SUSPEND
SHUTDOWN
```

3. If you update PgBouncer configuration by editing the `pgbouncer.ini` configuration file, you use the `RELOAD` command to reload the file:

```
pgbouncer=# RELOAD;
```
Mapping PgBouncer Clients to Greenplum Database Server Connections

To map a PgBouncer client to a Greenplum Database server connection, use the PgBouncer Administration Console `SHOW CLIENTS` and `SHOW SERVERS` commands:

1. Use `ptr` and `link` to map the local client connection to the server connection.
2. Use the `addr` and the `port` of the client connection to identify the TCP connection from the client.
3. Use `local_addr` and `local_port` to identify the TCP connection to the server.

Database Application Interfaces

You may want to develop your own client applications that interface to Greenplum Database. PostgreSQL provides a number of database drivers for the most commonly used database application programming interfaces (APIs), which can also be used with Greenplum Database. These drivers are available as a separate download. Each driver (except libpq, which comes with PostgreSQL) is an independent PostgreSQL development project and must be downloaded, installed and configured to connect to Greenplum Database. The following drivers are available:

Table 18: Greenplum Database Interfaces

<table>
<thead>
<tr>
<th>API</th>
<th>PostgreSQL Driver</th>
<th>Download Link</th>
</tr>
</thead>
<tbody>
<tr>
<td>JDBC</td>
<td>Greenplum DataDirect JDBC Driver</td>
<td><a href="https://network.pivotal.io/products/pivotal-gpdb">https://network.pivotal.io/products/pivotal-gpdb</a></td>
</tr>
<tr>
<td>Perl DBI</td>
<td>pgperl</td>
<td><a href="https://metacpan.org/release/DBD-Pg">https://metacpan.org/release/DBD-Pg</a></td>
</tr>
<tr>
<td>Python DBI</td>
<td>pygresql</td>
<td><a href="http://www.pygresql.org/">http://www.pygresql.org/</a></td>
</tr>
<tr>
<td>libpq C Library</td>
<td>libpq</td>
<td><a href="https://www.postgresql.org/docs/9.4/libpq.html">https://www.postgresql.org/docs/9.4/libpq.html</a></td>
</tr>
</tbody>
</table>

General instructions for accessing a Greenplum Database with an API are:

1. Download your programming language platform and respective API from the appropriate source. For example, you can get the Java Development Kit (JDK) and JDBC API from Oracle.
2. Write your client application according to the API specifications. When programming your application, be aware of the SQL support in Greenplum Database so you do not include any unsupported SQL syntax.

See the Greenplum Database Reference Guide for more information.

Download the appropriate driver and configure connectivity to your Greenplum Database master instance.

Troubleshooting Connection Problems

A number of things can prevent a client application from successfully connecting to Greenplum Database. This topic explains some of the common causes of connection problems and how to correct them.
Table 19: Common connection problems

<table>
<thead>
<tr>
<th>Problem</th>
<th>Solution</th>
</tr>
</thead>
<tbody>
<tr>
<td>No pg_hba.conf entry for host or user</td>
<td>To enable Greenplum Database to accept remote client connections, you must configure your Greenplum Database master instance so that connections are allowed from the client hosts and database users that will be connecting to Greenplum Database. This is done by adding the appropriate entries to the pg_hba.conf configuration file (located in the master instance's data directory). For more detailed information, see <a href="#">Allowing Connections to Greenplum Database</a>.</td>
</tr>
<tr>
<td>Greenplum Database is not running</td>
<td>If the Greenplum Database master instance is down, users will not be able to connect. You can verify that the Greenplum Database system is up by running the gpstate utility on the Greenplum master host.</td>
</tr>
<tr>
<td>Network problems Interconnect timeouts</td>
<td>If users connect to the Greenplum master host from a remote client, network problems can prevent a connection (for example, DNS host name resolution problems, the host system is down, and so on.). To ensure that network problems are not the cause, connect to the Greenplum master host from the remote client host. For example: <code>ping hostname</code>. If the system cannot resolve the host names and IP addresses of the hosts involved in Greenplum Database, queries and connections will fail. For some operations, connections to the Greenplum Database master use <code>localhost</code> and others use the actual host name, so you must be able to resolve both. If you encounter this error, first make sure you can connect to each host in your Greenplum Database array from the master host over the network. In the <code>/etc/hosts</code> file of the master and all segments, make sure you have the correct host names and IP addresses for all hosts involved in the Greenplum Database array. The <code>127.0.0.1</code> IP must resolve to <code>localhost</code>.</td>
</tr>
<tr>
<td>Too many clients already</td>
<td>By default, Greenplum Database is configured to allow a maximum of 250 concurrent user connections on the master and 750 on a segment. A connection attempt that causes that limit to be exceeded will be refused. This limit is controlled by the <code>max_connections</code> parameter in the <code>postgresql.conf</code> configuration file of the Greenplum Database master. If you change this setting for the master, you must also make appropriate changes at the segments.</td>
</tr>
</tbody>
</table>

**Configuring the Greenplum Database System**

Server configuration parameters affect the behavior of Greenplum Database. They are part of the PostgreSQL "Grand Unified Configuration" system, so they are sometimes called "GUCs." Most of the Greenplum Database server configuration parameters are the same as the PostgreSQL configuration parameters, but some are Greenplum-specific.

**About Greenplum Database Master and Local Parameters**

Server configuration files contain parameters that configure server behavior. The Greenplum Database configuration file, `postgresql.conf`, resides in the data directory of the database instance.

The master and each segment instance have their own `postgresql.conf` file. Some parameters are `local`: each segment instance examines its `postgresql.conf` file to get the value of that parameter. Set local parameters on the master and on each segment instance.

Other parameters are `master` parameters that you set on the master instance. The value is passed down to (or in some cases ignored by) the segment instances at query run time.

See the [Greenplum Database Reference Guide](#) for information about `local` and `master` server configuration parameters.
Setting Configuration Parameters

Many configuration parameters limit who can change them and where or when they can be set. For example, to change certain parameters, you must be a Greenplum Database superuser. Other parameters can be set only at the system level in the `postgresql.conf` file or require a system restart to take effect.

Many configuration parameters are session parameters. You can set session parameters at the system level, the database level, the role level, or the session level. Database users can change most session parameters within their session, but some require superuser permissions.

See the *Greenplum Database Reference Guide* for information about setting server configuration parameters.

Setting a Local Configuration Parameter

To change a local configuration parameter across multiple segments, update the parameter in the `postgresql.conf` file of each targeted segment, both primary and mirror. Use the `gpconfig` utility to set a parameter in all Greenplum `postgresql.conf` files. For example:

```
$ gpconfig -c gp_vmem_protect_limit -v 4096
```

Restart Greenplum Database to make the configuration changes effective:

```
$ gpstop -r
```

Setting a Master Configuration Parameter

To set a master configuration parameter, set it at the Greenplum Database master instance. If it is also a session parameter, you can set the parameter for a particular database, role, or session. If a parameter is set at multiple levels, the most granular level takes precedence. For example, session overrides role, role overrides database, and database overrides system.

Setting Parameters at the System Level

Master parameter settings in the master `postgresql.conf` file are the system-wide default. To set a master parameter:

1. Edit the `$MASTER_DATA_DIRECTORY/postgresql.conf` file.
2. Find the parameter to set, uncomment it (remove the preceding `#` character), and type the desired value.
3. Save and close the file.
4. For session parameters that do not require a server restart, upload the `postgresql.conf` changes as follows:

```
$ gpstop -u
```

5. For parameter changes that require a server restart, restart Greenplum Database as follows:

```
$ gpstop -r
```

For details about the server configuration parameters, see the *Greenplum Database Reference Guide*.

Setting Parameters at the Database Level

Use `ALTER DATABASE` to set parameters at the database level. For example:

```
=# ALTER DATABASE mydatabase SET search_path TO myschema;
```
When you set a session parameter at the database level, every session that connects to that database uses that parameter setting. Settings at the database level override settings at the system level.

**Setting Parameters at the Role Level**

Use `ALTER ROLE` to set a parameter at the role level. For example:

```sql
=# ALTER ROLE bob SET search_path TO bobschema;
```

When you set a session parameter at the role level, every session initiated by that role uses that parameter setting. Settings at the role level override settings at the database level.

**Setting Parameters in a Session**

Any session parameter can be set in an active database session using the `SET` command. For example:

```sql
=# SET statement_mem TO '200MB';
```

The parameter setting is valid for the rest of that session or until you issue a `RESET` command. For example:

```sql
=# RESET statement_mem;
```

Settings at the session level override those at the role level.

**Viewing Server Configuration Parameter Settings**

The SQL command `SHOW` allows you to see the current server configuration parameter settings. For example, to see the settings for all parameters:

```bash
$ psql -c 'SHOW ALL;'
```

`SHOW` lists the settings for the master instance only. To see the value of a particular parameter across the entire system (master and all segments), use the `gpconfig` utility. For example:

```bash
$ gpconfig --show max_connections
```

**Configuration Parameter Categories**

Configuration parameters affect categories of server behaviors, such as resource consumption, query tuning, and authentication. Refer to Parameter Categories in the *Greenplum Database Reference Guide* for a list of Greenplum server configuration parameter categories.

**Enabling Compression**

You can configure Greenplum Database to use data compression with some database features and with some utilities. Compression reduces disk usage and improves I/O across the system, however, it adds some performance overhead when compressing and decompressing data.

You can configure support for data compression with these features and utilities. See the specific feature or utility for information about support for compression.

- Append-optimized tables support compressing table data. See `CREATE TABLE`.
- User-defined data types can be defined to compress data. See `CREATE TYPE`.
- The external table protocols `gpfdist (gpfdists), s3, and pxf` support compression when accessing external data. For information about external tables, see `CREATE EXTERNAL TABLE`.
• Workfiles (temporary spill files that are created when executing a query that requires more memory than is allocated) can be compressed. See the server configuration parameter `gp_workfile_compression`.

• The Greenplum Database utilities `gpbackup`, `gprestore`, `gpcopy`, `gpload`, and `gplogfilter` support compression.

For some compression algorithms (such as zlib) Greenplum Database requires software packages installed on the host system. For information about required software packages, see the Greenplum Database Installation Guide.

**Enabling High Availability and Data Consistency Features**

The fault tolerance and the high-availability features of Greenplum Database can be configured.

**Important:** When data loss is not acceptable for a Pivotal Greenplum Database cluster, master and segment mirroring must be enabled in order for the cluster to be supported by Pivotal. Without mirroring, system and data availability is not guaranteed; Pivotal will make best efforts to restore a cluster in this case. For information about master and segment mirroring, see About Redundancy and Failover.

For information about the utilities that are used to enable high availability, see the Greenplum Database Utility Guide.

**Overview of Greenplum Database High Availability**

A Greenplum Database system can be made highly available by providing a fault-tolerant hardware platform, by enabling Greenplum Database high-availability features, and by performing regular monitoring and maintenance procedures to ensure the health of all system components.

Hardware components will eventually fail, whether due to normal wear or an unexpected circumstance. Loss of power can lead to temporarily unavailable components. A system can be made highly available by providing redundant standbys for components that can fail so that services can continue uninterrupted when a failure occurs. In some cases, the cost of redundancy is higher than users' tolerance for interruption in service. When this is the case, the goal is to ensure that full service is able to be restored, and can be restored within an expected timeframe.

With Greenplum Database, fault tolerance and data availability is achieved with:

- **Hardware level RAID storage protection**
- **Data storage checksums**
- **Greenplum segment mirroring**
- **Master mirroring**
- **Dual clusters**
- **Database backup and restore**

**Hardware level RAID**

A best practice Greenplum Database deployment uses hardware level RAID to provide high performance redundancy for single disk failure without having to go into the database level fault tolerance. This provides a lower level of redundancy at the disk level.

**Data storage checksums**

Greenplum Database uses checksums to verify that data loaded from disk to memory has not been corrupted on the file system.

Greenplum Database has two kinds of storage for user data: heap and append-optimized. Both storage models use checksums to verify data read from the file system and, with the default settings, they handle checksum verification errors in a similar way.
Greenplum Database master and segment database processes update data on pages in the memory they manage. When a memory page is updated and flushed to disk, checksums are computed and saved with the page. When a page is later retrieved from disk, the checksums are verified and the page is only permitted to enter managed memory if the verification succeeds. A failed checksum verification is an indication of corruption in the file system and causes Greenplum Database to generate an error, aborting the transaction.

The default checksum settings provide the best level of protection from undetected disk corruption propagating into the database and to mirror segments.

Heap checksum support is enabled by default when the Greenplum Database cluster is initialized with the `gpinit` management utility. Although it is strongly discouraged, a cluster can be initialized without heap checksum support by setting the `HEAP_CHECKSUM` parameter to off in the `gpinit` cluster configuration file. See `gpinit`.

Once initialized, it is not possible to change heap checksum support for a cluster without reinitializing the system and reloading databases.

You can check the read-only server configuration parameter `data_checkums` to see if heap checksums are enabled in a cluster:

```bash
$ gpconfig -s data_checkums
```

When a Greenplum Database cluster starts up, the `gpstart` utility checks that heap checksums are consistently enabled or disabled on the master and all segments. If there are any differences, the cluster fails to start. See `gpstart`.

In cases where it is necessary to ignore heap checksum verification errors so that data can be recovered, setting the `ignore_checksum_failure` system configuration parameter to on causes Greenplum Database to issue a warning when a heap checksum verification fails, but the page is then permitted to load into managed memory. If the page is updated and saved to disk, the corrupted data could be replicated to the mirror segment. Because this can lead to data loss, setting `ignore_checksum_failure` to on should only be done to enable data recovery.

For append-optimized storage, checksum support is one of several storage options set at the time an append-optimized table is created with the `CREATE TABLE` command. The default storage options are specified in the `gp_default_storage_options` server configuration parameter. The `checksum` storage option is enabled by default and disabling it is strongly discouraged.

If you choose to disable checksums for an append-optimized table, you can either

- change the `gp_default_storage_options` configuration parameter to include `checksum=false` before creating the table, or
- add the `checksum=false` option to the `WITH storage_options` clause of the `CREATE TABLE` statement.

Note that the `CREATE TABLE` statement allows you to set storage options, including checksums, for individual partition files.

See the `CREATE TABLE` command reference and the `gp_default_storage_options` configuration parameter reference for syntax and examples.

### Segment Mirroring

Greenplum Database stores data in multiple segment instances, each of which is a Greenplum Database PostgreSQL instance. The data for each table is spread between the segments based on the distribution policy that is defined for the table in the DDL at the time the table is created. When segment mirroring is enabled, for each segment instance there is a primary and mirror pair. The mirror segment is kept up to date with the primary segment using Write-Ahead Logging (WAL)-based streaming replication. See `Overview of Segment Mirroring`. 
The mirror instance for each segment is usually initialized with the `gpinit系统` utility or the `gpexpand` utility. As a best practice, the mirror runs on a different host than the primary instance to protect from a single machine failure. There are different strategies for assigning mirrors to hosts. When choosing the layout of the primaries and mirrors, it is important to consider the failure scenarios to ensure that processing skew is minimized in the case of a single machine failure.

**Master Mirroring**

There are two master instances in a highly available cluster, a primary and a standby. As with segments, the master and standby should be deployed on different hosts so that the cluster can tolerate a single host failure. Clients connect to the primary master and queries can be executed only on the primary master. The standby master is kept up to date with the primary master using Write-Ahead Logging (WAL)-based streaming replication. See [Overview of Master Mirroring](#).

If the master fails, the administrator runs the `gpactivatestandby` utility to have the standby master take over as the new primary master. You can configure a virtual IP address for the master and standby so that client programs do not have to switch to a different network address when the current master changes. If the master host fails, the virtual IP address can be swapped to the actual acting master.

**Dual Clusters**

An additional level of redundancy can be provided by maintaining two Greenplum Database clusters, both storing the same data.

Two methods for keeping data synchronized on dual clusters are "dual ETL" and "backup/restore."

Dual ETL provides a complete standby cluster with the same data as the primary cluster. ETL (extract, transform, and load) refers to the process of cleansing, transforming, validating, and loading incoming data into a data warehouse. With dual ETL, this process is executed twice in parallel, once on each cluster, and is validated each time. It also allows data to be queried on both clusters, doubling the query throughput. Applications can take advantage of both clusters and also ensure that the ETL is successful and validated on both clusters.

To maintain a dual cluster with the backup/restore method, create backups of the primary cluster and restore them on the secondary cluster. This method takes longer to synchronize data on the secondary cluster than the dual ETL strategy, but requires less application logic to be developed. Populating a second cluster with backups is ideal in use cases where data modifications and ETL are performed daily or less frequently.

**Backup and Restore**

Making regular backups of the databases is recommended except in cases where the database can be easily regenerated from the source data. Backups should be taken to protect from operational, software, and hardware errors.

Use the `gpbackup` utility to backup Greenplum databases. `gpbackup` performs the backup in parallel across segments, so backup performance scales up as hardware is added to the cluster.

When designing a backup strategy, a primary concern is where to store the backup data. The data each segment manages can be backed up on the segment's local storage, but should not be stored there permanently—the backup reduces disk space available to the segment and, more importantly, a hardware failure could simultaneously destroy the segment's live data and the backup. After performing a backup, the backup files should be moved from the primary cluster to separate, safe storage. Alternatively, the backup can be made directly to separate storage.

Using a Greenplum Database storage plugin with the `gpbackup` and `gprestore` utilities, you can send a backup to, or retrieve a backup from a remote location or a storage appliance. Greenplum Database storage plugins support connecting to locations including Amazon Simple Storage Service (Amazon S3) locations and Dell EMC Data Domain storage appliances.
Using the Backup/Restore Storage Plugin API you can create a custom plugin that the gpbackup and gprestore utilities can use to integrate a custom backup storage system with the Greenplum Database.

For information about using gpbackup and gprestore, see Parallel Backup with gpbackup and gprestore.

**Overview of Segment Mirroring**

When Greenplum Database High Availability is enabled, there are two types of segment instances: **primary** and **mirror**. Each primary segment has one corresponding mirror segment. A primary segment instance receives requests from the master to make changes to the segment data and then replicates those changes to the corresponding mirror. If Greenplum Database detects that a primary segment has failed or become unavailable, it changes the role of its mirror segment to primary segment and the role of the unavailable primary segment to mirror segment. Transactions in progress when the failure occurred roll back and must be restarted. The administrator must then recover the mirror segment, allow the mirror to synchronize with the current primary segment, and then exchange the primary and mirror segments so they are in their preferred roles.

If segment mirroring is not enabled, the Greenplum Database system shuts down if a segment instance fails. Administrators must manually recover all failed segments before Greenplum Database operations can resume.

When segment mirroring is enabled for an existing system, the primary segment instances continue to provide service to users while a snapshot of the primary segments are taken. While the snapshots are taken and deployed on the mirror segment instances, changes to the primary segment are also recorded. After the snapshot has been deployed on the mirror segment, the mirror segment is synchronized and kept current using Write-Ahead Logging (WAL)-based streaming replication. Greenplum Database WAL replication uses the walsender and walreceiver replication processes. The walsender process is a primary segment process. The walreceiver is a mirror segment process.

When database changes occur, the logs that capture the changes are streamed to the mirror segment to keep it current with the corresponding primary segments. During WAL replication, database changes are written to the logs before being applied, to ensure data integrity for any in-process operations.

When Greenplum Database detects a primary segment failure, the WAL replication process stops and the mirror segment automatically starts as the active primary segment. If a mirror segment fails or becomes inaccessible while the primary is active, the primary segment tracks database changes in logs that are applied to the mirror when it is recovered. For information about segment fault detection and the recovery process, see Detecting a Failed Segment.

These Greenplum Database system catalog tables contain mirroring and replication information.

- The catalog table gp_segment_configuration contains the current configuration and state of primary and mirror segment instances and the master and standby master instance.
- The catalog view gp_stat_replication contains replication statistics of the walsender processes that are used for Greenplum Database master and segment mirroring.

**About Segment Mirroring Configurations**

Mirror segment instances can be placed on hosts in the cluster in different configurations. As a best practice, a primary segment and the corresponding mirror are placed on different hosts. Each host must have the same number of primary and mirror segments. When you create segment mirrors with the Greenplum Database utilities gpinitdb or gpaddmirrors you can specify the segment mirror configuration, group mirroring (the default) or spread mirroring. With gpaddmirrors, you can create custom mirroring configurations with a gpaddmirrors configuration file and specify the file on the command line.

*Group mirroring* is the default mirroring configuration. The mirror segments for each host's primary segments are placed on one other host. If a single host fails, the number of active primary segments
doubles on the host that backs the failed host. The diagram *Figure 15: Group Segment Mirroring in Greenplum Database* illustrates a group mirroring configuration.

*Figure 15: Group Segment Mirroring in Greenplum Database*

*Spread mirroring* spreads each host's mirrors over multiple hosts so that if any single host fails, no other host will have more than one mirror promoted to an active primary segment. Spread mirroring is possible only if there are more hosts than segments per host. The diagram *Figure 16: Spread Segment Mirroring in Greenplum Database* illustrates the placement of mirrors in a spread segment mirroring configuration.
Overview of Master Mirroring

You can deploy a backup or mirror of the master instance on a separate host machine. The backup master instance, called the *standby master*, serves as a warm standby if the primary master becomes nonoperational. You create a standby master from the primary master while the primary is online.

When you enable master mirroring for an existing system, the primary master continues to provide service to users while a snapshot of the primary master instance is taken. While the snapshot is taken and deployed on the standby master, changes to the primary master are also recorded. After the snapshot has been deployed on the standby master, the standby master is synchronized and kept current using Write-Ahead Logging (WAL)-based streaming replication. Greenplum Database WAL replication uses the *walsender* and *walreceiver* replication processes. The *walsender* process is a primary master process. The *walreceiver* is a standby master process.
Figure 17: Master Mirroring in Greenplum Database

Since the master does not house user data, only system catalog tables are synchronized between the primary and standby masters. When these tables are updated, the replication logs that capture the changes are streamed to the standby master to keep it current with the primary. During WAL replication, all database modifications are written to replication logs before being applied, to ensure data integrity for any in-process operations.

This is how Greenplum Database handles a master failure.

- If the primary master fails, the Greenplum Database system shuts down and the master replication process stops. The administrator runs the `gpactivatestandby` utility to have the standby master take over as the new primary master. Upon activation of the standby master, the replicated logs reconstruct the state of the primary master at the time of the last successfully committed transaction. The activated standby master then functions as the Greenplum Database master, accepting connections on the port specified when standby master was initialized. See Recovering a Failed Master.
- If the standby master fails or becomes inaccessible while the primary master is active, the primary master tracks database changes in logs that are applied to the standby master when it is recovered.

These Greenplum Database system catalog tables contain mirroring and replication information.

- The catalog table `gp_segment_configuration` contains the current configuration and state of primary and mirror segment instances and the master and standby master instance.
- The catalog view `gp_stat_replication` contains replication statistics of the `walsender` processes that are used for Greenplum Database master and segment mirroring.

### Enabling Mirroring in Greenplum Database

You can configure your Greenplum Database system with mirroring at setup time using `gpinitsystem` or enable mirroring later using `gpaddmirrors` and `gpinitstandby`. This topic assumes you are adding mirrors to an existing system that was initialized without mirrors.

You can enable the following types of mirroring:

- **Enabling Segment Mirroring**
- **Enabling Master Mirroring**

**Enabling Segment Mirroring**

Mirror segments allow database queries to fail over to a backup segment if the primary segment is unavailable. By default, mirrors are configured on the same array of hosts as the primary segments. You may choose a completely different set of hosts for your mirror segments so they do not share machines with any of your primary segments.
**Important:** During the online data replication process, Greenplum Database should be in a quiescent state, workloads and other queries should not be running.

**To add segment mirrors to an existing system (same hosts as primaries)**

1. Allocate the data storage area for mirror data on all segment hosts. The data storage area must be different from your primary segments’ file system location.
2. Use `gpssh-exkeys` to ensure that the segment hosts can SSH and SCP to each other without a password prompt.
3. Run the `gpaddmirrors` utility to enable mirroring in your Greenplum Database system. For example, to add 10000 to your primary segment port numbers to calculate the mirror segment port numbers:

   ```bash
   $ gpaddmirrors -p 10000
   ``

   Where `-p` specifies the number to add to your primary segment port numbers. Mirrors are added with the default group mirroring configuration.

**To add segment mirrors to an existing system (different hosts from primaries)**

1. Ensure the Greenplum Database software is installed on all hosts. See the *Greenplum Database Installation Guide* for detailed installation instructions.
2. Allocate the data storage area for mirror data, and tablespaces if needed, on all segment hosts.
3. Use `gpssh-exkeys` to ensure the segment hosts can SSH and SCP to each other without a password prompt.
4. Create a configuration file that lists the host names, ports, and data directories on which to create mirrors. To create a sample configuration file to use as a starting point, run:

   ```bash
   $ gpaddmirrors -o filename
   ```

   The format of the mirror configuration file is:

   ```plaintext
   row_id=contentID|address|port|data_dir
   ```

   Where `row_id` is the row in the file, `contentID` is the segment instance content ID, `address` is the host name or IP address of the segment host, `port` is the communication port, and `data_dir` is the segment instance data directory.

   For example, this is contents of a mirror configuration file for two segment hosts and two segment instances per host:

   ```plaintext
   0=2|sdw1-1|41000|/data/mirror1/gp2
   1=3|sdw1-2|41001|/data/mirror2/gp3
   2=0|sdw2-1|41000|/data/mirror1/gp0
   3=1|sdw2-2|41001|/data/mirror2/gp1
   ```

5. Run the `gpaddmirrors` utility to enable mirroring in your Greenplum Database system:

   ```bash
   $ gpaddmirrors -i mirror_config_file
   ``

   The `-i` option specifies the mirror configuration file you created.

**Enabling Master Mirroring**

You can configure a new Greenplum Database system with a standby master using `gpinitsystem` or enable it later using `gpinitstandby`. This topic assumes you are adding a standby master to an existing system that was initialized without one.
For information about the utilities `gpinitsystem` and `gpinitstandby`, see the Greenplum Database Utility Guide.

To add a standby master to an existing system

1. Ensure the standby master host is installed and configured: `gpadmin` system user created, Greenplum Database binaries installed, environment variables set, SSH keys exchanged, and that the data directories and tablespace directories, if needed, are created.
2. Run the `gpinitstandby` utility on the currently active primary master host to add a standby master host to your Greenplum Database system. For example:

   ```bash
   $ gpinitstandby -s smdw
   ```

   Where `-s` specifies the standby master host name.

To switch operations to a standby master, see Recovering a Failed Master.

To check the status of the master mirroring process (optional)

You can run the `gpstate` utility with the `-f` option to display details of the standby master host.

```bash
$ gpstate -f
```

The standby master status should be passive, and the WAL sender state should be streaming.

For information about the `gpstate` utility, see the Greenplum Database Utility Guide.

Detecting a Failed Segment

With segment mirroring enabled, Greenplum Database automatically fails over to a mirror segment instance when a primary segment instance goes down. Provided one segment instance is online per portion of data, users may not realize a segment is down. If a transaction is in progress when a fault occurs, the in-progress transaction rolls back and restarts automatically on the reconfigured set of segments. The `gpstate` utility can be used to identify failed segments. The utility displays information from the catalog tables including `gp_segment_configuration`.

If the entire Greenplum Database system becomes nonoperational due to a segment failure (for example, if mirroring is not enabled or not enough segments are online to access all user data), users will see errors when trying to connect to a database. The errors returned to the client program may indicate the failure. For example:

```bash
ERROR: All segment databases are unavailable
```

How a Segment Failure is Detected and Managed

On the Greenplum Database master host, the Postgres `postmaster` process forks a fault probe process, `ftsprobe`. This is also known as the FTS (Fault Tolerance Server) process. The `postmaster` process restarts the FTS if it fails.

The FTS runs in a loop with a sleep interval between each cycle. On each loop, the FTS probes each primary segment instance by making a TCP socket connection to the segment instance using the hostname and port registered in the `gp_segment_configuration` table. If the connection succeeds, the segment performs a few simple checks and reports back to the FTS. The checks include executing a `stat` system call on critical segment directories and checking for internal faults in the segment instance. If no issues are detected, a positive reply is sent to the FTS and no action is taken for that segment instance.

If the connection cannot be made, or if a reply is not received in the timeout period, then a retry is attempted for the segment instance. If the configured maximum number of probe attempts fail, the FTS probes the segment's mirror to ensure that it is up, and then updates the `gp_segment_configuration`
table, marking the primary segment "down" and setting the mirror to act as the primary. The FTS updates the \texttt{gp_configuration_history} table with the operations performed.

When there is only an active primary segment and the corresponding mirror is down, the primary goes into the \textit{not synchronizing} state and continues logging database changes, so the mirror can be synchronized without performing a full copy of data from the primary to the mirror.

Running the \texttt{gpstate} utility with the \texttt{-e} option displays any issues with a primary or mirror segment instances. Other \texttt{gpstate} options that display information about all primary or mirror segment instances such as \texttt{-m} (mirror instance information) and \texttt{-c} (primary and mirror configuration information) also display information about primary and mirror issues.

You can also see the mode: \texttt{s} (synchronizing) or \texttt{n} (not synchronizing) for each segment instance, as well as the status \texttt{u} (up) or \texttt{d} (down), in the \texttt{gp_segment_configuration} table.

The \texttt{gprecoverseg} utility is used to bring up a mirror that is down. By default, \texttt{gprecoverseg} performs an incremental recovery, placing the mirror into synchronizing mode, which starts to replay the recorded changes from the primary onto the mirror. If the incremental recovery cannot be completed, the recovery fails and \texttt{gprecoverseg} should be run again with the \texttt{-F} option, to perform full recovery. This causes the primary to copy all of the data to the mirror.

After a segment instance has been recovered, the \texttt{gpstate -e} command might list primary and mirror segment instances that are switched. This indicates that the system is not balanced (the primary and mirror instances are not in their originally configured roles). If a system is not balanced, there might be skew resulting from the number of active primary segment instances on segment host systems.

The \texttt{gp_segment_configuration} table has columns \texttt{role} and \texttt{preferred_role}. These can have values of either \texttt{p} for primary or \texttt{m} for mirror. The \texttt{role} column shows the segment instance current role and the \texttt{preferred_role} shows the original role of the segment instance.

In a balanced system, the \texttt{role} and \texttt{preferred_role} matches for all segment instances. When they do not match the system is not balanced. To rebalance the cluster and bring all the segments into their preferred role, run the \texttt{gprecoverseg} command with the \texttt{-r} option.

### Simple Failover and Recovery Example

Consider a single primary-mirror segment instance pair where the primary segment has failed over to the mirror. The following table shows the segment instance preferred role, role, mode, and status from \texttt{gp_segment_configuration} table before beginning recovery of the failed primary segment.

You can also run \texttt{gpstate -e} to display any issues with a primary or mirror segment instances.

<table>
<thead>
<tr>
<th></th>
<th>preferred_role</th>
<th>role</th>
<th>mode</th>
<th>status</th>
</tr>
</thead>
<tbody>
<tr>
<td>Primary</td>
<td>\texttt{p}</td>
<td>\texttt{m}</td>
<td>\texttt{n}</td>
<td>\texttt{d}</td>
</tr>
<tr>
<td></td>
<td>(primary)</td>
<td>(mirror)</td>
<td>(not synchronizing)</td>
<td>(down)</td>
</tr>
<tr>
<td>Mirror</td>
<td>\texttt{m}</td>
<td>\texttt{p}</td>
<td>\texttt{n}</td>
<td>\texttt{u}</td>
</tr>
<tr>
<td></td>
<td>(mirror)</td>
<td>(primary)</td>
<td>(not synchronizing)</td>
<td>(up)</td>
</tr>
</tbody>
</table>

The segment instance roles are not in their preferred roles, and the primary is down. The mirror is up, the role is now primary, and it is not synchronizing because its mirror, the failed primary, is down. After fixing issues with the segment host and primary segment instance, you use \texttt{gprecoverseg} to prepare failed segment instances for recovery and initiate synchronization between the primary and mirror instances.

Once \texttt{gprecoverseg} has completed, the segments are in the states shown in the following table where the primary-mirror segment pair is up with the primary and mirror roles reversed from their preferred roles.
The `gprecoverseg -r` command rebalances the system by returning the segment roles to their preferred roles.

### Configuring FTS Behavior

There is a set of server configuration parameters that affect FTS behavior:

- **gp_fts_probe_interval**
  
  How often, in seconds, to begin a new FTS loop. For example if the setting is 60 and the probe loop takes 10 seconds, the FTS process sleeps 50 seconds. If the setting is 60 and probe loop takes 75 seconds, the process sleeps 0 seconds. The default is 60, and the maximum is 3600.

- **gp_fts_probe_timeout**
  
  Probe timeout between master and segment, in seconds. The default is 20, and the maximum is 3600.

- **gp_fts_probe_retries**
  
  The number of attempts to probe a segment. For example if the setting is 5 there will be 4 retries after the first attempt fails. Default: 5

- **gp_log_fts**
  
  Logging level for FTS. The value may be "off", "terse", "verbose", or "debug". The "verbose" setting can be used in production to provide useful data for troubleshooting. The "debug" setting should not be used in production. Default: "terse"

- **gp_segment_connect_timeout**
  
  The maximum time (in seconds) allowed for a mirror to respond. Default: 600 (10 minutes)

In addition to the fault checking performed by the FTS, a primary segment that is unable to send data to its mirror can change the status of the mirror to down. The primary queues up the data and after `gp_segment_connect_timeout` seconds passes, indicates a mirror failure, causing the mirror to be marked down and the primary to go into change tracking mode.

### Checking for Failed Segments

With mirroring enabled, you can have failed segment instances in the system without interruption of service or any indication that a failure has occurred. You can verify the status of your system using the `gpstate` utility. `gpstate` provides the status of each individual component of a Greenplum Database system, including primary segments, mirror segments, master, and standby master.
To check for failed segments

1. On the master host, run the `gpstate` utility with the `-e` option to show segment instances with error conditions:

   ```
   $ gpstate -e
   ```

   If the utility lists **Segments with Primary and Mirror Roles Switched**, the segment is not in its **preferred role** (the role to which it was assigned at system initialization). This means the system is in a potentially unbalanced state, as some segment hosts may have more active segments than is optimal for top system performance.

   Segments that display the **Config status** as **Down** indicate the corresponding mirror segment is down.

   See **Recovering From Segment Failures** for instructions to fix this situation.

2. To get detailed information about failed segments, you can check the `gp_segment_configuration` catalog table. For example:

   ```
   $ psql postgres -c "SELECT * FROM gp_segment_configuration WHERE status='d';"
   ```

3. For failed segment instances, note the host, port, preferred role, and data directory. This information will help determine the host and segment instances to troubleshoot.

4. To show information about mirror segment instances, run:

   ```
   $ gpstate -m
   ```

Checking the Log Files for Failed Segments

Log files can provide information to help determine an error's cause. The master and segment instances each have their own log file in `pg_log` of the data directory. The master log file contains the most information and you should always check it first.

Use the `gplogfilter` utility to check the Greenplum Database log files for additional information. To check the segment log files, run `gplogfilter` on the segment hosts using `gpssh`.

To check the log files

1. Use `gplogfilter` to check the master log file for **WARNING**, **ERROR**, **FATAL** or **PANIC** log level messages:

   ```
   $ gplogfilter -t
   ```

2. Use `gpssh` to check for **WARNING**, **ERROR**, **FATAL**, or **PANIC** log level messages on each segment instance. For example:

   ```
   $ gpssh -f seg_hosts_file -e 'source /usr/local/greenplum-db/greenplum_path.sh ; gplogfilter -t /data1/primary/*/pg_log/gpdb*.log' > seglog.out
   ```

Recovering a Failed Segment

If the master cannot connect to a segment instance, it marks that segment as down in the Greenplum Database system catalog. The segment instance remains offline until an administrator takes steps to bring the segment back online. The process for recovering a failed segment instance or host depends on the failure cause and whether or not mirroring is enabled. A segment instance can be unavailable for many reasons:

- A segment host is unavailable; for example, due to network or hardware failures.
- A segment instance is not running; for example, there is no `postgres` database listener process.
- The data directory of the segment instance is corrupt or missing; for example, data is not accessible, the file system is corrupt, or there is a disk failure.

*Figure 18: Segment Failure Troubleshooting Matrix* shows the high-level steps for each of the preceding failure scenarios.

### Recovering From Segment Failures

Segment host failures usually cause multiple segment failures: all primary or mirror segment instances on the host are marked as down and nonoperational. If mirroring is not enabled and a segment goes down, the system automatically becomes nonoperational.

A segment instance can fail for several reasons, such as a host failure, network failure, or disk failure. When a segment instance fails, its status is marked as down in the Greenplum Database system catalog, and its mirror is activated in *change tracking* mode. In order to bring the failed segment instance back into
operation again, you must first correct the problem that made it fail in the first place, and then recover the segment instance in Greenplum Database using `gprecoverseg`.

If a segment host is not recoverable and you have lost one or more segment instances with mirroring enabled, you can attempt to recover a segment instance from its mirror. See **When a segment host is not recoverable.** You can also recreate your Greenplum Database system from backup files. See **Backing Up and Restoring Databases.**

**To recover with mirroring enabled**

1. Ensure you can connect to the segment host from the master host. For example:

   ```bash
   $ ping failed_seg_host_address
   ```

2. Troubleshoot the problem that prevents the master host from connecting to the segment host. For example, the host machine may need to be restarted or replaced.

3. After the host is online and you can connect to it, run the `gprecoverseg` utility from the master host to reactivate the failed segment instances and start the process of synchronizing the master and mirror instances. For example:

   ```bash
   $ gprecoverseg
   ```

4. The recovery process brings up the failed segments and identifies the changed files that need to be synchronized. The process can take some time; wait for the process to complete.

5. After `gprecoverseg` completes, the system goes into Resynchronizing mode and begins copying the changed files. This process runs in the background while the system is online and accepting database requests.

6. When the resynchronization process completes, the system state is Synchronized. Run the `gpstate` utility to verify the status of the resynchronization process:

   ```bash
   $ gpstate -m
   ```

   **Note:** If incremental recovery was not successful and the down segment instance data is not corrupted, contact Pivotal Support.

**To return all segments to their preferred role**

When a primary segment instance goes down, the mirror activates and becomes the primary segment. After running `gprecoverseg`, the currently active segment instance remains the primary and the failed segment becomes the mirror. The segment instances are not returned to the preferred role that they were given at system initialization time. This means that the system could be in a potentially unbalanced state if segment hosts have more active segments than is optimal for top system performance. To check for unbalanced segments and rebalance the system, run:

```bash
$ gpstate -e
```

All segments must be online and fully synchronized to rebalance the system. Database sessions remain connected during rebalancing, but queries in progress are canceled and rolled back.

1. Run `gpstate -m` to ensure all mirrors are Synchronized.

   ```bash
   $ gpstate -m
   ```

2. If any mirrors are in Resynchronizing mode, wait for them to complete.

3. Run `gprecoverseg` with the `-r` option to return the segments to their preferred roles.

   ```bash
   $ gprecoverseg -r
   ```
4. After rebalancing, run `gpstate -e` to confirm all segments are in their preferred roles.

```bash
$ gpstate -e
```

**To recover from a double fault**

In a double fault, both a primary segment and its mirror are down. This can occur if hardware failures on different segment hosts happen simultaneously. Greenplum Database is unavailable if a double fault occurs.

To recover from a double fault.

1. Troubleshoot the problem that caused the double fault and ensure that the segment hosts are operational and are accessible from the master host.
2. Restart Greenplum Database. The `gpstop` option `-r` stops and restarts the system.

```bash
$ gpstop -r
```

3. After the system restarts, run `gprecoverseg` to reactivate the failed segment instances.

```bash
$ gprecoverseg
```

**Note:** If incremental recovery was not successful and the down segment instance data is not corrupted, contact Pivotal Support.

4. After `gprecoverseg` completes, use `gpstate` to check the status of your mirrors and ensure the segment instances have gone from Resynchronizing mode to Synchronized mode:

```bash
$ gpstate -m
```

5. If you still have segment instances in change tracking mode, you can run `gprecoverseg` with the `-F` option to perform a full segment recovery.

**Warning:** A full recovery deletes the data directory of the down segment instance before copying the data from the active (current primary) segment instance. Before performing a full recovery, ensure that the segment failure did not cause data corruption and that any host segment disk issues have been fixed.

```bash
$ gprecoverseg -F
```

6. If needed, return segment instances to their preferred role. See To return all segments to their preferred role.

**To recover without mirroring enabled**

1. Ensure you can connect to the segment host from the master host. For example:

```bash
$ ping failed_seg_host_address
```

2. Troubleshoot the problem that is preventing the master host from connecting to the segment host. For example, the host machine may need to be restarted.

3. After the host is online, verify that you can connect to it and restart Greenplum Database. The `gpstop` option `-r` stops and restarts the system:

```bash
$ gpstop -r
```

4. Run the `gpstate` utility to verify that all segment instances are online:

```bash
$ gpstate
```
**When a segment host is not recoverable**

If a host is nonoperational, for example, due to hardware failure, recover the segments onto a spare set of hardware resources. If mirroring is enabled, you can recover a segment instance from its mirror onto an alternate host using the `gprecoverseg` utility. For example:

```
$ gprecoverseg -i recover_config_file
```

Where the format of the `recover_config_file` file is:

```
<failed_host>|<port>|<data_dir>[ <recovery_host>|<port>|<recovery_data_dir>]
```

For example, to recover to a different host than the failed host without additional tablespaces configured (besides the default `pg_system` tablespace):

```
sdw1-1|50001|/data1/mirror/gpseg16 sdw4-1|50001|/data1/recover1/gpseg16
```

For information about creating a segment instance recovery file, see `gprecoverseg`.

The new recovery segment host must be pre-installed with the Greenplum Database software and configured exactly as the existing segment hosts.

**Recovering a Failed Master**

If the primary master fails, the Greenplum Database system is not accessible and WAL replication stops. Use `gpactivatestandby` to activate the standby master. Upon activation of the standby master, Greenplum Database reconstructs the master host state at the time of the last successfully committed transaction.

These steps assume a standby master host is configured for the system. See `Enabling Master Mirroring`.

**To activate the standby master**

1. Run the `gpactivatestandby` utility from the standby master host you are activating. For example:

```
$ gpactivatestandby -d /data/master/gpseg-1
```

   Where `-d` specifies the data directory of the master host you are activating.

   After you activate the standby, it becomes the *active* or *primary* master for your Greenplum Database array.

2. After the utility completes, run `gpstate` with the `-b` option to display a summary of the system status:

```
$ gpstate -b
```

   The master instance status should be *Active*. When a standby master is not configured, the command displays *No master standby configured* for the standby master status. If you configured a new standby master, its status is *Passive*.

3. Optional: If you have not already done so while activating the prior standby master, you can run `gpinitstandby` on the active master host to configure a new standby master.

   **Important:** You must initialize a new standby master to continue providing master mirroring.

   For information about restoring the original master and standby master configuration, see `Restoring Master Mirroring After a Recovery`. 
**Restoring Master Mirroring After a Recovery**

After you activate a standby master for recovery, the standby master becomes the primary master. You can continue running that instance as the primary master if it has the same capabilities and dependability as the original master host.

You must initialize a new standby master to continue providing master mirroring unless you have already done so while activating the prior standby master. Run `gpinitstandby` on the active master host to configure a new standby master. See Enabling Master Mirroring.

You can restore the primary and standby master instances on the original hosts. This process swaps the roles of the primary and standby master hosts, and it should be performed only if you strongly prefer to run the master instances on the same hosts they occupied prior to the recovery scenario.

**Important:** Restoring the primary and standby master instances to their original hosts is not an online operation. The master host must be stopped to perform the operation.

For information about the Greenplum Database utilities, see the Greenplum Database Utility Guide.

**To restore the master and standby instances on original hosts (optional)**

1. Ensure the original master host is in dependable running condition; ensure the cause of the original failure is fixed.
2. On the original master host, move or remove the data directory, gpseg-1. This example moves the directory to backup_gpseg-1:
   ```bash
   $ mv /data/master/gpseg-1 /data/master/backup_gpseg-1
   ```
   You can remove the backup directory once the standby is successfully configured.
3. Initialize a standby master on the original master host. For example, run this command from the current master host, smdw:
   ```bash
   $ gpinitstandby -s mdw
   ```
4. After the initialization completes, check the status of standby master, mdw. Run `gpstate` with the `-f` option to check the standby master status:
   ```bash
   $ gpstate -f
   ```
   The standby master status should be `passive`, and the WAL sender state should be `streaming`.
5. Stop the Greenplum Database master instance on the standby master. For example:
   ```bash
   $ gpstop -m
   ```
6. Run the `gpactivatestandby` utility from the original master host, mdw, that is currently a standby master. For example:
   ```bash
   $ gpactivatestandby -d $MASTER_DATA_DIRECTORY
   ```
   Where the `-d` option specifies the data directory of the host you are activating.
7. After the utility completes, run `gpstate` with the `-b` option to display a summary of the system status:
   ```bash
   $ gpstate -b
   ```
   The master instance status should be `Active`. When a standby master is not configured, the command displays `No master standby configured` for the standby master state.
8. On the standby master host, move or remove the data directory, \texttt{gpseg-1}. This example moves the directory:

\begin{verbatim}
$ mv /data/master/gpseg-1 /data/master/backup_gpseg-1
\end{verbatim}

You can remove the backup directory once the standby is successfully configured.

9. After the original master host runs the primary Greenplum Database master, you can initialize a standby master on the original standby master host. For example:

\begin{verbatim}
$ gpinitstandby -s smdw
\end{verbatim}

After the command completes, you can run the \texttt{gpstate -f} command on the primary master host, to check the standby master status.

**To check the status of the master mirroring process (optional)**

You can run the \texttt{gpstate} utility with the \texttt{-f} option to display details of the standby master host.

\begin{verbatim}
$ gpstate -f
\end{verbatim}

The standby master status should be \texttt{passive}, and the WAL sender state should be \texttt{streaming}.

For information about the \texttt{gpstate} utility, see the *Greenplum Database Utility Guide*.

### Backing Up and Restoring Databases

This topic describes how to use Greenplum backup and restore features.

Performing backups regularly ensures that you can restore your data or rebuild your Greenplum Database system if data corruption or system failure occur. You can also use backups to migrate data from one Greenplum Database system to another.

#### Backup and Restore Overview

Greenplum Database supports parallel and non-parallel methods for backing up and restoring databases. Parallel operations scale regardless of the number of segments in your system, because segment hosts each write their data to local disk storage simultaneously. With non-parallel backup and restore operations, the data must be sent over the network from the segments to the master, which writes all of the data to its storage. In addition to restricting I/O to one host, non-parallel backup requires that the master have sufficient local disk storage to store the entire database.

#### Parallel Backup with \texttt{gpbackup} and \texttt{gprestore}

\texttt{gpbackup} and \texttt{gprestore} are the Greenplum Database backup and restore utilities. \texttt{gpbackup} utilizes \texttt{ACCESS SHARE} locks at the individual table level, instead of \texttt{EXCLUSIVE} locks on the \texttt{pg_class} catalog table. This enables you to execute DML statements during the backup, such as \texttt{CREATE}, \texttt{ALTER}, \texttt{DROP}, and \texttt{TRUNCATE} operations, as long as those operations do not target the current backup set.

Backup files created with \texttt{gpbackup} are designed to provide future capabilities for restoring individual database objects along with their dependencies, such as functions and required user-defined datatypes. See *Parallel Backup with \texttt{gpbackup} and \texttt{gprestore}* for more information.

#### Non-Parallel Backup with \texttt{pg_dump}

The PostgreSQL \texttt{pg_dump} and \texttt{pg_dumpall} non-parallel backup utilities can be used to create a single dump file on the master host that contains all data from all active segments.

The PostgreSQL non-parallel utilities should be used only for special cases. They are much slower than using the Greenplum backup utilities since all of the data must pass through the master. Additionally, it is
often the case that the master host has insufficient disk space to save a backup of an entire distributed Greenplum database.

The `pg_restore` utility requires compressed dump files created by `pg_dump` or `pg_dumpall`. Before starting the restore, you should modify the `CREATE TABLE` statements in the dump files to include the Greenplum `DISTRIBUTED` clause. If you do not include the `DISTRIBUTED` clause, Greenplum Database assigns default values, which may not be optimal. For details, see `CREATE TABLE` in the *Greenplum Database Reference Guide*.

To perform a non-parallel restore using parallel backup files, you can copy the backup files from each segment host to the master host, and then load them through the master.

![Figure 19: Non-parallel Restore Using Parallel Backup Files](image)

Another non-parallel method for backing up Greenplum Database data is to use the `COPY TO SQL` command to copy all or a portion of a table out of the database to a delimited text file on the master host.

**Parallel Backup with gpbackup and gprestore**

gpbackup and gprestore are Greenplum Database utilities that create and restore backup sets for Greenplum Database. By default, `gpbackup` stores only the object metadata files and DDL files for a backup in the Greenplum Database master data directory. Greenplum Database segments use the `COPY ... ON SEGMENT` command to store their data for backed-up tables in compressed CSV data files, located in each segment's backups directory.

The backup metadata files contain all of the information that `gprestore` needs to restore a full backup set in parallel. Backup metadata also provides the framework for restoring only individual objects in the data set, along with any dependent objects, in future versions of `gprestore`. (See *Understanding Backup Files* for more information.) Storing the table data in CSV files also provides opportunities for using other restore utilities, such as `gpload`, to load the data either in the same cluster or another cluster. By default, one file is created for each table on the segment. You can specify the `--leaf-partition-data` option with `gpbackup` to create one data file per leaf partition of a partitioned table, instead of a single file. This option also enables you to filter backup sets by leaf partitions.

Each `gpbackup` task uses a single transaction in Greenplum Database. During this transaction, metadata is backed up on the master host, and data for each table on each segment host is written to CSV backup files using `COPY ... ON SEGMENT` commands in parallel. The backup process acquires an `ACCESS SHARE` lock on each table that is backed up.
For information about the `gpbackup` and `gprestore` utility options, see `gpbackup` and `gprestore`.

**Requirements and Limitations**

The `gpbackup` and `gprestore` utilities are compatible with these Greenplum Database versions:

- Pivotal Greenplum Database 4.3.22 and later
- Pivotal Greenplum Database 5.5.0 and later
- Pivotal Greenplum Database 6.0.0 and later

`gpbackup` and `gprestore` have the following limitations:

- If you create an index on a parent partitioned table, `gpbackup` does not back up that same index on child partitioned tables of the parent, as creating the same index on a child would cause an error. However, if you exchange a partition, `gpbackup` does not detect that the index on the exchanged partition is inherited from the new parent table. In this case, `gpbackup` backs up conflicting `CREATE INDEX` statements, which causes an error when you restore the backup set.
- You can execute multiple instances of `gpbackup`, but each execution requires a distinct timestamp.
- Database object filtering is currently limited to schemas and tables.
- If you use the `gpbackup` `--single-data-file` option to combine table backups into a single file per segment, you cannot perform a parallel restore operation with `gprestore` (cannot set `--jobs` to a value higher than 1).
- You cannot use the `--exclude-table-file` with `--leaf-partition-data`. Although you can specify leaf partition names in a file specified with `--exclude-table-file`, `gpbackup` ignores the partition names.
- Backing up a database with `gpbackup` while simultaneously running DDL commands might cause `gpbackup` to fail, in order to ensure consistency within the backup set. For example, if a table is dropped after the start of the backup operation, `gpbackup` exits and displays the error message `ERROR: relation <schema.table> does not exist`.

`gpbackup` might fail when a table is dropped during a backup operation due to table locking issues. `gpbackup` generates a list of tables to back up and acquires an ACCESS SHARED lock on the tables. If an EXCLUSIVE LOCK is held on a table, `gpbackup` acquires the ACCESS SHARED lock after the existing lock is released. If the table no longer exists when `gpbackup` attempts to acquire a lock on the table, `gpbackup` exits with the error message.

For tables that might be dropped during a backup, you can exclude the tables from a backup with a `gpbackup` table filtering option such as `--exclude-table` or `--exclude-schema`.

- A backup created with `gpbackup` can only be restored to a Greenplum Database cluster with the same number of segment instances as the source cluster. If you run `gpexpand` to add segments to the cluster, backups you made before starting the expand cannot be restored after the expansion has completed.

**Objects Included in a Backup or Restore**

The following table lists the objects that are backed up and restored with `gpbackup` and `gprestore`. Database objects are backed up for the database you specify with the `--dbname` option. Global objects (Greenplum Database system objects) are also backed up by default, but they are restored only if you include the `--with-globals` option to `gprestore`. 
### Table 20: Objects that are backed up and restored

<table>
<thead>
<tr>
<th>Database (for database specified with <code>--dbname</code>)</th>
<th>Global (requires the <code>--with-globals</code> option to restore)</th>
</tr>
</thead>
<tbody>
<tr>
<td>• Session-level configuration parameter settings (GUCs)</td>
<td>• Tablespaces</td>
</tr>
<tr>
<td>• Schemas, see Note</td>
<td>• Databases</td>
</tr>
<tr>
<td>• Procedural language extensions</td>
<td>• Database-wide configuration parameter settings (GUCs)</td>
</tr>
<tr>
<td>• Sequences</td>
<td>• Resource group definitions</td>
</tr>
<tr>
<td>• Comments</td>
<td>• Resource queue definitions</td>
</tr>
<tr>
<td>• Tables</td>
<td>• Roles</td>
</tr>
<tr>
<td>• Indexes</td>
<td>• GRANT assignments of roles to databases</td>
</tr>
<tr>
<td>• Owners</td>
<td></td>
</tr>
<tr>
<td>• Writable External Tables (DDL only)</td>
<td></td>
</tr>
<tr>
<td>• Readable External Tables (DDL only)</td>
<td></td>
</tr>
<tr>
<td>• Functions</td>
<td></td>
</tr>
<tr>
<td>• Aggregates</td>
<td></td>
</tr>
<tr>
<td>• Casts</td>
<td></td>
</tr>
<tr>
<td>• Types</td>
<td></td>
</tr>
<tr>
<td>• Views</td>
<td></td>
</tr>
<tr>
<td>• Protocols</td>
<td></td>
</tr>
<tr>
<td>• Triggers. (While Greenplum Database does not support triggers, any trigger definitions that are present are backed up and restored.)</td>
<td></td>
</tr>
<tr>
<td>• Rules</td>
<td></td>
</tr>
<tr>
<td>• Domains</td>
<td></td>
</tr>
<tr>
<td>• Operators, operator families, and operator classes</td>
<td></td>
</tr>
<tr>
<td>• Conversions</td>
<td></td>
</tr>
<tr>
<td>• Extensions</td>
<td></td>
</tr>
<tr>
<td>• Text search parsers, dictionaries, templates, and configurations</td>
<td></td>
</tr>
</tbody>
</table>

**Note:** These schemas are not included in a backup.

- `gp_toolkit`
- `information_schema`
- `pg_aoseg`
- `pg_bitmapindex`
- `pg_catalog`
- `pg_toast*`
- `pg_temp*`

When restoring to an existing database, `gprestore` assumes the `public` schema exists when restoring objects to the `public` schema. When restoring to a new database (with the `--create-db` option), `gprestore` creates the `public` schema automatically when creating a database with the `CREATE DATABASE` command. The command uses the `template0` database that contains the `public` schema.

See also [*Understanding Backup Files*](#).
Performing Basic Backup and Restore Operations

To perform a complete backup of a database, as well as Greenplum Database system metadata, use the command:

```
$ gpbackup --dbname <database_name>
```

For example:

```
$ gpbackup --dbname demo
```

The above command creates a file that contains global and database-specific metadata on the Greenplum Database master host in the default directory, $$MASTER\_DATA\_DIRECTORY/backups/<<YYYYMMDD>/<YYYYMMDDHHMMSS>>$$. For example:

```
$ ls /gpmaster/gpsne-1/backups/20180105/20180105112754
gpbackup_20180105112754_config.yaml   gpbackup_20180105112754_report
```
By default, each segment stores each table’s data for the backup in a separate compressed CSV file in <seg_dir>/backups/<YYYYMMDD>/<YYYYMMDDHHMMSS>/:

```
$ ls /gpdata1/gpsne0/backups/20180105/20180105112754/
gpbackup_0_20180105112754_17166.gz  gpbackup_0_20180105112754_26303.gz
```

To consolidate all backup files into a single directory, include the --backup-dir option. Note that you must specify an absolute path with this option:

```
$ gpbackup --dbname demo --backup-dir /home/gpadmin/backups
```

When performing a backup operation, you can use the --single-data-file in situations where the additional overhead of multiple files might be prohibitive. For example, if you use a third party storage solution such as Data Domain with backups.

### Restoring from Backup

To use gprestore to restore from a backup set, you must use the --timestamp option to specify the exact timestamp value (YYYYMMDDHHMMSS) to restore. Include the --create-db option if the database does not exist in the cluster. For example:

```
$ dropdb demo
$ gprestore --timestamp 20171103153156 --create-db
```

When performing a backup operation, you can use the --single-data-file in situations where the additional overhead of multiple files might be prohibitive. For example, if you use a third party storage solution such as Data Domain with backups.
If you specified a custom `--backup-dir` to consolidate the backup files, include the same `--backup-dir` option when using `gprestore` to locate the backup files:

```
$ dropdb demo
$ gprestore --backup-dir /home/gpadmin/backups/ --timestamp 20171103153156 --create-db
```

Test the number of parallel connections with your backup set to determine the ideal number for fast data recovery.

**Note:** You cannot perform a parallel restore operation with `gprestore` if the backup combined table backups into a single file per segment with the `gpbackup` option `--single-data-file`.

### Report Files

When performing a backup or restore operation, `gpbackup` and `gprestore` generate a report file. When email notification is configured, the email sent contains the contents of the report file. For information about email notification, see [Configuring Email Notifications](#).

The report file is placed in the Greenplum Database master backup directory. The report file name contains the timestamp of the operation. These are the formats of the `gpbackup` and `gprestore` report file names.

- `gpbackup_<backup_timestamp>_report`
- `gprestore_<backup_timestamp>_<restore_timestamp>_report`

For these example report file names, `20180213114446` is the timestamp of the backup and `20180213115426` is the timestamp of the restore operation.
This backup directory on a Greenplum Database master host contains both a `gpbackup` and `gprestore` report file.

```
$ ls -l /gpmaster/seg-1/backups/20180213/20180213114446
total 36
-r--r--r--. 1 gpadmin gpadmin  295 Feb 13 11:44 gpbackup_20180213114446_config.yaml
-r--r--r--. 1 gpadmin gpadmin 1855 Feb 13 11:44 gpbackup_20180213114446_metadata.sql
-r--r--r--. 1 gpadmin gpadmin 1402 Feb 13 11:44 gpbackup_20180213114446_report
-r--r--r--. 1 gpadmin gpadmin 2199 Feb 13 11:44 gpbackup_20180213114446_toc.yaml
-r--r--r--. 1 gpadmin gpadmin  404 Feb 13 11:54 gprestore_20180213115426_report
```

The contents of the report files are similar. This is an example of the contents of a `gprestore` report file.

```
Greenplum Database Restore Report

Timestamp Key: 20180213114446
GPDB Version: 5.4.1+dev.8.g9f83645 build
commit:9f836456b00f855959d52749d5790ed1c6efc042
gprestore Version: 1.0.0-alpha.3+dev.73.g0406681

Database Name: test
Command Line: gprestore --timestamp 20180213114446 --with-globals --createdb

Start Time: 2018-02-13 11:54:26
End Time: 2018-02-13 11:54:31
Duration: 0:00:05

Restore Status: Success
```

**History File**

When performing a backup operation, `gpbackup` appends backup information in the `gpbackup` history file, `gpbackup_history.yaml`, in the Greenplum Database master data directory. The file contains the backup timestamp, information about the backup options, and backup set information for incremental backups. This file is not backed up by `gpbackup`.

`gpbackup` uses the information in the file to find a matching backup for an incremental backup when you run `gpbackup` with the `--incremental` option and do not specify the `--from-timestamp` option to indicate the backup that you want to use as the latest backup in the incremental backup set. For information about incremental backups, see [Creating Incremental Backups with gpbackup and gprestore](#).

**Return Codes**

One of these codes is returned after `gpbackup` or `gprestore` completes.

- **0** – Backup or restore completed with no problems
- **1** – Backup or restore completed with non-fatal errors. See log file for more information.
- **2** – Backup or restore failed with a fatal error. See log file for more information.

**Filtering the Contents of a Backup or Restore**

`gpbackup` backs up all schemas and tables in the specified database, unless you exclude or include individual schema or table objects with schema level or table level filter options.
The schema level options are `--include-schema` or `--exclude-schema` command-line options to `gpbackup`. For example, if the "demo" database includes only two schemas, "wikipedia" and "twitter," both of the following commands back up only the "wikipedia" schema:

$$
gpbackup --dbname demo --include-schema wikipedia
$$
$$
gpbackup --dbname demo --exclude-schema twitter
$$

You can include multiple `--include-schema` options in a `gpbackup` or multiple `--exclude-schema` options. For example:

$$
gpbackup --dbname demo --include-schema wikipedia --include-schema twitter
$$

To filter the individual tables that are included in a backup set, or excluded from a backup set, specify individual tables with the `--include-table` option or the `--exclude-table` option. The table must be schema qualified, `<schema-name>.<table-name>`. The individual table filtering options can be specified multiple times. However, `--include-table` and `--exclude-table` cannot both be used in the same command.

You can create a list of qualified table names in a text file. When listing tables in a file, each line in the text file must define a single table using the format `<schema-name>.<table-name>`. The file must not include trailing lines. For example:

```
wikipedia.articles
twitter.message
```

If a table or schema name uses any character other than a lowercase letter, number, or an underscore character, then you must include that name in double quotes. For example:

```
beer."IPA"
"Wine".riesling
"Wine"."sauvignon blanc"
water.tonic
```

After creating the file, you can use it either to include or exclude tables with the `gpbackup` options `--include-table-file` or `--exclude-table-file`. For example:

$$
gpbackup --dbname demo --include-table-file /home/gpadmin/table-list.txt
$$

You can combine `--include_schema` with `--exclude-table` or `--exclude-table-file` for a backup. This example uses `--include-schema` with `--exclude-table` to back up a schema except for a single table.

$$
gpbackup --dbname demo --include-schema mydata --exclude-table mydata.addresses
$$

You cannot combine `--include-schema` with `--include-table` or `--include-table-file`, and you cannot combine `--exclude-schema` with any table filtering option such as `--exclude-table` or `--include-table`.

When you use `--include-table` or `--include-table-file` dependent objects are not automatically backed up or restored, you must explicitly specify the dependent objects that are required. For example, if you back up or restore a view, you must also specify the tables that the view uses. If you backup or restore a table that uses a sequence, you must also specify the sequence.

### Filtering by Leaf Partition

By default, `gpbackup` creates one file for each table on a segment. You can specify the `--leaf-partition-data` option to create one data file per leaf partition of a partitioned table, instead of a single
file. You can also filter backups to specific leaf partitions by listing the leaf partition names in a text file to include. For example, consider a table that was created using the statement:

```sql
demo=# CREATE TABLE sales (id int, date date, amt decimal(10,2))
DISTRIBUTED BY (id)
PARTITION BY RANGE (date)
( PARTITION Jan17 START (date '2017-01-01') INCLUSIVE ,
PARTITION Feb17 START (date '2017-02-01') INCLUSIVE ,
PARTITION Mar17 START (date '2017-03-01') INCLUSIVE ,
PARTITION Apr17 START (date '2017-04-01') INCLUSIVE ,
PARTITION May17 START (date '2017-05-01') INCLUSIVE ,
PARTITION Jun17 START (date '2017-06-01') INCLUSIVE ,
PARTITION Jul17 START (date '2017-07-01') INCLUSIVE ,
PARTITION Aug17 START (date '2017-08-01') INCLUSIVE ,
PARTITION Sep17 START (date '2017-09-01') INCLUSIVE ,
PARTITION Oct17 START (date '2017-10-01') INCLUSIVE ,
PARTITION Nov17 START (date '2017-11-01') INCLUSIVE ,
PARTITION Dec17 START (date '2017-12-01') INCLUSIVE
END (date '2018-01-01') EXCLUSIVE );
```

To back up only data for the last quarter of the year, first create a text file that lists those leaf partition names instead of the full table name:

```plaintext
public.sales_1_prt_oct17
public.sales_1_prt_nov17
public.sales_1_prt_dec17
```

Then specify the file with the `--include-table-file` option to generate one data file per leaf partition:

```
$ gpbackup --dbname demo --include-table-file last-quarter.txt --leaf-partition-data
```

When you specify `--leaf-partition-data`, `gpbackup` generates one data file per leaf partition when backing up a partitioned table. For example, this command generates one data file for each leaf partition:

```
$ gpbackup --dbname demo --include-table public.sales --leaf-partition-data
```
When leaf partitions are backed up, the leaf partition data is backed up along with the metadata for the entire partitioned table.

**Note:** You cannot use the `--exclude-table-file` option with `--leaf-partition-data`. Although you can specify leaf partition names in a file specified with `--exclude-table-file`, `gpbackup` ignores the partition names.

### Filtering with gprestore

After creating a backup set with `gpbackup`, you can filter the schemas and tables that you want to restore from the backup set using the `gprestore --include-schema` and `--include-table-file` options. These options work in the same way as their `gpbackup` counterparts, but have the following restrictions:

- The tables that you attempt to restore must not already exist in the database.
- If you attempt to restore a schema or table that does not exist in the backup set, the `gprestore` does not execute.
- If you use the `--include-schema` option, `gprestore` cannot restore objects that have dependencies on multiple schemas.
- If you use the `--include-table-file` option, `gprestore` does not create roles or set the owner of the tables. The utility restores table indexes and rules. Triggers are also restored but are not supported in Greenplum Database.
- The file that you specify with `--include-table-file` cannot include a leaf partition name, as it can when you specify this option with `gpbackup`. If you specified leaf partitions in the backup set, specify the partitioned table to restore the leaf partition data.

When restoring a backup set that contains data from some leaf partitions of a partitioned table, the partitioned table is restored along with the data for the leaf partitions. For example, you create a backup with the `gpbackup` option `--include-table-file` and the text file lists some leaf partitions of a partitioned table. Restoring the backup creates the partitioned table and restores the data only for the leaf partitions listed in the file.

### Configuring Email Notifications

`gpbackup` and `gprestore` can send email notifications after a backup or restore operation completes.

To have `gpbackup` or `gprestore` send out status email notifications, you must place a file named `gp_email_contacts.yaml` in the home directory of the user running `gpbackup` or `gprestore` in the same directory as the utilities (`$GPHOME/bin`). A utility issues a message if it cannot locate a `gp_email_contacts.yaml` file in either location. If both locations contain a `.yaml` file, the utility uses the file in user `$HOME`.

The email subject line includes the utility name, timestamp, status, and the name of the Greenplum Database master. This is an example subject line for a `gpbackup` email.

```
gpbackup 20180213613 on gp-master completed
```

The email contains summary information about the operation including options, duration, and number of objects backed up or restored. For information about the contents of a notification email, see Report Files.

**Note:** The UNIX mail utility must be running on the Greenplum Database host and must be configured to allow the Greenplum superuser (`gpadmin`) to send email. Also ensure that the mail program executable is locatable via the `gpadmin` user's `$PATH`.

### gpbackup and gprestore Email File Format

The `gpbackup` and `gprestore` email notification YAML file `gp_email_contacts.yaml` uses indentation (spaces) to determine the document hierarchy and the relationships of the sections to one another. The use of white space is significant. White space should not be used simply for formatting purposes, and tabs should not be used at all.
Note: If the status parameters are not specified correctly, the utility does not issue a warning. For example, if the success parameter is misspelled and is set to true, a warning is not issued and an email is not sent to the email address after a successful operation. To ensure email notification is configured correctly, run tests with email notifications configured.

This is the format of the gp_email_contacts.yaml YAML file for gpbackup email notifications:

```yaml
contacts:
gpbackup:
  - address: user@domain
    status:
      success: [true | false]
      success_with_errors: [true | false]
      failure: [true | false]
gprestore:
  - address: user@domain
    status:
      success: [true | false]
      success_with_errors: [true | false]
      failure: [true | false]
```

Email YAML File Sections

**contacts**

Required. The section that contains the gpbackup and gprestore sections. The YAML file can contain a gpbackup section, a gprestore section, or one of each.

**gpbackup**

Optional. Begins the gpbackup email section.

**address**

Required. At least one email address must be specified. Multiple email address parameters can be specified. Each address requires a status section.

*user@domain* is a single, valid email address.

**status**

Required. Specify when the utility sends an email to the specified email address. The default is to not send email notification.

You specify sending email notifications based on the completion status of a backup or restore operation. At least one of these parameters must be specified and each parameter can appear at most once.

**success**

Optional. Specify if an email is sent if the operation completes without errors. If the value is true, an email is sent if the operation completes without errors. If the value is false (the default), an email is not sent.

**success_with_errors**

Optional. Specify if an email is sent if the operation completes with errors. If the value is true, an email is sent if the operation completes with errors. If the value is false (the default), an email is not sent.

**failure**

Optional. Specify if an email is sent if the operation fails. If the value is true, an email is sent if the operation fails. If the value is false (the default), an email is not sent.

**gprestore**

Optional. Begins the gprestore email section. This section contains the address and status parameters that are used to send an email notification after a gprestore operation. The syntax is the same as the gpbackup section.
Examples
This example YAML file specifies sending email to email addresses depending on the success or failure of an operation. For a backup operation, an email is sent to a different address depending on the success or failure of the backup operation. For a restore operation, an email is sent to `gpadmin@example.com` only when the operation succeeds or completes with errors.

```
contacts:
gpbackup:
  - address: gpadmin@example.com
    status:
      success: true
  - address: my_dba@example.com
    status:
      success_with_errors: true
      failure: true

gprestore:
  - address: gpadmin@example.com
    status:
      success: true
      success_with_errors: true
```

Understanding Backup Files

**Warning:** All `gpbackup` metadata files are created with read-only permissions. Never delete or modify the metadata files for a `gpbackup` backup set. Doing so will render the backup files non-functional.

A complete backup set for `gpbackup` includes multiple metadata files, supporting files, and CSV data files, each designated with the timestamp at which the backup was created.

By default, metadata and supporting files are stored on the Greenplum Database master host in the directory `$MASTER_DATA_DIRECTORY/backups/YYYYMMDD/YYYYMMDDHHMMSS/`. If you specify a custom backup directory, this same file path is created as a subdirectory of the backup directory. The following table describes the names and contents of the metadata and supporting files.
### Table 21: gpbackup Metadata Files (master)

<table>
<thead>
<tr>
<th>File name</th>
<th>Description</th>
</tr>
</thead>
</table>
| gpbackup_<YYYYMMDDHHMMSS>_metadata.sql | Contains global and database-specific metadata:  
  - DDL for objects that are global to the Greenplum Database cluster, and not owned by a specific database within the cluster.  
  - DDL for objects in the backed-up database (specified with `--dbname`) that must be created before restoring the actual data, and DDL for objects that must be created after restoring the data.  
  
  Global objects include:  
  - Tablespaces  
  - Databases  
  - Database-wide configuration parameter settings (GUCs)  
  - Resource group definitions  
  - Resource queue definitions  
  - Roles  
  - `GRANT` assignments of roles to databases  
  
  **Note:** Global metadata is not restored by default. You must include the `--with-globals` option to the `gprestore` command to restore global metadata.  
  
  Database-specific objects that must be created before restoring the actual data include:  
  - Session-level configuration parameter settings (GUCs)

</table>

**Segment Data Files**

By default, each segment creates one compressed CSV file for each table that is backed up on the segment. You can optionally specify the --single-data-file option to create a single data file on each segment. The files are stored in `<seg_dir>/backups/YYYYMMDD/YYYYMMDDHHMMSS/`. If you specify a custom backup directory, segment data files are copied to this same file path as a subdirectory of the backup directory. If you include the --leaf-partition-data option, gpbackup creates one data file for each leaf partition of a partitioned table, instead of just one table for file.

Each data file uses the file name format `gpbackup_<content_id>_<YYYYMMDDHHMMSS>_<oid>.gz` where:
• `<content_id>` is the content ID of the segment.
• `<YYYYMMDDHHMMSS>` is the timestamp of the `gpbackup` operation.
• `<oid>` is the object ID of the table. The metadata file `gpbackup_<YYYYMMDDHHMMSS>_toc.yaml` references this `<oid>` to locate the data for a specific table in a schema.

You can optionally specify the gzip compression level (from 1-9) using the `--compression-level` option, or disable compression entirely with `--no-compression`. If you do not specify a compression level, `gpbackup` uses compression level 1 by default.

### Creating Incremental Backups with `gpbackup` and `gprestore`

The `gpbackup` and `gprestore` utilities support creating incremental backups of append-optimized tables and restoring from incremental backups. An incremental backup backs up all specified heap tables and backs up append-optimized tables (including append-optimized, column-oriented tables) only if the tables have changed. For example, if a row of an append-optimized table has changed, the table is backed up. For partitioned append-optimized tables, only the changed leaf partitions are backed up.

Incremental backups are efficient when the total amount of data in append-optimized tables or table partitions that changed is small compared to the data that has not changed since the last backup.

An incremental backup backs up an append-optimized table only if one of the following operations was performed on the table after the last full or incremental backup:

• `ALTER TABLE`
• `DELETE`
• `INSERT`
• `TRUNCATE`
• `UPDATE`
• `DROP` and then re-create the table

To restore data from incremental backups, you need a complete incremental backup set.

### About Incremental Backup Sets

An incremental backup set includes the following backups:

• A full backup. This is the full backup that the incremental backups are based on.
• The set of incremental backups that capture the changes to the database from the time of the full backup.

For example, you can create a full backup and then create three daily incremental backups. The full backup and all three incremental backups are the backup set. For information about using an incremental backup set, see Example Using Incremental Backup Sets.

When you create or add to an incremental backup set, `gpbackup` ensures that the backups in the set are created with a consistent set of backup options to ensure that the backup set can be used in a restore operation. For information about backup set consistency, see Using Incremental Backups.

When you create an incremental backup you include these options with the other `gpbackup` options to create a backup:

• `--leaf-partition-data` - Required for all backups in the incremental backup set.
• Required when you create a full backup that will be the base backup for an incremental backup set.
• Required when you create an incremental backup.
• `--incremental` - Required when you create an incremental backup.

You cannot combine `--data-only` or `--metadata-only` with `--incremental`.

• `--from-timestamp` - Optional. This option can be used with `--incremental`. The timestamp you specify is an existing backup. The timestamp can be either a full backup or incremental backup. The
backup being created must be compatible with the backup specified with the \texttt{--from-timestamp} option.

If you do not specify \texttt{--from-timestamp}, \texttt{gpbackup} attempts to find a compatible backup based on information in the \texttt{gpbackup} history file. See \textit{Incremental Backup Notes}.

\textbf{Using Incremental Backups}

\begin{itemize}
\item \textbf{Example Using Incremental Backup Sets}
\item \textbf{Creating an Incremental Backup with gpbackup}
\item \textbf{Restoring from an Incremental Backup with gprestore}
\item \textbf{Incremental Backup Notes}
\end{itemize}

When you add an incremental backup to a backup set, \texttt{gpbackup} ensures that the full backup and the incremental backups are consistent by checking these \texttt{gpbackup} options:

\begin{itemize}
\item \texttt{--dbname} - The database must be the same.
\item \texttt{--backup-dir} - The directory must be the same. The backup set, the full backup and the incremental backups, must be in the same location.
\item \texttt{--single-data-file} - This option must be either specified or absent for all backups in the set.
\item \texttt{--plugin-config} - If this option is specified, it must be specified for all backups in the backup set.
   The configuration must reference the same plugin binary.
\item \texttt{--include-table-file}, \texttt{--include-schema}, or any other options that filter tables and schemas must be the same.
\end{itemize}

When checking schema filters, only the schema names are checked, not the objects contained in the schemas.

\begin{itemize}
\item \texttt{--no-compression} - If this option is specified, it must be specified for all backups in the backup set.
\end{itemize}

If compression is used on the the full backup, compression must be used on the incremental backups. Different compression levels are allowed for the backups in the backup set. For a backup, the default is compression level 1.

If you try to add an incremental backup to a backup set, the backup operation fails if the \texttt{gpbackup} options are not consistent.

For information about the \texttt{gpbackup} and \texttt{gprestore} utility options, see \texttt{gpbackup} and \texttt{gprestore} in the \textit{Greenplum Database Utility Guide}.

\textbf{Example Using Incremental Backup Sets}

Each backup has a timestamp taken when the backup is created. For example, if you create a backup on May 14, 2017, the backup file names contain 20170514\textit{hhmmss}. The \textit{hhmmss} represents the time: hour, minute, and second.

This example assumes that you have created two full backups and incremental backups of the database \textit{mytest}. To create the full backups, you used this command:

\begin{verbatim}
gpbackup --dbname mytest --backup-dir /mybackup --leaf-partition-data
\end{verbatim}

You created incremental backups with this command:

\begin{verbatim}
gpbackup --dbname mytest --backup-dir /mybackup --leaf-partition-data --incremental
\end{verbatim}

When you specify the \texttt{--backup-dir} option, the backups are created in the \texttt{/mybackup} directory on each Greenplum Database host.

In the example, the full backups have the timestamp keys 20170514054532 and 20171114064330. The other backups are incremental backups. The example consists of two backup sets, the first with two
incremental backups, and second with one incremental backup. The backups are listed from earliest to most recent.

- 20170514054532 (full backup)
- 20170714095512
- 20170914081205
- 20171114064330 (full backup)
- 20180114051246

To create a new incremental backup based on the latest incremental backup, you must include the same --backup-dir option as the incremental backup as well as the options --leaf-partition-data and --incremental.

```
gpbackup --dbname mytest --backup-dir /mybackup --leaf-partition-data --incremental
```

You can specify the --from-timestamp option to create an incremental backup based on an existing incremental or full backup. Based on the example, this command adds a fourth incremental backup to the backup set that includes 20170914081205 as an incremental backup and uses 20170514054532 as the full backup.

```
gpbackup --dbname mytest --backup-dir /mybackup --leaf-partition-data --incremental --from-timestamp 20170914081205
```

This command creates an incremental backup set based on the full backup 20171114064330 and is separate from the backup set that includes the incremental backup 20180114051246.

```
gpbackup --dbname mytest --backup-dir /mybackup --leaf-partition-data --incremental --from-timestamp 20171114064330
```

To restore a database with the incremental backup 20170914081205, you need the incremental backups 20120914081205 and 20170714095512, and the full backup 20170514054532. This would be the gprestore command.

```
gprestore --backup-dir /backupdir --timestamp 20170914081205
```

### Creating an Incremental Backup with gpbackup

The `gpbackup` output displays the timestamp of the backup on which the incremental backup is based. In this example, the incremental backup is based on the backup with timestamp 20180802171642. The backup 20180802171642 can be an incremental or full backup.

```
$ gpbackup --dbname test --backup-dir /backups --leaf-partition-data --incremental
20180803:15:40:51 gpbackup:gpadmin:mdw:002907-[INFO]:Starting backup of database test
20180803:15:40:52 gpbackup:gpadmin:mdw:002907-[INFO]:Backup Timestamp = 20180803154051
20180803:15:40:52 gpbackup:gpadmin:mdw:002907-[INFO]:Backup Database = test
20180803:15:40:52 gpbackup:gpadmin:mdw:002907-[INFO]:Gathering list of tables for backup
20180803:15:40:52 gpbackup:gpadmin:mdw:002907-[INFO]:Acquiring ACCESS SHARE locks on tables
Locks acquired: 5 / 5
[================================================================]== 100.00%
0s
20180803:15:40:52 gpbackup:gpadmin:mdw:002907-[INFO]:Gathering additional table metadata
```
Restoring from an Incremental Backup with gprestore

When restoring an from an incremental backup, you can specify the `--verbose` option to display the backups that are used in the restore operation on the command line. For example, the following `gprestore` command restores a backup using the timestamp 20180807162904, an incremental backup. The output includes the backups that were used to restore the database data.

```
$ gprestore --create-db --timestamp 20180807162904 --verbose
...  
20180807:16:31:56 gprestore:gpadmin:mdw:008603-[INFO]:-Pre-data metadata restore complete
20180807:16:31:56 gprestore:gpadmin:mdw:008603-[DEBUG]:-Reading data for table public.tbl_ao from file (table 1 of 1)
20180807:16:31:56 gprestore:gpadmin:mdw:008603-[DEBUG]:-Checking whether segment agents had errors during restore
20180807:16:31:56 gprestore:gpadmin:mdw:008603-[DEBUG]:-Reading data for table public.test_ao from file (table 1 of 1)
20180807:16:31:56 gprestore:gpadmin:mdw:008603-[DEBUG]:-Checking whether segment agents had errors during restore
20180807:16:31:56 gprestore:gpadmin:mdw:008603-[DEBUG]:-Reading data for table public.homes2 from file (table 1 of 4)
20180807:16:31:56 gprestore:gpadmin:mdw:008603-[DEBUG]:-Reading data for table public.test2 from file (table 2 of 4)
```
The output shows that the restore operation used three backups. When restoring an from an incremental backup, `gprestore` also lists the backups that are used in the restore operation in the `gprestore` log file. During the restore operation, `gprestore` displays an error if the full backup or other required incremental backup is not available.

### Incremental Backup Notes

To create an incremental backup, or to restore data from an incremental backup set, you need the complete backup set. When you archive incremental backups, the complete backup set must be archived. You must archive all the files created on the master and all segments.

Each time `gpbackup` runs, the utility adds backup information to the history file `gpbackup_history.yaml` in the Greenplum Database master data directory. The file includes backup options and other backup information.

If you do not specify the `--from-timestamp` option when you create an incremental backup, `gpbackup` uses the most recent backup with a consistent set of options. The utility checks the backup history file to find the backup with a consistent set of options. If the utility cannot find a backup with a consistent set of options or the history file does not exist, `gpbackup` displays a message stating that a full backup must be created before an incremental can be created.

If you specify the `--from-timestamp` option when you create an incremental backup, `gpbackup` ensures that the options of the backup that is being created are consistent with the options of the specified backup.

The `gpbackup` option `--with-stats` is not required to be the same for all backups in the backup set. However, to perform a restore operation with the `gprestore` option `--with-stats` to restore statistics, the backup you specify must have must have used the `--with-stats` when creating the backup.

You can perform a restore operation from any backup in the backup set. However, changes captured in incremental backups later than the backup use to restore database data will not be restored.

When restoring from an incremental backup set, `gprestore` checks the backups and restores each append-optimized table from the most recent version of the append-optimized table in the backup set and restores the heap tables from the latest backup.

The incremental back up set, a full backup and associated incremental backups, must be on a single device. For example, the backups in a backup set must all be on a file system or must all be on a Data Domain system.

**Warning:** Changes to the Greenplum Database segment configuration invalidate incremental backups. After you change the segment configuration (add or remove segment instances), you must create a full backup before you can create an incremental backup.
Using gpbackup and gprestore with BoostFS

You can use the Greenplum Database gpbackup and gprestore utilities with the Data Domain DD Boost File System Plug-In (BoostFS) to access a Data Domain system. BoostFS leverages DD Boost technology and helps reduce bandwidth usage, can improve backup-times, offers load-balancing and in-flight encryption, and supports the Data Domain multi-tenancy feature set.

You install the BoostFS plug-in on the Greenplum Database host systems to provide access to a Data Domain system as a standard file system mount point. With direct access to a BoostFS mount point, gpbackup and gprestore can leverage the storage and network efficiencies of the DD Boost protocol for backup and recovery.

For information about configuring BoostFS, you can download the BoostFS for Linux Configuration Guide from the Dell support site https://www.dell.com/support (requires login). After logging into the support site, you can find the guide by searching for "BoostFS for Linux Configuration Guide". You can limit your search results by choosing to list only Manuals & Documentation as resources.

To back up or restore with BoostFS, you include the option --backup-dir with the gpbackup or gprestore command to access the Data Domain system.

Installing BoostFS

Download the latest BoostFS RPM from the Dell support site https://www.dell.com/support (requires login).

After logging into the support site, you can find the RPM by searching for "boostfs". You can limit your search results by choosing to list only Downloads & Drivers as resources. To list the most recent RPM near the top of your search results, sort your results by descending date.

The RPM supports both RHEL and SuSE.

These steps install BoostFS and create a mounted directory that accesses a Data Domain system.

Perform the steps on all Greenplum Database hosts. The mounted directory you create must be the same on all hosts.

1. Copy the BoostFS RPM to the host and install the RPM.

   After installation, the DDBoostFS package files are located under /opt/emc/boostfs.

2. Set up the BoostFS lockbox with the storage unit with the boostfs utility. Enter the Data Domain user password at the prompts.

   ```bash
   /opt/emc/boostfs/bin/boostfs lockbox set -d <Data_Domain_IP> -s <Storage_Unit> -u <Data_Domain_User>
   ```

   The `<Storage_Unit>` is the Data Domain storage unit ID. The `<Data_Domain_User>` is a Data Domain user with access to the storage unit.

3. Create the directory in the location you want to mount BoostFS.

   ```bash
   mkdir <path_to_mount_directory>
   ```

4. Mount the Data Domain storage unit with the boostfs utility. Use the mount option -allow-others=true to allow other users to write to the BoostFS mounted file system.

   ```bash
   /opt/emc/boostfs/bin/boostfs mount <path_to_mount_directory> -d $<Data_Domain_IP> -s <Storage_Unit> -o allow-others=true
   ```

5. Confirm that the mount was successful by running this command.

   ```bash
   mountpoint <mounted_directory>
   ```
The command lists the directory as a mount point.

`<mounted_directory>` is a mountpoint

You can now run `gpbackup` and `gprestore` with the `--backup-dir` option to back up a database to `<mounted_directory>` on the Data Domain system and restore data from the Data Domain system.

**Backing Up and Restoring with BoostFS**

These are required `gpbackup` options when backing up data to a Data Domain system with BoostFS.

- `--backup-dir` - Specify the mounted Data Domain storage unit.
- `--single-data-file` - Create a single data file on each segment host. A single data file avoids a BoostFS stream limitation.

When you use `gprestore` to restore a backup from a Data Domain system with BoostFS, you must specify the mounted Data Domain storage unit with the option `--backup-dir`.

When you use the `gpbackup` option `--single-data-file`, you cannot specify the `--jobs` option to perform a parallel restore operation with `gprestore`.

This example `gpbackup` command backs up the database `test`. The example assumes that the directory `/boostfs-test` is the mounted Data Domain storage unit.

```
$ gpbackup --dbname test --backup-dir /boostfs-test/ --single-data-file --no-compression
```

These commands drop the database `test` and restore the database from the backup.

```
$ dropdb test
$ gprestore --backup-dir /boostfs-test/ --timestamp 20171103153156 --create-db
```

The value `20171103153156` is the timestamp of the `gpbackup` backup set to restore. For information about how `gpbackup` uses timesamps when creating backups, see Parallel Backup with `gpbackup` and `gprestore`. For information about the `--timestamp` option, see `gprestore`.

**Using gpbackup Storage Plugins**

You can configure the Greenplum Database `gpbackup` and `gprestore` utilities to use a storage plugin to process backup files during a backup or restore operation. For example, during a backup operation, the plugin sends the backup files to a remote location. During a restore operation, the plugin retrieves the files from the remote location.

You can also develop a custom storage plugin with the Greenplum Database Backup/Restore Storage Plugin API (Beta). See Backup/Restore Storage Plugin API (Beta).

**Note:** Only the Backup/Restore Storage Plugin API is a Beta feature. The storage plugins are supported features.

**Using the S3 Storage Plugin with gpbackup and gprestore**

The S3 storage plugin application lets you use an Amazon Simple Storage Service (Amazon S3) location to store and retrieve backups when you run `gpbackup` and `gprestore`. Amazon S3 provides secure, durable, highly-scalable object storage.

The S3 storage plugin can also connect to an Amazon S3 compatible service such as Dell EMC Elastic Cloud Storage (ECS) and Minio.
To use the S3 storage plugin application, you specify the location of the plugin and the S3 login and backup location in a configuration file. When you run `gpbackup` or `gprestore`, you specify the configuration file with the option `--plugin-config`. For information about the configuration file, see S3 Storage Plugin Configuration File Format.

If you perform a backup operation with the `gpbackup` option `--plugin-config`, you must also specify the `--plugin-config` option when you restore the backup with `gprestore`.

**S3 Storage Plugin Configuration File Format**

The configuration file specifies the absolute path to the Greenplum Database S3 storage plugin executable, connection credentials, and S3 location.

The S3 storage plugin configuration file uses the YAML 1.1 document format and implements its own schema for specifying the location of the Greenplum Database S3 storage plugin, connection credentials, and S3 location and login information.

The configuration file must be a valid YAML document. The `gpbackup` and `gprestore` utilities process the control file document in order and use indentation (spaces) to determine the document hierarchy and the relationships of the sections to one another. The use of white space is significant. White space should not be used simply for formatting purposes, and tabs should not be used at all.

This is the structure of a S3 storage plugin configuration file.

```yaml
executablepath: <absolute-path-to-gpbackup_s3_plugin>
options:
  region: <aws-region>
  endpoint: <S3-endpoint>
  aws_access_key_id: <aws-user-id>
  aws_secret_access_key: <aws-user-id-key>
  bucket: <s3-bucket>
  folder: <s3-location>
  encryption: [on|off]
```

**executablepath**

Required. Absolute path to the plugin executable. For example, the Pivotal Greenplum Database installation location is `$GPHOME/bin/gpbackup_s3_plugin`. The plugin must be in the same location on every Greenplum Database host.

**options**

Required. Begins the S3 storage plugin options section.

**region**

Required for AWS S3. If connecting to an S3 compatible service, this option is not required.

**endpoint**

Required for an S3 compatible service. Specify this option to connect to an S3 compatible service such as ECS. The plugin connects to the specified S3 endpoint (hostname or IP address) to access the S3 compatible data store.

If this option is specified, the plugin ignores the `region` option and does not use AWS to resolve the endpoint. When this option is not specified, the plugin uses the `region` to determine AWS S3 endpoint.

**aws_access_key_id**

Optional. The S3 ID to access the S3 bucket location that stores backup files.

If this parameter is not specified, S3 authentication information from the session environment is used. See Notes.

**aws_secret_access_key**
Required only if you specify `aws_access_key_id`. The S3 passcode for the S3 ID to access the S3 bucket location.

**bucket**

Required. The name of the S3 bucket in the AWS region or S3 compatible data store. The bucket must exist.

**folder**

Required. The S3 location for backups. During a backup operation, the plugin creates the S3 location if it does not exist in the S3 bucket.

**encryption**

Optional. Enable or disable use of Secure Sockets Layer (SSL) when connecting to an S3 location. Default value is on, use connections that are secured with SSL. Set this option to off to connect to an S3 compatible service that is not configured to use SSL. Any value other than off is treated as on.

### Example

This is an example S3 storage plugin configuration file that is used in the next `gpbackup` example command. The name of the file is `s3-test-config.yaml`.

```yaml
executablepath: $GPHOME/bin/gpbackup_s3_plugin
options:
  region: us-west-2
  aws_access_key_id: test-s3-user
  aws_secret_access_key: asdf1234asdf
  bucket: gpdb-backup
  folder: test/backup3
```

This `gpbackup` example backs up the database demo using the S3 storage plugin. The absolute path to the S3 storage plugin configuration file is `/home/gpadmin/s3-test`.

```
gpbackup --dbname demo --plugin-config /home/gpadmin/s3-test-config.yaml
```

The S3 storage plugin writes the backup files to this S3 location in the AWS region us-west-2.

```
gpdb-backup/test/backup3/backups/YYYYMMDD/YYYYMMDDHHMMSS/
```

### Notes

The S3 storage plugin application must be in the same location on every Greenplum Database host. The configuration file is required only on the master host.

When you perform a backup with the S3 storage plugin, the plugin stores the backup files in this location in the S3 bucket.

```
<folder>/backups/<datestamp>/<timestamp>
```

Where `folder` is the location you specified in the S3 configuration file, and `datestamp` and `timestamp` are the backup date and time stamps.

Using Amazon S3 to back up and restore data requires an Amazon AWS account with access to the Amazon S3 bucket. These are the Amazon S3 bucket permissions required for backing up and restoring data.

- Upload/Delete for the S3 user ID that uploads the files
- Open/Download and View for the S3 user ID that accesses the files
If `aws_access_key_id` and `aws_secret_access_key` are not specified in the configuration file, the S3 plugin uses S3 authentication information from the system environment of the session running the backup operation. The S3 plugin searches for the information in these sources, using the first available source.

1. The environment variables `AWS_ACCESS_KEY_ID` and `AWS_SECRET_ACCESS_KEY`.
2. The authentication information set with the AWS CLI command `aws configure`.
3. The credentials of the Amazon EC2 IAM role if the backup is run from an EC2 instance.

For information about Amazon S3, see Amazon S3.

- For information about Amazon S3 regions and endpoints, see [http://docs.aws.amazon.com/general/latest/gr/rande.html#s3_region](http://docs.aws.amazon.com/general/latest/gr/rande.html#s3_region).
- For information about S3 buckets and folders, see the Amazon S3 documentation [https://aws.amazon.com/documentation/s3/](https://aws.amazon.com/documentation/s3/).

### Using the DD Boost Storage Plugin with gpbackup and gprestore

**Note:** The DD Boost storage plugin is available only in the commercial release of Pivotal Greenplum Database.

Dell EMC Data Domain Boost (DD Boost) is Dell EMC software that can be used with the `gpbackup` and `gprestore` utilities to perform faster backups to the Dell EMC Data Domain storage appliance. You can also replicate a backup on a separate, remote Data Domain system for disaster recovery.

To use the DD Boost storage plugin application, you first create a configuration file to specify the location of the plugin, the DD Boost login, and the backup location. When you run `gpbackup` or `gprestore`, you specify the configuration file with the option `--plugin-config`. For information about the configuration file, see [DD Boost Storage Plugin Configuration File Format](#).

If you perform a backup operation with the `gpbackup` option `--plugin-config`, you must also specify the `--plugin-config` option when you restore the backup with `gprestore`.

To replicate a backup set on a separate Data Domain system for disaster recovery, add the backup replication options to the configuration file. Set the `replication` option to `on` and add the options that the plugin uses to access the remote Data Domain system that stores the replicated backup. During the backup operation, the DD Boost storage plugin replicates the backup set on the remote Data Domain system with DD Boost managed file replication.

To restore data from a replicated backup, you can use `gprestore` with the DD Boost storage plugin and specify the location of the backup in the DD Boost configuration file.

### DD Boost Storage Plugin Configuration File Format

The configuration file specifies the absolute path to the Greenplum Database DD Boost storage plugin executable, DD Boost connection credentials, and Data Domain location.

The DD Boost storage plugin configuration file uses the YAML 1.1 document format and implements its own schema for specifying the DD Boost information.

The configuration file must be a valid YAML document. The `gpbackup` and `gprestore` utilities process the configuration file document in order and use indentation (spaces) to determine the document hierarchy and the relationships of the sections to one another. The use of white space is significant. White space should not be used simply for formatting purposes, and tabs should not be used at all.

This is the structure of a DD Boost storage plugin configuration file.

```
exectutablepath: <absolute-path-to-gpbackup_ddboost_plugin>
options:
  hostname: "<data-domain-host>"
  username: "<ddboost-ID>"
  password: "<ddboost-pwd>"
  storage_unit: "<data-domain-id>"
  directory: "<data-domain-dir>"
```
**executablepath**
- Required. Absolute path to the plugin executable. For example, the Pivotal Greenplum Database installation location is `$GPHOME/bin/gpbackup_ddboost_plugin`. The plugin must be in the same location on every Greenplum Database host.

**options**
- Required. Begins the DD Boost storage plugin options section.
  - **hostname**
    - Required. The IP address or hostname of the host. There is a 30-character limit.
  - **username**
    - Required. The Data Domain Boost user name. There is a 30-character limit.
  - **password**
    - Required. The passcode for the DD Boost user to access the Data Domain storage unit.
  - **storage-unit**
    - Required. A valid storage unit name for the Data Domain system that is used for backup and restore operations.
  - **directory**
    - Required. The location for the backup files, configuration files, and global objects on the Data Domain system. The location on the system is `/<data-domain-dir>` in the storage unit of the system.
    - During a backup operation, the plugin creates the directory location if it does not exist in the storage unit and stores the backup in this directory `/<data-domain-dir>/YYYYMMDD/YYYYMMDDHHMMSS/`.

**replication**
- Optional. Enables or disables backup replication with DD Boost managed file replication when `gpbackup` performs a backup operation. Value is either `on` or `off`. Default value is `off`, backup replication is disabled. When the value is `on`, the DD Boost plugin replicates the backup on the Data Domain system that you specify with the `remote_*` options.
  - The `replication` option and `remote_*` options are ignored when performing a restore operation with `gprestore`. The `remote_*` options are ignored if `replication` is `off`.
  - **remote_hostname**
    - Required if `replication` is `on`. The IP address or hostname of the Data Domain system that is used for remote backup storage. There is a 30-character limit.
  - **remote_username**
    - Required if `replication` is `on`. The Data Domain Boost user name that accesses the remote Data Domain system. There is a 30-character limit.
  - **remote_password**
    - Required if `replication` is `on`. The passcode for the DD Boost user to access the Data Domain storage unit on the remote system.
  - **remote_storage-unit**
    - Required if `replication` is `on`. A valid storage unit name for the remote Data Domain system that is used for backup replication.
**remote_directory**

Required if replication is on. The location for the replicated backup files, configuration files, and global objects on the remote Data Domain system. The location on the system is `/<remote-dd-dir>` in the storage unit of the remote system.

During a backup operation, the plugin creates the directory location if it does not exist in the storage unit of the remote Data Domain system and stores the replicated backup in this directory `/<remote-dd-dir>/YYYYMMDD/YYYYMMDDHHMMSS/`.

**Example**

This is an example DD Boost storage plugin configuration file that is used in the next `gpbackup` example command. The name of the file is `ddboost-test-config.yaml`.

```yaml
executablepath: $GPHOME/bin/gpbackup_ddboost_plugin
options:
  hostname: "192.0.2.230"
  username: "test-ddb-user"
  password: "asdf1234asdfs"
  storage_unit: "gpdb-backup"
  directory: "test/backup"
```

This `gpbackup` example backs up the database demo using the DD Boost storage plugin. The absolute path to the DD Boost storage plugin configuration file is `/home/gpadmin/ddboost-test-config.yml`.

```
gpbackup --dbname demo --single-data-file --plugin-config /home/gpadmin/ddboost-test-config.yaml
```

The DD Boost storage plugin writes the backup files to this directory of the Data Domain storage unit `gpdb-backup`.

```
/test/backup/YYYYMMDD/YYYYMMDDHHMMSS/
```

This is an example DD Boost storage plugin configuration file that enables replication.

```yaml
executablepath: $GPHOME/bin/gpbackup_ddboost_plugin
options:
  hostname: "192.0.2.230"
  username: "test-ddb-user"
  password: "asdf1234asdfs"
  storage_unit: "gpdb-backup"
  directory: "test/backup"
  replication: "on"
  remote_hostname: "192.0.3.20"
  remote_username: "test-dd-remote"
  remote_password: "qwer2345erty"
  remote_storage_unit: "gpdb-remote"
  remote_directory: "test/replication"
```

To restore from the replicated backup in the previous example, you can run `gprestore` with the DD Boost storage plugin and specify a configuration file with this information.

```yaml
executablepath: $GPHOME/bin/gpbackup_ddboost_plugin
options:
  hostname: "192.0.3.20"
  remote_username: "test-dd-remote"
  remote_password: "qwer2345erty"
  storage_unit: "gpdb-remote"
  directory: "test/replication"
```
Notes

Dell EMC DD Boost is integrated with Pivotal Greenplum Database and requires a DD Boost license. Open source Greenplum Database cannot use the DD Boost software, but can back up to a Dell EMC Data Domain system mounted as an NFS share on the Greenplum master and segment hosts.

The DD Boost storage plugin application must be in the same location on every Greenplum Database host. The configuration file is required only on the master host.

When you perform a backup with the DD Boost storage plugin, the plugin stores the backup files in this location in the Data Domain storage unit.

<directory>/backups/<datestamp>/<timestamp>

where <directory> is the location you specified in the DD Boost configuration file, and <datestamp> and <timestamp> are the backup date and time stamps.

When performing a backup operation with replication, the Data Domain system where the backup is stored must have access to the remote Data Domain system where the replicated backup is stored.

Performing a backup operation with replication increases the time required to perform a backup. The backup set is copied to the local Data Domain system, and then replicated on the remote Data Domain system using DD Boost managed file replication. The backup operation completes after the backup set is replicated on the remote system.

Backup/Restore Storage Plugin API (Beta)

This topic describes how to develop a custom storage plugin with the Greenplum Database Backup/Restore Storage Plugin API.

Note: Only the Backup/Restore Storage Plugin API is Beta feature. The storage plugins are supported features.

The Backup/Restore Storage Plugin API provides a framework that you can use to develop and integrate a custom backup storage system with the Greenplum Database gpbackup and gprestore utilities.

The Backup/Restore Storage Plugin API defines a set of interfaces that a plugin must support. The API also specifies the format and content of a configuration file for a plugin.

When you use the Backup/Restore Storage Plugin API, you create a plugin that the Greenplum Database administrator deploys to the Greenplum Database cluster. Once deployed, the plugin is available for use in certain backup and restore operations.

This topic includes the following subtopics:

- Plugin Configuration File
- Plugin API
- Plugin Commands
- Implementing a Backup/Restore Storage Plugin
- Verifying a Backup/Restore Storage Plugin
- Packaging and Deploying a Backup/Restore Storage Plugin

Plugin Configuration File

Specifying the --plugin-config option to the gpbackup and gprestore commands instructs the utilities to use the plugin specified in the configuration file for the operation.

The plugin configuration file provides information for both Greenplum Database and the plugin. The Backup/Restore Storage Plugin API defines the format of, and certain keywords used in, the plugin configuration file.
A plugin configuration file is a YAML file in the following format:

```yaml
executablepath: path_to_plugin_executable
options:
  keyword1: value1
  keyword2: value2
  ...
  keywordN: valueN
```

gpbackup and gprestore use the `executablepath` value to determine the file system location of the plugin executable program.

The plugin configuration file may also include keywords and values specific to a plugin instance. A backup/restore storage plugin can use the `options` block specified in the file to obtain information from the user that may be required to perform its tasks. This information may include location, connection, or authentication information, for example. The plugin should both specify and consume the content of this information in `keyword: value` syntax.

A sample plugin configuration file for the Greenplum Database S3 backup/restore storage plugin follows:

```yaml
executablepath: $GPHOME/bin/gpbackup_s3_plugin
options:
  region: us-west-2
  aws_access_key_id: notarealID
  aws_secret_access_key: notarealkey
  bucket: gp_backup_bucket
  folder: greenplum_backups
```

### Plugin API

The plugin that you implement when you use the Backup/Restore Storage Plugin API is an executable program that supports specific `commands` invoked by gpbackup and gprestore at defined points in their respective life cycle operations:

- The Greenplum Database Backup/Restore Storage Plugin API provides hooks into the `gpbackup` lifecycle at initialization, during backup, and at cleanup/exit time.
- The API provides hooks into the `gprestore` lifecycle at initialization, during restore, and at cleanup/exit time.
- The API provides arguments that specify the execution scope (master host, segment host, or segment instance) for a plugin setup or cleanup command. The scope can be one of these values.
  - `master` - Execute the plugin once on the master host.
  - `segment_host` - Execute the plugin once on each of the segment hosts.
  - `segment` - Execute the plugin once for each active segment instance on the host running the segment instance.

The Greenplum Database hosts and segment instances are based on the Greenplum Database configuration when the back up started. The values `segment_host` and `segment` are provided as a segment host can host multiple segment instances. There might be some setup or cleanup required at the segment host level as compared to each segment instance.

The Backup/Restore Storage Plugin API defines the following call syntax for a backup/restore storage plugin executable program:

```bash
plugin_executable command config_file args
```

where:

- `plugin_executable` - The absolute path of the backup/restore storage plugin executable program. This path is determined by the `executablepath` property value configured in the plugin's configuration YAML file.
- **command** - The name of a Backup/Restore Storage Plugin API command that identifies a specific entry point to a `gpbackup` or `gprestore` lifecycle operation.
- **config_file** - The absolute path of the plugin’s configuration YAML file.
- **args** - The command arguments; the actual arguments differ depending upon the **command** specified.

**Plugin Commands**

The Greenplum Database Backup/Restore Storage Plugin API defines the following commands:

**Table 22: Backup/Restore Storage Plugin API Commands**

<table>
<thead>
<tr>
<th>Command Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>plugin_api_version</code></td>
<td>Return the version of the Backup/Restore Storage Plugin API supported by the plugin. The only supported version is 0.3.0.</td>
</tr>
<tr>
<td><code>setup_plugin_for_backup</code></td>
<td>Initialize the plugin for a backup operation.</td>
</tr>
<tr>
<td><code>backup_file</code></td>
<td>Move a backup file to the remote storage system.</td>
</tr>
<tr>
<td><code>backup_data</code></td>
<td>Move streaming data from <code>stdin</code> to a file on the remote storage system.</td>
</tr>
<tr>
<td><code>cleanup_plugin_for_backup</code></td>
<td>Clean up after a backup operation.</td>
</tr>
<tr>
<td><code>setup_plugin_for_restore</code></td>
<td>Initialize the plugin for a restore operation.</td>
</tr>
<tr>
<td><code>restore_file</code></td>
<td>Move a backup file from the remote storage system to a designated location on the local host.</td>
</tr>
<tr>
<td><code>restore_data</code></td>
<td>Move a backup file from the remote storage system, streaming the data to <code>stdout</code>.</td>
</tr>
<tr>
<td><code>cleanup_plugin_for_restore</code></td>
<td>Clean up after a restore operation.</td>
</tr>
</tbody>
</table>

A backup/restore storage plugin must support every command identified above, even if it is a no-op.

**Implementing a Backup/Restore Storage Plugin**

You can implement a backup/restore storage plugin executable in any programming or scripting language. The tasks performed by a backup/restore storage plugin will be very specific to the remote storage system. As you design the plugin implementation, you will want to:

- Examine the connection and data transfer interface to the remote storage system.
- Identify the storage path specifics of the remote system.
- Identify configuration information required from the user.
- Define the keywords and value syntax for information required in the plugin configuration file.
- Determine if, and how, the plugin will modify (compress, etc.) the data en route to/from the remote storage system.
- Define a mapping between a `gpbackup` file path and the remote storage system.
- Identify how `gpbackup` options affect the plugin, as well as which are required and/or not applicable. For example, if the plugin performs its own compression, `gpbackup` must be invoked with the `--no-compression` option to prevent the utility from compressing the data.

A backup/restore storage plugin that you implement must:

- Support all plugin commands identified in **Plugin Commands**. Each command must exit with the values identified on the command reference page.

Refer to the `gpbackup-s3-plugin` github repository for an example plugin implementation.
Verifying a Backup/Restore Storage Plugin

The Backup/Restore Storage Plugin API includes a test bench that you can run to ensure that a plugin is well integrated with gpbackup and gprestore.

The test bench is a bash script that you run in a Greenplum Database installation. The script generates a small (<1MB) data set in a Greenplum Database table, explicitly tests each command, and runs a backup and restore of the data (file and streaming). The test bench invokes gpbackup and gprestore, which in turn individually call/test each Backup/Restore Storage Plugin API command implemented in the plugin.

The test bench program calling syntax is:

```
plugin_test_bench.sh plugin_executable plugin_config
```

Procedure

To run the Backup/Restore Storage Plugin API test bench against a plugin:

1. Log in to the Greenplum Database master host and set up your environment. For example:

   ```
   $ ssh gpadmin@gpmaster
   gpadmin@gpmaster$ . /usr/local/greenplum-db/greenplum_path.sh
   ```

2. Obtain a copy of the test bench from the gpbackup github repository. For example:

   ```
   $ git clone git@github.com:greenplum-db/gpbackup.git
   ```

   The clone operation creates a directory named gpbackup/ in the current working directory.

3. Locate the test bench program in the gpbackup/master/plugins directory. For example:

   ```
   $ ls gpbackup/master/plugins/plugin_test_bench.sh
   ```

4. Copy the plugin executable program and the plugin configuration YAML file from your development system to the Greenplum Database master host. Note the file system location to which you copied the files.

5. Copy the plugin executable program from the Greenplum Database master host to the same file system location on each segment host.

6. If required, edit the plugin configuration YAML file to specify the absolute path of the plugin executable program that you just copied to the Greenplum segments.

7. Run the test bench program against the plugin. For example:

   ```
   $ gpbackup/master/plugins/plugin_test_bench.sh /path/to/pluginexec /path/to/plugincfg.yaml
   ```

8. Examine the test bench output. Your plugin passed the test bench if all output messages specify RUNNING and PASSED. For example:

   ```
   # ----------------------------------------------
   # Starting gpbackup plugin tests
   # ----------------------------------------------
   [RUNNING] plugin_api_version
   [PASSED] plugin_api_version
   [RUNNING] setup_plugin_for_backup
   [RUNNING] backup_file
   [RUNNING] setup_plugin_for_restore
   [RUNNING] restore_file
   [PASSED] setup_plugin_for_backup
   [PASSED] backup_file
   [PASSED] setup_plugin_for_restore
   [PASSED] restore_file
   ```
### Packaging and Deploying a Backup/Restore Storage Plugin

Your backup/restore storage plugin is ready to be deployed to a Greenplum Database installation after the plugin passes your testing and the test bench verification. When you package the backup/restore storage plugin, consider the following:

- The backup/restore storage plugin must be installed in the same file system location on every host in the Greenplum Database cluster. Provide installation instructions for the plugin identifying the same.
- The `gpadmin` user must have permission to traverse the file system path to the backup/restore plugin executable program.
- Include a template configuration file with the plugin.
- Document the valid plugin configuration keywords, making sure to include the syntax of expected values.
- Document required `gpbackup` options and how they affect plugin processing.

### backup_data

Plugin command to move streaming data from `stdin` to the remote storage system.

### Synopsis

```
plugin_executable backup_data plugin_config_file data_filenamekey
```

### Description

`gpbackup` invokes the `backup_data` plugin command on each segment host during a streaming backup.

The `backup_data` implementation should read a potentially large stream of data from `stdin` and write the data to a single file on the remote storage system. The data is sent to the command as a single continuous stream per Greenplum Database segment. If `backup_data` modifies the data in any manner (i.e., compresses), `restore_data` must perform the reverse operation.

Name or maintain a mapping from the destination file to `data_filenamekey`. This will be the file key used for the restore operation.

### Arguments

- **plugin_config_file**
  
  The absolute path to the plugin configuration YAML file.

- **data_filenamekey**
  
  The mapping key for a specially-named backup file for streamed data.
Exit Code
The `backup_data` command must exit with a value of 0 on success, non-zero if an error occurs. In the case of a non-zero exit code, `gpbackup` displays the contents of `stderr` to the user.

**backup_file**
Plugin command to move a backup file to the remote storage system.

**Synopsis**
```
plugin_executable backup_file plugin_config_file file_to_backup
```

**Description**
`gpbackup` invokes the `backup_file` plugin command on the master and each segment host for the file that `gpbackup` writes to a backup directory on local disk.

The `backup_file` implementation should process and copy the file to the remote storage system. Do not remove the local copy of the file that you specify with `file_to_backup`.

**Arguments**
- `plugin_config_file`: The absolute path to the plugin configuration YAML file.
- `file_to_backup`: The absolute path to a local backup file generated by `gpbackup`. Do not remove the local copy of the file that you specify with `file_to_backup`.

Exit Code
The `backup_file` command must exit with a value of 0 on success, non-zero if an error occurs. In the case of a non-zero exit code, `gpbackup` displays the contents of `stderr` to the user.

**cleanup_plugin_for_backup**
Plugin command to clean up a storage plugin after backup.

**Synopsis**
```
plugin_executable cleanup_plugin_for_backup plugin_config_file local_backup_dir scope
```

**Description**
`gpbackup` invokes the `cleanup_plugin_for_backup` plugin command when a `gpbackup` operation completes, both in success and failure cases. The `scope` argument specifies the execution scope. `gpbackup` will invoke the command with each of the `scope` values.

The `cleanup_plugin_for_backup` command should perform the actions necessary to clean up the remote storage system after a backup. Clean up activities may include removing remote directories or temporary files created during the backup, disconnecting from the backup service, etc.

**Arguments**
- `plugin_config_file`: The absolute path to the plugin configuration YAML file.
**local_backup_dir**
The local directory on the Greenplum Database host (master and segments) to which `gpbackup` wrote backup files.
- When `scope` is `master`, the `local_backup_dir` is the backup directory of the Greenplum Database master.
- When `scope` is `segment`, the `local_backup_dir` is the backup directory of a segment instance. The `contentID` identifies the segment instance.
- When the `scope` is `segment_host`, the `local_backup_dir` is an arbitrary backup directory on the host.

**scope**
The execution scope value indicates the host and number of times the plugin command is executed. `scope` can be one of these values:
- `master`: Execute the plugin command once on the master host.
- `segment_host`: Execute the plugin command once on each of the segment hosts.
- `segment`: Execute the plugin command once for each active segment instance on the host running the segment instance. The `contentID` identifies the segment instance.

The Greenplum Database hosts and segment instances are based on the Greenplum Database configuration when the back up was first initiated.

**contentID**
The `contentID` of the Greenplum Database master or segment instance corresponding to the scope. `contentID` is passed only when the `scope` is `master` or `segment`.
- When `scope` is `master`, the `contentID` is `-1`.
- When `scope` is `segment`, the `contentID` is the content identifier of an active segment instance.

**Exit Code**
The `cleanup_plugin_for_backup` command must exit with a value of 0 on success, non-zero if an error occurs. In the case of a non-zero exit code, `gpbackup` displays the contents of `stderr` to the user.

**cleanup_plugin_for_restore**
Plugin command to clean up a storage plugin after restore.

**Synopsis**
```
plugin_executable cleanup_plugin_for_restore plugin_config_file local_backup_dir scope
```

**Description**
`gprestore` invokes the `cleanup_plugin_for_restore` plugin command when a `gprestore` operation completes, both in success and failure cases. The `scope` argument specifies the execution scope. `gprestore` will invoke the command with each of the `scope` values.

The `cleanup_plugin_for_restore` implementation should perform the actions necessary to clean up the remote storage system after a restore. Clean up activities may include removing remote directories or temporary files created during the restore, disconnecting from the backup service, etc.

**Arguments**
```
plugin_config_file
```
The absolute path to the plugin configuration YAML file.

**local_backup_dir**
The local directory on the Greenplum Database host (master and segments) from which `gprestore` reads backup files.

- When `scope` is `master`, the `local_backup_dir` is the backup directory of the Greenplum Database master.
- When `scope` is `segment`, the `local_backup_dir` is the backup directory of a segment instance. The `contentID` identifies the segment instance.
- When the `scope` is `segment_host`, the `local_backup_dir` is an arbitrary backup directory on the host.

**scope**
The execution scope value indicates the host and number of times the plugin command is executed. `scope` can be one of these values:

- `master` - Execute the plugin command once on the master host.
- `segment_host` - Execute the plugin command once on each of the segment hosts.
- `segment` - Execute the plugin command once for each active segment instance on the host running the segment instance. The `contentID` identifies the segment instance.

The Greenplum Database hosts and segment instances are based on the Greenplum Database configuration when the back up was first initiated.

**contentID**
The `contentID` of the Greenplum Database master or segment instance corresponding to the `scope`. `contentID` is passed only when the `scope` is `master` or `segment`.

- When `scope` is `master`, the `contentID` is `-1`.
- When `scope` is `segment`, the `contentID` is the content identifier of an active segment instance.

**Exit Code**
The `cleanup_plugin_for_restore` command must exit with a value of 0 on success, non-zero if an error occurs. In the case of a non-zero exit code, `gprestore` displays the contents of `stderr` to the user.

**plugin_api_version**
Plugin command to display the supported Backup Storage Plugin API version.

**Synopsis**

```
plugin_executable plugin_api_version
```

**Description**
`gpbackup` and `gprestore` invoke the `plugin_api_version` plugin command before a backup or restore operation to determine Backup Storage Plugin API version compatibility.

**Return Value**
The `plugin_api_version` command must return the Backup Storage Plugin API version number supported by the storage plugin, "0.3.0".

**restore_data**
Plugin command to stream data from the remote storage system to `stdout`.
Synopsis

```
plugin_executable restore_data plugin_config_file data_filenamekey
```

Description

gprestore invokes the `restore_data` plugin command on each segment host when restoring a streaming backup.

The `restore_data` implementation should read a potentially large data file named or mapped to `data_filenamekey` from the remote storage system and write the contents to `stdout`. If the `backup_data` command modified the data in any way (i.e. compressed), `restore_data` should perform the reverse operation.

Arguments

- **plugin_config_file**
  - The absolute path to the plugin configuration YAML file.

- **data_filenamekey**
  - The mapping key to a backup file on the remote storage system. `data_filenamekey` is the same key provided to the `backup_data` command.

Exit Code

The `restore_data` command must exit with a value of 0 on success, non-zero if an error occurs. In the case of a non-zero exit code, `gprestore` displays the contents of `stderr` to the user.

**restore_file**

Plugin command to move a backup file from the remote storage system.

Synopsis

```
plugin_executable restore_file plugin_config_file file_to_restore
```

Description

gprestore invokes the `restore_file` plugin command on the master and each segment host for the file that `gprestore` will read from a backup directory on local disk.

The `restore_file` command should process and move the file from the remote storage system to `file_to_restore` on the local host.

Arguments

- **plugin_config_file**
  - The absolute path to the plugin configuration YAML file.

- **file_to_restore**
  - The absolute path to which to move a backup file from the remote storage system.

Exit Code

The `restore_file` command must exit with a value of 0 on success, non-zero if an error occurs. In the case of a non-zero exit code, `gprestore` displays the contents of `stderr` to the user.

**setup_plugin_for_backup**

Plugin command to initialize a storage plugin for the backup operation.
Synopsis

`plugin_executable setup_plugin_for_backup plugin_config_file local_backup_dir scope`

Description

`gpbackup` invokes the `setup_plugin_for_backup` plugin command during `gpbackup` initialization phase. The `scope` argument specifies the execution scope. `gpbackup` will invoke the command with each of the `scope` values.

The `setup_plugin_for_backup` command should perform the activities necessary to initialize the remote storage system before backup begins. Set up activities may include creating remote directories, validating connectivity to the remote storage system, checking disks, and so forth.

Arguments

`plugin_config_file`

The absolute path to the plugin configuration YAML file.

`local_backup_dir`

The local directory on the Greenplum Database host (master and segments) to which `gpbackup` will write backup files. `gpbackup` creates this local directory.

- When `scope` is `master`, the `local_backup_dir` is the backup directory of the Greenplum Database master.
- When `scope` is `segment`, the `local_backup_dir` is the backup directory of a segment instance. The `contentID` identifies the segment instance.
- When the scope is `segment_host`, the `local_backup_dir` is an arbitrary backup directory on the host.

`scope`

The execution scope value indicates the host and number of times the plugin command is executed. `scope` can be one of these values:

- `master` - Execute the plugin command once on the master host.
- `segment_host` - Execute the plugin command once on each of the segment hosts.
- `segment` - Execute the plugin command once for each active segment instance on the host running the segment instance. The `contentID` identifies the segment instance.

The Greenplum Database hosts and segment instances are based on the Greenplum Database configuration when the back up was first initiated.

`contentID`

The `contentID` of the Greenplum Database master or segment instance corresponding to the scope. `contentID` is passed only when the `scope` is `master` or `segment`.

- When `scope` is `master`, the `contentID` is `-1`.
- When `scope` is `segment`, the `contentID` is the content identifier of an active segment instance.

Exit Code

The `setup_plugin_for_backup` command must exit with a value of 0 on success, non-zero if an error occurs. In the case of a non-zero exit code, `gpbackup` displays the contents of `stderr` to the user.
**setup_plugin_for_restore**

Plugin command to initialize a storage plugin for the restore operation.

**Synopsis**

```
plugin_executable setup_plugin_for_restore plugin_config_file local_backup_dir scope
```

**Description**

`gprestore` invokes the `setup_plugin_for_restore` plugin command during `gprestore` initialization phase. The `scope` argument specifies the execution scope. `gprestore` will invoke the command with each of the `scope` values.

The `setup_plugin_for_restore` command should perform the activities necessary to initialize the remote storage system before a restore operation begins. Set up activities may include creating remote directories, validating connectivity to the remote storage system, etc.

**Arguments**

**plugin_config_file**

The absolute path to the plugin configuration YAML file.

**local_backup_dir**

The local directory on the Greenplum Database host (master and segments) from which `gprestore` reads backup files. `gprestore` creates this local directory.

- When `scope` is `master`, the `local_backup_dir` is the backup directory of the Greenplum Database master.
- When `scope` is `segment`, the `local_backup_dir` is the backup directory of a segment instance. The `contentID` identifies the segment instance.
- When the `scope` is `segment_host`, the `local_backup_dir` is an arbitrary backup directory on the host.

**scope**

The execution scope value indicates the host and number of times the plugin command is executed. `scope` can be one of these values:

- `master` - Execute the plugin command once on the master host.
- `segment_host` - Execute the plugin command once on each of the segment hosts.
- `segment` - Execute the plugin command once for each active segment instance on the host running the segment instance. The `contentID` identifies the segment instance.

The Greenplum Database hosts and segment instances are based on the Greenplum Database configuration when the back up was first initiated.

**contentID**

The `contentID` of the Greenplum Database master or segment instance corresponding to the scope. `contentID` is passed only when the `scope` is `master` or `segment`.

- When `scope` is `master`, the `contentID` is `-1`.
- When `scope` is `segment`, the `contentID` is the content identifier of an active segment instance.
Exit Code

The `setup_plugin_for_restore` command must exit with a value of 0 on success, non-zero if an error occurs. In the case of a non-zero exit code, `gprestore` displays the contents of `stderr` to the user.

Expanding a Greenplum System

To scale up performance and storage capacity, expand your Greenplum Database system by adding hosts to the system. In general, adding nodes to a Greenplum cluster achieves a linear scaling of performance and storage capacity.

Data warehouses typically grow over time as additional data is gathered and the retention periods increase for existing data. At times, it is necessary to increase database capacity to consolidate different data warehouses into a single database. Additional computing capacity (CPU) may also be needed to accommodate newly added analytics projects. Although it is wise to provide capacity for growth when a system is initially specified, it is not generally possible to invest in resources long before they are required. Therefore, you should expect to execute a database expansion project periodically.

Because of the Greenplum MPP architecture, when you add resources to the system, the capacity and performance are the same as if the system had been originally implemented with the added resources. Unlike data warehouse systems that require substantial downtime in order to dump and restore the data, expanding a Greenplum Database system is a phased process with minimal downtime. Regular and ad hoc workloads can continue while data is redistributed and transactional consistency is maintained. The administrator can schedule the distribution activity to fit into ongoing operations and can pause and resume as needed. Tables can be ranked so that datasets are redistributed in a prioritized sequence, either to ensure that critical workloads benefit from the expanded capacity sooner, or to free disk space needed to redistribute very large tables.

The expansion process uses standard Greenplum Database operations so it is transparent and easy for administrators to troubleshoot. Segment mirroring and any replication mechanisms in place remain active, so fault-tolerance is uncompromised and disaster recovery measures remain effective.

System Expansion Overview

You can perform a Greenplum Database expansion to add segment instances and segment hosts with minimal downtime. In general, adding nodes to a Greenplum cluster achieves a linear scaling of performance and storage capacity.

Data warehouses typically grow over time, often at a continuous pace, as additional data is gathered and the retention period increases for existing data. At times, it is necessary to increase database capacity to consolidate disparate data warehouses into a single database. The data warehouse may also require additional computing capacity (CPU) to accommodate added analytics projects. It is good to provide capacity for growth when a system is initially specified, but even if you anticipate high rates of growth, it is generally unwise to invest in capacity long before it is required. Database expansion, therefore, is a project that you should expect to have to execute periodically.

When you expand your database, you should expect the following qualities:

- Scalable capacity and performance. When you add resources to a Greenplum Database, the capacity and performance are the same as if the system had been originally implemented with the added resources.
- Uninterrupted service during expansion. Regular workloads, both scheduled and ad-hoc, are not interrupted.
- Transactional consistency.
- Fault tolerance. During the expansion, standard fault-tolerance mechanisms—such as segment mirroring—remain active, consistent, and effective.
- Replication and disaster recovery. Any existing replication mechanisms continue to function during expansion. Restore mechanisms needed in case of a failure or catastrophic event remain effective.
- Transparency of process. The expansion process employs standard Greenplum Database mechanisms, so administrators can diagnose and troubleshoot any problems.
• Configurable process. Expansion can be a long running process, but it can be fit into a schedule of ongoing operations. The expansion schema's tables allow administrators to prioritize the order in which tables are redistributed, and the expansion activity can be paused and resumed.

The planning and physical aspects of an expansion project are a greater share of the work than expanding the database itself. It will take a multi-discipline team to plan and execute the project. For on-premise installations, space must be acquired and prepared for the new servers. The servers must be specified, acquired, installed, cabled, configured, and tested. For cloud deployments, similar plans should also be made. Planning New Hardware Platforms describes general considerations for deploying new hardware.

After you provision the new hardware platforms and set up their networks, configure the operating systems and run performance tests using Greenplum utilities. The Greenplum Database software distribution includes utilities that are helpful to test and burn-in the new servers before beginning the software phase of the expansion. See Preparing and Adding Hosts for steps to prepare the new hosts for Greenplum Database.

Once the new servers are installed and tested, the software phase of the Greenplum Database expansion process begins. The software phase is designed to be minimally disruptive, transactionally consistent, reliable, and flexible.

• The first step of the software phase of expansion process is preparing the Greenplum Database system: adding new segment hosts and initializing new segment instances. This phase can be scheduled to occur during a period of low activity to avoid disrupting ongoing business operations. During the initialization process, the following tasks are performed:
  • Greenplum Database software is installed.
  • Databases and database objects are created in the new segment instances on the new segment hosts.
  • The gpexpand schema is created in the postgres database. You can use the tables and view in the schema to monitor and control the expansion process.

After the system has been updated, the new segment instances on the new segment hosts are available.

• New segments are immediately available and participate in new queries and data loads. The existing data, however, is skewed. It is concentrated on the original segments and must be redistributed across the new total number of primary segments.
• Because some of the table data is skewed, some queries might be less efficient because more data motion operations might be needed.

• The last step of the software phase is redistributing table data. Using the expansion control tables in the gpexpand schema as a guide, tables are redistributed. For each table:
  • The gpexpand utility redistributes the table data, across all of the servers, old and new, according to the distribution policy.
  • The table's status is updated in the expansion control tables.
  • After data redistribution, the query optimizer creates more efficient execution plans when data is not skewed.

When all tables have been redistributed, the expansion is complete.

Important: The gprestore utility cannot restore backups you made before the expansion with the gpbackup utility, so back up your databases immediately after the system expansion is complete.

Redistributing table data is a long-running process that creates a large volume of network and disk activity. It can take days to redistribute some very large databases. To minimize the effects of the increased activity on business operations, system administrators can pause and resume expansion activity on an ad hoc basis, or according to a predetermined schedule. Datasets can be prioritized so that critical applications benefit first from the expansion.

In a typical operation, you run the gpexpand utility four times with different options during the complete expansion process.
1. To create an expansion input file:
   
   ```bash
   gpexpand -f hosts_file
   ```

2. To initialize segments and create the expansion schema:
   
   ```bash
   gpexpand -i input_file
   ```

   `gpexpand` creates a data directory, copies user tables from all existing databases on the new segments, and captures metadata for each table in an expansion schema for status tracking. After this process completes, the expansion operation is committed and irrevocable.

3. To redistribute table data:
   
   ```bash
   gpexpand -d duration
   ```

   During initialization, `gpexpand` adds and initializes new segment instances. To complete system expansion, you must run `gpexpand` to redistribute data tables across the newly added segment instances. Depending on the size and scale of your system, redistribution can be accomplished in a single session during low-use hours, or you can divide the process into batches over an extended period. Each table or partition is unavailable for read or write operations during redistribution. As each table is redistributed across the new segments, database performance should incrementally improve until it exceeds pre-expansion performance levels.

   You may need to run `gpexpand` several times to complete the expansion in large-scale systems that require multiple redistribution sessions. `gpexpand` can benefit from explicit table redistribution ranking; see `Planning Table Redistribution`.

   Users can access Greenplum Database during initialization, but they may experience performance degradation on systems that rely heavily on hash distribution of tables. Normal operations such as ETL jobs, user queries, and reporting can continue, though users might experience slower response times.

4. To remove the expansion schema:
   
   ```bash
   gpexpand -c
   ```

   For information about the `gpexpand` utility and the other utilities that are used for system expansion, see the `Greenplum Database Utility Guide`.

### Planning Greenplum System Expansion

Careful planning will help to ensure a successful Greenplum expansion project.

The topics in this section help to ensure that you are prepared to execute a system expansion.

- **System Expansion Checklist** is a checklist you can use to prepare for and execute the system expansion process.
- **Planning New Hardware Platforms** covers planning for acquiring and setting up the new hardware.
- **Planning New Segment Initialization** provides information about planning to initialize new segment hosts with `gpexpand`.
- **Planning Table Redistribution** provides information about planning the data redistribution after the new segment hosts have been initialized.

### System Expansion Checklist

This checklist summarizes the tasks for a Greenplum Database system expansion.
## Table 23: Greenplum Database System Expansion Checklist

<table>
<thead>
<tr>
<th><strong>Online Pre-Expansion Tasks</strong></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>* System is up and available</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Devise and execute a plan for ordering, building, and networking new hardware platforms, or provisioning cloud resources.</td>
</tr>
<tr>
<td></td>
<td>Devise a database expansion plan. Map the number of segments per host, schedule the downtime period for testing performance and creating the expansion schema, and schedule the intervals for table redistribution.</td>
</tr>
<tr>
<td></td>
<td>Perform a complete schema dump.</td>
</tr>
<tr>
<td></td>
<td>Install Greenplum Database binaries on new hosts.</td>
</tr>
<tr>
<td></td>
<td>Copy SSH keys to the new hosts (gpssh-exkeys).</td>
</tr>
<tr>
<td></td>
<td>Validate disk I/O and memory bandwidth of the new hardware or cloud resources (gpcheckperf).</td>
</tr>
<tr>
<td></td>
<td>Validate that the master data directory has no extremely large files in the <code>pg_log</code> or <code>gpperfmon/data</code> directories.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th><strong>Offline Pre-Expansion Tasks</strong></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>* The system is unavailable to all user activity during this process.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Validate that there are no catalog issues (gpcheckcat).</td>
</tr>
<tr>
<td></td>
<td>Validate disk I/O and memory bandwidth of the combined existing and new hardware or cloud resources (gpcheckperf).</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th><strong>Online Segment Instance Initialization</strong></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>* System is up and available</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Prepare an expansion input file (gpexpand).</td>
</tr>
<tr>
<td></td>
<td>Initialize new segments into the array and create an expansion schema (gpexpand -i <code>input_file</code>).</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th><strong>Online Expansion and Table Redistribution</strong></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>* System is up and available</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Before you start table redistribution, stop any automated snapshot processes or other processes that consume disk space.</td>
</tr>
</tbody>
</table>
Redistribute tables through the expanded system (`gpexpand`).

Remove expansion schema (`gpexpand -c`).

Run `analyze` to update distribution statistics.
During the expansion, use `gpexpand -a`, and post-expansion, use `analyze`.

**Back Up Databases**
* System is up and available

Back up databases using the `gpbackup` utility. Backups you created before you began the system expansion cannot be restored to the newly expanded system because the `gprestore` utility can only restore backups to a Greenplum Database system with the same number of segments.

**Planning New Hardware Platforms**
A deliberate, thorough approach to deploying compatible hardware greatly minimizes risk to the expansion process.

Hardware resources and configurations for new segment hosts should match those of the existing hosts. Work with *Pivotal Support* before making a hardware purchase to expand Greenplum Database.

The steps to plan and set up new hardware platforms vary for each deployment. Some considerations include how to:

- Prepare the physical space for the new hardware; consider cooling, power supply, and other physical factors.
- Determine the physical networking and cabling required to connect the new and existing hardware.
- Map the existing IP address spaces and developing a networking plan for the expanded system.
- Capture the system configuration (users, profiles, NICs, and so on) from existing hardware to use as a detailed list for ordering new hardware.
- Create a custom build plan for deploying hardware with the desired configuration in the particular site and environment.

After selecting and adding new hardware to your network environment, ensure you perform the burn-in tasks described in `#unique_284`.

**Planning New Segment Initialization**
Expanding Greenplum Database can be performed when the system is up and available. Run `gpexpand` to initialize new segment instances into the array and create an expansion schema.

The time required depends on the number of schema objects in the Greenplum system and other factors related to hardware performance. In most environments, the initialization of new segments requires less than thirty minutes offline.

These utilities cannot be run while `gpexpand` is performing segment initialization.

- `gpbackup`
- `gpcheckcat`
- `gpconfig`
- `gppkg`
- `gprestore`
Important: After you begin initializing new segments, you can no longer restore the system using backup files created for the pre-expansion system. When initialization successfully completes, the expansion is committed and cannot be rolled back.

**Planning Mirror Segments**

If your existing system has mirror segments, the new segments must have mirroring configured. If there are no mirrors configured for existing segments, you cannot add mirrors to new hosts with the `gpexpand` utility. For more information about segment mirroring, see About Segment Mirroring.

For Greenplum Database arrays with mirror segments, ensure you add enough new host machines to accommodate new mirror segments. The number of new hosts required depends on your mirroring strategy:

- **Spread Mirroring** — Add at least one more host to the array than the number of segments per host. The number of separate hosts must be greater than the number of segment instances per host to ensure even spreading. You can specify this type of mirroring during system initialization or when you enable segment mirroring for an existing system.
- **Grouped Mirroring** — Add at least two new hosts so the mirrors for the first host can reside on the second host, and the mirrors for the second host can reside on the first. This is the default type of mirroring if you enable segment mirroring during system initialization.
- **Block Mirroring** — Adding one or more blocks of host systems. For example, add a block of four or eight hosts. Block mirroring is a custom mirroring configuration. For more information about block mirroring, see Segment Mirroring in the Greenplum Database Best Practices Guide.

**Increasing Segments Per Host**

By default, new hosts are initialized with as many primary segments as existing hosts have. You can increase the segments per host or add new segments to existing hosts.

For example, if existing hosts currently have two segments per host, you can use `gpexpand` to initialize two additional segments on existing hosts for a total of four segments and initialize four new segments on new hosts.

The interactive process for creating an expansion input file prompts for this option; you can also specify new segment directories manually in the input configuration file. For more information, see Creating an Input File for System Expansion.

**About the Expansion Schema**

At initialization, the `gpexpand` utility creates an expansion schema named `gpexpand` in the `postgres` database.

The expansion schema stores metadata for each table in the system so its status can be tracked throughout the expansion process. The expansion schema consists of two tables and a view for tracking expansion operation progress:

- `gpexpand.status`
- `gpexpand.status_detail`
- `gpexpand.expansion_progress`

Control expansion process aspects by modifying `gpexpand.status_detail`. For example, removing a record from this table prevents the system from expanding the table across new segments. Control the order in which tables are processed for redistribution by updating the `rank` value for a record. For more information, see Ranking Tables for Redistribution.

**Planning Table Redistribution**

Table redistribution is performed while the system is online. For many Greenplum systems, table redistribution completes in a single `gpexpand` session scheduled during a low-use period. Larger systems
may require multiple sessions and setting the order of table redistribution to minimize performance impact. Complete the table redistribution in one session if possible.

**Important:** To perform table redistribution, your segment hosts must have enough disk space to temporarily hold a copy of your largest table. All tables are unavailable for read and write operations during redistribution.

The performance impact of table redistribution depends on the size, storage type, and partitioning design of a table. For any given table, redistributing it with `gpexpand` takes as much time as a `CREATE TABLE AS SELECT` operation would. When redistributing a terabyte-scale fact table, the expansion utility can use much of the available system resources, which could affect query performance or other database workloads.

**Managing Redistribution in Large-Scale Greenplum Systems**

When planning the redistribution phase, consider the impact of the `ACCESS EXCLUSIVE` lock taken on each table, and the table data redistribution method. User activity on a table can delay its redistribution, but also tables are unavailable for user activity during redistribution.

You can manage the order in which tables are redistributed by adjusting their ranking. See *Ranking Tables for Redistribution*. Manipulating the redistribution order can help adjust for limited disk space and restore optimal query performance for high-priority queries sooner.

**Table Redistribution Methods**

There are two methods of redistributing data when performing a Greenplum Database expansion.

- **rebuild** - Create a new table, copy all the data from the old to the new table, and replace the old table. This is the default. The rebuild method is similar to creating a new table with a `CREATE TABLE AS SELECT` command. During data redistribution, an `ACCESS EXCLUSIVE` lock is acquired on the table.

- **move** - Scan all the data and perform an `UPDATE` operation to move rows as needed to different segment instances. During data redistribution, an `ACCESS EXCLUSIVE` lock is acquired on the table. In general, this method requires less disk space, however, it creates obsolete table rows and might require a `VACUUM` operation on the table after the data redistribution. Also, this method updates indexes one row at a time, which can be much slower than rebuilding the index with the `CREATE INDEX` command.

**Systems with Abundant Free Disk Space**

In systems with abundant free disk space (required to store a copy of the largest table), you can focus on restoring optimum query performance as soon as possible by first redistributing important tables that queries use heavily. Assign high ranking to these tables, and schedule redistribution operations for times of low system usage. Run one redistribution process at a time until large or critical tables have been redistributed.

**Systems with Limited Free Disk Space**

If your existing hosts have limited disk space, you may prefer to first redistribute smaller tables (such as dimension tables) to clear space to store a copy of the largest table. Available disk space on the original segments increases as each table is redistributed across the expanded array. When enough free space exists on all segments to store a copy of the largest table, you can redistribute large or critical tables.

Redistribution of large tables requires exclusive locks; schedule this procedure for off-peak hours. Also consider the following:

- Run multiple parallel redistribution processes during off-peak hours to maximize available system resources.
- When running multiple processes, operate within the connection limits for your Greenplum system. For information about limiting concurrent connections, see *Limiting Concurrent Connections*. 

**Redistributing Append-Optimized and Compressed Tables**

`gpexpand` redistributes append-optimized and compressed append-optimized tables at different rates than heap tables. The CPU capacity required to compress and decompress data tends to increase the impact on system performance. For similar-sized tables with similar data, you may find overall performance differences like the following:

- Uncompressed append-optimized tables expand 10% faster than heap tables.
- Append-optimized tables that are defined to use data compression expand at a significantly slower rate than uncompressed append-optimized tables, potentially up to 80% slower.
- Systems with data compression such as ZFS/LZJB take longer to redistribute.

**Important:** If your system hosts use data compression, use identical compression settings on the new hosts to avoid disk space shortage.

**Redistributing Partitioned Tables**

Because the expansion utility can process each individual partition on a large table, an efficient partition design reduces the performance impact of table redistribution. Only the child tables of a partitioned table are set to a random distribution policy. The read/write lock for redistribution applies to only one child table at a time.

**Redistributing Indexed Tables**

Because the `gpexpand` utility must re-index each indexed table after redistribution, a high level of indexing has a large performance impact. Systems with intensive indexing have significantly slower rates of table redistribution.

**Preparing and Adding Hosts**

Verify your new host systems are ready for integration into the existing Greenplum system.

To prepare new host systems for expansion, install the Greenplum Database software binaries, exchange the required SSH keys, and run performance tests.

Run performance tests first on the new hosts and then all hosts. Run the tests on all hosts with the system offline so user activity does not distort results.

Generally, you should run performance tests when an administrator modifies host networking or other special conditions in the system. For example, if you will run the expanded system on two network clusters, run tests on each cluster.

**Adding New Hosts to the Trusted Host Environment**

New hosts must exchange SSH keys with the existing hosts to enable Greenplum administrative utilities to connect to all segments without a password prompt. Perform the key exchange process twice with the `gpssh-exkeys` utility.

First perform the process as `root`, for administration convenience, and then as the user `gpadmin`, for management utilities. Perform the following tasks in order:

1. To exchange SSH keys as `root`
2. To create the `gpadmin` user
3. To exchange SSH keys as the `gpadmin` user

**Note:** The Greenplum Database segment host naming convention is `sdwN` where `sdw` is a prefix and `N` is an integer (sdw1, sdw2 and so on). For hosts with multiple interfaces, the convention is to append a dash (-) and number to the host name. For example, `sdw1-1` and `sdw1-2` are the two interface names for host `sdw1`. 
To exchange SSH keys as root

1. Create a host file with the existing host names in your array and a separate host file with the new expansion host names. For existing hosts, you can use the same host file used to set up SSH keys in the system. In the files, list all hosts (master, backup master, and segment hosts) with one name per line and no extra lines or spaces. Exchange SSH keys using the configured host names for a given host if you use a multi-NIC configuration. In this example, mdw is configured with a single NIC, and sdw1, sdw2, and sdw3 are configured with 4 NICs:

```text
mdw
sdw1-1
sdw1-2
sdw1-3
sdw1-4
sdw2-1
sdw2-2
sdw2-3
sdw2-4
sdw3-1
sdw3-2
sdw3-3
sdw3-4
```

2. Log in as root on the master host, and source the `greenplum_path.sh` file from your Greenplum installation.

```
$ su -
# source /usr/local/greenplum-db/greenplum_path.sh
```

3. Run the `gpssh-exkeys` utility referencing the host list files. For example:

```
# gpssh-exkeys -e /home/gpadmin/existing_hosts_file -x /home/gpadmin/new_hosts_file
```

4. `gpssh-exkeys` checks the remote hosts and performs the key exchange between all hosts. Enter the root user password when prompted. For example:

```
***Enter password for root@hostname: <root_password>
```

To create the `gpadmin` user

1. Use `gpssh` to create the `gpadmin` user on all the new segment hosts (if it does not exist already). Use the list of new hosts you created for the key exchange. For example:

```
# gpssh -f new_hosts_file '/usr/sbin/useradd gpadmin -d /home/gpadmin -s /bin/bash'
```

2. Set a password for the new `gpadmin` user. On Linux, you can do this on all segment hosts simultaneously using `gpssh`. For example:

```
# gpssh -f new_hosts_file 'echo gpadmin_password | passwd gpadmin --stdin'
```

3. Verify the `gpadmin` user has been created by looking for its home directory:

```
# gpssh -f new_hosts_file ls -l /home
```
To exchange SSH keys as the `gpadmin` user

1. Log in as `gpadmin` and run the `gpssh-exkeys` utility referencing the host list files. For example:

   ```bash
   # gpssh-exkeys -e /home/gpadmin/existing_hosts_file -x /home/gpadmin/new_hosts_file
   ```

2. `gpssh-exkeys` will check the remote hosts and perform the key exchange between all hosts. Enter the `gpadmin` user password when prompted. For example:

   ```bash
   ***Enter password for gpadmin@hostname: <gpadmin_password>
   ```

**Validating Disk I/O and Memory Bandwidth**

Use the `gpcheckperf` utility to test disk I/O and memory bandwidth.

**To run gpcheckperf**

1. Run the `gpcheckperf` utility using the host file for new hosts. Use the `-d` option to specify the file systems you want to test on each host. You must have write access to these directories. For example:

   ```bash
   $ gpcheckperf -f new_hosts_file -d /data1 -d /data2 -v
   ```

2. The utility may take a long time to perform the tests because it is copying very large files between the hosts. When it is finished, you will see the summary results for the Disk Write, Disk Read, and Stream tests.

For a network divided into subnets, repeat this procedure with a separate host file for each subnet.

**Integrating New Hardware into the System**

Before initializing the system with the new segments, shut down the system with `gpstop` to prevent user activity from skewing performance test results. Then, repeat the performance tests using host files that include all hosts, existing and new.

**Initializing New Segments**

Use the `gpexpand` utility to create and initialize the new segment instances and create the expansion schema.

The first time you run `gpexpand` with a valid input file it creates and initializes segment instances and creates the expansion schema. After these steps are completed, running `gpexpand` detects if the expansion schema has been created and, if so, performs table redistribution.

- **Creating an Input File for System Expansion**
- **Running gpexpand to Initialize New Segments**
- **Rolling Back a Failed Expansion Setup**

**Creating an Input File for System Expansion**

To begin expansion, `gpexpand` requires an input file containing information about the new segments and hosts. If you run `gpexpand` without specifying an input file, the utility displays an interactive interview that collects the required information and automatically creates an input file.

If you create the input file using the interactive interview, you may specify a file with a list of expansion hosts in the interview prompt. If your platform or command shell limits the length of the host list, specifying the hosts with `-f` may be mandatory.

**Creating an input file in Interactive Mode**

Before you run `gpexpand` to create an input file in interactive mode, ensure you know:
• The number of new hosts (or a hosts file)
• The new hostnames (or a hosts file)
• The mirroring strategy used in existing hosts, if any
• The number of segments to add per host, if any

The utility automatically generates an input file based on this information, dbid, content ID, and data directory values stored in gp_segment_configuration, and saves the file in the current directory.

**To create an input file in interactive mode**

1. Log in on the master host as the user who will run your Greenplum Database system; for example, gpadmin.
2. Run gpexpand. The utility displays messages about how to prepare for an expansion operation, and it prompts you to quit or continue.
   
   Optionally, specify a hosts file using `-f`. For example:
   
   ```
   $ gpexpand -f /home/gpadmin/new_hosts_file
   ```
3. At the prompt, select `Y` to continue.
4. Unless you specified a hosts file using `-f`, you are prompted to enter hostnames. Enter a comma separated list of the hostnames of the new expansion hosts. Do not include interface hostnames. For example:
   
   ```
   > sdw4, sdw5, sdw6, sdw7
   ```
   To add segments to existing hosts only, enter a blank line at this prompt. Do not specify localhost or any existing host name.
5. Enter the mirroring strategy used in your system, if any. Options are spread|grouped|none. The default setting is grouped.
   
   Ensure you have enough hosts for the selected grouping strategy. For more information about mirroring, see [Planning Mirror Segments](#).
6. Enter the number of new primary segments to add, if any. By default, new hosts are initialized with the same number of primary segments as existing hosts. Increase segments per host by entering a number greater than zero. The number you enter will be the number of additional segments initialized on all hosts. For example, if existing hosts currently have two segments each, entering a value of 2 initializes two more segments on existing hosts, and four segments on new hosts.
7. If you are adding new primary segments, enter the new primary data directory root for the new segments. Do not specify the actual data directory name, which is created automatically by gpexpand based on the existing data directory names.
   
   For example, if your existing data directories are as follows:
   
   ```
   /gpdata/primary/gp0
   /gpdata/primary/gp1
   ```
   then enter the following (one at each prompt) to specify the data directories for two new primary segments:
   
   ```
   /gpdata/primary
   /gpdata/primary
   ```
   When the initialization runs, the utility creates the new directories gp2 and gp3 under /gpdata/primary.
8. If you are adding new mirror segments, enter the new mirror data directory root for the new segments. Do not specify the data directory name; it is created automatically by gpexpand based on the existing data directory names.
For example, if your existing data directories are as follows:

```
/gpdata/mirror/gp0
/gpdata/mirror/gp1
```

enter the following (one at each prompt) to specify the data directories for two new mirror segments:

```
/gpdata/mirror
/gpdata/mirror
```

When the initialization runs, the utility will create the new directories `gp2` and `gp3` under `/gpdata/mirror`.

These primary and mirror root directories for new segments must exist on the hosts, and the user running `gpexpand` must have permissions to create directories in them.

After you have entered all required information, the utility generates an input file and saves it in the current directory. For example:

```
gpexpand_inputfile_yyyymmdd_145134
```

**Expansion Input File Format**

Use the interactive interview process to create your own input file unless your expansion scenario has atypical needs.

The format for expansion input files is:

```
hostname|address|port|datadir|dbid|content|preferred_role
```

For example:

```
sdw5|sdw5-1|50011|/gpdata/primary/gp9|11|9|p
sdw5|sdw5-2|50012|/gpdata/primary/gp10|12|10|p
sdw5|sdw5-2|60011|/gpdata/mirror/gp9|13|9|m
sdw5|sdw5-1|60012|/gpdata/mirror/gp10|14|10|m
```

For each new segment, this format of expansion input file requires the following:

**Table 24: Data for the expansion configuration file**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Valid Values</th>
<th>Description</th>

</table>

**Running gpexpand to Initialize New Segments**

After you have created an input file, run gpexpand to initialize new segment instances.

**To run gpexpand with an input file**

1. Log in on the master host as the user who will run your Greenplum Database system; for example, gpadmin.
2. Run the gpexpand utility, specifying the input file with -i. For example:

   ```
   $ gpexpand -i input_file
   ```

   The utility detects if an expansion schema exists for the Greenplum Database system. If a gpexpand schema exists, remove it with gpexpand -c before you start a new expansion operation. See Removing the Expansion Schema.

   When the new segments are initialized and the expansion schema is created, the utility prints a success message and exits.

   When the initialization process completes, you can connect to Greenplum Database and view the expansion schema. The gpexpand schema resides in the postgres database. For more information, see About the Expansion Schema.

**Rolling Back a Failed Expansion Setup**

You can roll back an expansion setup operation (adding segment instances and segment hosts) only if the operation fails.

If the expansion fails during the initialization step, while the database is down, you must first restart the database in master-only mode by running the gpstart -m command.
Roll back the failed expansion with the following command:

```
gpexpand --rollback
```

**Monitoring the Cluster Expansion State**

At any time, you can check the state of cluster expansion by running the `gpstate` utility with the `-x` flag:

```
$ gpstate -x
```

If the expansion schema exists in the `postgres` database, `gpstate -x` reports on the progress of the expansion. During the first expansion phase, `gpstate` reports on the progress of new segment initialization. During the second phase, `gpstate` reports on the progress of table redistribution, and whether redistribution is paused or active.

You can also query the expansion schema to see expansion status. See Monitoring Table Redistribution for more information.

**Redistributing Tables**

Redistribute tables to balance existing data over the newly expanded cluster.

After creating an expansion schema, you can redistribute tables across the entire system with `gpexpand`. Plan to run this during low-use hours when the utility's CPU usage and table locks have minimal impact on operations. Rank tables to redistribute the largest or most critical tables first.

**Note:** When redistributing data, Greenplum Database must be running in production mode. Greenplum Database cannot be in restricted mode or in master mode. The `gpstart` options `-R` or `-m` cannot be specified to start Greenplum Database.

While table redistribution is underway, any new tables or partitions created are distributed across all segments exactly as they would be under normal operating conditions. Queries can access all segments, even before the relevant data is redistributed to tables on the new segments. The table or partition being redistributed is locked and unavailable for read or write operations. When its redistribution completes, normal operations resume.

- Ranking Tables for Redistribution
- Redistributing Tables Using `gpexpand`
- Monitoring Table Redistribution

**Ranking Tables for Redistribution**

For large systems, you can control the table redistribution order. Adjust tables’ `rank` values in the expansion schema to prioritize heavily-used tables and minimize performance impact. Available free disk space can affect table ranking; see Managing Redistribution in Large-Scale Greenplum Systems.

To rank tables for redistribution by updating `rank` values in `gexpand.status_detail`, connect to Greenplum Database using `psql` or another supported client. Update `gexpand.status_detail` with commands such as:

```sql
=> UPDATE gexpand.status_detail SET rank=10;
=> UPDATE gexpand.status_detail SET rank=1 WHERE fq_name = 'public.lineitem';
=> UPDATE gexpand.status_detail SET rank=2 WHERE fq_name = 'public.orders';
```

These commands lower the priority of all tables to 10 and then assign a rank of 1 to `lineitem` and a rank of 2 to `orders`. When table redistribution begins, `lineitem` is redistributed first, followed by `orders` and all other tables in `gexpand.status_detail`. To exclude a table from redistribution, remove the table from the `gexpand.status_detail` table.
**Redistributing Tables Using gpexpand**

**To redistribute tables with gpexpand**

1. Log in on the master host as the user who will run your Greenplum Database system, for example, `gpadmin`.
2. Run the `gpexpand` utility. You can use the `-d` or `-e` option to define the expansion session time period. For example, to run the utility for up to 60 consecutive hours:

   ```
   $ gpexpand -d 60:00:00
   ```

   The utility redistributes tables until the last table in the schema completes or it reaches the specified duration or end time. `gpexpand` updates the status and time in `gpexpand.status` when a session starts and finishes.

**Monitoring Table Redistribution**

You can query the expansion schema during the table redistribution process. The view `gpexpand.expansion_progress` provides a current progress summary, including the estimated rate of table redistribution and estimated time to completion. You can query the table `gpexpand.status_detail` for per-table status information.

See also **Monitoring the Cluster Expansion State** for information about monitoring the overall expansion progress with the `gpstate` utility.

**Viewing Expansion Status**

After the first table completes redistribution, `gpexpand.expansion_progress` calculates its estimates and refreshes them based on all tables' redistribution rates. Calculations restart each time you start a table redistribution session with `gpexpand`. To monitor progress, connect to Greenplum Database using `psql` or another supported client; query `gpexpand.expansion_progress` with a command like the following:

```
=# SELECT * FROM gpexpand.expansion_progress;

<table>
<thead>
<tr>
<th>name</th>
<th>value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bytes Left</td>
<td>5534842880</td>
</tr>
<tr>
<td>Bytes Done</td>
<td>142475264</td>
</tr>
<tr>
<td>Estimated Expansion Rate</td>
<td>680.75667095996092 MB/s</td>
</tr>
<tr>
<td>Estimated Time to Completion</td>
<td>00:01:01:00.008047</td>
</tr>
<tr>
<td>Tables Expanded</td>
<td>4</td>
</tr>
<tr>
<td>Tables Left</td>
<td>4</td>
</tr>
</tbody>
</table>

(6 rows)
```

**Viewing Table Status**

The table `gpexpand.status_detail` stores status, time of last update, and more facts about each table in the schema. To see a table's status, connect to Greenplum Database using `psql` or another supported client and query `gpexpand.status_detail`:

```
=> SELECT status, expansion_started, source_bytes FROM gpexpand.status_detail WHERE fq_name = 'public.sales';

<table>
<thead>
<tr>
<th>status</th>
<th>expansion_started</th>
<th>source_bytes</th>
</tr>
</thead>
<tbody>
<tr>
<td>COMPLETED</td>
<td>2017-02-20 10:54:10:043869</td>
<td>4929748992</td>
</tr>
</tbody>
</table>

(1 row)
```
Removing the Expansion Schema
To clean up after expanding the Greenplum cluster, remove the expansion schema.
You can safely remove the expansion schema after the expansion operation is complete and verified. To run another expansion operation on a Greenplum system, first remove the existing expansion schema.

To remove the expansion schema
1. Log in on the master host as the user who will be running your Greenplum Database system (for example, gpadmin).
2. Run the gpxpand utility with the -c option. For example:

   $ gxpexpand -c

   **Note:** Some systems require you to press Enter twice.

Migrating Data with gpcopy
You can use the gpcopy utility to transfer data between databases in different Greenplum Database clusters.

**gpcopy** is a high-performance utility that can copy metadata and data from one Greenplum database to another Greenplum database. You can migrate the entire contents of a database, or just selected tables. The clusters can have different Greenplum Database versions. For example, you can use gpcopy to migrate data from Greenplum 5 to Greenplum 6.

   **Note:** The gpcopy utility is available as a separate download for the commercial release of Pivotal Greenplum Database. See the Pivotal gpcopy Documentation.

Monitoring a Greenplum System
You can monitor a Greenplum Database system using a variety of tools included with the system or available as add-ons.

Observing the Greenplum Database system day-to-day performance helps administrators understand the system behavior, plan workflow, and troubleshoot problems. This chapter discusses tools for monitoring database performance and activity.

Also, be sure to review Recommended Monitoring and Maintenance Tasks for monitoring activities you can script to quickly detect problems in the system.

Monitoring Database Activity and Performance
Greenplum Database includes an optional system monitoring and management database, gpperfmon, that administrators can enable. The gpperfmon_install command-line utility creates the gpperfmon database and enables data collection agents that collect and store query and system metrics in the database. Administrators can query metrics in the gpperfmon database. See the documentation for the gpperfmon database in the Greenplum Database Reference Guide.

Pivotal Greenplum Command Center, an optional web-based interface, provides cluster status information, graphical administrative tools, real-time query monitoring, and historical cluster and query data. Download the Greenplum Command Center package from Pivotal Network and view the documentation at the Greenplum Command Center Documentation web site.

Monitoring System State
As a Greenplum Database administrator, you must monitor the system for problem events such as a segment going down or running out of disk space on a segment host. The following topics describe
how to monitor the health of a Greenplum Database system and examine certain state information for a Greenplum Database system.

- Checking System State
- Checking Disk Space Usage
- Checking for Data Distribution Skew
- Viewing Metadata Information about Database Objects
- Viewing Session Memory Usage Information
- Viewing Query Workfile Usage Information

Checking System State

A Greenplum Database system is comprised of multiple PostgreSQL instances (the master and segments) spanning multiple machines. To monitor a Greenplum Database system, you need to know information about the system as a whole, as well as status information of the individual instances. The `gpstate` utility provides status information about a Greenplum Database system.

**Viewing Master and Segment Status and Configuration**

The default `gpstate` action is to check segment instances and show a brief status of the valid and failed segments. For example, to see a quick status of your Greenplum Database system:

```bash
$ gpstate
```

To see more detailed information about your Greenplum Database array configuration, use `gpstate` with the `-s` option:

```bash
$ gpstate -s
```

**Viewing Your Mirroring Configuration and Status**

If you are using mirroring for data redundancy, you may want to see the list of mirror segment instances in the system, their current synchronization status, and the mirror to primary mapping. For example, to see the mirror segments in the system and their status:

```bash
$ gpstate -m
```

To see the primary to mirror segment mappings:

```bash
$ gpstate -c
```

To see the status of the standby master mirror:

```bash
$ gpstate -f
```

Checking Disk Space Usage

A database administrator's most important monitoring task is to make sure the file systems where the master and segment data directories reside do not grow to more than 70 percent full. A filled data disk will not result in data corruption, but it may prevent normal database activity from continuing. If the disk grows too full, it can cause the database server to shut down.

You can use the `gp_disk_free` external table in the `gp_toolkit` administrative schema to check for remaining free space (in kilobytes) on the segment host file systems. For example:

```sql
=# SELECT * FROM gp_toolkit.gp_disk_free
ORDER BY dfsegment;
```
Checking Sizing of Distributed Databases and Tables

The `gp_toolkit` administrative schema contains several views that you can use to determine the disk space usage for a distributed Greenplum Database database, schema, table, or index.

For a list of the available sizing views for checking database object sizes and disk space, see the Greenplum Database Reference Guide.

Viewing Disk Space Usage for a Database

To see the total size of a database (in bytes), use the `gp_size_of_database` view in the `gp_toolkit` administrative schema. For example:

```sql
=> SELECT * FROM gp_toolkit.gp_size_of_database
    ORDER BY sodddatname;
```

Viewing Disk Space Usage for a Table

The `gp_toolkit` administrative schema contains several views for checking the size of a table. The table sizing views list the table by object ID (not by name). To check the size of a table by name, you must look up the relation name (`relname`) in the `pg_class` table. For example:

```sql
=> SELECT relname AS name, sotdsize AS size, sotdtoastsize AS toast, sotdadditionalsize AS other
    FROM gp_toolkit.gp_size_of_table_disk as sotd, pg_class
    WHERE sotd.sotdoid=pg_class.oid ORDER BY relname;
```

For a list of the available table sizing views, see the Greenplum Database Reference Guide.

Viewing Disk Space Usage for Indexes

The `gp_toolkit` administrative schema contains a number of views for checking index sizes. To see the total size of all index(es) on a table, use the `gp_size_of_all_table_indexes` view. To see the size of a particular index, use the `gp_size_of_index` view. The index sizing views list tables and indexes by object ID (not by name). To check the size of an index by name, you must look up the relation name (`relname`) in the `pg_class` table. For example:

```sql
=> SELECT soisize, relname as indexname
    FROM pg_class, gp_toolkit.gp_size_of_index
    WHERE pg_class.oid=gp_size_of_index.soioid AND pg_class.relkind='i';
```

Checking for Data Distribution Skew

All tables in Greenplum Database are distributed, meaning their data is divided across all of the segments in the system. Unevenly distributed data may diminish query processing performance. A table's distribution policy, set at table creation time, determines how the table's rows are distributed. For information about choosing the table distribution policy, see the following topics:

- Viewing a Table's Distribution Key
- Viewing Data Distribution
- Checking for Query Processing Skew

The `gp_toolkit` administrative schema also contains a number of views for checking data distribution skew on a table. For information about how to check for uneven data distribution, see the Greenplum Database Reference Guide.
**Viewing a Table's Distribution Key**

To see the columns used as the data distribution key for a table, you can use the `\d+` meta-command in `psql` to examine the definition of a table. For example:

```sql
=# \d+ sales
Table "retail.sales"

<table>
<thead>
<tr>
<th>Column</th>
<th>Type</th>
<th>Modifiers</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sale_id</td>
<td>integer</td>
<td></td>
<td></td>
</tr>
<tr>
<td>amt</td>
<td>float</td>
<td></td>
<td></td>
</tr>
<tr>
<td>date</td>
<td>date</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Has OIDs: no
Distributed by: (sale_id)
```

When you create a *replicated* table, Greenplum Database stores all rows in the table on every segment. Replicated tables have no distribution key. Where the `\d+` meta-command reports the distribution key for a normally distributed table, it shows *Distributed Replicated* for a replicated table.

**Viewing Data Distribution**

To see the data distribution of a table's rows (the number of rows on each segment), you can run a query such as:

```sql
=# SELECT gp_segment_id, count(*)
    FROM table_name
    GROUP BY gp_segment_id;
```

A table is considered to have a balanced distribution if all segments have roughly the same number of rows.

**Note:** If you run this query on a replicated table, it fails because Greenplum Database does not permit user queries to reference the system column `gp_segment_id` (or the system columns `ctid`, `cmin`, `cmax`, `xmin`, and `xmax`) in replicated tables. Because every segment has all of the tables' rows, replicated tables are evenly distributed by definition.

**Checking for Query Processing Skew**

When a query is being processed, all segments should have equal workloads to ensure the best possible performance. If you identify a poorly-performing query, you may need to investigate further using the `EXPLAIN` command. For information about using the `EXPLAIN` command and query profiling, see *Query Profiling*.

Query processing workload can be skewed if the table's data distribution policy and the query predicates are not well matched. To check for processing skew, you can run a query such as:

```sql
=# SELECT gp_segment_id, count(*)
    FROM table_name
    WHERE column='value'
    GROUP BY gp_segment_id;
```

This will show the number of rows returned by segment for the given `WHERE` predicate.

As noted in *Viewing Data Distribution*, this query will fail if you run it on a replicated table because you cannot reference the `gp_segment_id` system column in a query on a replicated table.

**Avoiding an Extreme Skew Warning**

You may receive the following warning message while executing a query that performs a hash join operation:

```
Extreme skew in the innerside of Hashjoin
```
This occurs when the input to a hash join operator is skewed. It does not prevent the query from completing successfully. You can follow these steps to avoid skew in the plan:

1. Ensure that all fact tables are analyzed.
2. Verify that any populated temporary table used by the query is analyzed.
3. View the EXPLAIN ANALYZE plan for the query and look for the following:
   - If there are scans with multi-column filters that are producing more rows than estimated, then set the `gp_selectivity_damping_factor` server configuration parameter to 2 or higher and retest the query.
   - If the skew occurs while joining a single fact table that is relatively small (less than 5000 rows), set the `gp_segments_for_planner` server configuration parameter to 1 and retest the query.
4. Check whether the filters applied in the query match distribution keys of the base tables. If the filters and distribution keys are the same, consider redistributing some of the base tables with different distribution keys.
5. Check the cardinality of the join keys. If they have low cardinality, try to rewrite the query with different joining columns or or additional filters on the tables to reduce the number of rows. These changes could change the query semantics.

**Viewing Metadata Information about Database Objects**

Greenplum Database tracks various metadata information in its system catalogs about the objects stored in a database, such as tables, views, indexes and so on, as well as global objects such as roles and tablespaces.

**Viewing the Last Operation Performed**

You can use the system views `pg_stat_operations` and `pg_stat_partition_operations` to look up actions performed on an object, such as a table. For example, to see the actions performed on a table, such as when it was created and when it was last vacuumed and analyzed:

```
=> SELECT schemaname as schema, objname as table, 
    usename as role, actionname as action, 
    subtype as type, statime as time 
FROM pg_stat_operations 
WHERE objname='cust';
```

```
schema | table | role | action  | type  | time
--------+-------+------+---------+-------+--------------------------
sales   | cust  | main | CREATE  | TABLE | 2016-02-09 18:10:07.867977-08
sales   | cust  | main | VACUUM  |       | 2016-02-10 13:32:39.068219-08
sales   | cust  | main | ANALYZE |       | 2016-02-25 16:07:01.157168-08
(3 rows)
```

**Viewing the Definition of an Object**

To see the definition of an object, such as a table or view, you can use the `\d+` meta-command when working in `psql`. For example, to see the definition of a table:

```
=> \d+ mytable
```

**Viewing Session Memory Usage Information**

You can create and use the `session_level_memory_consumption` view that provides information about the current memory utilization for sessions that are running queries on Greenplum Database. The view contains session information and information such as the database that the session is connected to, the query that the session is currently running, and memory consumed by the session processes.
**Creating the session_level_memory_consumption View**

To create the `session_state.session_level_memory_consumption` view in a Greenplum Database, run the script `CREATE EXTENSION gp_internal_tools;` once for each database. For example, to install the view in the database `testdb`, use this command:

```
$ psql -d testdb -c "CREATE EXTENSION gp_internal_tools;"
```

**The session_level_memory_consumption View**

The `session_state.session_level_memory_consumption` view provides information about memory consumption and idle time for sessions that are running SQL queries.

When resource queue-based resource management is active, the column `is_runaway` indicates whether Greenplum Database considers the session a runaway session based on the vmem memory consumption of the session's queries. Under the resource queue-based resource management scheme, Greenplum Database considers the session a runaway when the queries consume an excessive amount of memory. The Greenplum Database server configuration parameter `runaway_detector_activation_percent` governs the conditions under which Greenplum Database considers a session a runaway session.

The `is_runaway`, `runaway_vmem_mb`, and `runaway_command_cnt` columns are not applicable when resource group-based resource management is active.

**Table 25: session_state.session_level_memory_consumption**

<table>
<thead>
<tr>
<th>column</th>
<th>type</th>

<td>Number of active query processes for the session.</td>
</tr>
</tbody>
</table>
### Viewing Query Workfile Usage Information

The Greenplum Database administrative schema `gp_toolkit` contains views that display information about Greenplum Database workfiles. Greenplum Database creates workfiles on disk if it does not have sufficient memory to execute the query in memory. This information can be used for troubleshooting and tuning queries. The information in the views can also be used to specify the values for the Greenplum Database configuration parameters `gp_workfile_limit_per_query` and `gp_workfile_limit_per_segment`.

These are the views in the schema `gp_toolkit`:
- The `gp_workfile_entries` view contains one row for each operator using disk space for workfiles on a segment at the current time.
- The `gp_workfile_usage_per_query` view contains one row for each query using disk space for workfiles on a segment at the current time.
- The `gp_workfile_usage_per_segment` view contains one row for each segment. Each row displays the total amount of disk space used for workfiles on the segment at the current time.

For information about using `gp_toolkit`, see Using `gp_toolkit`.

### Viewing the Database Server Log Files

Every database instance in Greenplum Database (master and segments) runs a PostgreSQL database server with its own server log file. Log files are created in the `pg_log` directory of the master and each segment data directory.

#### Log File Format

The server log files are written in comma-separated values (CSV) format. Some log entries will not have values for all log fields. For example, only log entries associated with a query worker process will have the `slice_id` populated. You can identify related log entries of a particular query by the query's session identifier (`gp_session_id`) and command identifier (`gp_command_count`).

The following fields are written to the log:

<table>
<thead>
<tr>
<th>column</th>
<th>type</th>
<th>references</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dirty_qe_count</td>
<td>integer</td>
<td></td>
<td>Number of query processes that have not yet released their memory. The value is (-1) for sessions that are not running.</td>
</tr>
<tr>
<td>runaway_vmem_mb</td>
<td>integer</td>
<td></td>
<td>Amount of vmem memory that the session was consuming when it was marked as a runaway session.</td>
</tr>
<tr>
<td>runaway_command_cnt</td>
<td>integer</td>
<td></td>
<td>Command count for the session when it was marked as a runaway session.</td>
</tr>
<tr>
<td>idle_start</td>
<td>timestamptz</td>
<td></td>
<td>The last time a query process in this session became idle.</td>
</tr>
</tbody>
</table>
Table 26: Greenplum Database Server Log Format

### Searching the Greenplum Server Log Files

Greenplum Database provides a utility called `gplogfilter` can search through a Greenplum Database log file for entries matching the specified criteria. By default, this utility searches through the Greenplum Database master log file in the default logging location. For example, to display the last three lines of the master log file:

```bash
$ gplogfilter -n 3
```

To search through all segment log files simultaneously, run `gplogfilter` through the `gpssh` utility. For example, to display the last three lines of each segment log file:

```bash
$ gpssh -f seg_host_file

=> source /usr/local/greenplum-db/greenplum_path.sh
=> gplogfilter -n 3 /gpdata/gp*/pg_log/gpdb*.log
```

### Using gp_toolkit

Use the Greenplum Database administrative schema `gp_toolkit` to query the system catalogs, log files, and operating environment for system status information. The `gp_toolkit` schema contains several views you can access using SQL commands. The `gp_toolkit` schema is accessible to all database users. Some objects require superuser permissions. Use a command similar to the following to add the `gp_toolkit` schema to your schema search path:

```sql
=> ALTER ROLE myrole SET search_path TO myschema,gp_toolkit;
```

For a description of the available administrative schema views and their usages, see the Greenplum Database Reference Guide.

### SQL Standard Error Codes

The following table lists all the defined error codes. Some are not used, but are defined by the SQL standard. The error classes are also shown. For each error class there is a standard error code having the last three characters 000. This code is used only for error conditions that fall within the class but do not have any more-specific code assigned.

The PL/pgSQL condition name for each error code is the same as the phrase shown in the table, with underscores substituted for spaces. For example, code 22012, DIVISION BY ZERO, has condition name DIVISION_BY_ZERO. Condition names can be written in either upper or lower case.

**Note:** PL/pgSQL does not recognize warning, as opposed to error, condition names; those are classes 00, 01, and 02.

**Routine System Maintenance Tasks**

To keep a Greenplum Database system running efficiently, the database must be regularly cleared of expired data and the table statistics must be updated so that the query optimizer has accurate information.

Greenplum Database requires that certain tasks be performed regularly to achieve optimal performance. The tasks discussed here are required, but database administrators can automate them using standard UNIX tools such as `cron` scripts. An administrator sets up the appropriate scripts and checks that they execute successfully. See [Recommended Monitoring and Maintenance Tasks](#) for additional suggested maintenance activities you can implement to keep your Greenplum system running optimally.

**Routine Vacuum and Analyze**

The design of the MVCC transaction concurrency model used in Greenplum Database means that deleted or updated data rows still occupy physical space on disk even though they are not visible to new transactions. If your database has many updates and deletes, many expired rows exist and the space they use must be reclaimed with the `VACUUM` command. The `VACUUM` command also collects table-level statistics, such as numbers of rows and pages, so it is also necessary to vacuum append-optimized tables, even when there is no space to reclaim from updated or deleted rows.

Vacuuming an append-optimized table follows a different process than vacuuming heap tables. On each segment, a new segment file is created and visible rows are copied into it from the current segment. When the segment file has been copied, the original is scheduled to be dropped and the new segment file is made available. This requires sufficient available disk space for a copy of the visible rows until the original segment file is dropped.

If the ratio of hidden rows to total rows in a segment file is less than a threshold value (10, by default), the segment file is not compacted. The threshold value can be configured with the `gp_appendonly_compaction_threshold` server configuration parameter. `VACUUM FULL` ignores the value of `gp_appendonly_compaction_threshold` and rewrites the segment file regardless of the ratio.

You can use the `__gp_aovisimap_compaction_info()` function in the `gp_toolkit` schema to investigate the effectiveness of a `VACUUM` operation on append-optimized tables.

For information about the `__gp_aovisimap_compaction_info()` function see, "Checking Append-Optimized Tables" in the [Greenplum Database Reference Guide](#).
VACUUM can be disabled for append-optimized tables using the `gp_appendonly_compaction` server configuration parameter.

For details about vacuuming a database, see *Vacuuming the Database*.

For information about the `gp_appendonly_compaction_threshold` server configuration parameter and the VACUUM command, see the *Greenplum Database Reference Guide*.

**Transaction ID Management**

Greenplum's MVCC transaction semantics depend on comparing transaction ID (XID) numbers to determine visibility to other transactions. Transaction ID numbers are compared using modulo $2^{32}$ arithmetic, so a Greenplum system that runs more than about two billion transactions can experience transaction ID wraparound, where past transactions appear to be in the future. This means past transactions' outputs become invisible. Therefore, it is necessary to VACUUM every table in every database at least once per two billion transactions.

Greenplum Database assigns XID values only to transactions that involve DDL or DML operations, which are typically the only transactions that require an XID.

**Important:** Greenplum Database monitors transaction IDs. If you do not vacuum the database regularly, Greenplum Database will generate a warning and error.

Greenplum Database issues the following warning when a significant portion of the transaction IDs are no longer available and before transaction ID wraparound occurs:

```plaintext
WARNING: database "database_name" must be vacuumed within number_of_transactions transactions
```

When the warning is issued, a VACUUM operation is required. If a VACUUM operation is not performed, Greenplum Database stops creating transactions when it reaches a limit prior to when transaction ID wraparound occurs. Greenplum Database issues this error when it stops creating transactions to avoid possible data loss:

```plaintext
FATAL: database is not accepting commands to avoid wraparound data loss in database "database_name"
```

The Greenplum Database configuration parameter `xid_warn_limit` controls when the warning is displayed. The parameter `xid_stop_limit` controls when Greenplum Database stops creating transactions.

**Recovering from a Transaction ID Limit Error**

When Greenplum Database reaches the `xid_stop_limit` transaction ID limit due to infrequent VACUUM maintenance, it becomes unresponsive. To recover from this situation, perform the following steps as database administrator:

1. Shut down Greenplum Database.
2. Temporarily lower the `xid_stop_limit` by 10,000,000.
3. Start Greenplum Database.
4. Run VACUUM FREEZE on all affected databases.
5. Reset the `xid_stop_limit` to its original value.
6. Restart Greenplum Database.

For information about the configuration parameters, see the *Greenplum Database Reference Guide*.

For information about transaction ID wraparound see the *PostgreSQL documentation*.

**System Catalog Maintenance**

Numerous database updates with CREATE and DROP commands increase the system catalog size and affect system performance. For example, running many DROP TABLE statements degrades the overall
system performance due to excessive data scanning during metadata operations on catalog tables. The performance loss occurs between thousands to tens of thousands of `DROP TABLE` statements, depending on the system.

You should run a system catalog maintenance procedure regularly to reclaim the space occupied by deleted objects. If a regular procedure has not been run for a long time, you may need to run a more intensive procedure to clear the system catalog. This topic describes both procedures.

**Regular System Catalog Maintenance**

It is recommended that you periodically run `REINDEX` and `VACUUM` on the system catalog to clear the space that deleted objects occupy in the system indexes and tables. If regular database operations include numerous `DROP` statements, it is safe and appropriate to run a system catalog maintenance procedure with `VACUUM` daily at off-peak hours. You can do this while the system is available.

These are Greenplum Database system catalog maintenance steps.

1. Perform a `REINDEX` on the system catalog tables to rebuild the system catalog indexes. This removes bloat in the indexes and improves `VACUUM` performance.
   
   **Note:** When performing `REINDEX` on the system catalog tables, locking will occur on the tables and might have an impact on currently running queries. You can schedule the `REINDEX` operation during a period of low activity to avoid disrupting ongoing business operations.

2. Perform a `VACUUM` on the system catalog tables.

3. Perform an `ANALYZE` on the system catalog tables to update the catalog table statistics.

This example script performs a `REINDEX`, `VACUUM`, and `ANALYZE` of a Greenplum Database system catalog. In the script, replace `<database-name>` with a database name.

```bash
#!/bin/bash
DBNAME="<database-name>"
SYSTABLES="' pg_catalog.' || relname || ';' FROM pg_class a, pg_namespace b
WHERE a.relnamespace=b.oid AND b.nspname='pg_catalog' AND a.relkind='r'"

reindexdb --system -d $DBNAME
psql -tc "SELECT 'VACUUM' || $SYSTABLES" $DBNAME | psql -a $DBNAME
analyzedb -s pg_catalog -d $DBNAME
```

**Note:** If you are performing catalog maintenance during a maintenance period and you need to stop a process due to time constraints, run the Greenplum Database function `pg_cancel_backend(<PID>)` to safely stop the Greenplum Database process.

**Intensive System Catalog Maintenance**

If system catalog maintenance has not been performed in a long time, the catalog can become bloated with dead space; this causes excessively long wait times for simple metadata operations. A wait of more than two seconds to list user tables, such as with the `\d` metacommand from within `psql`, is an indication of catalog bloat.

If you see indications of system catalog bloat, you must perform an intensive system catalog maintenance procedure with `VACUUM FULL` during a scheduled downtime period. During this period, stop all catalog activity on the system; the `VACUUM FULL` system catalog maintenance procedure takes exclusive locks against the system catalog.

Running regular system catalog maintenance procedures can prevent the need for this more costly procedure.

These are steps for intensive system catalog maintenance.

1. Stop all catalog activity on the Greenplum Database system.
2. Perform a `REINDEX` on the system catalog tables to rebuild the system catalog indexes. This removes bloat in the indexes and improves `VACUUM` performance.
3. Perform a VACUUM FULL on the system catalog tables. See the following Note.
4. Perform an ANALYZE on the system catalog tables to update the catalog table statistics.

Note: The system catalog table `pg_attribute` is usually the largest catalog table. If the `pg_attribute` table is significantly bloated, a VACUUM FULL operation on the table might require a significant amount of time and might need to be performed separately. The presence of both of these conditions indicate a significantly bloated `pg_attribute` table that might require a long VACUUM FULL time:

- The `pg_attribute` table contains a large number of records.
- The diagnostic message for `pg_attribute` is significant amount of bloat in the `gp_toolkit.gp_bloat_diag` view.

**Vacuum and Analyze for Query Optimization**

Greenplum Database uses a cost-based query optimizer that relies on database statistics. Accurate statistics allow the query optimizer to better estimate selectivity and the number of rows that a query operation retrieves. These estimates help it choose the most efficient query plan. The ANALYZE command collects column-level statistics for the query optimizer.

You can run both VACUUM and ANALYZE operations in the same command. For example:

```
=# VACUUM ANALYZE mytable;
```

Running the VACUUM ANALYZE command might produce incorrect statistics when the command is run on a table with a significant amount of bloat (a significant amount of table disk space is occupied by deleted or obsolete rows). For large tables, the ANALYZE command calculates statistics from a random sample of rows. It estimates the number rows in the table by multiplying the average number of rows per page in the sample by the number of actual pages in the table. If the sample contains many empty pages, the estimated row count can be inaccurate.

For a table, you can view information about the amount of unused disk space (space that is occupied by deleted or obsolete rows) in the `gp_toolkit` view `gp_bloat_diag`. If the `bdidiag` column for a table contains the value significant amount of bloat suspected, a significant amount of table disk space consists of unused space. Entries are added to the `gp_bloat_diag` view after a table has been vacuumed.

To remove unused disk space from the table, you can run the command VACUUM FULL on the table. Due to table lock requirements, VACUUM FULL might not be possible until a maintenance period.

As a temporary workaround, run ANALYZE to compute column statistics and then run VACUUM on the table to generate an accurate row count. This example runs ANALYZE and then VACUUM on the `cust_info` table.

```
ANALYZE cust_info;
VACUUM cust_info;
```

Important: If you intend to execute queries on partitioned tables with GPORCA enabled (the default), you must collect statistics on the partitioned table root partition with the ANALYZE command. For information about GPORCA, see Overview of GPORCA.

Note: You can use the Greenplum Database utility analyzedb to update table statistics. Tables can be analyzed concurrently. For append optimized tables, analyzedb updates statistics only if the statistics are not current. See the analyzedb utility.

**Routine Reindexing**

For B-tree indexes, a freshly-constructed index is slightly faster to access than one that has been updated many times because logically adjacent pages are usually also physically adjacent in a newly built index. Reindexing older indexes periodically can improve access speed. If all but a few index keys on a page have been deleted, there will be wasted space on the index page. A reindex will reclaim that wasted space.
In Greenplum Database it is often faster to drop an index (DROP INDEX) and then recreate it (CREATE INDEX) than it is to use the REINDEX command.

For table columns with indexes, some operations such as bulk updates or inserts to the table might perform more slowly because of the updates to the indexes. To enhance performance of bulk operations on tables with indexes, you can drop the indexes, perform the bulk operation, and then re-create the index.

### Managing Greenplum Database Log Files

- **Database Server Log Files**
- **Management Utility Log Files**

#### Database Server Log Files

Greenplum Database log output tends to be voluminous, especially at higher debug levels, and you do not need to save it indefinitely. Administrators should purge older log files periodically.

Greenplum Database by default has log file rotation enabled for the master and segment database logs. Log files are created in the `pg_log` subdirectory of the master and each segment data directory using the following naming convention: `gpdb-YYYY-MM-DD_hhmmss.csv`. Administrators need to implement scripts or programs to periodically clean up old log files in the `pg_log` directory of the master and each segment instance.

Log rotation can be triggered by the size of the current log file or the age of the current log file. The `log_rotation_size` configuration parameter sets the size of an individual log file that triggers log rotation. When the log file size is equal to or greater than the specified size, the file is closed and a new log file is created. The `log_rotation_size` value is specified in kilobytes. The default is 1048576 kilobytes, or 1GB. If `log_rotation_size` is set to 0, size-based rotation is disabled.

The `log_rotation_age` configuration parameter specifies the age of a log file that triggers rotation. When the specified amount of time has elapsed since the log file was created, the file is closed and a new log file is created. The default `log_rotation_age`, 1d, creates a new log file 24 hours after the current log file was created. If `log_rotation_age` is set to 0, time-based rotation is disabled.

For information about viewing the database server log files, see [Viewing the Database Server Log Files](#).

#### Management Utility Log Files

Log files for the Greenplum Database management utilities are written to `~/gpAdminLogs` by default. The naming convention for management log files is:

```
script_name_date.log
```

The log entry format is:

```
timestamp:utility:host:user:[INFO|WARN|FATAL]:message
```

The log file for a particular utility execution is appended to its daily log file each time that utility is run.

### Recommended Monitoring and Maintenance Tasks

This section lists monitoring and maintenance activities recommended to ensure high availability and consistent performance of your Greenplum Database cluster.

The tables in the following sections suggest activities that a Greenplum System Administrator can perform periodically to ensure that all components of the system are operating optimally. Monitoring activities help you to detect and diagnose problems early. Maintenance activities help you to keep the system up-to-date and avoid deteriorating performance, for example, from bloated system tables or diminishing free disk space.
It is not necessary to implement all of these suggestions in every cluster; use the frequency and severity recommendations as a guide to implement measures according to your service requirements.

### Database State Monitoring Activities

**Table 28: Database State Monitoring Activities**

<table>
<thead>
<tr>
<th>Activity</th>
<th>Procedure</th>
<th>Corrective Actions</th>
</tr>
</thead>
</table>
| List segments that are currently down. If any rows are returned, this should generate a warning or alert. Recommended frequency: run every 5 to 10 minutes Severity: IMPORTANT | Run the following query in the postgres database: ```sql SELECT * FROM gp_segment_configuration WHERE status <> 'u'; ``` | If the query returns any rows, follow these steps to correct the problem:  
1. Verify that the hosts with down segments are responsive.  
2. If hosts are OK, check the pg\_log files for the primaries and mirrors of the down segments to discover the root cause of the segments going down.  
3. If no unexpected errors are found, run the gprecoverseg utility to bring the segments back online. |
| Check for segments that are currently in change tracking mode. If any rows are returned, this should generate a warning or alert. Recommended frequency: run every 5 to 10 minutes Severity: IMPORTANT | Execute the following query in the postgres database: ```sql SELECT * FROM gp_segment_configuration WHERE mode = 'c'; ``` | If the query returns any rows, follow these steps to correct the problem:  
1. Verify that hosts with down segments are responsive.  
2. If hosts are OK, check the pg\_log files for the primaries and mirrors of the down segments to determine the root cause of the segments going down.  
3. If no unexpected errors are found, run the gprecoverseg utility to bring the segments back online. |
<p>| Check for segments that are currently re-syncing. If rows are returned, this should generate a warning or alert. Recommended frequency: run every 5 to 10 minutes Severity: IMPORTANT | Execute the following query in the postgres database: <code>sql SELECT * FROM gp_segment_configuration WHERE mode = 'r'; </code> | When this query returns rows, it implies that the segments are in the process of being re-synched. If the state does not change from 'r' to 's', then check the pg_log files from the primaries and mirrors of the affected segments for errors. |</p>

<td>Run the repair scripts for any issues identified.</td>
</tr>
</tbody>
</table>

## Data Maintenance

### Table 32: Data Maintenance Activities

<table>
<thead>
<tr>
<th>Activity</th>
<th>Procedure</th>
<th>Corrective Actions</th>
</tr>
</thead>
<tbody>
<tr>
<td>Check for missing statistics on tables.</td>
<td>Check the <code>gp_stats_missing</code> view in each database: <code>SELECT * FROM gp_toolkit.gp_stats_missing;</code></td>
<td>Run ANALYZE on tables that are missing statistics.</td>
</tr>
<tr>
<td>Check for tables that have bloat (dead space) in data files that cannot be recovered by a regular VACUUM command.</td>
<td>Check the <code>gp_bloat_diag</code> view in each database: <code>SELECT * FROM gp_toolkit.gp_bloat_diag;</code></td>
<td>Execute a VACUUM FULL statement at a time when users are not accessing the table to remove bloat and compact the data.</td>
</tr>
</tbody>
</table>
## Database Maintenance

### Table 33: Database Maintenance Activities

<table>
<thead>
<tr>
<th>Activity</th>
<th>Procedure</th>
<th>Corrective Actions</th>
</tr>
</thead>
<tbody>
<tr>
<td>Mark deleted rows in heap tables so that the space they occupy can be reused. Recommended frequency: daily Severity: CRITICAL</td>
<td>Vacuum user tables: <code>VACUUM &lt;table&gt;;</code></td>
<td>Vacuum updated tables regularly to prevent bloating.</td>
</tr>
<tr>
<td>Update table statistics. Recommended frequency: after loading data and before executing queries Severity: CRITICAL</td>
<td>Analyze user tables. You can use the <code>analyzedb</code> management utility: <code>analyzedb -d &lt;database&gt; -a</code></td>
<td>Analyze updated tables regularly so that the optimizer can produce efficient query execution plans.</td>
</tr>
<tr>
<td>Backup the database data. Recommended frequency: daily, or as required by your backup plan Severity: CRITICAL</td>
<td>Run the <code>gpbackup</code> utility to create a backup of the master and segment databases in parallel.</td>
<td>Best practice is to have a current backup ready in case the database must be restored.</td>
</tr>
</tbody>
</table>
| Vacuum, reindex, and analyze system catalogs to maintain an efficient catalog. Recommended frequency: weekly, or more often if database objects are created and dropped frequently | 1. **VACUUM** the system tables in each database.  
2. Run **REINDEX** `SYSTEM` in each database, or use the `reindexdb` command-line utility with the `-s` option: `reindexdb -s <database>`  
3. **ANALYZE** each of the system tables: `analyzedb -s pg_catalog -d <database>` | The optimizer retrieves information from the system tables to create query plans. If system tables and indexes are allowed to become bloated over time, scanning the system tables increases query execution time. It is important to run **ANALYZE** after reindexing, because **REINDEX** leaves indexes with no statistics. |
## Patching and Upgrading

### Table 34: Patch and Upgrade Activities

<table>
<thead>
<tr>
<th>Activity</th>
<th>Procedure</th>
<th>Corrective Actions</th>
</tr>
</thead>
</table>
| Ensure any bug fixes or enhancements are applied to the kernel.  
Recommended frequency: at least every 6 months  
Severity: IMPORTANT | Follow the vendor's instructions to update the Linux kernel.             | Keep the kernel current to include bug fixes and security fixes, and to avoid difficult future upgrades. |
| Install Greenplum Database minor releases, for example 5.0.x.  
Recommended frequency: quarterly  
Managing Greenplum Database Access

Securing Greenplum Database includes protecting access to the database through network configuration, database user authentication, and encryption.

This section contains the following topics:

- Configuring Client Authentication
  - Using LDAP Authentication with TLS/SSL
  - Using Kerberos Authentication
  - Managing Roles and Privileges

Configuring Client Authentication

This topic explains how to configure client connections and authentication for Greenplum Database.

When a Greenplum Database system is first initialized, the system contains one predefined superuser role. This role will have the same name as the operating system user who initialized the Greenplum Database system. This role is referred to as gpadmin. By default, the system is configured to only allow local connections to the database from the gpadmin role. If you want to allow any other roles to connect, or if you want to allow connections from remote hosts, you have to configure Greenplum Database to allow such connections. This section explains how to configure client connections and authentication to Greenplum Database.

Allowing Connections to Greenplum Database

Client access and authentication is controlled by the standard PostgreSQL host-based authentication file, pg_hba.conf. For detailed information about this file, see The pg_hba.conf File in the PostgreSQL documentation.

In Greenplum Database, the pg_hba.conf file of the master instance controls client access and authentication to your Greenplum Database system. The Greenplum Database segments also have pg_hba.conf files, but these are already correctly configured to allow only client connections from the master host. The segments never accept outside client connections, so there is no need to alter the pg_hba.conf file on segments.

The general format of the pg_hba.conf file is a set of records, one per line. Greenplum Database ignores blank lines and any text after the # comment character. A record consists of a number of fields that are separated by spaces or tabs. Fields can contain white space if the field value is quoted. Records cannot be continued across lines. Each remote client access record has the following format:

```
host  database  role  address  authentication-method
```

Each UNIX-domain socket access record is in this format:

```
local  database  role  authentication-method
```

The following table describes meaning of each field.

Table 35: pg_hba.conf Fields

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>local</td>
<td>Matches connection attempts using UNIX-domain sockets. Without a record of this type, UNIX-domain socket connections are disallowed.</td>

<tr>
<td>-----------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>address</td>
<td>Specifies the client machine addresses that this record matches. This field can contain an IP address, an IP address range, or a host name.                                                                                                           An IP address range is specified using standard numeric notation for the range's starting address, then a slash (/) and a CIDR mask length. The mask length indicates the number of high-order bits of the client IP address that must match. Bits to the right of this should be zero in the given IP address. There must not be any white space between the IP address, the /, and the CIDR mask length. Typical examples of an IPv4 address range specified this way are 172.20.143.89/32 for a single host, or 172.20.143.0/24 for a small network, or 10.6.0.0/16 for a larger one. An IPv6 address range might look like ::1/128 for a single host (in this case the IPv6 loopback address) or fe80::7a31:c1ff:0000:0000/96 for a small network. 0.0.0.0/0 represents all IPv4 addresses, and ::/0 represents all IPv6 addresses. To specify a single host, use a mask length of 32 for IPv4 or 128 for IPv6. In a network address, do not omit trailing zeroes. An entry given in IPv4 format will match only IPv4 connections, and an entry given in IPv6 format will match only IPv6 connections, even if the represented address is in the IPv4-in-IPv6 range. <strong>Note:</strong> Entries in IPv6 format will be rejected if the host system C library does not have support for IPv6 addresses. If a host name is specified (an address that is not an IP address or IP range is treated as a host name), that name is compared with the result of a reverse name resolution of the client IP address (for example, reverse DNS lookup, if DNS is used). Host name comparisons are case insensitive. If there is a match, then a forward name resolution (for example, forward DNS lookup) is performed on the host name to check whether any of the addresses it resolves to are equal to the client IP address. If both directions match, then the entry is considered to match. Some host name databases allow associating an IP address with multiple host names, but the operating system only returns one host name when asked to resolve an IP address. The host name that is used in pg_hba.conf must be the one that the address-to-name resolution of the client IP address returns, otherwise the line will not be considered a match. When host names are specified in pg_hba.conf, you should ensure that name resolution is reasonably fast. It can be of advantage to set up a local name resolution cache such as nscd. Also, you can enable the server configuration parameter log_hostname to see the client host name instead of the IP address in the log.</td>
</tr>
<tr>
<td>IP-address</td>
<td>These fields can be used as an alternative to the CIDR address notation. Instead of specifying the mask length, the actual mask is specified in a separate column. For example, 255.0.0.0 represents an IPv4 CIDR mask length of 8, and 255.255.255.255 represents a CIDR mask length of 32.</td>
</tr>
<tr>
<td>IP-mask</td>
<td></td>
</tr>
<tr>
<td>authentication-method</td>
<td>Specifies the authentication method to use when connecting. Greenplum supports the <a href="http://www.greenplum.com">authentication methods</a> supported by PostgreSQL 9.4. Caution: For a more secure system, consider removing records for remote connections that use trust authentication from the pg_hba.conf file. Trust authentication grants any user who can connect to the server access to the database using any role they specify. You can safely replace</td>
</tr>
</tbody>
</table>
trust authentication with ident authentication for local UNIX-socket connections. You can also use
ident authentication for local and remote TCP clients, but the client host must be running an ident
service and you must trust the integrity of that machine.

**Editing the pg_hba.conf File**

Initially, the `pg_hba.conf` file is set up with generous permissions for the gpadmin user and no database
access for other Greenplum Database roles. You will need to edit the `pg_hba.conf` file to enable
users' access to databases and to secure the gpadmin user. Consider removing entries that have trust
authentication, since they allow anyone with access to the server to connect with any role they choose.
For local (UNIX socket) connections, use ident authentication, which requires the operating system user
to match the role specified. For local and remote TCP connections, ident authentication requires the
client's host to run an indent service. You can install an indent service on the master host and then use
ident authentication for local TCP connections, for example `127.0.0.1/28`. Using ident authentication for
remote TCP connections is less secure because it requires you to trust the integrity of the indent service on
the client's host.

This example shows how to edit the `pg_hba.conf` file of the master to allow remote client access to all
databases from all roles using encrypted password authentication.

**Editing pg_hba.conf**

1. Open the file `$MASTER_DATA_DIRECTORY/pg_hba.conf` in a text editor.
2. Add a line to the file for each type of connection you want to allow. Records are read sequentially,
   so the order of the records is significant. Typically, earlier records will have tight connection match
   parameters and weaker authentication methods, while later records will have looser match parameters
   and stronger authentication methods. For example:

```
# allow the gpadmin user local access to all databases
# using ident authentication
local   all   gpadmin   ident         sameuser
host    all   gpadmin   127.0.0.1/32  ident
host    all   gpadmin   ::1/128       ident

# allow the 'dba' role access to any database from any
# host with IP address 192.168.x.x and use md5 encrypted
# passwords to authenticate the user
host    all   dba   192.168.0.0/32  md5

# allow all roles access to any database from any
# host and use ldap to authenticate the user. Greenplum role
# names must match the LDAP common name.
host    all   all   192.168.0.0/32  ldap
    ldapserver=usldap1  ldapprefix="cn=" ldapsuffix="",ou=People,dc=company,dc=com"
```

3. Save and close the file.
4. Reload the `pg_hba.conf` configuration file for your changes to take effect:

```
$ gpstop -u
```

**Note:** Note that you can also control database access by setting object privileges as described
in *Managing Object Privileges*. The `pg_hba.conf` file just controls who can initiate a database
session and how those connections are authenticated.
Limiting Concurrent Connections

Greenplum Database allocates some resources on a per-connection basis, so setting the maximum number of connections allowed is recommended.

To limit the number of active concurrent sessions to your Greenplum Database system, you can configure the max_connections server configuration parameter. This is a local parameter, meaning that you must set it in the postgresql.conf file of the master, the standby master, and each segment instance (primary and mirror). The recommended value of max_connections on segments is 5-10 times the value on the master.

When you set max_connections, you must also set the dependent parameter max_prepared_transactions. This value must be at least as large as the value of max_connections on the master, and segment instances should be set to the same value as the master.

For example:

- In $MASTER_DATA_DIRECTORY/postgresql.conf (including standby master):
  ```
  max_connections=100
  max_prepared_transactions=100
  ```

- In SEGMENT_DATA_DIRECTORY/postgresql.conf for all segment instances:
  ```
  max_connections=500
  max_prepared_transactions=100
  ```

The following steps set the parameter values with the Greenplum Database utility gpconfig.

For information about gpconfig, see the Greenplum Database Utility Guide.

To change the number of allowed connections

1. Log into the Greenplum Database master host as the Greenplum Database administrator and source the file $GPHOME/greenplum_path.sh.

2. Set the value of the max_connections parameter. This gpconfig command sets the value on the segments to 1000 and the value on the master to 200.

   ```
   $ gpconfig -c max_connections -v 1000 -m 200
   ```

   The value on the segments must be greater than the value on the master. The recommended value of max_connections on segments is 5-10 times the value on the master.

3. Set the value of the max_prepared_transactions parameter. This gpconfig command sets the value to 200 on the master and all segments.

   ```
   $ gpconfig -c max_prepared_transactions -v 200
   ```

   The value of max_prepared_transactions must be greater than or equal to max_connections on the master.

4. Stop and restart your Greenplum Database system.

   ```
   $ gpstop -r
   ```

5. You can check the value of parameters on the master and segments with the gpconfig -s option. This gpconfig command displays the values of the max_connections parameter.

   ```
   $ gpconfig -s max_connections
   ```
Note: Raising the values of these parameters may cause Greenplum Database to request more shared memory. To mitigate this effect, consider decreasing other memory-related parameters such as `gp_cached_segworkers_threshold`.

**Encrypting Client/Server Connections**

Enable SSL for client connections to Greenplum Database to encrypt the data passed over the network between the client and the database.

Greenplum Database has native support for SSL connections between the client and the master server. SSL connections prevent third parties from snooping on the packets, and also prevent man-in-the-middle attacks. SSL should be used whenever the client connection goes through an insecure link, and must be used whenever client certificate authentication is used.

To enable SSL requires that OpenSSL be installed on both the client and the master server. Greenplum Database can be started with SSL enabled by setting the server configuration parameter `ssl=on` in the master `postgresql.conf`. When starting in SSL mode, the server will look for the files `server.key` (server private key) and `server.crt` (server certificate) in the master data directory. These files must be set up correctly before an SSL-enabled Greenplum Database system can start.

**Important:** Do not protect the private key with a passphrase. The server does not prompt for a passphrase for the private key, and the database startup fails with an error if one is required.

A self-signed certificate can be used for testing, but a certificate signed by a certificate authority (CA) should be used in production, so the client can verify the identity of the server. Either a global or local CA can be used. If all the clients are local to the organization, a local CA is recommended.

**Creating a Self-signed Certificate without a Passphrase for Testing Only**

To create a quick self-signed certificate for the server for testing, use the following OpenSSL command:

```
# openssl req -new -text -out server.req
```

Enter the information requested by the prompts. Be sure to enter the local host name as *Common Name*. The challenge password can be left blank.

The program will generate a key that is passphrase protected, and does not accept a passphrase that is less than four characters long.

To use this certificate with Greenplum Database, remove the passphrase with the following commands:

```
# openssl rsa -in privkey.pem -out server.key
# rm privkey.pem
```

Enter the old passphrase when prompted to unlock the existing key.

Then, enter the following command to turn the certificate into a self-signed certificate and to copy the key and certificate to a location where the server will look for them.

```
# openssl req -x509 -in server.req -text -key server.key -out server.crt
```

Finally, change the permissions on the key with the following command. The server will reject the file if the permissions are less restrictive than these.

```
# chmod og-rwx server.key
```

For more details on how to create your server private key and certificate, refer to the *OpenSSL documentation*. 
Using LDAP Authentication with TLS/SSL

You can control access to Greenplum Database with an LDAP server and, optionally, secure the connection with encryption by adding parameters to `pg_hba.conf` file entries.

Greenplum Database supports LDAP authentication with the TLS/SSL protocol to encrypt communication with an LDAP server:

- LDAP authentication with STARTTLS and TLS protocol – STARTTLS starts with a clear text connection (no encryption) and upgrades it to a secure connection (with encryption).
- LDAP authentication with a secure connection and TLS/SSL (LDAPS) – Greenplum Database uses the TLS or SSL protocol based on the protocol that is used by the LDAP server.

If no protocol is specified, Greenplum Database communicates with the LDAP server with a clear text connection.

To use LDAP authentication, the Greenplum Database master host must be configured as an LDAP client. See your LDAP documentation for information about configuring LDAP clients.

Enabling LDAP Authentication with STARTTLS and TLS

To enable STARTTLS with the TLS protocol, in the `pg_hba.conf` file, add an `ldap` line and specify the `ldaptls` parameter with the value 1. The default port is 389. In this example, the authentication method parameters include the `ldaptls` parameter.

```
ldap ldapserver=myldap.com ldaptls=1 ldapprefix="uid=
ldapsuffix=",ou=People,dc=example,dc=com"
```

Specify a non-default port with the `ldapport` parameter. In this example, the authentication method includes the `ldaptls` parameter and the `ldapport` parameter to specify the port 550.

```
ldap ldapserver=myldap.com ldaptls=1 ldapport=500 ldapprefix="uid=
ldapsuffix=",ou=People,dc=example,dc=com"
```

Enabling LDAP Authentication with a Secure Connection and TLS/SSL

To enable a secure connection with TLS/SSL, add `ldaps://` as the prefix to the LDAP server name specified in the `ldapserver` parameter. The default port is 636.

This example `ldapserver` parameter specifies a secure connection and the TLS/SSL protocol for the LDAP server `myldap.com`.

```
ldapserver=ldaps://myldap.com
```

To specify a non-default port, add a colon (:) and the port number after the LDAP server name. This example `ldapserver` parameter includes the `ldaps://` prefix and the non-default port 550.

```
ldapserver=ldaps://myldap.com:550
```

Configuring Authentication with a System-wide OpenLDAP System

If you have a system-wide OpenLDAP system and logins are configured to use LDAP with TLS or SSL in the `pg_hba.conf` file, logins may fail with the following message:

```
could not start LDAP TLS session: error code '-11'
```
To use an existing OpenLDAP system for authentication, Greenplum Database must be set up to use the LDAP server’s CA certificate to validate user certificates. Follow these steps on both the master and standby hosts to configure Greenplum Database:

1. Copy the base64-encoded root CA chain file from the Active Directory or LDAP server to the Greenplum Database master and standby master hosts. This example uses the directory `/etc/pki/tls/certs`.

2. Change to the directory where you copied the CA certificate file and, as the root user, generate the hash for OpenLDAP:

   ```bash
   # cd /etc/pki/tls/certs
   # openssl x509 -noout -hash -in <ca-certificate-file>
   # ln -s <ca-certificate-file> <ca-certificate-file>.0
   ``

3. Configure an OpenLDAP configuration file for Greenplum Database with the CA certificate directory and certificate file specified.

   As the root user, edit the OpenLDAP configuration file `/etc/openldap/ldap.conf`:

   ```conf
   SASL_NOCANON on
   URI ldaps://ldapA.example.priv ldaps://ldapB.example.priv ldaps://ldapC.example.priv
   BASE dc=example,dc=priv
   TLS_CACERTDIR /etc/pki/tls/certs
   TLS_CACERT /etc/pki/tls/certs/<ca-certificate-file>
   
   Note: For certificate validation to succeed, the hostname in the certificate must match a hostname in the URI property. Otherwise, you must also add TLS_REQCERT allow to the file.
   ```

4. As the gpadmin user, edit `/usr/local/greenplum-db/greenplum_path.sh` and add the following line.

   ```bash
   export LDAPCONF=/etc/openldap/ldap.conf
   ```

**Notes**

Greenplum Database logs an error if the following are specified in an `pg_hba.conf` file entry:

- If both the `ldaps://` prefix and the `ldap_tls=1` parameter are specified.
- If both the `ldaps://` prefix and the `ldap_port` parameter are specified.

Enabling encrypted communication for LDAP authentication only encrypts the communication between Greenplum Database and the LDAP server.

See *Encrypting Client/Server Connections* for information about encrypting client connections.

**Examples**

These are example entries from an `pg_hba.conf` file.

This example specifies LDAP authentication with no encryption between Greenplum Database and the LDAP server.

```conf
host all plainuser 0.0.0.0/0 ldap ldapserver=myldap.com ldapprefix="uid="
   ldapsuffix="",ou=People,dc=example,dc=com"
```

This example specifies LDAP authentication with the STARTTLS and TLS protocol between Greenplum Database and the LDAP server.

```conf
host all tlsuser 0.0.0.0/0 ldap ldapserver=myldap.com ldap_tls=1
   ldapprefix="uid=" ldapsuffix="",ou=People,dc=example,dc=com"
```
Using Kerberos Authentication

You can control access to Greenplum Database with a Kerberos authentication server. Greenplum Database supports the Generic Security Service Application Program Interface (GSSAPI) with Kerberos authentication. GSSAPI provides automatic authentication (single sign-on) for systems that support it. You specify the Greenplum Database users (roles) that require Kerberos authentication in the Greenplum Database configuration file `pg_hba.conf`. The login fails if Kerberos authentication is not available when a role attempts to log in to Greenplum Database.

Kerberos provides a secure, encrypted authentication service. It does not encrypt data exchanged between the client and database and provides no authorization services. To encrypt data exchanged over the network, you must use an SSL connection. To manage authorization for access to Greenplum databases and objects such as schemas and tables, you use settings in the `pg_hba.conf` file and privileges given to Greenplum Database users and roles within the database. For information about managing authorization privileges, see Managing Roles and Privileges.

For more information about Kerberos, see [http://web.mit.edu/kerberos/](http://web.mit.edu/kerberos/).

Prerequisites

Before configuring Kerberos authentication for Greenplum Database, ensure that:

- You can identify the KDC server you use for Kerberos authentication and the Kerberos realm for your Greenplum Database system.
- If you plan to use an MIT Kerberos KDC server but have not yet configured it, see Installing and Configuring a Kerberos KDC Server for example instructions.
- If you are using an existing Active Directory KDC server, also ensure that you have:
  - Installed all Active Directory service roles on your AD KDC server.
  - Enabled the LDAP service.
- System time on the Kerberos Key Distribution Center (KDC) server and Greenplum Database master is synchronized. (For example, install the `ntp` package on both servers.)
- Network connectivity exists between the KDC server and the Greenplum Database master host.
- Java 1.7.0_17 or later is installed on all Greenplum Database hosts. Java 1.7.0_17 is required to use Kerberos-authenticated JDBC on Red Hat Enterprise Linux 6.x or 7.x.

Procedure

Following are the tasks to complete to set up Kerberos authentication for Greenplum Database.

- Creating Greenplum Database Principals in the KDC Database
- Installing the Kerberos Client on the Master Host
- Configuring Greenplum Database to use Kerberos Authentication
- Mapping Kerberos Principals to Greenplum Database Roles
- Configuring JDBC Kerberos Authentication for Greenplum Database
- Configuring Kerberos on Windows for Greenplum Database Clients
- Configuring Client Authentication with Active Directory
Creating Greenplum Database Principals in the KDC Database

Create a service principal for the Greenplum Database service and a Kerberos admin principal that allows managing the KDC database as the gpadmin user.

1. Log in to the Kerberos KDC server as the root user.

```
$ ssh root@<kdc-server>
```

2. Create a principal for the Greenplum Database service.

```
# kadmin.local -q "addprinc -randkey postgres/mdw@GPDB.KRB"
```

The `-randkey` option prevents the command from prompting for a password.

The `postgres` part of the principal names matches the value of the Greenplum Database `krb_srvname` server configuration parameter, which is `postgres` by default.

The host name part of the principal name must match the output of the `hostname` command on the Greenplum Database master host. If the `hostname` command shows the fully qualified domain name (FQDN), use it in the principal name, for example `postgres/mdw.example.com@GPDB.KRB`.

The `GPDB.KRB` part of the principal name is the Kerberos realm name.

3. Create a principal for the gpadmin/admin role.

```
# kadmin.local -q "addprinc gpadmin/admin@GPDB.KRB"
```

This principal allows you to manage the KDC database when you are logged in as gpadmin. Make sure that the Kerberos `kadm.acl` configuration file contains an ACL to grant permissions to this principal. For example, this ACL grants all permissions to any admin user in the GPDB.KRB realm.

```
*/admin@GPDB.KRB *
```

4. Create a keytab file with `kadmin.local`. The following example creates a keytab file `gpdb-kerberos.keytab` in the current directory with authentication information for the Greenplum Database service principal and the gpadmin/admin principal.

```
# kadmin.local -q "ktadd -k gpdb-kerberos.keytab postgres/mdw@GPDB.KRB
gadmin/admin@GPDB.KRB"
```

5. Copy the keytab file to the master host.

```
# scp gpdb-kerberos.keytab gpadmin@mdw:~
```

Installing the Kerberos Client on the Master Host

Install the Kerberos client utilities and libraries on the Greenplum Database master.

1. Install the Kerberos packages on the Greenplum Database master.

```
$ sudo yum install krb5-libs krb5-workstation
```

2. Copy the `/etc/krb5.conf` file from the KDC server to `/etc/krb5.conf` on the Greenplum Master host.

Configuring Greenplum Database to use Kerberos Authentication

Configure Greenplum Database to use Kerberos.
1. Log in to the Greenplum Database master host as the gpadmin user.

   ```
   $ ssh gpadmin@<master>
   $ source /usr/local/greenplum-db/greenplum_path.sh
   ```

2. Set the ownership and permissions of the keytab file you copied from the KDC server.

   ```
   $ chown gpadmin:gpadmin /home/gpadmin/gpdb-kerberos.keytab
   $ chmod 400 /home/gpadmin/gpdb-kerberos.keytab
   ```

3. Configure the location of the keytab file by setting the Greenplum Database `krb_server_keyfile` server configuration parameter. This `gpconfig` command specifies the folder `/home/gpadmin` as the location of the keytab file `gpdb-kerberos.keytab`.

   ```
   $ gpconfig -c krb_server_keyfile -v '/home/gpadmin/gpdb-kerberos.keytab'
   ```

4. Modify the Greenplum Database file `pg_hba.conf` to enable Kerberos support. For example, adding the following line to `pg_hba.conf` adds GSSAPI and Kerberos authentication support for connection requests from all users and hosts on the same network to all Greenplum Database databases.

   ```
   host all all 0.0.0.0/0 gss include_realm=0 krb_realm=GPDB.KRB
   ```

   Setting the `krb_realm` option to a realm name ensures that only users from that realm can successfully authenticate with Kerberos. Setting the `include_realm` option to 0 excludes the realm name from the authenticated user name. For information about the `pg_hba.conf` file, see `The pg_hba.conf file` in the PostgreSQL documentation.

5. Restart Greenplum Database after updating the `krb_server_keyfile` parameter and the `pg_hba.conf` file.

   ```
   $ gpstop -ar
   ```

6. Create the gpadmin/admin Greenplum Database superuser role.

   ```
   $ createuser gpadmin/admin
   Shall the new role be a superuser? (y/n) y
   ```

   The Kerberos keys for this database role are in the keyfile you copied from the KDC server.

7. Create a ticket using `kinit` and show the tickets in the Kerberos ticket cache with `klist`.

   ```
   $ LD_LIBRARY_PATH= kinit -k -t /home/gpadmin/gpdb-kerberos.keytab gpadmin/admin@GPDB.KRB
   $ LD_LIBRARY_PATH= klist
   Ticket cache: FILE:/tmp/krb5cc_1000
   Default principal: gpadmin/admin@GPDB.KRB
   Valid starting       Expires              Service principal
   06/13/2018 17:37:35  06/14/2018 17:37:35  krbtgt/GPDB.KRB@GPDB.KRB
   ```

   **Note:** When you set up the Greenplum Database environment by sourcing the `greenplum-db_path.sh` script, the `LD_LIBRARY_PATH` environment variable is set to include the Greenplum Database lib directory, which includes Kerberos libraries. This may cause Kerberos utility commands such as `kinit` and `klist` to fail due to version conflicts. The solution is to run Kerberos utilities before you source the `greenplum-db_path.sh` file or temporarily unset the `LD_LIBRARY_PATH` variable when you execute Kerberos utilities, as shown in the example.

8. As a test, log in to the postgres database with the `gpadmin/admin` role:

   ```
   $ psql -U "gpadmin/admin" -h mdw postgres
   psql (9.4.20)
   Type "help" for help.
   ```
postgres=# select current_user;
current_user
-----------
gpadmin/admin
(1 row)

**Note:** When you start **psql** on the master host, you must include the `-h <master-hostname>` option to force a TCP connection because Kerberos authentication does not work with local connections.

If a Kerberos principal is not a Greenplum Database user, a message similar to the following is displayed from the **psql** command line when the user attempts to log in to the database:

```
psql: krb5_sendauth: Bad response
```

The principal must be added as a Greenplum Database user.

### Mapping Kerberos Principals to Greenplum Database Roles

To connect to a Greenplum Database system with Kerberos authentication enabled, a user first requests a ticket-granting ticket from the KDC server using the **kinit** utility with a password or a keytab file provided by the Kerberos admin. When the user then connects to the Kerberos-enabled Greenplum Database system, the user's Kerberos principle name will be the Greenplum Database role name, subject to transformations specified in the options field of the **gss** entry in the Greenplum Database **pg_hba.conf** file:

- If the `krb_realm=<realm>` option is present, Greenplum Database only accepts Kerberos principals who are members of the specified realm.
- If the `include_realm=0` option is specified, the Greenplum Database role name is the Kerberos principal name without the Kerberos realm. If the `include_realm=1` option is instead specified, the Kerberos realm is not stripped from the Greenplum Database rolename. The role must have been created with the Greenplum Database `CREATE ROLE` command.
- If the `map=<map-name>` option is specified, the Kerberos principal name is compared to entries labeled with the specified `<map-name>` in the `$MASTER_DATA_DIRECTORY/pg_ident.conf` file and replaced with the Greenplum Database role name specified in the first matching entry.

A user name map is defined in the `$MASTER_DATA_DIRECTORY/pg_ident.conf` configuration file. This example defines a map named `mymap` with two entries.

```
# MAPNAME   SYSTEM-USERNAME        GP-USERNAME
mymap       /^admin@GPDB.KRB$      gpadmin
mymap       /^(.*)_gp)@GPDB.KRB$   \1
```

The map name is specified in the **pg_hba.conf** Kerberos entry in the options field:

```
host all all 0.0.0.0/0 gss include_realm=0 krb_realm=GPDB.KRB map=mymap
```

The first map entry matches the Kerberos principal `admin@GPDB.KRB` and replaces it with the Greenplum Database `gpadmin` role name. The second entry uses a wildcard to match any Kerberos principal in the `GPDB-KRB` realm with a name ending with the characters `_gp` and replaces it with the initial portion of the principal name. Greenplum Database applies the first matching map entry in the **pg_ident.conf** file, so the order of entries is significant.

For more information about using username maps see *Username maps* in the PostgreSQL documentation.
Configuring JDBC Kerberos Authentication for Greenplum Database

Enable Kerberos-authenticated JDBC access to Greenplum Database.

You can configure Greenplum Database to use Kerberos to run user-defined Java functions.

1. Ensure that Kerberos is installed and configured on the Greenplum Database master. See Installing the Kerberos Client on the Master Host.
2. Create the file .java.login.config in the folder /home/gpadmin and add the following text to the file:

   ```
   pgjdbc {
       com.sun.security.auth.module.Krb5LoginModule required
donotPrompt=true
useTicketCache=true
debug=true
client=true;
   }
   ```

3. Create a Java application that connects to Greenplum Database using Kerberos authentication. The following example database connection URL uses a PostgreSQL JDBC driver and specifies parameters for Kerberos authentication:

   ```
   jdbc:postgresql://mdw:5432/mytest?kerberosServerName=postgres&jaasApplicationName=pgjdbc&user=gpadmin/gpdb-kdc
   ```

   The parameter names and values specified depend on how the Java application performs Kerberos authentication.
4. Test the Kerberos login by running a sample Java application from Greenplum Database.

Installing and Configuring a Kerberos KDC Server

Steps to set up a Kerberos Key Distribution Center (KDC) server on a Red Hat Enterprise Linux host for use with Greenplum Database.

If you do not already have a KDC, follow these steps to install and configure a KDC server on a Red Hat Enterprise Linux host with a GPDB.KRB realm. The host name of the KDC server in this example is gpdb-kdc.

1. Install the Kerberos server and client packages:

   ```
   $ sudo yum install krb5-libs krb5-server krb5-workstation
   ```

2. Edit the /etc/krb5.conf configuration file. The following example shows a Kerberos server configured with a default GPDB.KRB realm.

   ```
   [logging]
default = FILE:/var/log/krb5libs.log
kdc = FILE:/var/log/krb5kdc.log
admin_server = FILE:/var/log/kadmind.log

[libdefaults]
default_realm = GPDB.KRB
dns_lookup_realm = false
dns_lookup_kdc = false
ticket_lifetime = 24h
renew_lifetime = 7d
forwardable = true
default_tgs_enctypes = aes128-cts des3-hmac-shal des-cbc-crc des-cbc-md5
default_tkt_enctypes = aes128-cts des3-hmac-shal des-cbc-crc des-cbc-md5
permitted_enctypes = aes128-cts des3-hmac-shal des-cbc-crc des-cbc-md5
   ```
The `kdc` and `admin_server` keys in the `[realms]` section specify the host (gpdb-kdc) and port where the Kerberos server is running. IP numbers can be used in place of host names.

If your Kerberos server manages authentication for other realms, you would instead add the `GPDB.KRB` realm in the `[realms]` and `[domain_realm]` section of the `kdc.conf` file. See the Kerberos documentation for information about the `kdc.conf` file.

3. To create the Kerberos database, run the `kdb5_util`.

   ```
   # kdb5_util create -s
   ```

   The `kdb5_util create` command creates the database to store keys for the Kerberos realms that are managed by this KDC server. The `-s` option creates a stash file. Without the stash file, every time the KDC server starts it requests a password.

4. Add an administrative user to the KDC database with the `kadmin.local` utility. Because it does not itself depend on Kerberos authentication, the `kadmin.local` utility allows you to add an initial administrative user to the local Kerberos server. To add the user `gpadmin` as an administrative user to the KDC database, run the following command:

   ```
   # kadmin.local -q "addprinc gpadmin/admin"
   ```

   Most users do not need administrative access to the Kerberos server. They can use `kadmin` to manage their own principals (for example, to change their own password). For information about `kadmin`, see the Kerberos documentation.

5. If needed, edit the `/var/kerberos/krb5kdc/kadm5.acl` file to grant the appropriate permissions to `gpadmin`.

6. Start the Kerberos daemons:

   ```
   # /sbin/service krb5kdc start
   # /sbin/service kadmin start
   ```

7. To start Kerberos automatically upon restart:

   ```
   # /sbin/chkconfig krb5kdc on
   # /sbin/chkconfig kadmin on
   ```
Configuring Kerberos for Linux Clients

You can configure Linux client applications to connect to a Greenplum Database system that is configured to authenticate with Kerberos.

If your JDBC application on Red Hat Enterprise Linux uses Kerberos authentication when it connects to your Greenplum Database, your client system must be configured to use Kerberos authentication. If you are not using Kerberos authentication to connect to a Greenplum Database, Kerberos is not needed on your client system.

- **Requirements**
- **Setting Up Client System with Kerberos Authentication**
- **Running a Java Application**

For information about enabling Kerberos authentication with Greenplum Database, see the chapter "Setting Up Kerberos Authentication" in the *Greenplum Database Administrator Guide*.

**Requirements**

The following are requirements to connect to a Greenplum Database that is enabled with Kerberos authentication from a client system with a JDBC application.

- **Prerequisites**
- **Required Software on the Client Machine**

**Prerequisites**

- Kerberos must be installed and configured on the Greenplum Database master host.

  **Important:** Greenplum Database must be configured so that a remote user can connect to Greenplum Database with Kerberos authentication. Authorization to access Greenplum Database is controlled by the `pg_hba.conf` file. For details, see "Editing the pg_hba.conf File" in the *Greenplum Database Administration Guide*, and also see the *Greenplum Database Security Configuration Guide*.

- The client system requires the Kerberos configuration file `krb5.conf` from the Greenplum Database master.
- The client system requires a Kerberos keytab file that contains the authentication credentials for the Greenplum Database user that is used to log into the database.
- The client machine must be able to connect to Greenplum Database master host.

  If necessary, add the Greenplum Database master host name and IP address to the system `hosts` file.

  On Linux systems, the `hosts` file is in `/etc`.

**Required Software on the Client Machine**

- The Kerberos `kinit` utility is required on the client machine. The `kinit` utility is available when you install the Kerberos packages:
  - `krb5-libs`
  - `krb5-workstation`

  **Note:** When you install the Kerberos packages, you can use other Kerberos utilities such as `klist` to display Kerberos ticket information.

Java applications require this additional software:

- **Java JDK**

  Java JDK 1.7.0_17 is supported on Red Hat Enterprise Linux 6.x.

  Ensure that JAVA_HOME is set to the installation directory of the supported Java JDK.
**Setting Up Client System with Kerberos Authentication**

To connect to Greenplum Database with Kerberos authentication requires a Kerberos ticket. On client systems, tickets are generated from Kerberos keytab files with the `kinit` utility and are stored in a cache file.

1. Install a copy of the Kerberos configuration file `krb5.conf` from the Greenplum Database master. The file is used by the Greenplum Database client software and the Kerberos utilities.

   Install `krb5.conf` in the directory `/etc`.

   If needed, add the parameter `default_ccache_name` to the `[libdefaults]` section of the `krb5.ini` file and specify location of the Kerberos ticket cache file on the client system.

2. Obtain a Kerberos keytab file that contains the authentication credentials for the Greenplum Database user.

3. Run `kinit` specifying the keytab file to create a ticket on the client machine. For this example, the keytab file `gpdb-kerberos.keytab` is in the current directory. The ticket cache file is in the `gpadmin` user home directory.

   ```
   > kinit -k -t gpdb-kerberos.keytab -c /home/gpadmin/cache.txt
   gpadmin/kerberos-gpdb@KRB.EXAMPLE.COM
   ```

**Running psql**

From a remote system, you can access a Greenplum Database that has Kerberos authentication enabled.

**To connect to Greenplum Database with psql**

1. As the `gpadmin` user, open a command window.
2. Start `psql` from the command window and specify a connection to the Greenplum Database specifying the user that is configured with Kerberos authentication.

   The following example logs into the Greenplum Database on the machine `kerberos-gpdb` as the `gpadmin` user with the Kerberos credentials `gpadmin/kerberos-gpdb`:

   ```
   $ psql -U "gpadmin/kerberos-gpdb" -h kerberos-gpdb postgres
   ```

**Running a Java Application**

Accessing Greenplum Database from a Java application with Kerberos authentication uses the Java Authentication and Authorization Service (JAAS)

1. Create the file `.java.login.config` in the user home folder.

   For example, on a Linux system, the home folder is similar to `/home/gpadmin`.

   Add the following text to the file:

   ```
   pgjdbc {
      com.sun.security.auth.module.Krb5LoginModule required
      doNotPrompt=true
      useTicketCache=true
      ticketCache = "/home/gpadmin/cache.txt"
      debug=true
      client=true;
    };
   ```

2. Create a Java application that connects to Greenplum Database using Kerberos authentication and run the application as the user.
This example database connection URL uses a PostgreSQL JDBC driver and specifies parameters for Kerberos authentication.

```
jdbc:postgresql://kerberos-gpdb:5432/mytest?
  kerberosServerName=postgres&jaasApplicationName=pgjdbc&
  user=gpadmin/kerberos-gpdb
```

The parameter names and values specified depend on how the Java application performs Kerberos authentication.

**Configuring Kerberos For Windows Clients**

You can configure Microsoft Windows client applications to connect to a Greenplum Database system that is configured to authenticate with Kerberos.

- Configuring Kerberos on Windows for Greenplum Database Clients
- Configuring Client Authentication with Active Directory

For information about configuring Greenplum Database with Kerberos authentication, see Using Kerberos Authentication.

**Configuring Kerberos on Windows for Greenplum Database Clients**

When a Greenplum Database system is configured to authenticate with Kerberos, you can configure Kerberos authentication for the Greenplum Database client utilities `gpload` and `psql` on a Microsoft Windows system. The Greenplum Database clients authenticate with Kerberos directly, not with Microsoft Active Directory (AD).

This section contains the following information.

- Installing Kerberos on a Windows System
- Running the psql Utility
- Example gpload YAML File
- Creating a Kerberos Keytab File
- Issues and Possible Solutions

These topics assume that the Greenplum Database system is configured to authenticate with Kerberos and Microsoft Active Directory. See Configuring Client Authentication with Active Directory.

**Installing Kerberos on a Windows System**

To use Kerberos authentication with the Greenplum Database clients on a Windows system, the MIT Kerberos Windows client must be installed on the system. For the clients you can install MIT Kerberos for Windows 4.0.1 (for krb5) that is available at [http://web.mit.edu/kerberos/dist/index.html](http://web.mit.edu/kerberos/dist/index.html).

On the Windows system, you manage Kerberos tickets with the Kerberos `kinit` utility

The automatic start up of the Kerberos service is not enabled. The service cannot be used to authenticate with Greenplum Database.

Create a copy of the Kerberos configuration file `/etc/krb5.conf` from the Greenplum Database master and place it in the default Kerberos location on the Windows system `C:\ProgramData\MIT\Kerberos5\krb5.ini`. In the file section `[libdefaults]`, remove the location of the Kerberos ticket cache `default_ccache_name`.

On the Windows system, use the environment variable `KRB5CCNAME` to specify the location of the Kerberos ticket. The value for the environment variable is a file, not a directory and should be unique to each login on the server.
This is an example configuration file with default_ccache_name removed. Also, the section [logging] is removed.

```
[libdefaults]
default_etypes = aes256-cts-hmac-shal-96
default_realm = EXAMPLE.LOCAL
dns_lookup_realm = false
dns_lookup_kdc = false
ticket_lifetime = 24h
renew_lifetime = 7d
forwardable = true

[realms]
EXAMPLE.LOCAL = {
    kdc = bocdc.example.local
    admin_server = bocdc.example.local
}

[domain_realm]
.example.local = EXAMPLE.LOCAL
e.xampl.e.loca.l = EXAMPLE.LOCAL
```

When specifying a Kerberos ticket with KRB5CCNAME, you can specify the value in either a local user environment or within a session. These commands set KRB5CCNAME, runs kinit, and runs the batch file to set the environment variables for the Greenplum Database clients.

```
set KRB5CCNAME=%USERPROFILE%\krb5cache
kinit
"c:\Program Files (x86)\Greenplum\greenplum-clients-<version>\greenplum_clients_path.bat"
```

**Running the psql Utility**

After installing and configuring Kerberos and the Kerberos ticket on a Windows system, you can run the Greenplum Database command line client `psql`.

If you get warnings indicating that the Console code page differs from Windows code page, you can run the Windows utility `chcp` to change the code page. This is an example of the warning and fix.

```
psql -h prod1.example.local warehouse
psql (9.4.20)
WARNING: Console code page (850) differs from Windows code page (1252)
  8-bit characters might not work correctly. See psql reference
  page "Notes for Windows users" for details.
Type "help" for help.
warehouse=# \q
chcp 1252
Active code page: 1252
psql -h prod1.example.local warehouse
psql (9.4.20)
Type "help" for help.
```
Creating a Kerberos Keytab File

You can create and use a Kerberos keytab file to avoid entering a password at the command line or the listing a password in a script file when connecting to a Greenplum Database system. You can create a keytab file with these utilities:

- Windows Kerberos utility `ktpass`
- Java JRE keytab utility `ktab`

If you use AES256-CTS-HMAC-SHA1-96 encryption, you need to download and install the Java extension `Java Cryptography Extension (JCE) Unlimited Strength Jurisdiction Policy Files for JDK/JRE` from Oracle. This command creates the keytab file `svcPostgresProd1.keytab`.

You run the `ktpass` utility as an AD Domain Administrator. The utility expects a user account to have a Service Principal Name (SPN) defined as an AD user attribute, however, it does not appear to be required. You can specify it as a parameter to `ktpass` and ignore the warning that it cannot be set.

The Java JRE `ktab` utility does not require an AD Domain Administrator and does not require an SPN.

**Note:** When you enter the password to create the keytab file, the password is visible on screen.

This example runs the `ktpass` utility to create the keytab file `dev1.keytab`.

```bash
ktpass -out dev1.keytab -princ dev1@EXAMPLE.LOCAL -mapUser dev1 -pass your_password -crypto all -ptype KRB5_NT_PRINCIPAL
```

It works despite the warning message _Unable to set SPN mapping data._

This example runs the Java `ktab.exe` to create a keytab file (`-a` option) and list the keytab name and entries (`-l -e -t` options).

```bash
C:\Users\dev1>"\Program Files\Java\jre1.8.0_77\bin\\"\ktab -a dev1
Password for dev1@EXAMPLE.LOCAL: your_password
Done!
Service key for dev1 is saved in C: \Users\dev1\krb5.keytab

C:\Users\dev1>"\Program Files\Java\jre1.8.0_77\bin\\"\ktab -l -e -t
Keytab name: C:\Users\dev1\krb5.keytab
KVNO Timestamp Principal
---- -------------- ------------------------------------------------------
4 13/04/16 19:14 dev1@EXAMPLE.LOCAL (18:AES256 CTS mode with HMAC SHA1-96)
4 13/04/16 19:14 dev1@EXAMPLE.LOCAL (17:AES128 CTS mode with HMAC SHA1-96)
4 13/04/16 19:14 dev1@EXAMPLE.LOCAL (16:DES3 CBC mode with SHA1-KD)
4 13/04/16 19:14 dev1@EXAMPLE.LOCAL (23:RC4 with HMAC)
```

You can then use a keytab with the following:

```bash
kinit -kt dev1.keytab dev1
or
kinit -kt %USERPROFILE%\krb5.keytab dev1
```

Example gpload YAML File

This is an example of running a `gpload` job with the user `dev1` logged onto a Windows desktop with the AD domain.

In the example `test.yaml` control file, the USER: line has been removed. Kerberos authentication is used.

```yaml
---
VERSION: 1.0.0.1
DATABASE: warehouse
HOST: prod1.example.local
```
PORT: 5432

GPLOAD:
  INPUT:
  - SOURCE:
    PORT_RANGE: [18080,18080]
    FILE:
    - /Users/dev1/Downloads/test.csv
  - FORMAT: text
  - DELIMITER: ','
  - QUOTE: '"'
  - ERROR_LIMIT: 25
  - LOG_ERRORS: true

OUTPUT:
  - TABLE: public.test
  - MODE: INSERT

PRELOAD:
  - REUSE_TABLES: true

These commands run `kinit` and then `gpload` with the `test.yaml` file and displays successful `gpload` output.

```
kinit -kt %USERPROFILE%\krb5.keytab dev1
gpload.py -f test.yaml
2016-04-10 16:54:12|INFO|gpload session started 2016-04-10 16:54:12
2016-04-10 16:54:12|INFO|started gpfdist -p 18080 -P 18080 -f "~/Users/dev1/Downloads/test.csv" -t 30
2016-04-10 16:54:13|INFO|running time: 0.23 seconds
2016-04-10 16:54:13|INFO|rows Inserted = 3
2016-04-10 16:54:13|INFO|rows Updated = 0
2016-04-10 16:54:13|INFO|data formatting errors = 0
2016-04-10 16:54:13|INFO|gpload succeeded
```

**Issues and Possible Solutions**

- This message indicates that Kerberos cannot find your cache file:

```
Credentials cache I/O operation failed XXX
(Kerberos error 193)
krb5_cc_default() failed
```

To ensure that Kerberos can find the file set the environment variable `KRB5CCNAME` and run `kinit`.

```
set KRB5CCNAME=%USERPROFILE%\krb5cache
kinit
```

- This `kinit` message indicates that the `kinit -k -t` command could not find the keytab.

```
kinit: Generic preauthentication failure while getting initial credentials
```

Confirm the full path and filename for the Kerberos keytab file is correct.

**Configuring Client Authentication with Active Directory**

You can configure a Microsoft Windows user with a Microsoft Active Directory (AD) account for single sign-on to a Greenplum Database system.

You configure an AD user account to support logging in with Kerberos authentication.
With AD single sign-on, a Windows user can use Active Directory credentials with a Windows client application to log into a Greenplum Database system. For Windows applications that use ODBC, the ODBC driver can use Active Directory credentials to connect to a Greenplum Database system.

Note: Greenplum Database clients that run on Windows, like gpload, connect with Greenplum Database directly and do not use Active Directory. For information about connecting Greenplum Database clients on Windows to a Greenplum Database system with Kerberos authentication, see Configuring Kerberos on Windows for Greenplum Database Clients.

This section contains the following information.
- Prerequisites
- Setting Up Active Directory
- Setting Up Greenplum Database for Active Directory
- Single Sign-On Examples
- Issues and Possible Solutions for Active Directory

Prerequisites
These items are required to enable AD single sign-on to a Greenplum Database system.

- The Greenplum Database system must be configured to support Kerberos authentication. For information about configuring Greenplum Database with Kerberos authentication, see Configuring Kerberos For Windows Clients.
- You must know the fully-qualified domain name (FQDN) of the Greenplum Database master host. Also, the Greenplum Database master host name must have a domain portion. If the system does not have a domain, you must configure the system to use a domain.

This Linux hostname command displays the FQDN.

```bash
hostname --fqdn
```

- You must confirm that the Greenplum Database system has the same date and time as the Active Directory domain. For example, you could set the Greenplum Database system NTP time source to be an AD Domain Controller, or configure the master host to use the same external time source as the AD Domain Controller.
- To support single sign-on, you configure an AD user account as a Managed Service Account in AD. These are requirements for Kerberos authentication.

  - You need to add the Service Principal Name (SPN) attribute to the user account information because the Kerberos utilities require the information during Kerberos authentication.
  - Also, as Greenplum Database has unattended startups, you must also provide the account login details in a Kerberos keytab file.

  Note: Setting the SPN and creating the keytab requires AD administrative permissions.

Setting Up Active Directory
The AD naming convention should support multiple Greenplum Database systems. In this example, we create a new AD Managed Service Account svcPostresProd1 for our prod1 Greenplum Database system master host.

The Active Directory domain is example.local.

The fully qualified domain name for the Greenplum Database master host is prod1.example.local.

We will add the SPN postgres/prod1.example.local to this account. Service accounts for other Greenplum Database systems will all be in the form postgres/fully.qualified.hostname.
In this example, the AD password is set to never expire and cannot be changed by the user. The AD account password is only used when creating the Kerberos keytab file. There is no requirement to provide it to a database administrator.
An AD administrator must add the Service Principal Name attribute to the account from the command line with the Windows `setspn` command. This example command set the SPN attribute value to `postgres/prod1.example.local` for the AD user `svcPostgresProd1`:

```
setspn -A postgres/prod1.example.local svcPostgresProd1
```

You can see the SPN if Advanced Features are set in the Active Directory Users and Computers view. Find `servicePrincipalName` in the Attribute Editor tab and edit it if necessary.
The next step is to create a Kerberos keytab file.

You can select a specific cryptography method if your security requirements require it, but in the absence of that, it is best to get it to work first and then remove any cryptography methods you do not want.

As an AD Domain Administrator, you can list the types of encryption that your AD domain controller supports with this `ktpass` command:

```
ktpass /?
```

As an AD Domain Administrator, you can run the `ktpass` command to create a keytab file. This example command creates the file `svcPostgresProd1.keytab` with this information:

- **ServicePrincipalName (SPN):** `postgres/prod1.example.local@EXAMPLE.LOCAL`
- **AD user:** `svcPostgresProd1`
- **Encryption methods:** `ALL available on AD`
- **Principal Type:** `KR85_NT_PRINCIPAL`

```
ktpass -out svcPostgresProd1.keytab -princ postgres/prod1.example.local@EXAMPLE.LOCAL -mapUser svcPostgresProd1 -pass your_password -crypto all -ptype KR85_NT_PRINCIPAL
```

**Note:** The AD domain `@EXAMPLE.LOCAL` is appended to the SPN.
You copy the keytab file `svcPostgresProd1.keytab` to the Greenplum Database master host.

As an alternative to running `ktpass` as an AD Domain Administrator, you can run the Java `ktab.exe` utility to generate a keytab file if you have the Java JRE installed on your desktop. When you enter the password using either `ktpass` or `ktab.exe`, the password will be visible on the screen as a command line argument.

This example command creates the keytab file `svcPostgresProd1.keytab`.

```
"c:\Program Files\Java\jre1.8.0_77\bin\ktab.exe" -a svcPostgresprod1 -k svcPostgresProd1.keytab
Password for svcPostgresprod1@EXAMPLE.LOCAL: your_password
Done!
Service key for svcPostgresprod1 is saved in svcPostgresProd1.keytab
```

**Note:** If you use AES256-CTS-HMAC-SHA1-96 encryption, you must download and install the Java extension *Java Cryptography Extension (JCE) Unlimited Strength Jurisdiction Policy Files for JDK/JRE* from Oracle.

**Setting Up Greenplum Database for Active Directory**

These instructions assume that the Kerberos workstation utilities `krb5-workstation` are installed on the Greenplum Database master host.

Update `/etc/krb5.conf` with the AD domain name details and the location of an AD domain controller. This is an example configuration.

```
[logging]
    default = FILE:/var/log/krb5libs.log
    kdc = FILE:/var/log/krb5kdc.log
    admin_server = FILE:/var/log/kadmind.log

[libdefaults]
    default_realm = EXAMPLE.LOCAL
    dns_lookup_realm = false
    dns_lookup_kdc = false
    ticket_lifetime = 24h
    renew_lifetime = 7d
    forwardable = true

[realms]
    EXAMPLE.LOCAL = {
        kdc = bocdc.example.local
        admin_server = bocdc.example.local
    }

[domain_realm]
    .example.local = EXAMPLE.LOCAL
    example.com = EXAMPLE.LOCAL
```

Copy the Kerberos keytab file that contains the AD user information to the Greenplum Database master directory. This example copies the `svcPostgresProd1.keytab` that was created in *Active Directory Setup*.

```
my $svcPostgresProd1.keytab $MASTER_DATA_DIRECTORY
chown gpadmin:gpadmin $MASTER_DATA_DIRECTORY/svcPostgresProd1.keytab
chmod 600 $MASTER_DATA_DIRECTORY/svcPostgresProd1.keytab
```
Add this line as the last line in the Greenplum Database `pg_hba.conf` file. This line configures Greenplum Database authentication to use Active Directory for authentication for connection any attempt that is not matched by a previous line.

```
host all all 0.0.0.0/0 gss include_realm=0
```

Update the Greenplum Database `postgresql.conf` file with the location details for the keytab file and the principal name to use. The fully qualified host name and the default realm from `/etc/krb5.conf` forms the full service principal name.

```
krb_server_keyfile = '/data/master/gpseg-1/svcPostgresProd1.keytab'
krb_srvname = 'postgres'
```

Create a database role for the AD user. This example logs into the default database and runs the `CREATE ROLE` command. The user `dev1` was the user specified when creating the keytab file in *Active Directory Setup*.

```
psql
create role dev1 with login superuser;
```

Restart the database to use the updated authentication information:

```
gpstop -a
gpstart
```

**Note:** The Greenplum Database libraries might conflict with the Kerberos workstation utilities such as `kinit`. If you are using these utilities on the Greenplum Database master, you can either run a `gpadmin` shell that does not source the `$GPHOME/greenplum_path.sh` script, or unset the `LD_LIBRARY_PATH` environment variable similar to this example:

```
unset LD_LIBRARY_PATH
kinit
source $GPHOME/greenplum_path.sh
```

Confirm Greenplum Database access with Kerberos authentication:

```
kinit dev1
psql -h prod1.example.local -U dev1
```

**Single Sign-On Examples**

These single sign-on examples that use AD and Kerberos assume that the AD user `dev1` configured for single sign-on is logged into the Windows desktop.

This example configures Aginity Workbench for Greenplum Database. When using single sign-on, you enable Use Integrated Security.
This example configures an ODBC source. When setting up the ODBC source, do not enter a User Name or Password. This DSN can then be used by applications as an ODBC data source.
You can use the DSN `testdata` with an R client. This example configures R to access the DSN.

```r
library("RODBC")
conn <- odbcDriverConnect("testdata")
sql <- "select * from public.data1"
my_data <- sqlQuery(conn,sql)
print(my_data)
```

**Issues and Possible Solutions for Active Directory**

- Kerberos tickets contain a version number that must match the version number for AD.
  
  To display the version number in your keytab file, use the `klist -ket` command. For example:

  ```bash
  klist -ket svcPostgresProd1.keytab
  ```

  To get the corresponding value from AD domain controller, run this command as an AD Administrator:

  ```bash
  kvno postgres/prod1.example.local@EXAMPLE.LOCAL
  ```

- This login error can occur when there is a mismatch between the Windows ID and the Greenplum Database user role ID. This log file entry shows the login error. A user `dev22` is attempting to login from a Windows desktop where the user is logged in as a different Windows user.

The error can also occur when the user can be authenticated, but does not have a Greenplum Database user role.

Ensure that the user is using the correct Windows ID and that a Greenplum Database user role is configured for the user ID.

• This error can occur when the Kerberos keytab does not contain a matching cryptographic type to a client attempting to connect.

```sql
psql -h 'hostname' postgres
pgsql: GSSAPI continuation error: Unspecified GSS failure. Minor code may provide more information
GSSAPI continuation error: Key version is not available
```

The resolution is to add the additional encryption types to the keytab using `ktutil` or recreating the postgres keytab with all crypto systems from AD.

### Managing Roles and Privileges

The Greenplum Database authorization mechanism stores roles and permissions to access database objects in the database and is administered using SQL statements or command-line utilities.

Greenplum Database manages database access permissions using roles. The concept of roles subsumes the concepts of users and groups. A role can be a database user, a group, or both. Roles can own database objects (for example, tables) and can assign privileges on those objects to other roles to control access to the objects. Roles can be members of other roles, thus a member role can inherit the object privileges of its parent role.

Every Greenplum Database system contains a set of database roles (users and groups). Those roles are separate from the users and groups managed by the operating system on which the server runs. However, for convenience you may want to maintain a relationship between operating system user names and Greenplum Database role names, since many of the client applications use the current operating system user name as the default.

In Greenplum Database, users log in and connect through the master instance, which then verifies their role and access privileges. The master then issues commands to the segment instances behind the scenes as the currently logged in role.

Roles are defined at the system level, meaning they are valid for all databases in the system.

In order to bootstrap the Greenplum Database system, a freshly initialized system always contains one predefined superuser role (also referred to as the system user). This role will have the same name as the operating system user that initialized the Greenplum Database system. Customarily, this role is named `gpadmin`. In order to create more roles you first have to connect as this initial role.

### Security Best Practices for Roles and Privileges

**Secure the gpadmin system user.** Greenplum requires a UNIX user id to install and initialize the Greenplum Database system. This system user is referred to as `gpadmin` in the Greenplum documentation. This `gpadmin` user is the default database superuser in Greenplum Database, as well as the file system owner of the Greenplum installation and its underlying data files. This default administrator account is fundamental to the design of Greenplum Database. The system cannot run without it, and there is no way to limit the access of this `gpadmin` user id. Use roles to manage who has access to the database for specific purposes. You should only use the `gpadmin` account for system maintenance tasks such as expansion and upgrade. Anyone who logs on to a Greenplum host as this user id can read, alter or delete any data; including system catalog data and database access rights. Therefore, it is very important to secure the `gpadmin` user id and only provide access to essential system administrators. Administrators should only log in to Greenplum as `gpadmin` when performing
certain system maintenance tasks (such as upgrade or expansion). Database users should never log on as gpadmin, and ETL or production workloads should never run as gpadmin.

• **Assign a distinct role to each user that logs in.** For logging and auditing purposes, each user that is allowed to log in to Greenplum Database should be given their own database role. For applications or web services, consider creating a distinct role for each application or service. See Creating New Roles (Users).

• **Use groups to manage access privileges.** See Role Membership.

• **Limit users who have the SUPERUSER role attribute.** Roles that are superusers bypass all access privilege checks in Greenplum Database, as well as resource queuing. Only system administrators should be given superuser rights. See Altering Role Attributes.

### Creating New Roles (Users)

A user-level role is considered to be a database role that can log in to the database and initiate a database session. Therefore, when you create a new user-level role using the `CREATE ROLE` command, you must specify the `LOGIN` privilege. For example:

```sql
=# CREATE ROLE jsmith WITH LOGIN;
```

A database role may have a number of attributes that define what sort of tasks that role can perform in the database. You can set these attributes when you create the role, or later using the `ALTER ROLE` command. See Table 36: Role Attributes for a description of the role attributes you can set.

### Altering Role Attributes

A database role may have a number of attributes that define what sort of tasks that role can perform in the database.

#### Table 36: Role Attributes

<table>
<thead>
<tr>
<th>Attributes</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SUPERUSER</td>
<td>NOSUPERUSER</td>
</tr>
<tr>
<td>CREATEDB</td>
<td>NOCREATEDB</td>
</tr>
<tr>
<td>CREATEROLE</td>
<td>NOCREATEROLE</td>
</tr>
<tr>
<td>INHERIT</td>
<td>NOINHERIT</td>
</tr>
<tr>
<td>LOGIN</td>
<td>NOLOGIN</td>
</tr>
<tr>
<td>CONNECTION LIMIT connlimit</td>
<td>If role can log in, this specifies how many concurrent connections the role can make. -1 (the default) means no limit.</td>
</tr>
<tr>
<td>Attributes</td>
<td>Description</td>
</tr>
<tr>
<td>--------------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>CREATEEXTABLE</td>
<td>NOCREATEEXTABLE</td>
</tr>
<tr>
<td>PASSWORD 'password'</td>
<td>Sets the role’s password. If you do not plan to use password authentication you can omit this option. If no password is specified, the password will be set to null and password authentication will always fail for that user. A null password can optionally be written explicitly as PASSWORD NULL.</td>
</tr>
<tr>
<td>ENCRYPTED</td>
<td>UNENCRYPTED</td>
</tr>
<tr>
<td>VALID UNTIL 'timestamp'</td>
<td>Sets a date and time after which the role’s password is no longer valid. If omitted the password will be valid for all time.</td>
</tr>
<tr>
<td>RESOURCE QUEUE queue_name</td>
<td>Assigns the role to the named resource queue for workload management. Any statement that role issues is then subject to the resource queue’s limits. Note that the RESOURCE QUEUE attribute is not inherited; it must be set on each user-level (LOGIN) role.</td>
</tr>
<tr>
<td>DENY (deny_interval</td>
<td>deny_point)</td>
</tr>
</tbody>
</table>

You can set these attributes when you create the role, or later using the ALTER ROLE command. For example:

```sql
=# ALTER ROLE jsmith WITH PASSWORD 'passwd123';
=# ALTER ROLE admin VALID UNTIL 'infinity';
=# ALTER ROLE jsmith LOGIN;
=# ALTER ROLE jsmith RESOURCE QUEUE adhoc;
=# ALTER ROLE jsmith DENY DAY 'Sunday';
```

A role can also have role-specific defaults for many of the server configuration settings. For example, to set the default schema search path for a role:

```sql
=# ALTER ROLE admin SET search_path TO myschema, public;
```

**Role Membership**

It is frequently convenient to group users together to ease management of object privileges: that way, privileges can be granted to, or revoked from, a group as a whole. In Greenplum Database this is done by creating a role that represents the group, and then granting membership in the group role to individual user roles.
Use the `CREATE ROLE` SQL command to create a new group role. For example:

```sql
=# CREATE ROLE admin CREATEROLE CREATEDB;
```

Once the group role exists, you can add and remove members (user roles) using the `GRANT` and `REVOKE` commands. For example:

```sql
=# GRANT admin TO john, sally;
=# REVOKE admin FROM bob;
```

For managing object privileges, you would then grant the appropriate permissions to the group-level role only (see Table 37: Object Privileges). The member user roles then inherit the object privileges of the group role. For example:

```sql
=# GRANT ALL ON TABLE mytable TO admin;
=# GRANT ALL ON SCHEMA myschema TO admin;
=# GRANT ALL ON DATABASE mydb TO admin;
```

The role attributes `LOGIN`, `SUPERUSER`, `CREATEDB`, `CREATEROLE`, `CREATEEXTTABLE`, and `RESOURCE QUEUE` are never inherited as ordinary privileges on database objects are. User members must actually `SET ROLE` to a specific role having one of these attributes in order to make use of the attribute. In the above example, we gave `CREATEDB` and `CREATEROLE` to the `admin` role. If `sally` is a member of `admin`, she could issue the following command to assume the role attributes of the parent role:

```sql
=> SET ROLE admin;
```

### Managing Object Privileges

When an object (table, view, sequence, database, function, language, schema, or tablespace) is created, it is assigned an owner. The owner is normally the role that executed the creation statement. For most kinds of objects, the initial state is that only the owner (or a superuser) can do anything with the object. To allow other roles to use it, privileges must be granted. Greenplum Database supports the following privileges for each object type:

#### Table 37: Object Privileges

<table>
<thead>
<tr>
<th>Object Type</th>
<th>Privileges</th>
</tr>
</thead>
<tbody>
<tr>
<td>Tables, Views, Sequences</td>
<td>SELECT, INSERT, UPDATE, DELETE, RULE, ALL</td>
</tr>
<tr>
<td>External Tables</td>
<td>SELECT, RULE, ALL</td>
</tr>
</tbody>
</table>
### Object Type

<table>
<thead>
<tr>
<th></th>
<th>Privileges</th>
</tr>
</thead>
<tbody>
<tr>
<td>Databases</td>
<td>CONNECT</td>
</tr>
<tr>
<td></td>
<td>CREATE</td>
</tr>
<tr>
<td></td>
<td>TEMPORARY</td>
</tr>
<tr>
<td>Functions</td>
<td>EXECUTE</td>
</tr>
<tr>
<td>Procedural Languages</td>
<td>USAGE</td>
</tr>
<tr>
<td>Schemas</td>
<td>CREATE</td>
</tr>
<tr>
<td></td>
<td>USAGE</td>
</tr>
<tr>
<td></td>
<td>ALL</td>
</tr>
<tr>
<td>Custom Protocol</td>
<td>SELECT</td>
</tr>
<tr>
<td></td>
<td>INSERT</td>
</tr>
<tr>
<td></td>
<td>UPDATE</td>
</tr>
<tr>
<td></td>
<td>DELETE</td>
</tr>
<tr>
<td></td>
<td>RULE</td>
</tr>
<tr>
<td></td>
<td>ALL</td>
</tr>
</tbody>
</table>

**Note:** You must grant privileges for each object individually. For example, granting ALL on a database does not grant full access to the objects within that database. It only grants all of the database-level privileges (CONNECT, CREATE, TEMPORARY) to the database itself.

Use the GRANT SQL command to give a specified role privileges on an object. For example, to grant the role named jsmith insert privileges on the table named mytable:

```
=# GRANT INSERT ON mytable TO jsmith;
```

Similarly, to grant jsmith select privileges only to the column named col1 in the table named table2:

```
=# GRANT SELECT (col1) on TABLE table2 TO jsmith;
```

To revoke privileges, use the REVOKE command. For example:

```
=# REVOKE ALL PRIVILEGES ON mytable FROM jsmith;
```

You can also use the DROP OWNED and REASSIGN OWNED commands for managing objects owned by deprecated roles (Note: only an object's owner or a superuser can drop an object or reassign ownership). For example:

```
=# REASSIGN OWNED BY sally TO bob;
=# DROP OWNED BY visitor;
```

**Simulating Row Level Access Control**

Greenplum Database does not support row-level access or row-level, labeled security. You can simulate row-level access by using views to restrict the rows that are selected. You can simulate row-level labels by adding an extra column to the table to store sensitivity information, and then using views to control row-level access based on this column. You can then grant roles access to the views rather than to the base table.
Encrypting Data

Greenplum Database is installed with an optional module of encryption/decryption functions called pgcrypto. The pgcrypto functions allow database administrators to store certain columns of data in encrypted form. This adds an extra layer of protection for sensitive data, as data stored in Greenplum Database in encrypted form cannot be read by anyone who does not have the encryption key, nor can it be read directly from the disks.

**Note:** The pgcrypto functions run inside the database server, which means that all the data and passwords move between pgcrypto and the client application in clear-text. For optimal security, consider also using SSL connections between the client and the Greenplum master server.

To use pgcrypto functions, register the pgcrypto extension in each database in which you want to use the functions. For example:

```sql
$ psql -d testdb -c "CREATE EXTENSION pgcrypto"
```

See pgcrypto in the PostgreSQL documentation for more information about individual functions.

Protecting Passwords in Greenplum Database

In its default configuration, Greenplum Database saves MD5 hashes of login users' passwords in the pg_authid system catalog rather than saving clear text passwords. Anyone who is able to view the pg_authid table can see hash strings, but no passwords. This also ensures that passwords are obscured when the database is dumped to backup files.

The hash function executes when the password is set by using any of the following commands:

- `CREATE USER name WITH ENCRYPTED PASSWORD 'password'`
- `CREATE ROLE name WITH LOGIN ENCRYPTED PASSWORD 'password'`
- `ALTER USER name WITH ENCRYPTED PASSWORD 'password'`
- `ALTER ROLE name WITH ENCRYPTED PASSWORD 'password'`

The `ENCRYPTED` keyword may be omitted when the `password_encryption` system configuration parameter is `on`, which is the default value. The `password_encryption` configuration parameter determines whether clear text or hashed passwords are saved when the `ENCRYPTED` or `UNENCRYPTED` keyword is not present in the command.

**Note:** The SQL command syntax and `password_encryption` configuration variable include the term `encrypt`, but the passwords are not technically encrypted. They are `hashed` and therefore cannot be decrypted.

The hash is calculated on the concatenated clear text password and role name. The MD5 hash produces a 32-byte hexadecimal string prefixed with the characters `md5`. The hashed password is saved in the rolpassword column of the pg_authid system table.

Although it is not recommended, passwords may be saved in clear text in the database by including the `UNENCRYPTED` keyword in the command or by setting the `password_encryption` configuration variable to `off`. Note that changing the configuration value has no effect on existing passwords, only newly created or updated passwords.

To set `password_encryption` globally, execute these commands in a shell as the `gpadmin` user:

```bash
$ gpconfig -c password_encryption -v 'off'
$ gpstop -u
```

To set `password_encryption` in a session, use the SQL `SET` command:

```sql
=# SET password_encryption = 'on';
```
Passwords may be hashed using the SHA-256 hash algorithm instead of the default MD5 hash algorithm. The algorithm produces a 64-byte hexadecimal string prefixed with the characters `sha256`.

**Note:**

Although SHA-256 uses a stronger cryptographic algorithm and produces a longer hash string, it cannot be used with the MD5 authentication method. To use SHA-256 password hashing the authentication method must be set to `password` in the `pg_hba.conf` configuration file so that clear text passwords are sent to Greenplum Database. Because clear text passwords are sent over the network, it is very important to use SSL for client connections when you use SHA-256. The default `md5` authentication method, on the other hand, hashes the password twice before sending it to Greenplum Database, once on the password and role name and then again with a salt value shared between the client and server, so the clear text password is never sent on the network.

To enable SHA-256 hashing, change the `password_hash_algorithm` configuration parameter from its default value, `md5`, to `sha-256`. The parameter can be set either globally or at the session level. To set `password_hash_algorithm` globally, execute these commands in a shell as the `gpadmin` user:

```bash
$ gpconfig -c password_hash_algorithm -v 'sha-256'
$ gpstop -u
```

To set `password_hash_algorithm` in a session, use the SQL `SET` command:

```sql
=# SET password_hash_algorithm = 'sha-256';
```

**Time-based Authentication**

Greenplum Database enables the administrator to restrict access to certain times by role. Use the `CREATE ROLE` or `ALTER ROLE` commands to specify time-based constraints.

For details, refer to the *Greenplum Database Security Configuration Guide*. 
Defining Database Objects

This section covers data definition language (DDL) in Greenplum Database and how to create and manage database objects.

Creating objects in a Greenplum Database includes making up-front choices about data distribution, storage options, data loading, and other Greenplum features that will affect the ongoing performance of your database system. Understanding the options that are available and how the database will be used will help you make the right decisions.

Most of the advanced Greenplum features are enabled with extensions to the SQL `CREATE` DDL statements.

Creating and Managing Databases

A Greenplum Database system is a single instance of Greenplum Database. There can be several separate Greenplum Database systems installed, but usually just one is selected by environment variable settings. See your Greenplum administrator for details.

There can be multiple databases in a Greenplum Database system. This is different from some database management systems (such as Oracle) where the database instance is the database. Although you can create many databases in a Greenplum system, client programs can connect to and access only one database at a time — you cannot cross-query between databases.

About Template and Default Databases

Greenplum Database provides some template databases and a default database, `template1`, `template0`, and `postgres`.

By default, each new database you create is based on a `template` database. Greenplum Database uses `template1` to create databases unless you specify another template. Creating objects in `template1` is not recommended. The objects will be in every database you create using the default template database.

Greenplum Database uses another database template, `template0`, internally. Do not drop or modify `template0`. You can use `template0` to create a completely clean database containing only the standard objects predefined by Greenplum Database at initialization.

You can use the `postgres` database to connect to Greenplum Database for the first time. Greenplum Database uses `postgres` as the default database for administrative connections. For example, `postgres` is used by startup processes, the Global Deadlock Detector process, and the FTS (Fault Tolerance Server) process for catalog access.

Creating a Database

The `CREATE` DATABASE command creates a new database. For example:

```
=> CREATE DATABASE new_dbname;
```

To create a database, you must have privileges to create a database or be a Greenplum Database superuser. If you do not have the correct privileges, you cannot create a database. Contact your Greenplum Database administrator to either give you the necessary privilege or to create a database for you.
You can also use the client program `createdb` to create a database. For example, running the following command in a command line terminal connects to Greenplum Database using the provided host name and port and creates a database named `mydatabase`:

```bash
$ createdb -h masterhost -p 5432 mydatabase
```

The host name and port must match the host name and port of the installed Greenplum Database system. Some objects, such as roles, are shared by all the databases in a Greenplum Database system. Other objects, such as tables that you create, are known only in the database in which you create them.

**Warning:** The `CREATE DATABASE` command is not transactional.

**Cloning a Database**

By default, a new database is created by cloning the standard system database template, `template1`. Any database can be used as a template when creating a new database, thereby providing the capability to 'clone' or copy an existing database and all objects and data within that database. For example:

```sql
=> CREATE DATABASE new_dbname TEMPLATE old_dbname;
```

**Creating a Database with a Different Owner**

Another database owner can be assigned when a database is created:

```sql
=> CREATE DATABASE new_dbname WITH owner=new_user;
```

**Viewing the List of Databases**

If you are working in the `psql` client program, you can use the `\l` meta-command to show the list of databases and templates in your Greenplum Database system. If using another client program and you are a superuser, you can query the list of databases from the `pg_database` system catalog table. For example:

```sql
=> SELECT datname from pg_database;
```

**Altering a Database**

The `ALTER DATABASE` command changes database attributes such as owner, name, or default configuration attributes. For example, the following command alters a database by setting its default schema search path (the `search_path` configuration parameter):

```sql
=> ALTER DATABASE mydatabase SET search_path TO myschema, public, pg_catalog;
```

To alter a database, you must be the owner of the database or a superuser.

**Dropping a Database**

The `DROP DATABASE` command drops (or deletes) a database. It removes the system catalog entries for the database and deletes the database directory on disk that contains the data. You must be the database owner or a superuser to drop a database, and you cannot drop a database while you or anyone else is connected to it. Connect to `postgres` (or another database) before dropping a database. For example:

```sql
=> \c postgres
=> DROP DATABASE mydatabase;
```
You can also use the client program `dropdb` to drop a database. For example, the following command connects to Greenplum Database using the provided host name and port and drops the database `mydatabase`:

```
$ dropdb -h masterhost -p 5432 mydatabase
```

**Warning**: Dropping a database cannot be undone. The `DROP DATABASE` command is not transactional.

### Creating and Managing Tablespaces

Tablespaces allow database administrators to have multiple file systems per machine and decide how to best use physical storage to store database objects. Tablespaces allow you to assign different storage for frequently and infrequently used database objects or to control the I/O performance on certain database objects. For example, place frequently-used tables on file systems that use high performance solid-state drives (SSD), and place other tables on standard hard drives.

A tablespace requires a host file system location to store its database files. In Greenplum Database, the file system location must exist on all hosts including the hosts running the master, standby master, each primary segment, and each mirror segment.

A tablespace is Greenplum Database system object (a global object), you can use a tablespace from any database if you have appropriate privileges.

#### Creating a Tablespace

The `CREATE TABLESPACE` command defines a tablespace. For example:

```
CREATE TABLESPACE fastspace LOCATION '/fastdisk/gpdb';
```

Database superusers define tablespaces and grant access to database users with the `GRANT CREATE` command. For example:

```
GRANT CREATE ON TABLESPACE fastspace TO admin;
```

#### Using a Tablespace to Store Database Objects

Users with the `CREATE` privilege on a tablespace can create database objects in that tablespace, such as tables, indexes, and databases. The command is:

```
CREATE TABLE tablename(options) TABLESPACE spacename
```

For example, the following command creates a table in the tablespace `space1`:

```
CREATE TABLE foo(i int) TABLESPACE space1;
```

You can also use the `default_tablespace` parameter to specify the default tablespace for `CREATE TABLE` and `CREATE INDEX` commands that do not specify a tablespace:

```
SET default_tablespace = space1;
CREATE TABLE foo(i int);
```

There is also the `temp_tablespaces` configuration parameter, which determines the placement of temporary tables and indexes, as well as temporary files that are used for purposes such as sorting large data sets. This can be a comma-separate list of tablesnapce names, rather than only one, so that the load associated with temporary objects can be spread over multiple tablespaces. A random member of the list is picked each time a temporary object is to be created.
The tablespace associated with a database stores that database's system catalogs, temporary files created by server processes using that database, and is the default tablespace selected for tables and indexes created within the database, if no TABLESPACE is specified when the objects are created. If you do not specify a tablespace when you create a database, the database uses the same tablespace used by its template database.

You can use a tablespace from any database in the Greenplum Database system if you have appropriate privileges.

**Viewing Existing Tablespaces**

Every Greenplum Database system has the following default tablespaces.

- `pg_global` for shared system catalogs.
- `pg_default`, the default tablespace. Used by the `template1` and `template0` databases.

These tablespaces use the default system location, the data directory locations created at system initialization.

To see tablespace information, use the `pg_tablespace` catalog table to get the object ID (OID) of the tablespace and then use `gp_tablespace_location()` function to display the tablespace directories. This is an example that lists one user-defined tablespace, `myspace`:

```sql
SELECT oid, * FROM pg_tablespace ;

<table>
<thead>
<tr>
<th>oid</th>
<th>spcname</th>
<th>spcowner</th>
<th>spcacl</th>
<th>spcoptions</th>
</tr>
</thead>
<tbody>
<tr>
<td>1663</td>
<td>pg_default</td>
<td>10</td>
<td></td>
<td></td>
</tr>
<tr>
<td>1664</td>
<td>pg_global</td>
<td>10</td>
<td></td>
<td></td>
</tr>
<tr>
<td>16391</td>
<td>myspace</td>
<td>10</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
```

The OID for the tablespace `myspace` is 16391. Run `gp_tablespace_location()` to display the tablespace locations for a system that consists of two segment instances and the master.

```sql
# SELECT * FROM gp_tablespace_location(16391);

<table>
<thead>
<tr>
<th>gp_segment_id</th>
<th>tblspc_loc</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>/data/mytblspace</td>
</tr>
<tr>
<td>1</td>
<td>/data/mytblspace</td>
</tr>
<tr>
<td>-1</td>
<td>/data/mytblspace</td>
</tr>
</tbody>
</table>
```

This query uses `gp_tablespace_location()` the `gp_segment_configuration` catalog table to display segment instance information with the file system location for the `myspace` tablespace.

```sql
WITH spc AS (SELECT * FROM gp_tablespace_location(16391))
SELECT seg.role, spc.gp_segment_id as seg_id, seg.hostname, seg.datadir, tblspc_loc
FROM spc, gp_segment_configuration AS seg
WHERE spc.gp_segment_id = seg.content ORDER BY seg_id;

<table>
<thead>
<tr>
<th>role</th>
<th>seg_id</th>
<th>hostname</th>
<th>datadir</th>
<th>tblspc_loc</th>
</tr>
</thead>
<tbody>
<tr>
<td>p</td>
<td>-1</td>
<td>testhost</td>
<td>/data/master/gpseg-1</td>
<td>/data/mytblspace</td>
</tr>
<tr>
<td>p</td>
<td>0</td>
<td>testhost</td>
<td>/data/data1/gpseg0</td>
<td>/data/mytblspace</td>
</tr>
<tr>
<td>p</td>
<td>1</td>
<td>testhost</td>
<td>/data/data2/gpseg1</td>
<td>/data/mytblspace</td>
</tr>
</tbody>
</table>
```

This is information for a test system that consists of two segment instances and the master on a single host.
Dropping Tablespaces
To drop a tablespace, you must be the tablespace owner or a superuser. You cannot drop a tablespace until all objects in all databases using the tablespace are removed.

The `DROP TABLESPACE` command removes an empty tablespace.

Note: You cannot drop a tablespace if it is not empty or if it stores temporary or transaction files.

Moving the Location of Temporary or Transaction Files
You can move temporary or transaction files to a specific tablespace to improve database performance when running queries, creating backups, and to store data more sequentially.

The Greenplum Database server configuration parameter `temp_tablespaces` controls the location for both temporary tables and temporary spill files for hash aggregate and hash join queries. (Temporary files for purposes such as sorting large data sets are stored with general segment data in `<data_dir>/seg_ID/base/pgsql_tmp`.)

`temp_tablespaces` specifies tablespaces in which to create temporary objects (temp tables and indexes on temp tables) when a `CREATE` command does not explicitly specify a tablespace.

Also note the following information about temporary or transaction files:

- You can dedicate only one tablespace for temporary or transaction files, although you can use the same tablespace to store other types of files.
- You cannot drop a tablespace if it used by temporary files.

Creating and Managing Schemas
Schemas logically organize objects and data in a database. Schemas allow you to have more than one object (such as tables) with the same name in the database without conflict if the objects are in different schemas.

The Default "Public" Schema
Every database has a default schema named `public`. If you do not create any schemas, objects are created in the `public` schema. All database roles (users) have `CREATE` and `USAGE` privileges in the `public` schema. When you create a schema, you grant privileges to your users to allow access to the schema.

Creating a Schema
Use the `CREATE SCHEMA` command to create a new schema. For example:

```
=> CREATE SCHEMA myschema;
```

To create or access objects in a schema, write a qualified name consisting of the schema name and table name separated by a period. For example:

```
myschema.table
```

See `Schema Search Paths` for information about accessing a schema.

You can create a schema owned by someone else, for example, to restrict the activities of your users to well-defined namespaces. The syntax is:

```
=> CREATE SCHEMA schemaname AUTHORIZATION username;
```
Schema Search Paths
To specify an object's location in a database, use the schema-qualified name. For example:

```sql
=> SELECT * FROM myschema.mytable;
```

You can set the `search_path` configuration parameter to specify the order in which to search the available schemas for objects. The schema listed first in the search path becomes the default schema. If a schema is not specified, objects are created in the default schema.

Setting the Schema Search Path
The `search_path` configuration parameter sets the schema search order. The `ALTER DATABASE` command sets the search path. For example:

```sql
=> ALTER DATABASE mydatabase SET search_path TO myschema, public, pg_catalog;
```

You can also set `search_path` for a particular role (user) using the `ALTER ROLE` command. For example:

```sql
=> ALTER ROLE sally SET search_path TO myschema, public, pg_catalog;
```

Viewing the Current Schema
Use the `current_schema()` function to view the current schema. For example:

```sql
=> SELECT current_schema();
```

Use the `SHOW` command to view the current search path. For example:

```sql
=> SHOW search_path;
```

Dropping a Schema
Use the `DROP SCHEMA` command to drop (delete) a schema. For example:

```sql
=> DROP SCHEMA myschema;
```

By default, the schema must be empty before you can drop it. To drop a schema and all of its objects (tables, data, functions, and so on) use:

```sql
=> DROP SCHEMA myschema CASCADE;
```

System Schemas
The following system-level schemas exist in every database:

- `pg_catalog` contains the system catalog tables, built-in data types, functions, and operators. It is always part of the schema search path, even if it is not explicitly named in the search path.
- `information_schema` consists of a standardized set of views that contain information about the objects in the database. These views get system information from the system catalog tables in a standardized way.
- `pg_toast` stores large objects such as records that exceed the page size. This schema is used internally by the Greenplum Database system.
• pg_bitmapindex stores bitmap index objects such as lists of values. This schema is used internally by the Greenplum Database system.
• pg_aoseg stores append-optimized table objects. This schema is used internally by the Greenplum Database system.
• gp_toolkit is an administrative schema that contains external tables, views, and functions that you can access with SQL commands. All database users can access gp_toolkit to view and query the system log files and other system metrics.

Creating and Managing Tables

Greenplum Database tables are similar to tables in any relational database, except that table rows are distributed across the different segments in the system. When you create a table, you specify the table’s distribution policy.

Creating a Table

The CREATE TABLE command creates a table and defines its structure. When you create a table, you define:

• The columns of the table and their associated data types. See Choosing Column Data Types.
• Any table or column constraints to limit the data that a column or table can contain. See Setting Table and Column Constraints.
• The distribution policy of the table, which determines how Greenplum Database divides data across the segments. See Choosing the Table Distribution Policy.
• The way the table is stored on disk. See Choosing the Table Storage Model.
• The table partitioning strategy for large tables. See Creating and Managing Databases.

Choosing Column Data Types

The data type of a column determines the types of data values the column can contain. Choose the data type that uses the least possible space but can still accommodate your data and that best constrains the data. For example, use character data types for strings, date or timestamp data types for dates, and numeric data types for numbers.

For table columns that contain textual data, specify the data type VARCHAR or TEXT. Specifying the data type CHAR is not recommended. In Greenplum Database, the data types VARCHAR or TEXT handle padding added to the data (space characters added after the last non-space character) as significant characters, the data type CHAR does not. For information on the character data types, see the CREATE TABLE command in the Greenplum Database Reference Guide.

Use the smallest numeric data type that will accommodate your numeric data and allow for future expansion. For example, using BIGINT for data that fits in INT or SMALLINT wastes storage space. If you expect that your data values will expand over time, consider that changing from a smaller datatype to a larger datatypetype after loading large amounts of data is costly. For example, if your current data values fit in a SMALLINT but it is likely that the values will expand, INT is the better long-term choice.

Use the same data types for columns that you plan to use in cross-table joins. Cross-table joins usually use the primary key in one table and a foreign key in the other table. When the data types are different, the database must convert one of them so that the data values can be compared correctly, which adds unnecessary overhead.

Greenplum Database has a rich set of native data types available to users. See the Greenplum Database Reference Guide for information about the built-in data types.

Setting Table and Column Constraints

You can define constraints on columns and tables to restrict the data in your tables. Greenplum Database support for constraints is the same as PostgreSQL with some limitations, including:
• **CHECK** constraints can refer only to the table on which they are defined.
• **UNIQUE** and **PRIMARY KEY** constraints must be compatible with their table#s distribution key and partitioning key, if any.
  
  **Note:** **UNIQUE** and **PRIMARY KEY** constraints are not allowed on append-optimized tables because the **UNIQUE** indexes that are created by the constraints are not allowed on append-optimized tables.

• **FOREIGN KEY** constraints are allowed, but not enforced.
• Constraints that you define on partitioned tables apply to the partitioned table as a whole. You cannot define constraints on the individual parts of the table.

**Check Constraints**

Check constraints allow you to specify that the value in a certain column must satisfy a Boolean (truth-value) expression. For example, to require positive product prices:

```sql
=> CREATE TABLE products
    ( product_no integer,
      name text,
      price numeric CHECK (price > 0) );
```

**Not-Null Constraints**

Not-null constraints specify that a column must not assume the null value. A not-null constraint is always written as a column constraint. For example:

```sql
=> CREATE TABLE products
    ( product_no integer NOT NULL,
      name text NOT NULL,
      price numeric );
```

**Unique Constraints**

Unique constraints ensure that the data contained in a column or a group of columns is unique with respect to all the rows in the table. The table must be hash-distributed or replicated (not DISTRIBUTED RANDOMLY). If the table is hash-distributed, the constraint columns must be the same as (or a superset of) the table’s distribution key columns. For example:

```sql
=> CREATE TABLE products
    ( product_no integer UNIQUE,
      name text,
      price numeric)
  DISTRIBUTED BY (product_no);
```

**Primary Keys**

A primary key constraint is a combination of a **UNIQUE** constraint and a **NOT NULL** constraint. The table must be hash-distributed (not DISTRIBUTED RANDOMLY), and the primary key columns must be the same as (or a superset of) the table’s distribution key columns. If a table has a primary key, this column (or group of columns) is chosen as the distribution key for the table by default. For example:

```sql
=> CREATE TABLE products
    ( product_no integer PRIMARY KEY,
      name text,
      price numeric)
  DISTRIBUTED BY (product_no);
```

**Foreign Keys**

Foreign keys are not supported. You can declare them, but referential integrity is not enforced.

Foreign key constraints specify that the values in a column or a group of columns must match the values appearing in some row of another table to maintain referential integrity between two related tables. Referential integrity checks cannot be enforced between the distributed table segments of a Greenplum database.

**Choosing the Table Distribution Policy**

All Greenplum Database tables are distributed. When you create or alter a table, you optionally specify `DISTRIBUTED BY` (hash distribution), `DISTRIBUTED RANDOMLY` (round-robin distribution), or `DISTRIBUTED REPLICATED` (fully distributed) to determine the table row distribution.

*Note:* The Greenplum Database server configuration parameter `gp_create_table_random_default_distribution` controls the table distribution policy if the `DISTRIBUTED BY` clause is not specified when you create a table.

For information about the parameter, see "Server Configuration Parameters" of the *Greenplum Database Reference Guide*.

Consider the following points when deciding on a table distribution policy.

- **Even Data Distribution** — For the best possible performance, all segments should contain equal portions of data. If the data is unbalanced or skewed, the segments with more data must work harder to perform their portion of the query processing. Choose a distribution key that is unique for each record, such as the primary key.
- **Local and Distributed Operations** — Local operations are faster than distributed operations. Query processing is fastest if the work associated with join, sort, or aggregation operations is done locally, at the segment level. Work done at the system level requires distributing tuples across the segments, which is less efficient. When tables share a common distribution key, the work of joining or sorting on their shared distribution key columns is done locally. With a random distribution policy, local join operations are not an option.
- **Even Query Processing** — For best performance, all segments should handle an equal share of the query workload. Query workload can be skewed if a table's data distribution policy and the query predicates are not well matched. For example, suppose that a sales transactions table is distributed on the customer ID column (the distribution key). If a predicate in a query references a single customer ID, the query processing work is concentrated on just one segment.

The replicated table distribution policy (`DISTRIBUTED REPLICATED`) should be used only for small tables. Replicating data to every segment is costly in both storage and maintenance, and prohibitive for large fact tables. The primary use cases for replicated tables are to:

- remove restrictions on operations that user-defined functions can perform on segments, and
- improve query performance by making it unnecessary to broadcast frequently used tables to all segments.

*Note:* The hidden system columns (`ctid`, `cmin`, `cmax`, `xmin`, `xmax`, and `gp_segment_id`) cannot be referenced in user queries on replicated tables because they have no single, unambiguous value. Greenplum Database returns a `column does not exist` error for the query.

**Declaring Distribution Keys**

`CREATE TABLE`'s optional clauses `DISTRIBUTED BY`, `DISTRIBUTED RANDOMLY`, and `DISTRIBUTED REPLICATED` specify the distribution policy for a table. The default is a hash distribution policy that uses either the `PRIMARY KEY` (if the table has one) or the first column of the table as the distribution key. Columns with geometric or user-defined data types are not eligible as Greenplum Database distribution
key columns. If a table does not have an eligible column, Greenplum Database distributes the rows randomly or in round-robin fashion.

Replicated tables have no distribution key because every row is distributed to every Greenplum Database segment instance.

To ensure even distribution of hash-distributed data, choose a distribution key that is unique for each record. If that is not possible, choose DISTRIBUTED RANDOMLY. For example:

```sql
=> CREATE TABLE products
   (name varchar(40),
    prod_id integer,
    supplier_id integer)
   DISTRIBUTED BY (prod_id);
```

```sql
=> CREATE TABLE random_stuff
   (things text,
    doodads text,
    etc text)
   DISTRIBUTED RANDOMLY;
```

**Important:** If a primary key exists, it is the default distribution key for the table. If no primary key exists, but a unique key exists, this is the default distribution key for the table.

### Custom Distribution Key Hash Functions

The hash function used for hash distribution policy is defined by the hash operator class for the column's data type. As the default Greenplum Database uses the data type's default hash operator class, the same operator class used for hash joins and hash aggregates, which is suitable for most use cases. However, you can declare a non-default hash operator class in the DISTRIBUTED BY clause.

Using a custom hash operator class can be useful to support co-located joins on a different operator than the default equality operator (=).

### Example Custom Hash Operator Class

This example creates a custom hash operator class for the integer data type that is used to improve query performance. The operator class compares the absolute values of integers.

Create a function and an equality operator that returns true if the absolute values of two integers are equal.

```sql
CREATE FUNCTION abseq(int, int) RETURNS BOOL AS
$$
begin return abs($1) = abs($2); end;
$$ LANGUAGE plpgsql STRICT IMMUTABLE;

CREATE OPERATOR |=| (PROCEDURE = abseq,
    LEFTARG = int,
    RIGHTARG = int,
    COMMUTATOR = |=|,
    hashes, merges);
```

Now, create a hash function and operator class that uses the operator.

```sql
CREATE FUNCTION abshashfunc(int) RETURNS int AS
$$
begin return hashint4(abs($1)); end;
$$ LANGUAGE plpgsql STRICT IMMUTABLE;

CREATE OPERATOR CLASS abs_int_hash_ops FOR TYPE int4
USING hash AS
OPERATOR 1 |=|,
FUNCTION 1 abshashfunc(int);

Also, create less than and greater than operators, and a btree operator class for them. We don’t need them
for our queries, but the Postgres Planner will not consider co-location of joins without them.

CREATE FUNCTION absslt(int, int) RETURNS BOOL AS
$$
  begin return abs($1) < abs($2); end;
$$ LANGUAGE plpgsql STRICT IMMUTABLE;

CREATE OPERATOR |<| (  
  PROCEDURE = absslt,
  LEFTARG = int,
  RIGHTARG = int);

CREATE FUNCTION abssgt(int, int) RETURNS BOOL AS
$$
  begin return abs($1) > abs($2); end;
$$ LANGUAGE plpgsql STRICT IMMUTABLE;

CREATE OPERATOR |>| (  
  PROCEDURE = abssgt,
  LEFTARG = int,
  RIGHTARG = int);

CREATE FUNCTION absncmp(int, int) RETURNS int AS
$$
  begin return btint4cmp(abs($1),abs($2)); end;
$$ LANGUAGE plpgsql STRICT IMMUTABLE;

CREATE OPERATOR CLASS abs_int_btree_ops FOR TYPE int4
USING btree AS
  OPERATOR 1 |<|,
  OPERATOR 3 |=|,
  OPERATOR 5 |>|,
  FUNCTION 1 abscmp(int, int);

Now, you can use the custom hash operator class in tables.

CREATE TABLE atab (a int) DISTRIBUTED BY (a abs_int_hash_ops);
CREATE TABLE btab (b int) DISTRIBUTED BY (b abs_int_hash_ops);

INSERT INTO atab VALUES (-1), (0), (1);
INSERT INTO btab VALUES (-1), (0), (1), (2);

Queries that perform a join that use the custom equality operator |= can take advantage of the co-
location.

With the default integer opclass, this query requires Redistribute Motion nodes.

EXPLAIN (COSTS OFF) SELECT a, b FROM atab, btab WHERE a = b;

-----------------------------
| Gather Motion 4:1 (slice3; segments: 4) |
|                                   -> Hash Join |
|                                       Hash Cond: (atab.a = btab.b) |
|                                   -> Redistribute Motion 4:4 (slice1; segments: 4) |
|                                       Hash Key: atab.a |
|                                   -> Seq Scan on atab |
|                                   -> Hash |
With the custom opclass, a more efficient plan is possible.

```
EXPLAIN (COSTS OFF) SELECT a, b FROM atab, btab WHERE a |=| b;
```

```
QUERY PLAN
--------------------------------------------
Gather Motion 4:1  (slice1; segments: 4)
  ->  Hash Join
    Hash Cond: (atab.a |=| btab.b)
    ->  Seq Scan on atab
    ->  Hash
    ->  Seq Scan on btab
Optimizer: Postgres query optimizer
(7 rows)
```

Choosing the Table Storage Model

Greenplum Database supports several storage models and a mix of storage models. When you create a table, you choose how to store its data. This topic explains the options for table storage and how to choose the best storage model for your workload.

- **Heap Storage**
- **Append-Optimized Storage**
- **Choosing Row or Column-Oriented Storage**
- **Using Compression (Append-Optimized Tables Only)**
- **Checking the Compression and Distribution of an Append-Optimized Table**
- **Altering a Table**
- **Dropping a Table**

**Note:** To simplify the creation of database tables, you can specify the default values for some table storage options with the Greenplum Database server configuration parameter `gp_default_storage_options`.

For information about the parameter, see "Server Configuration Parameters" in the Greenplum Database Reference Guide.

Heap Storage

By default, Greenplum Database uses the same heap storage model as PostgreSQL. Heap table storage works best with OLTP-type workloads where the data is often modified after it is initially loaded. `UPDATE` and `DELETE` operations require storing row-level versioning information to ensure reliable database transaction processing. Heap tables are best suited for smaller tables, such as dimension tables, that are often updated after they are initially loaded.

Append-Optimized Storage

Append-optimized table storage works best with denormalized fact tables in a data warehouse environment. Denormalized fact tables are typically the largest tables in the system. Fact tables are usually loaded in batches and accessed by read-only queries. Moving large fact tables to an append-optimized storage model eliminates the storage overhead of the per-row update visibility information, saving about 20 bytes per row. This allows for a leaner and easier-to-optimize page structure. The storage model of append-optimized tables is optimized for bulk data loading. Single row `INSERT` statements are not recommended.
To create a heap table

Row-oriented heap tables are the default storage type.

```sql
=> CREATE TABLE foo (a int, b text) DISTRIBUTED BY (a);
```

To create an append-optimized table

Use the `WITH` clause of the `CREATE TABLE` command to declare the table storage options. The default is to create the table as a regular row-oriented heap-storage table. For example, to create an append-optimized table with no compression:

```sql
=> CREATE TABLE bar (a int, b text)
    WITH (appendoptimized=true)
    DISTRIBUTED BY (a);
```

**Note:** You use the `appendoptimized=value` syntax to specify the append-optimized table storage type. `appendoptimized` is a thin alias for the `appendonly` legacy storage option. Greenplum Database stores `appendonly` in the catalog, and displays the same when listing storage options for append-optimized tables.

UPDATE and DELETE are not allowed on append-optimized tables in a repeatable read or serializable transaction and will cause the transaction to abort. CLUSTER, DECLARE...FOR UPDATE, and triggers are not supported with append-optimized tables.

Choosing Row or Column-Oriented Storage

Greenplum provides a choice of storage orientation models: row, column, or a combination of both. This topic provides general guidelines for choosing the optimum storage orientation for a table. Evaluate performance using your own data and query workloads.

- **Row-oriented storage:** good for OLTP types of workloads with many iterative transactions and many columns of a single row needed all at once, so retrieving is efficient.
- **Column-oriented storage:** good for data warehouse workloads with aggregations of data computed over a small number of columns, or for single columns that require regular updates without modifying other column data.

For most general purpose or mixed workloads, row-oriented storage offers the best combination of flexibility and performance. However, there are use cases where a column-oriented storage model provides more efficient I/O and storage. Consider the following requirements when deciding on the storage orientation model for a table:

- **Updates of table data.** If you load and update the table data frequently, choose a row-oriented heap table. Column-oriented table storage is only available on append-optimized tables.

  See Heap Storage for more information.

- **Frequent INSERTs.** If rows are frequently inserted into the table, consider a row-oriented model. Column-oriented tables are not optimized for write operations, as column values for a row must be written to different places on disk.

- **Number of columns requested in queries.** If you typically request all or the majority of columns in the `SELECT` list or `WHERE` clause of your queries, consider a row-oriented model. Column-oriented tables are best suited to queries that aggregate many values of a single column where the `WHERE` or `HAVING` predicate is also on the aggregate column. For example:

  ```sql
  SELECT SUM(salary)...
  SELECT AVG(salary)...
  WHERE salary > 10000
  ```
Or where the `WHERE` predicate is on a single column and returns a relatively small number of rows. For example:

```
SELECT salary, dept ... WHERE state='CA'
```

- **Number of columns in the table.** Row-oriented storage is more efficient when many columns are required at the same time, or when the row-size of a table is relatively small. Column-oriented tables can offer better query performance on tables with many columns where you access a small subset of columns in your queries.

- **Compression.** Column data has the same data type, so storage size optimizations are available in column-oriented data that are not available in row-oriented data. For example, many compression schemes use the similarity of adjacent data to compress. However, the greater adjacent compression achieved, the more difficult random access can become, as data must be uncompressed to be read.

### To create a column-oriented table

The `WITH` clause of the `CREATE TABLE` command specifies the table’s storage options. The default is a row-oriented heap table. Tables that use column-oriented storage must be append-optimized tables. For example, to create a column-oriented table:

```
=> CREATE TABLE bar (a int, b text)
    WITH (appendoptimized=true, orientation=column)
    DISTRIBUTED BY (a);
```

### Using Compression (Append-Optimized Tables Only)

There are two types of in-database compression available in the Greenplum Database for append-optimized tables:

- Table-level compression is applied to an entire table.
- Column-level compression is applied to a specific column. You can apply different column-level compression algorithms to different columns.

The following table summarizes the available compression algorithms.

<table>
<thead>
<tr>
<th>Table Orientation</th>
<th>Available Compression Types</th>
<th>Supported Algorithms</th>
</tr>
</thead>
<tbody>
<tr>
<td>Row</td>
<td>Table</td>
<td>ZLIB, ZSTD, and QUICKLZ¹</td>
</tr>
<tr>
<td>Column</td>
<td>Column and Table</td>
<td>RLE_TYPE, ZLIB, ZSTD, and QUICKLZ¹</td>
</tr>
</tbody>
</table>

**Note:** ¹QuickLZ compression is not available in the open source version of Greenplum Database.

When choosing a compression type and level for append-optimized tables, consider these factors:

- **CPU usage.** Your segment systems must have the available CPU power to compress and uncompress the data.
- **Compression ratio/disk size.** Minimizing disk size is one factor, but also consider the time and CPU capacity required to compress and scan data. Find the optimal settings for efficiently compressing data without causing excessively long compression times or slow scan rates.
- **Speed of compression.** QuickLZ compression generally uses less CPU capacity and compresses data faster at a lower compression ratio than zlib. zlib provides higher compression ratios at lower speeds.

For example, at compression level 1 (`compresslevel=1`), QuickLZ and zlib have comparable compression ratios, though at different speeds. Using zlib with `compresslevel=6` can significantly increase the compression ratio compared to QuickLZ, though with lower compression speed.
ZStandard compression can provide for either good compression ratio or speed, depending on compression level, or a good compromise on both.

- Speed of decompression/scan rate. Performance with compressed append-optimized tables depends on hardware, query tuning settings, and other factors. Perform comparison testing to determine the actual performance in your environment.

  **Note:** Do not create compressed append-optimized tables on file systems that use compression. If the file system on which your segment data directory resides is a compressed file system, your append-optimized table must not use compression.

Performance with compressed append-optimized tables depends on hardware, query tuning settings, and other factors. You should perform comparison testing to determine the actual performance in your environment.

  **Note:** Zstd compression level can be set to values between 1 and 19. QuickLZ compression level can only be set to level 1; no other values are available. Compression level with zlib can be set to values from 1 - 9. Compression level with RLE can be set to values from 1 - 4.

An **ENCODING** clause specifies compression type and level for individual columns. When an **ENCODING** clause conflicts with a **WITH** clause, the **ENCODING** clause has higher precedence than the **WITH** clause.

### To create a compressed table

The **WITH** clause of the **CREATE TABLE** command declares the table storage options. Tables that use compression must be append-optimized tables. For example, to create an append-optimized table with zlib compression at a compression level of 5:

```sql
=> CREATE TABLE foo (a int, b text)
WITH (appendoptimized=true, compressstype=zlib, compresslevel=5);
```

### Checking the Compression and Distribution of an Append-Optimized Table

Greenplum provides built-in functions to check the compression ratio and the distribution of an append-optimized table. The functions take either the object ID or a table name. You can qualify the table name with a schema name.

**Table 39: Functions for compressed append-optimized table metadata**

<table>
<thead>
<tr>
<th>Function</th>
<th>Return Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>get_ao_distribution(name)</td>
<td>Set of (dbid, tuplecount) rows</td>
<td>Shows the distribution of an append-optimized table's rows across the array. Returns a set of rows, each of which includes a segment dbid and the number of tuples stored on the segment.</td>
</tr>
<tr>
<td>get_ao_distribution(oid)</td>
<td></td>
<td></td>
</tr>
<tr>
<td>get_ao_compression_ratio(name)</td>
<td>float8</td>
<td>Calculates the compression ratio for a compressed append-optimized table. If information is not available, this function returns a value of -1.</td>
</tr>
<tr>
<td>get_ao_compression_ratio(oid)</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

The compression ratio is returned as a common ratio. For example, a returned value of 3.19, or 3.19:1, means that the uncompressed table is slightly larger than three times the size of the compressed table.
The distribution of the table is returned as a set of rows that indicate how many tuples are stored on each segment. For example, in a system with four primary segments with `dbid` values ranging from 0 - 3, the function returns four rows similar to the following:

```
=# SELECT get_ao_distribution('lineitem_comp');
  get_ao_distribution
--------------------
     (0,7500721)
     (1,7501365)
     (2,7499978)
     (3,7497731)
(4 rows)
```

**Support for Run-length Encoding**

Greenplum Database supports Run-length Encoding (RLE) for column-level compression. RLE data compression stores repeated data as a single data value and a count. For example, in a table with two columns, a date and a description, that contains 200,000 entries containing the value `date1` and 400,000 entries containing the value `date2`, RLE compression for the date field is similar to `date1 200000 date2 400000`. RLE is not useful with files that do not have large sets of repeated data as it can greatly increase the file size.

There are four levels of RLE compression available. The levels progressively increase the compression ratio, but decrease the compression speed.

Greenplum Database versions 4.2.1 and later support column-oriented RLE compression. To backup a table with RLE compression that you intend to restore to an earlier version of Greenplum Database, alter the table to have no compression or a compression type supported in the earlier version (ZLIB or QUICKLZ) before you start the backup operation.

Greenplum Database combines delta compression with RLE compression for data in columns of type BIGINT, INTEGER, DATE, TIME, or TIMESTAMP. The delta compression algorithm is based on the change between consecutive column values and is designed to improve compression when data is loaded in sorted order or when the compression is applied to data in sorted order.

**Adding Column-level Compression**

You can add the following storage directives to a column for append-optimized tables with column orientation:

- Compression type
- Compression level
- Block size for a column

Add storage directives using the `CREATE TABLE`, `ALTER TABLE`, and `CREATE TYPE` commands.

The following table details the types of storage directives and possible values for each.
### Table 40: Storage Directives for Column-level Compression

<table>
<thead>
<tr>
<th>Name</th>
<th>Definition</th>
<th>Values</th>
<th>Comment</th>
</tr>
</thead>
<tbody>
<tr>
<td>compressstype</td>
<td>Type of compression.</td>
<td>zstd: ZStandard algorithm</td>
<td>Values are not case-sensitive.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>zlib: deflate algorithm</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>quicklz: fast compression</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>RLE_TYPE: run-length encoding</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>none: no compression</td>
<td></td>
</tr>
<tr>
<td>compresslevel</td>
<td>Compression level.</td>
<td>zlib compression: 1-9</td>
<td>1 is the fastest method with the least compression. 1 is the default.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>9 is the slowest method with the most compression.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>zstd compression: 1-19</td>
<td>1 is the fastest method with the least compression. 1 is the default.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>19 is the slowest method with the most compression.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>QuickLZ compression: 1 – use compression</td>
<td>1 is the default.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>RLE_TYPE compression: 1 – 4</td>
<td>1 is the fastest method with the least compression. 1 is the default.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>1 - apply RLE only</td>
<td>4 is the slowest method with the most compression. 1 is the default.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>2 - apply RLE then apply zlib compression level 1</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>3 - apply RLE then apply zlib compression level 5</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>4 - apply RLE then apply zlib compression level 9</td>
<td></td>
</tr>
<tr>
<td>blocksize</td>
<td>The size in bytes</td>
<td>8192 – 2097152</td>
<td>The value must be a multiple of 8192.</td>
</tr>
<tr>
<td></td>
<td>for each block in</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>the table</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

The following is the format for adding storage directives.

```sql
[ ENCODING ( storage_directive [,... ] ) ]
```

where the word ENCODING is required and the storage directive has three parts:

- The name of the directive
An equals sign
The specification
Separate multiple storage directives with a comma. Apply a storage directive to a single column or
designate it as the default for all columns, as shown in the following CREATE TABLE clauses.

General Usage:

```
column_name data_type ENCODING ( storage_directive [, … ] ), …
```

```
COLUMN column_name ENCODING ( storage_directive [, … ] ), …
```

```
DEFAULT COLUMN ENCODING ( storage_directive [, … ] )
```

Example:

```
C1 char ENCODING (compressstype=quicklz, blocksize=65536)
```

```
COLUMN C1 ENCODING (compressstype=zlib, compresslevel=6, blocksize=65536)
```

```
DEFAULT COLUMN ENCODING (compressstype=quicklz)
```

Default Compression Values

If the compression type, compression level and block size are not defined, the default is no compression,
and the block size is set to the Server Configuration Parameter block_size.

Precedence of Compression Settings

Column compression settings are inherited from the type level to the table level to the partition level to the
subpartition level. The lowest-level settings have priority.

- Column compression settings defined at the table level override any compression settings for the type.
- Column compression settings specified at the table level override any compression settings for the
  entire table.
- Column compression settings specified for partitions override any compression settings at the column
  or table levels.
- Column compression settings specified for subpartitions override any compression settings at the
  partition, column or table levels.
- When an ENCODING clause conflicts with a WITH clause, the ENCODING clause has higher precedence
  than the WITH clause.

  Note: The INHERITS clause is not allowed in a table that contains a storage directive or a column
  reference storage directive.

  Tables created using the LIKE clause ignore storage directive and column reference storage
  directives.

Optimal Location for Column Compression Settings

The best practice is to set the column compression settings at the level where the data resides. See
Example 5, which shows a table with a partition depth of 2. RLE_TYPE compression is added to a column
at the subpartition level.

Storage Directives Examples

The following examples show the use of storage directives in CREATE TABLE statements.
Example 1
In this example, column c1 is compressed using zstd and uses the block size defined by the system. Column c2 is compressed with quicklz, and uses a block size of 65536. Column c3 is not compressed and uses the block size defined by the system.

```sql
CREATE TABLE T1 (c1 int ENCODING (compresstype=zstd),
    c2 char ENCODING (compresstype=quicklz, blocksize=65536),
    c3 char) WITH (appendoptimized=true, orientation=column);
```

Example 2
In this example, column c1 is compressed using zlib and uses the block size defined by the system. Column c2 is compressed with quicklz, and uses a block size of 65536. Column c3 is compressed using RLE_TYPE and uses the block size defined by the system.

```sql
CREATE TABLE T2 (c1 int ENCODING (compresstype=zlib),
    c2 char ENCODING (compresstype=quicklz, blocksize=65536),
    c3 char,
    COLUMN c3 ENCODING (compresstype=RLE_TYPE))
    WITH (appendoptimized=true, orientation=column);
```

Example 3
In this example, column c1 is compressed using zlib and uses the block size defined by the system. Column c2 is compressed with quicklz, and uses a block size of 65536. Column c3 is compressed using zlib and uses the block size defined by the system. Note that column c3 uses zlib (not RLE_TYPE) in the partitions, because the column storage in the partition clause has precedence over the storage directive in the column definition for the table.

```sql
CREATE TABLE T3 (c1 int ENCODING (compresstype=zlib),
    c2 char ENCODING (compresstype=quicklz, blocksize=65536),
    c3 text, COLUMN c3 ENCODING (compresstype=RLE_TYPE))
    WITH (appendoptimized=true, orientation=column)
    PARTITION BY RANGE (c3) (START ('1900-01-01'::DATE)
    END ('2100-12-31'::DATE),
    COLUMN c3 ENCODING (compresstype=zlib));
```

Example 4
In this example, CREATE TABLE assigns the zlib compresstype storage directive to c1. Column c2 has no storage directive and inherits the compression type (quicklz) and block size (65536) from the DEFAULT COLUMN ENCODING clause.

Column c3's ENCODING clause defines its compression type, RLE_TYPE. The ENCODING clause defined for a specific column overrides the DEFAULT ENCODING clause, so column c3 uses the default block size, 32768.

Column c4 has a compress type of none and uses the default block size.

```sql
CREATE TABLE T4 (c1 int ENCODING (compresstype=zlib),
    c2 char,
    c3 text,
    c4 smallint ENCODING (compresstype=none),
    DEFAULT COLUMN ENCODING (compresstype=quicklz, blocksize=65536),
    COLUMN c3 ENCODING (compresstype=RLE_TYPE))
```
**Example 5**

This example creates an append-optimized, column-oriented table, T5. T5 has two partitions, p1 and p2, each of which has subpartitions. Each subpartition has **ENCODING** clauses:

- The **ENCODING** clause for partition p1’s subpartition sp1 defines column i’s compression type as **zlib** and block size as 65536.
- The **ENCODING** clauses for partition p2’s subpartition sp1 defines column i’s compression type as **rle_type** and block size is the default value. Column k uses the default compression and its block size is 8192.

```sql
CREATE TABLE T5(i int, j int, k int, l int)
WITH (appendoptimized=true, orientation=column)
PARTITION BY range(i) SUBPARTITION BY range(j)
(
  partition p1 start(1) end(2)
    ( subpartition sp1 start(1) end(2)
      column i encoding(compressstype=zlib, blocksize=65536)
    ),
  partition p2 start(2) end(3)
    ( subpartition sp1 start(1) end(2)
      column i encoding(compressstype=rle_type)
      column k encoding(blocksize=8192)
    )
);```

For an example showing how to add a compressed column to an existing table with the **ALTER TABLE** command, see **Adding a Compressed Column to Table**.

**Adding Compression in a TYPE Command**

When you create a new type, you can define default compression attributes for the type. For example, the following **CREATE TYPE** command defines a type named **int33** that specifies **quicklz** compression:

```sql
CREATE TYPE int33 (
  internallength = 4,
  input = int33_in,
  output = int33_out,
  alignment = int4,
  default = 123,
  passedbyvalue,
  compressstype="quicklz",
  blocksize=65536,
  compresslevel=1
);
```

When you specify **int33** as a column type in a **CREATE TABLE** command, the column is created with the storage directives you specified for the type:

```sql
CREATE TABLE t2 (c1 int33)
WITH (appendoptimized=true, orientation=column);
```

Table- or column- level storage attributes that you specify in a table definition override type-level storage attributes. For information about creating and adding compression attributes to a type, see **CREATE TYPE**. For information about changing compression specifications in a type, see **ALTER TYPE**.
Choosing Block Size

The blocksize is the size, in bytes, for each block in a table. Block sizes must be between 8192 and 2097152 bytes, and be a multiple of 8192. The default is 32768.

Specifying large block sizes can consume large amounts of memory. Block size determines buffering in the storage layer. Greenplum maintains a buffer per partition, and per column in column-oriented tables. Tables with many partitions or columns consume large amounts of memory.

Altering a Table

The \texttt{ALTER TABLE} command changes the definition of a table. Use \texttt{ALTER TABLE} to change table attributes such as column definitions, distribution policy, storage model, and partition structure (see also \textit{Maintaining Partitioned Tables}). For example, to add a not-null constraint to a table column:

\begin{verbatim}
=> ALTER TABLE address ALTER COLUMN street SET NOT NULL;
\end{verbatim}

Altering Table Distribution

\texttt{ALTER TABLE} provides options to change a table's distribution policy. When the table distribution options change, the table data may be redistributed on disk, which can be resource intensive. You can also redistribute table data using the existing distribution policy.

Changing the Distribution Policy

For partitioned tables, changes to the distribution policy apply recursively to the child partitions. This operation preserves the ownership and all other attributes of the table. For example, the following command redistributes the table sales across all segments using the customer\_id column as the distribution key:

\begin{verbatim}
ALTER TABLE sales SET DISTRIBUTED BY (customer_id);
\end{verbatim}

When you change the hash distribution of a table, table data is automatically redistributed. Changing the distribution policy to a random distribution does not cause the data to be redistributed. For example, the following \texttt{ALTER TABLE} command has no immediate effect:

\begin{verbatim}
ALTER TABLE sales SET DISTRIBUTED RANDOMLY;
\end{verbatim}

Changing the distribution policy of a table to \texttt{DISTRIBUTED REPLICATED} or from \texttt{DISTRIBUTED REPLICATED} automatically redistributes the table data.

Redistributing Table Data

To redistribute table data for tables with a random distribution policy (or when the hash distribution policy has not changed) use \texttt{REORGANIZE=TRUE}. Reorganizing data may be necessary to correct a data skew problem, or when segment resources are added to the system. For example, the following command redistributes table data across all segments using the current distribution policy, including random distribution.

\begin{verbatim}
ALTER TABLE sales SET WITH (REORGANIZE=TRUE);
\end{verbatim}

Changing the distribution policy of a table to \texttt{DISTRIBUTED REPLICATED} or from \texttt{DISTRIBUTED REPLICATED} always redistributes the table data, even when you use \texttt{REORGANIZE=FALSE}. 
## Altering the Table Storage Model

Table storage, compression, and orientation can be declared only at creation. To change the storage model, you must create a table with the correct storage options, load the original table data into the new table, drop the original table, and rename the new table with the original table's name. You must also re-grant any table permissions. For example:

```sql
CREATE TABLE sales2 (LIKE sales)
    WITH (appendoptimized=true, compresstype=quicklz,
         compresslevel=1, orientation=column);
INSERT INTO sales2 SELECT * FROM sales;
DROP TABLE sales;
ALTER TABLE sales2 RENAME TO sales;
GRANT ALL PRIVILEGES ON sales TO admin;
GRANT SELECT ON sales TO guest;
```

See [Splitting a Partition](#) to learn how to change the storage model of a partitioned table.

## Adding a Compressed Column to Table

Use `ALTER TABLE` command to add a compressed column to a table. All of the options and constraints for compressed columns described in [Adding Column-level Compression](#) apply to columns added with the `ALTER TABLE` command.

The following example shows how to add a column with `zlib` compression to a table, `T1`.

```sql
ALTER TABLE T1
    ADD COLUMN c4 int DEFAULT 0
    ENCODING (compresstype=zlib);
```

## Inheritance of Compression Settings

A partition added to a table that has subpartitions defined with compression settings inherits the compression settings from the subpartition. The following example shows how to create a table with subpartition encodings, then alter it to add a partition.

```sql
CREATE TABLE ccddl (i int, j int, k int, l int)
    WITH
        (appendoptimized = TRUE, orientation=COLUMN)
    PARTITION BY range(j)
    SUBPARTITION BY list (k)
    SUBPARTITION template(
        SUBPARTITION sp1 values(1, 2, 3, 4, 5),
        COLUMN i ENCODING(compresstype=ZLIB),
        COLUMN j ENCODING(compresstype=QUICKLZ),
        COLUMN k ENCODING(compresstype=ZLIB),
        COLUMN l ENCODING(compresstype=ZLIB))
    (PARTITION p1 START(1) END(10),
     PARTITION p2 START(10) END(20))
;
ALTER TABLE ccddl
    ADD PARTITION p3 START(20) END(30)
;
```

Running the `ALTER TABLE` command creates partitions of table `ccddl` named `ccddl_1_prt_p3` and `ccddl_1_prt_p3_2_prt_sp1`. Partition `ccddl_1_prt_p3` inherits the different compression encodings of subpartition `sp1`. 
**Dropping a Table**

The `DROP TABLE` command removes tables from the database. For example:

```sql
DROP TABLE mytable;
```

To empty a table of rows without removing the table definition, use `DELETE` or `TRUNCATE`. For example:

```sql
DELETE FROM mytable;
TRUNCATE mytable;
```

`DROP TABLE` always removes any indexes, rules, triggers, and constraints that exist for the target table. Specify `CASCADE` to drop a table that is referenced by a view. `CASCADE` removes dependent views.

---

**Partitioning Large Tables**

Table partitioning enables supporting very large tables, such as fact tables, by logically dividing them into smaller, more manageable pieces. Partitioned tables can improve query performance by allowing the Greenplum Database query optimizer to scan only the data needed to satisfy a given query instead of scanning all the contents of a large table.

- **About Table Partitioning**
- **Deciding on a Table Partitioning Strategy**
- **Creating Partitioned Tables**
- **Loading Partitioned Tables**
- **Verifying Your Partition Strategy**
- **Viewing Your Partition Design**
- **Maintaining Partitioned Tables**

**About Table Partitioning**

Partitioning does not change the physical distribution of table data across the segments. Table distribution is physical: Greenplum Database physically divides partitioned tables and non-partitioned tables across segments to enable parallel query processing. Table partitioning is logical: Greenplum Database logically divides big tables to improve query performance and facilitate data warehouse maintenance tasks, such as rolling old data out of the data warehouse.

Greenplum Database supports:

- **range partitioning**: division of data based on a numerical range, such as date or price.
- **list partitioning**: division of data based on a list of values, such as sales territory or product line.
- A combination of both types.
Table Partitioning in Greenplum Database

Greenplum Database divides tables into parts (also known as partitions) to enable massively parallel processing. Tables are partitioned during CREATE TABLE using the PARTITION BY (and optionally the SUBPARTITION BY) clause. Partitioning creates a top-level (or parent) table with one or more levels of sub-tables (or child tables). Internally, Greenplum Database creates an inheritance relationship between the top-level table and its underlying partitions, similar to the functionality of the INHERITS clause of PostgreSQL.

Greenplum uses the partition criteria defined during table creation to create each partition with a distinct CHECK constraint, which limits the data that table can contain. The query optimizer uses CHECK constraints to determine which table partitions to scan to satisfy a given query predicate.

The Greenplum system catalog stores partition hierarchy information so that rows inserted into the top-level parent table propagate correctly to the child table partitions. To change the partition design or table structure, alter the parent table using ALTER TABLE with the PARTITION clause.

To insert data into a partitioned table, you specify the root partitioned table, the table created with the CREATE TABLE command. You also can specify a leaf child table of the partitioned table in an INSERT command. An error is returned if the data is not valid for the specified leaf child table. Specifying a non-leaf or a non-root partition table in the DML command is not supported.

Deciding on a Table Partitioning Strategy

Greenplum Database does not support partitioning replicated tables (DISTRIBUTED REPLICATED). Not all hash-distributed or randomly distributed tables are good candidates for partitioning. If the answer is yes to all or most of the following questions, table partitioning is a viable database design strategy for improving query performance. If the answer is no to most of the following questions, table partitioning is not the right solution for that table. Test your design strategy to ensure that query performance improves as expected.

- **Is the table large enough?** Large fact tables are good candidates for table partitioning. If you have millions or billions of records in a table, you may see performance benefits from logically breaking that data up into smaller chunks. For smaller tables with only a few thousand rows or less, the administrative overhead of maintaining the partitions will outweigh any performance benefits you might see.

- **Are you experiencing unsatisfactory performance?** As with any performance tuning initiative, a table should be partitioned only if queries against that table are producing slower response times than desired.
- **Do your query predicates have identifiable access patterns?** Examine the *WHERE* clauses of your query workload and look for table columns that are consistently used to access data. For example, if most of your queries tend to look up records by date, then a monthly or weekly date-partitioning design might be beneficial. Or if you tend to access records by region, consider a list-partitioning design to divide the table by region.

- **Does your data warehouse maintain a window of historical data?** Another consideration for partition design is your organization's business requirements for maintaining historical data. For example, your data warehouse may require that you keep data for the past twelve months. If the data is partitioned by month, you can easily drop the oldest monthly partition from the warehouse and load current data into the most recent monthly partition.

- **Can the data be divided into somewhat equal parts based on some defining criteria?** Choose partitioning criteria that will divide your data as evenly as possible. If the partitions contain a relatively equal number of records, query performance improves based on the number of partitions created. For example, by dividing a large table into 10 partitions, a query will execute 10 times faster than it would against the unpartitioned table, provided that the partitions are designed to support the query's criteria. Do not create more partitions than are needed. Creating too many partitions can slow down management and maintenance jobs, such as vacuuming, recovering segments, expanding the cluster, checking disk usage, and others.

Partitioning does not improve query performance unless the query optimizer can eliminate partitions based on the query predicates. Queries that scan every partition run slower than if the table were not partitioned, so avoid partitioning if few of your queries achieve partition elimination. Check the explain plan for queries to make sure that partitions are eliminated. See *Query Profiling* for more about partition elimination.

**Warning:** Be very careful with multi-level partitioning because the number of partition files can grow very quickly. For example, if a table is partitioned by both day and city, and there are 1,000 days of data and 1,000 cities, the total number of partitions is one million. Column-oriented tables store each column in a physical table, so if this table has 100 columns, the system would be required to manage 100 million files for the table, for each segment.

Before settling on a multi-level partitioning strategy, consider a single level partition with bitmap indexes. Indexes slow down data loads, so performance testing with your data and schema is recommended to decide on the best strategy.

### Creating Partitioned Tables

You partition tables when you create them with `CREATE TABLE`. This topic provides examples of SQL syntax for creating a table with various partition designs.

To partition a table:

1. Decide on the partition design: date range, numeric range, or list of values.
2. Choose the column(s) on which to partition the table.
3. Decide how many levels of partitions you want. For example, you can create a date range partition table by month and then subpartition the monthly partitions by sales region.

- **Defining Date Range Table Partitions**
- **Defining Numeric Range Table Partitions**
- **Defining List Table Partitions**
- **Defining Multi-level Partitions**
- **Partitioning an Existing Table**

#### Defining Date Range Table Partitions

A date range partitioned table uses a single `date` or `timestamp` column as the partition key column. You can use the same partition key column to create subpartitions if necessary, for example, to partition by month and then subpartition by day. Consider partitioning by the most granular level. For example, for a table partitioned by date, you can partition by day and have 365 daily partitions, rather than partition by
year then subpartition by month then subpartition by day. A multi-level design can reduce query planning
time, but a flat partition design runs faster.

You can have Greenplum Database automatically generate partitions by giving a **START** value, an **END**
value, and an **EVERY** clause that defines the partition increment value. By default, **START** values are
always inclusive and **END** values are always exclusive. For example:

```sql
CREATE TABLE sales (id int, date date, amt decimal(10,2))
DISTRIBUTED BY (id)
PARTITION BY RANGE (date)
( START (date '2016-01-01') INCLUSIVE
  END (date '2017-01-01') EXCLUSIVE
  EVERY (INTERVAL '1 day') );
```

You can also declare and name each partition individually. For example:

```sql
CREATE TABLE sales (id int, date date, amt decimal(10,2))
DISTRIBUTED BY (id)
PARTITION BY RANGE (date)
( PARTITION Jan16 START (date '2016-01-01') INCLUSIVE ,
  PARTITION Feb16 START (date '2016-02-01') INCLUSIVE ,
  PARTITION Mar16 START (date '2016-03-01') INCLUSIVE ,
  PARTITION Apr16 START (date '2016-04-01') INCLUSIVE ,
  PARTITION May16 START (date '2016-05-01') INCLUSIVE ,
  PARTITION Jun16 START (date '2016-06-01') INCLUSIVE ,
  PARTITION Jul16 START (date '2016-07-01') INCLUSIVE ,
  PARTITION Aug16 START (date '2016-08-01') INCLUSIVE ,
  PARTITION Sep16 START (date '2016-09-01') INCLUSIVE ,
  PARTITION Oct16 START (date '2016-10-01') INCLUSIVE ,
  PARTITION Nov16 START (date '2016-11-01') INCLUSIVE ,
  PARTITION Dec16 START (date '2016-12-01') INCLUSIVE
  END (date '2017-01-01') EXCLUSIVE );
```

You do not have to declare an **END** value for each partition, only the last one. In this example, Jan16 ends
where Feb16 starts.

**Defining Numeric Range Table Partitions**

A numeric range partitioned table uses a single numeric data type column as the partition key column. For
example:

```sql
CREATE TABLE rank (id int, rank int, year int, gender char(1), count int)
DISTRIBUTED BY (id)
PARTITION BY RANGE (year)
  DEFAULT PARTITION extra );
```

For more information about default partitions, see *Adding a Default Partition*.

**Defining List Table Partitions**

A list partitioned table can use any data type column that allows equality comparisons as its partition key
column. A list partition can also have a multi-column (composite) partition key, whereas a range partition
only allows a single column as the partition key. For list partitions, you must declare a partition specification
for every partition (list value) you want to create. For example:

```sql
CREATE TABLE rank (id int, rank int, year int, gender char(1), count int )
DISTRIBUTED BY (id)
PARTITION BY LIST (gender)
```
Note: The current Postgres Planner allows list partitions with multi-column (composite) partition keys. A range partition only allows a single column as the partition key. The Greenplum Query Optimizer does not support composite keys, so you should not use composite partition keys.

For more information about default partitions, see Adding a Default Partition.

**Defining Multi-level Partitions**

You can create a multi-level partition design with subpartitions of partitions. Using a *subpartition template* ensures that every partition has the same subpartition design, including partitions that you add later. For example, the following SQL creates the two-level partition design shown in Figure 20: Example Multi-level Partition Design:

```sql
CREATE TABLE sales (trans_id int, date date, amount decimal(9,2), region text)
DISTRIBUTED BY (trans_id)
PARTITION BY RANGE (date)
SUBPARTITION BY LIST (region)
SUBPARTITION TEMPLATE
( SUBPARTITION usa VALUES ('usa'),
  SUBPARTITION asia VALUES ('asia'),
  SUBPARTITION europe VALUES ('eupe'),
  DEFAULT SUBPARTITION other_regions)
(START (date '2011-01-01') INCLUSIVE
 END (date '2012-01-01') EXCLUSIVE
 EVERY (INTERVAL '1 month'),
 DEFAULT PARTITION outlying_dates );
```

The following example shows a three-level partition design where the `sales` table is partitioned by `year`, then `month`, then `region`. The *SUBPARTITION TEMPLATE* clauses ensure that each yearly partition has the same subpartition structure. The example declares a *DEFAULT* partition at each level of the hierarchy.

```sql
CREATE TABLE p3_sales (id int, year int, month int, day int,
 region text)
DISTRIBUTED BY (id)
PARTITION BY RANGE (year)
    SUBPARTITION BY RANGE (month)
    SUBPARTITION TEMPLATE (
      START (1) END (13) EVERY (1),
      DEFAULT SUBPARTITION other_months )
    SUBPARTITION BY LIST (region)
    SUBPARTITION TEMPLATE (
      SUBPARTITION usa VALUES ('usa'),
      SUBPARTITION europe VALUES ('europe'),
      SUBPARTITION asia VALUES ('asia'),
      DEFAULT SUBPARTITION other_regions )
 DEFAULT PARTITION outlying_years );
```

Caution: When you create multi-level partitions on ranges, it is easy to create a large number of subpartitions, some containing little or no data. This can add many entries to the system tables, which increases the time and memory required to optimize and execute queries. Increase the range interval or choose a different partitioning strategy to reduce the number of subpartitions created.
Partitioning an Existing Table

Tables can be partitioned only at creation. If you have a table that you want to partition, you must create a partitioned table, load the data from the original table into the new table, drop the original table, and rename the partitioned table with the original table’s name. You must also re-grant any table permissions. For example:

```sql
CREATE TABLE sales2 (LIKE sales)
PARTITION BY RANGE (date)
( START (date '2016-01-01') INCLUSIVE
  END (date '2017-01-01') EXCLUSIVE
  EVERY (INTERVAL '1 month') )
INSERT INTO sales2 SELECT * FROM sales;
DROP TABLE sales;
ALTER TABLE sales2 RENAME TO sales;
GRANT ALL PRIVILEGES ON sales TO admin;
GRANT SELECT ON sales TO guest;
```

Limitations of Partitioned Tables

For each partition level, a partitioned table can have a maximum of 32,767 partitions.

A primary key or unique constraint on a partitioned table must contain all the partitioning columns. A unique index can omit the partitioning columns; however, it is enforced only on the parts of the partitioned table, not on the partitioned table as a whole.

Tables created with the DISTRIBUTED REPLICATED distribution policy cannot be partitioned.

GPORCA, the Greenplum next generation query optimizer, supports uniform multi-level partitioned tables. If GPORCA is enabled (the default) and the multi-level partitioned table is not uniform, Greenplum Database executes queries against the table with the Postgres Planner. For information about uniform multi-level partitioned tables, see About Uniform Multi-level Partitioned Tables.

For information about exchanging a leaf child partition with an external table, see Exchanging a Leaf Child Partition with an External Table.

These are limitations for partitioned tables when a leaf child partition of the table is an external table:

- Queries that run against partitioned tables that contain external table partitions are executed with the Postgres Planner.
- The external table partition is a read only external table. Commands that attempt to access or modify data in the external table partition return an error. For example:
  - INSERT, DELETE, and UPDATE commands that attempt to change data in the external table partition return an error.
  - TRUNCATE commands return an error.
  - COPY commands cannot copy data to a partitioned table that updates an external table partition.
  - COPY commands that attempt to copy from an external table partition return an error unless you specify the IGNORE EXTERNAL PARTITIONS clause with COPY command. If you specify the clause, data is not copied from external table partitions.

To use the COPY command against a partitioned table with a leaf child table that is an external table, use an SQL query to copy the data. For example, if the table `my_sales` contains a with a leaf child table that is an external table, this command sends the data to stdout:

```sql
COPY (SELECT * FROM my_sales) TO stdout
```

- VACUUM commands skip external table partitions.
- The following operations are supported if no data is changed on the external table partition. Otherwise, an error is returned.
• Adding or dropping a column.
• Changing the data type of column.
• These `ALTER PARTITION` operations are not supported if the partitioned table contains an external table partition:
  • Setting a subpartition template.
  • Altering the partition properties.
  • Creating a default partition.
  • Setting a distribution policy.
  • Setting or dropping a `NOT NULL` constraint of column.
  • Adding or dropping constraints.
  • Splitting an external partition.
• The Greenplum Database `gpbackup` utility does not back up data from a leaf child partition of a partitioned table if the leaf child partition is a readable external table.

Loading Partitioned Tables

After you create the partitioned table structure, top-level parent tables are empty. Data is routed to the bottom-level child table partitions. In a multi-level partition design, only the subpartitions at the bottom of the hierarchy can contain data.

Rows that cannot be mapped to a child table partition are rejected and the load fails. To avoid unmapped rows being rejected at load time, define your partition hierarchy with a `DEFAULT` partition. Any rows that do not match a partition's `CHECK` constraints load into the `DEFAULT` partition. See Adding a Default Partition.

At runtime, the query optimizer scans the entire table inheritance hierarchy and uses the `CHECK` table constraints to determine which of the child table partitions to scan to satisfy the query's conditions. The `DEFAULT` partition (if your hierarchy has one) is always scanned. `DEFAULT` partitions that contain data slow down the overall scan time.

When you use `COPY` or `INSERT` to load data into a parent table, the data is automatically rerouted to the correct partition, just like a regular table.

Best practice for loading data into partitioned tables is to create an intermediate staging table, load it, and then exchange it into your partition design. See Exchanging a Partition.

Verifying Your Partition Strategy

When a table is partitioned based on the query predicate, you can use `EXPLAIN` to verify that the query optimizer scans only the relevant data to examine the query plan.

For example, suppose a `sales` table is date-range partitioned by month and subpartitioned by region as shown in Figure 20: Example Multi-level Partition Design. For the following query:

```
EXPLAIN SELECT * FROM sales WHERE date='01-07-12' AND region='usa';
```

The query plan for this query should show a table scan of only the following tables:
• the default partition returning 0-1 rows (if your partition design has one)
• the January 2012 partition (`sales_1_prt_1`) returning 0-1 rows
• the USA region subpartition (`sales_1_2_prt_usa`) returning some number of rows.

The following example shows the relevant portion of the query plan.

```
->  Seq Scan on sales_1_prt_1 sales (cost=0.00..0.00 rows=0 width=0)
    Filter: "date"=01-07-12::date AND region='USA':text
->  Seq Scan on sales_1_2_prt_usa sales (cost=0.00..9.87
```
Ensure that the query optimizer does not scan unnecessary partitions or subpartitions (for example, scans of months or regions not specified in the query predicate), and that scans of the top-level tables return 0-1 rows.

**Troubleshooting Selective Partition Scanning**

The following limitations can result in a query plan that shows a non-selective scan of your partition hierarchy.

- The query optimizer can selectively scan partitioned tables only when the query contains a direct and simple restriction of the table using immutable operators such as:
  
  \( =, \leq, \geq, <, >, \neq \)

- Selective scanning recognizes \texttt{STABLE} and \texttt{IMMUTABLE} functions, but does not recognize \texttt{VOLATILE} functions within a query. For example, \texttt{WHERE} clauses such as \texttt{date > CURRENT_DATE} cause the query optimizer to selectively scan partitioned tables, but \texttt{time > TIMEOFDAY} does not.

**Viewing Your Partition Design**

You can look up information about your partition design using the \texttt{pg_partitions} system view. For example, to see the partition design of the \texttt{sales} table:

```sql
SELECT partitionboundary, partitiontablename, partitionname, partitionlevel, partitionrank
FROM pg_partitions
WHERE tablename='sales';
```

The following table and views also show information about partitioned tables.

- \texttt{pg_partition} - Tracks partitioned tables and their inheritance level relationships.
- \texttt{pg_partition_templates} - Shows the subpartitions created using a subpartition template.
- \texttt{pg_partition_columns} - Shows the partition key columns used in a partition design.

For information about Greenplum Database system catalog tables and views, see the \textit{Greenplum Database Reference Guide}.

**Maintaining Partitioned Tables**

To maintain a partitioned table, use the \texttt{ALTER TABLE} command against the top-level parent table. The most common scenario is to drop old partitions and add new ones to maintain a rolling window of data in a range partition design. You can convert (exchange) older partitions to the append-optimized compressed storage format to save space. If you have a default partition in your partition design, you add a partition by splitting the default partition.

- \texttt{Adding a Partition}
- \texttt{Renaming a Partition}
- \texttt{Adding a Default Partition}
- \texttt{Dropping a Partition}
- \texttt{Truncating a Partition}
- \texttt{Exchanging a Partition}
- \texttt{Splitting a Partition}
- \texttt{Modifying a Subpartition Template}
- \texttt{Exchanging a Leaf Child Partition with an External Table}

**Important:** When defining and altering partition designs, use the given partition name, not the table object name. The given partition name is the \texttt{partitionname} column value in the \texttt{pg_partitions}
system view. Although you can query and load any table (including partitioned tables) directly using SQL commands, you can only modify the structure of a partitioned table using the `ALTER TABLE...PARTITION` clauses.

Partitions are not required to have names. If a partition does not have a name, use one of the following expressions to specify a partition: `PARTITION FOR (value)` or `PARTITION FOR (RANK(number))`.

For a multi-level partitioned table, you identify a specific partition to change with `ALTER PARTITION` clauses. For each partition level in the table hierarchy that is above the target partition, specify the partition that is related to the target partition in an `ALTER PARTITION` clause. For example, if you have a partitioned table that consists of three levels, year, quarter, and region, this `ALTER TABLE` command exchanges a leaf partition `region` with the table `region_new`.

```
ALTER TABLE sales ALTER PARTITION year_1 ALTER PARTITION quarter_4 EXCHANGE PARTITION region WITH TABLE region_new;
```

The two `ALTER PARTITION` clauses identify which `region` partition to exchange. Both clauses are required to identify the specific leaf partition to exchange.

### Adding a Partition

You can add a partition to a partition design with the `ALTER TABLE` command. If the original partition design included subpartitions defined by a `subpartition template`, the newly added partition is subpartitioned according to that template. For example:

```
ALTER TABLE sales ADD PARTITION
START (date '2017-02-01') INCLUSIVE
END (date '2017-03-01') EXCLUSIVE;
```

If you did not use a subpartition template when you created the table, you define subpartitions when adding a partition:

```
ALTER TABLE sales ADD PARTITION
START (date '2017-02-01') INCLUSIVE
END (date '2017-03-01') EXCLUSIVE
(SUBPARTITION usa VALUES ('usa'),
SUBPARTITION asia VALUES ('asia'),
SUBPARTITION europe VALUES ('europe'));
```

When you add a subpartition to an existing partition, you can specify the partition to alter. For example:

```
ALTER TABLE sales ALTER PARTITION FOR (RANK(12))
ADD PARTITION africa VALUES ('africa');
```

**Note:** You cannot add a partition to a partition design that has a default partition. You must split the default partition to add a partition. See **Splitting a Partition**.

### Renaming a Partition

Partitioned tables use the following naming convention. Partitioned subtable names are subject to uniqueness requirements and length limitations.

```
<parentname>_<level>_prt_<partition_name>
```

For example:

```
sales_1_prt_jan16
```
For auto-generated range partitions, where a number is assigned when no name is given):

```
sales_1_prt_1
```

To rename a partitioned child table, rename the top-level parent table. The `<parentname>` changes in the table names of all associated child table partitions. For example, the following command:

```
ALTER TABLE sales RENAME TO globalsales;
```

Changes the associated table names:

```
globalsales_1_prt_1
```

You can change the name of a partition to make it easier to identify. For example:

```
ALTER TABLE sales RENAME PARTITION FOR ('2016-01-01') TO jan16;
```

Changes the associated table name as follows:

```
sales_1_prt_jan16
```

When altering partitioned tables with the `ALTER TABLE` command, always refer to the tables by their partition name (`jan16`) and not their full table name (`sales_1_prt_jan16`).

**Note**: The table name cannot be a partition name in an `ALTER TABLE` statement. For example, `ALTER TABLE sales...` is correct, `ALTER TABLE sales_1_part_jan16...` is not allowed.

### Adding a Default Partition

You can add a default partition to a partition design with the `ALTER TABLE` command.

```
ALTER TABLE sales ADD DEFAULT PARTITION other;
```

If your partition design is multi-level, each level in the hierarchy must have a default partition. For example:

```
ALTER TABLE sales ALTER PARTITION FOR (RANK(1)) ADD DEFAULT PARTITION other;

ALTER TABLE sales ALTER PARTITION FOR (RANK(2)) ADD DEFAULT PARTITION other;

ALTER TABLE sales ALTER PARTITION FOR (RANK(3)) ADD DEFAULT PARTITION other;
```

If incoming data does not match a partition's `CHECK` constraint and there is no default partition, the data is rejected. Default partitions ensure that incoming data that does not match a partition is inserted into the default partition.

### Dropping a Partition

You can drop a partition from your partition design using the `ALTER TABLE` command. When you drop a partition that has subpartitions, the subpartitions (and all data in them) are automatically dropped as well. For range partitions, it is common to drop the older partitions from the range as old data is rolled out of the data warehouse. For example:

```
ALTER TABLE sales DROP PARTITION FOR (RANK(1));
```
**Truncating a Partition**

You can truncate a partition using the `ALTER TABLE` command. When you truncate a partition that has subpartitions, the subpartitions are automatically truncated as well.

```sql
ALTER TABLE sales TRUNCATE PARTITION FOR (RANK(1));
```

**Exchanging a Partition**

You can exchange a partition using the `ALTER TABLE` command. Exchanging a partition swaps one table in place of an existing partition. You can exchange partitions only at the lowest level of your partition hierarchy (only partitions that contain data can be exchanged).

You cannot exchange a partition with a replicated table. Exchanging a partition with a partitioned table or a child partition of a partitioned table is not supported.

Partition exchange can be useful for data loading. For example, load a staging table and swap the loaded table into your partition design. You can use partition exchange to change the storage type of older partitions to append-optimized tables. For example:

```sql
CREATE TABLE jan12 (LIKE sales) WITH (appendoptimized=true);
INSERT INTO jan12 SELECT * FROM sales_1_prt_1;
ALTER TABLE sales EXCHANGE PARTITION FOR (DATE '2012-01-01')
WITH TABLE jan12;
```

**Note:** This example refers to the single-level definition of the table `sales`, before partitions were added and altered in the previous examples.

**Warning:** If you specify the `WITHOUT VALIDATION` clause, you must ensure that the data in table that you are exchanging for an existing partition is valid against the constraints on the partition. Otherwise, queries against the partitioned table might return incorrect results.

The Greenplum Database server configuration parameter `gp_enable_exchange_default_partition` controls availability of the `EXCHANGE DEFAULT PARTITION` clause. The default value for the parameter is `off`, the clause is not available and Greenplum Database returns an error if the clause is specified in an `ALTER TABLE` command.

For information about the parameter, see "Server Configuration Parameters" in the Greenplum Database Reference Guide.

**Warning:** Before you exchange the default partition, you must ensure the data in the table to be exchanged, the new default partition, is valid for the default partition. For example, the data in the new default partition must not contain data that would be valid in other leaf child partitions of the partitioned table. Otherwise, queries against the partitioned table with the exchanged default partition that are executed by GPORCA might return incorrect results.

**Splitting a Partition**

Splitting a partition divides a partition into two partitions. You can split a partition using the `ALTER TABLE` command. You can split partitions only at the lowest level of your partition hierarchy (partitions that contain data). For a multi-level partition, only range partitions can be split, not list partitions. The split value you specify goes into the `latter` partition.

For example, to split a monthly partition into two with the first partition containing dates January 1-15 and the second partition containing dates January 16-31:

```sql
ALTER TABLE sales SPLIT PARTITION FOR ('2017-01-01')
AT ('2017-01-16')
INTO (PARTITION jan171to15, PARTITION jan1716to31);
```
If your partition design has a default partition, you must split the default partition to add a partition.

When using the `INTO` clause, specify the current default partition as the second partition name. For example, to split a default range partition to add a new monthly partition for January 2017:

```sql
ALTER TABLE sales SPLIT DEFAULT PARTITION
START ('2017-01-01') INCLUSIVE
END ('2017-02-01') EXCLUSIVE
INTO (PARTITION jan17, default partition);
```

### Modifying a Subpartition Template

Use `ALTER TABLE SET SUBPARTITION TEMPLATE` to modify the subpartition template of a partitioned table. Partitions added after you set a new subpartition template have the new partition design. Existing partitions are not modified.

The following example alters the subpartition template of this partitioned table:

```sql
CREATE TABLE sales (trans_id int, date date, amount decimal(9,2), region text)
  DISTRIBUTED BY (trans_id)
  PARTITION BY RANGE (date)
  SUBPARTITION BY LIST (region)
  SUBPARTITION TEMPLATE
    ( SUBPARTITION usa VALUES ('usa'),
      SUBPARTITION asia VALUES ('asia'),
      SUBPARTITION europe VALUES ('europe'),
      DEFAULT SUBPARTITION other_regions )
  ( START (date '2014-01-01') INCLUSIVE
  END (date '2014-04-01') EXCLUSIVE
  EVERY (INTERVAL '1 month' ) );
```

This `ALTER TABLE` command, modifies the subpartition template.

```sql
ALTER TABLE sales SET SUBPARTITION TEMPLATE
( SUBPARTITION usa VALUES ('usa'),
  SUBPARTITION asia VALUES ('asia'),
  SUBPARTITION europe VALUES ('europe'),
  SUBPARTITION africa VALUES ('africa'),
  DEFAULT SUBPARTITION regions );
```

When you add a date-range partition of the table sales, it includes the new regional list subpartition for Africa. For example, the following command creates the subpartitions `usa, asia, europe, africa`, and a default partition named `other`:

```sql
ALTER TABLE sales ADD PARTITION "4"
START ('2014-04-01') INCLUSIVE
END ('2014-05-01') EXCLUSIVE ;
```

To view the tables created for the partitioned table `sales`, you can use the command `\dt sales*` from the psql command line.

To remove a subpartition template, use `SET SUBPARTITION TEMPLATE` with empty parentheses. For example, to clear the sales table subpartition template:

```sql
ALTER TABLE sales SET SUBPARTITION TEMPLATE ();
```
**Exchanging a Leaf Child Partition with an External Table**

You can exchange a leaf child partition of a partitioned table with a readable external table. The external table data can reside on a host file system, an NFS mount, or a Hadoop file system (HDFS).

For example, if you have a partitioned table that is created with monthly partitions and most of the queries against the table only access the newer data, you can copy the older, less accessed data to external tables and exchange older partitions with the external tables. For queries that only access the newer data, you could create queries that use partition elimination to prevent scanning the older, unneeded partitions.

Exchanging a leaf child partition with an external table is not supported if the partitioned table contains a column with a check constraint or a `NOT NULL` constraint.

For information about exchanging and altering a leaf child partition, see the `ALTER TABLE` command in the *Greenplum Database Command Reference*.

For information about limitations of partitioned tables that contain a external table partition, see *Limitations of Partitioned Tables*.

**Example Exchanging a Partition with an External Table**

This is a simple example that exchanges a leaf child partition of this partitioned table for an external table. The partitioned table contains data for the years 2010 through 2013.

```sql
CREATE TABLE sales (id int, year int, qtr int, day int, region text)
DISTRIBUTED BY (id)
PARTITION BY RANGE (year)
( PARTITION yr START (2010) END (2014) EVERY (1) ) ;
```

There are four leaf child partitions for the partitioned table. Each leaf child partition contains the data for a single year. The leaf child partition table `sales_1_prt_yr_1` contains the data for the year 2010. These steps exchange the table `sales_1_prt_yr_1` with an external table the uses the `gpfdist` protocol:

1. Ensure that the external table protocol is enabled for the Greenplum Database system.

   This example uses the `gpfdist` protocol. This command starts the `gpfdist` protocol.

   ```
   $ gpfdist
   ```

2. Create a writable external table.

   This `CREATE WRITABLE EXTERNAL TABLE` command creates a writable external table with the same columns as the partitioned table.

   ```sql
   CREATE WRITABLE EXTERNAL TABLE my_sales_ext ( LIKE sales_1_prt_yr_1 )
   LOCATION ( 'gpfdist://gpdb_test/sales_2010' )
   FORMAT 'csv'
   DISTRIBUTED BY (id) ;
   ```

3. Create a readable external table that reads the data from that destination of the writable external table created in the previous step.

   This `CREATE EXTERNAL TABLE` create a readable external that uses the same external data as the writable external data.

   ```sql
   CREATE EXTERNAL TABLE sales_2010_ext ( LIKE sales_1_prt_yr_1)
   LOCATION ( 'gpfdist://gpdb_test/sales_2010' )
   FORMAT 'csv' ;
   ```

4. Copy the data from the leaf child partition into the writable external table.
This INSERT command copies the data from the child leaf partition table of the partitioned table into the external table.

```
INSERT INTO my_sales_ext SELECT * FROM sales_1_prt_yr_1 ;
```

5. Exchange the existing leaf child partition with the external table.

This ALTER TABLE command specifies the EXCHANGE PARTITION clause to switch the readable external table and the leaf child partition.

```
ALTER TABLE sales ALTER PARTITION yr_1
   EXCHANGE PARTITION yr_1
   WITH TABLE sales_2010_ext WITHOUT VALIDATION;
```

The external table becomes the leaf child partition with the table name sales_1_prt_yr_1 and the old leaf child partition becomes the table sales_2010_ext.

**Warning:** In order to ensure queries against the partitioned table return the correct results, the external table data must be valid against the CHECK constraints on the leaf child partition. In this case, the data was taken from the child leaf partition table on which the CHECK constraints were defined.

6. Drop the table that was rolled out of the partitioned table.

```
DROP TABLE sales_2010_ext ;
```

You can rename the name of the leaf child partition to indicate that sales_1_prt_yr_1 is an external table.

This example command changes the `partitionname` to `yr_1_ext` and the name of the child leaf partition table to `sales_1_prt_yr_1_ext`.

```
ALTER TABLE sales RENAME PARTITION yr_1 TO yr_1_ext ;
```

---

**Creating and Using Sequences**

A Greenplum Database sequence object is a special single row table that functions as a number generator. You can use a sequence to generate unique integer identifiers for a row that you add to a table. Declaring a column of type SERIAL implicitly creates a sequence counter for use in that table column.

Greenplum Database provides commands to create, alter, and drop a sequence. Greenplum Database also provides built-in functions to return the next value in the sequence \( \text{nextval()} \) or to set the sequence to a specific start value \( \text{setval()} \).

**Note:** The PostgreSQL `currval()` and `lastval()` sequence functions are not supported in Greenplum Database.

Attributes of a sequence object include the name of the sequence, its increment value, and the last, minimum, and maximum values of the sequence counter. Sequences also have a special boolean attribute named `is_called` that governs the auto-increment behavior of a `nextval()` operation on the sequence counter. When a sequence's `is_called` attribute is `true`, `nextval()` increments the sequence counter before returning the value. When the `is_called` attribute value of a sequence is `false`, `nextval()` does not increment the counter before returning the value.
Creating a Sequence

The `CREATE SEQUENCE` command creates and initializes a sequence with the given sequence name and optional start value. The sequence name must be distinct from the name of any other sequence, table, index, or view in the same schema. For example:

```
CREATE SEQUENCE myserial START 101;
```

When you create a new sequence, Greenplum Database sets the sequence `is_called` attribute to `false`. Invoking `nextval()` on a newly-created sequence does not increment the sequence counter, but returns the sequence start value and sets `is_called` to `true`.

Using a Sequence

After you create a sequence with the `CREATE SEQUENCE` command, you can examine the sequence and use the sequence built-in functions.

Examining Sequence Attributes

To examine the current attributes of a sequence, query the sequence directly. For example, to examine a sequence named `myserial`:

```
SELECT * FROM myserial;
```

Returning the Next Sequence Counter Value

You can invoke the `nextval()` built-in function to return and use the next value in a sequence. The following command inserts the next value of the sequence named `myserial` into the first column of a table named `vendors`:

```
INSERT INTO vendors VALUES (nextval('myserial'), 'acme');
```

`nextval()` uses the sequence's `is_called` attribute value to determine whether or not to increment the sequence counter before returning the value. `nextval()` advances the counter when `is_called` is `true`. `nextval()` sets the sequence `is_called` attribute to `true` before returning.

A `nextval()` operation is never rolled back. A fetched value is considered used, even if the transaction that performed the `nextval()` fails. This means that failed transactions can leave unused holes in the sequence of assigned values.

**Note:** You cannot use the `nextval()` function in `UPDATE` or `DELETE` statements if mirroring is enabled in Greenplum Database.

Setting the Sequence Counter Value

You can use the Greenplum Database `setval()` built-in function to set the counter value for a sequence. For example, the following command sets the counter value of the sequence named `myserial` to `201`:

```
SELECT setval('myserial', 201);
```

`setval()` has two function signatures: `setval(sequence, start_val)` and `setval(sequence, start_val, is_called)`. The default behaviour of `setval(sequence, start_val)` sets the sequence `is_called` attribute value to `true`.

If you do not want the sequence counter advanced on the next `nextval()` call, use the `setval(sequence, start_val, is_called)` function signature, passing a false argument:

```
SELECT setval('myserial', 201, false);
```

`setval()` operations are never rolled back.

**Altering a Sequence**

The `ALTER SEQUENCE` command changes the attributes of an existing sequence. You can alter the sequence start, minimum, maximum, and increment values. You can also restart the sequence at the start value or at a specified value.

Any parameters not set in the `ALTER SEQUENCE` command retain their prior settings.

- `ALTER SEQUENCE sequence START WITH start_value` sets the sequence’s `start_value` attribute to the new starting value. It has no effect on the `last_value` attribute or the value returned by the `nextval(sequence)` function.

- `ALTER SEQUENCE sequence RESTART` resets the sequence’s `last_value` attribute to the current value of the `start_value` attribute and the `is_called` attribute to false. The next call to the `nextval(sequence)` function returns `start_value`.

- `ALTER SEQUENCE sequence RESTART WITH restart_value` sets the sequence’s `last_value` attribute to the new value and the `is_called` attribute to false. The next call to the `nextval(sequence)` returns `restart_value`. This is the equivalent of calling `setval(sequence, restart_value, false)`.

The following command restarts the sequence named `myserial` at value 105:

```
ALTER SEQUENCE myserial RESTART WITH 105;
```

**Dropping a Sequence**

The `DROP SEQUENCE` command removes a sequence. For example, the following command removes the sequence named `myserial`:

```
DROP SEQUENCE myserial;
```

**Specifying a Sequence as the Default Value for a Column**

You can reference a sequence directly in the `CREATE TABLE` command in addition to using the `SERIAL` or `BIGSERIAL` types. For example:

```
CREATE TABLE tablename ( id INT4 DEFAULT nextval('myserial'), name text );
```

You can also alter a table column to set its default value to a sequence counter:

```
ALTER TABLE tablename ALTER COLUMN id SET DEFAULT nextval('myserial');
```

**Sequence Wraparound**

By default, a sequence does not wrap around. That is, when a sequence reaches the max value (+32767 for `SMALLSERIAL`, +2147483647 for `SERIAL`, +9223372036854775807 for `BIGSERIAL`), every subsequent `nextval()` call produces an error. You can alter a sequence to make it cycle around and start at 1 again:

```
ALTER SEQUENCE myserial CYCLE;
```
You can also specify the wraparound behaviour when you create the sequence:

```
CREATE SEQUENCE myserial CYCLE;
```

## Using Indexes in Greenplum Database

In most traditional databases, indexes can greatly improve data access times. However, in a distributed database such as Greenplum, indexes should be used more sparingly. Greenplum Database performs very fast sequential scans; indexes use a random seek pattern to locate records on disk. Greenplum data is distributed across the segments, so each segment scans a smaller portion of the overall data to get the result. With table partitioning, the total data to scan may be even smaller. Because business intelligence (BI) query workloads generally return very large data sets, using indexes is not efficient.

First try your query workload without adding indexes. Indexes are more likely to improve performance for OLTP workloads, where the query is returning a single record or a small subset of data. Indexes can also improve performance on compressed append-optimized tables for queries that return a targeted set of rows, as the optimizer can use an index access method rather than a full table scan when appropriate. For compressed data, an index access method means only the necessary rows are uncompressed.

Greenplum Database automatically creates `PRIMARY KEY` constraints for tables with primary keys. To create an index on a partitioned table, create an index on the partitioned table that you created. The index is propagated to all the child tables created by Greenplum Database. Creating an index on a table that is created by Greenplum Database for use by a partitioned table is not supported.

Note that a `UNIQUE CONSTRAINT` (such as a `PRIMARY KEY CONSTRAINT`) implicitly creates a `UNIQUE INDEX` that must include all the columns of the distribution key and any partitioning key. The `UNIQUE CONSTRAINT` is enforced across the entire table, including all table partitions (if any).

Indexes add some database overhead — they use storage space and must be maintained when the table is updated. Ensure that the query workload uses the indexes that you create, and check that the indexes you add improve query performance (as compared to a sequential scan of the table). To determine whether indexes are being used, examine the query `EXPLAIN` plans. See *Query Profiling*.

Consider the following points when you create indexes.

- **Your Query Workload.** Indexes improve performance for workloads where queries return a single record or a very small data set, such as OLTP workloads.
- **Compressed Tables.** Indexes can improve performance on compressed append-optimized tables for queries that return a targeted set of rows. For compressed data, an index access method means only the necessary rows are uncompressed.
- **Avoid indexes on frequently updated columns.** Creating an index on a column that is frequently updated increases the number of writes required when the column is updated.
- **Create selective B-tree indexes.** Index selectivity is a ratio of the number of distinct values a column has divided by the number of rows in a table. For example, if a table has 1000 rows and a column has 800 distinct values, the selectivity of the index is 0.8, which is considered good. Unique indexes always have a selectivity ratio of 1.0, which is the best possible. Greenplum Database allows unique indexes only on distribution key columns.
- **Use Bitmap indexes for low selectivity columns.** The Greenplum Database Bitmap index type is not available in regular PostgreSQL. See *About Bitmap Indexes*.
- **Index columns used in joins.** An index on a column used for frequent joins (such as a foreign key column) can improve join performance by enabling more join methods for the query optimizer to use.
- **Index columns frequently used in predicates.** Columns that are frequently referenced in `WHERE` clauses are good candidates for indexes.
- **Avoid overlapping indexes.** Indexes that have the same leading column are redundant.
- **Drop indexes for bulk loads.** For mass loads of data into a table, consider dropping the indexes and re-creating them after the load completes. This is often faster than updating the indexes.
• **Consider a clustered index.** Clustering an index means that the records are physically ordered on disk according to the index. If the records you need are distributed randomly on disk, the database has to seek across the disk to fetch the records requested. If the records are stored close together, the fetching operation is more efficient. For example, a clustered index on a date column where the data is ordered sequentially by date. A query against a specific date range results in an ordered fetch from the disk, which leverages fast sequential access.

### To cluster an index in Greenplum Database

Using the `CLUSTER` command to physically reorder a table based on an index can take a long time with very large tables. To achieve the same results much faster, you can manually reorder the data on disk by creating an intermediate table and loading the data in the desired order. For example:

```sql
CREATE TABLE new_table (LIKE old_table)
   AS SELECT * FROM old_table ORDER BY myixcolumn;
DROP old_table;
ALTER TABLE new_table RENAME TO old_table;
CREATE INDEX myixcolumn_ix ON old_table;
VACUUM ANALYZE old_table;
```

### Index Types

Greenplum Database supports the Postgres index types B-tree, GiST, SP-GiST, and GIN. Hash indexes are not supported. Each index type uses a different algorithm that is best suited to different types of queries. B-tree indexes fit the most common situations and are the default index type. See [Index Types](#) in the PostgreSQL documentation for a description of these types.

**Note:** Greenplum Database allows unique indexes only if the columns of the index key are the same as (or a superset of) the Greenplum distribution key. Unique indexes are not supported on append-optimized tables. On partitioned tables, a unique index cannot be enforced across all child table partitions of a partitioned table. A unique index is supported only within a partition.

### About Bitmap Indexes

Greenplum Database provides the Bitmap index type. Bitmap indexes are best suited to data warehousing applications and decision support systems with large amounts of data, many ad hoc queries, and few data modification (DML) transactions.

An index provides pointers to the rows in a table that contain a given key value. A regular index stores a list of tuple IDs for each key corresponding to the rows with that key value. Bitmap indexes store a bitmap for each key value. Regular indexes can be several times larger than the data in the table, but bitmap indexes provide the same functionality as a regular index and use a fraction of the size of the indexed data.

Each bit in the bitmap corresponds to a possible tuple ID. If the bit is set, the row with the corresponding tuple ID contains the key value. A mapping function converts the bit position to a tuple ID. Bitmaps are compressed for storage. If the number of distinct key values is small, bitmap indexes are much smaller, compress better, and save considerable space compared with a regular index. The size of a bitmap index is proportional to the number of rows in the table times the number of distinct values in the indexed column.

Bitmap indexes are most effective for queries that contain multiple conditions in the `WHERE` clause. Rows that satisfy some, but not all, conditions are filtered out before the table is accessed. This improves response time, often dramatically.

### When to Use Bitmap Indexes

Bitmap indexes are best suited to data warehousing applications where users query the data rather than update it. Bitmap indexes perform best for columns that have between 100 and 100,000 distinct values and when the indexed column is often queried in conjunction with other indexed columns. Columns with fewer than 100 distinct values, such as a gender column with two distinct values (male and female), usually
do not benefit much from any type of index. On a column with more than 100,000 distinct values, the performance and space efficiency of a bitmap index decline.

Bitmap indexes can improve query performance for ad hoc queries. AND and OR conditions in the WHERE clause of a query can be resolved quickly by performing the corresponding Boolean operations directly on the bitmaps before converting the resulting bitmap to tuple ids. If the resulting number of rows is small, the query can be answered quickly without resorting to a full table scan.

**When Not to Use Bitmap Indexes**

Do not use bitmap indexes for unique columns or columns with high cardinality data, such as customer names or phone numbers. The performance gains and disk space advantages of bitmap indexes start to diminish on columns with 100,000 or more unique values, regardless of the number of rows in the table.

Bitmap indexes are not suitable for OLTP applications with large numbers of concurrent transactions modifying the data.

Use bitmap indexes sparingly. Test and compare query performance with and without an index. Add an index only if query performance improves with indexed columns.

**Creating an Index**

The `CREATE INDEX` command defines an index on a table. A B-tree index is the default index type. For example, to create a B-tree index on the column `gender` in the table `employee`:

```
CREATE INDEX gender_idx ON employee (gender);
```

To create a bitmap index on the column `title` in the table `films`:

```
CREATE INDEX title_bmp_idx ON films USING bitmap (title);
```

**Indexes on Expressions**

An index column need not be just a column of the underlying table, but can be a function or scalar expression computed from one or more columns of the table. This feature is useful to obtain fast access to tables based on the results of computations.

Index expressions are relatively expensive to maintain, because the derived expressions must be computed for each row upon insertion and whenever it is updated. However, the index expressions are not recomputed during an indexed search, since they are already stored in the index. In both of the following examples, the system sees the query as just WHERE indexedcolumn = 'constant' and so the speed of the search is equivalent to any other simple index query. Thus, indexes on expressions are useful when retrieval speed is more important than insertion and update speed.

The first example is a common way to do case-insensitive comparisons with the `lower` function:

```
SELECT * FROM test1 WHERE lower(col1) = 'value';
```

This query can use an index if one has been defined on the result of the `lower(col1)` function:

```
CREATE INDEX test1_lower_col1_idx ON test1 (lower(col1));
```

This example assumes the following type of query is performed often.

```
SELECT * FROM people WHERE (first_name || ' ' || last_name) = 'John Smith';
```

The query might benefit from the following index.

```
CREATE INDEX people_names ON people ((first_name || ' ' || last_name));
```
The syntax of the `CREATE INDEX` command normally requires writing parentheses around index expressions, as shown in the second example. The parentheses can be omitted when the expression is just a function call, as in the first example.

### Examining Index Usage

Greenplum Database indexes do not require maintenance and tuning. You can check which indexes are used by the real-life query workload. Use the `EXPLAIN` command to examine index usage for a query.

The query plan shows the steps or *plan nodes* that the database will take to answer a query and time estimates for each plan node. To examine the use of indexes, look for the following query plan node types in your `EXPLAIN` output:

- **Index Scan** - A scan of an index.
- **Bitmap Heap Scan** - Retrieves all from the bitmap generated by BitmapAnd, BitmapOr, or BitmapIndexScan and accesses the heap to retrieve the relevant rows.
- **Bitmap Index Scan** - Compute a bitmap by OR-ing all bitmaps that satisfy the query predicates from the underlying index.
- **BitmapAnd** or **BitmapOr** - Takes the bitmaps generated from multiple BitmapIndexScan nodes, ANDs or ORs them together, and generates a new bitmap as its output.

You have to experiment to determine the indexes to create. Consider the following points.

- Run `ANALYZE` after you create or update an index. `ANALYZE` collects table statistics. The query optimizer uses table statistics to estimate the number of rows returned by a query and to assign realistic costs to each possible query plan.
- Use real data for experimentation. Using test data for setting up indexes tells you what indexes you need for the test data, but that is all.
- Do not use very small test data sets as the results can be unrealistic or skewed.
- Be careful when developing test data. Values that are similar, completely random, or inserted in sorted order will skew the statistics away from the distribution that real data would have.
- You can force the use of indexes for testing purposes by using run-time parameters to turn off specific plan types. For example, turn off sequential scans (`enable_seqscan`) and nested-loop joins (`enable_nestloop`), the most basic plans, to force the system to use a different plan. Time your query with and without indexes and use the `EXPLAIN ANALYZE` command to compare the results.

### Managing Indexes

Use the `REINDEX` command to rebuild a poorly-performing index. `REINDEX` rebuilds an index using the data stored in the index’s table, replacing the old copy of the index.

#### To rebuild all indexes on a table

```sql
REINDEX my_table;
```

#### To rebuild a particular index

```sql
REINDEX my_index;
```

### Dropping an Index

The `DROP INDEX` command removes an index. For example:

```sql
DROP INDEX title_idx;
```
When loading data, it can be faster to drop all indexes, load, then recreate the indexes.

Creating and Managing Views

Views enable you to save frequently used or complex queries, then access them in a `SELECT` statement as if they were a table. A view is not physically materialized on disk: the query runs as a subquery when you access the view.

If a subquery is associated with a single query, consider using the `WITH` clause of the `SELECT` command instead of creating a seldom-used view.

Creating Views

The `CREATE VIEW` command defines a view of a query. For example:

```
CREATE VIEW comedies AS SELECT * FROM films WHERE kind = 'comedy';
```

Views ignore `ORDER BY` and `SORT` operations stored in the view.

Dropping Views

The `DROP VIEW` command removes a view. For example:

```
DROP VIEW topten;
```

The `DROP VIEW ... CASCADE` command also removes all dependent objects. As example, if another view depends on the view which is about to be dropped, the other view will be dropped as well. Without the `CASCADE` option, the `DROP VIEW` command will fail.
Distribution and Skew

Greenplum Database relies on even distribution of data across segments.

In an MPP shared nothing environment, overall response time for a query is measured by the completion time for all segments. The system is only as fast as the slowest segment. If the data is skewed, segments with more data will take more time to complete, so every segment must have an approximately equal number of rows and perform approximately the same amount of processing. Poor performance and out of memory conditions may result if one segment has significantly more data to process than other segments.

Optimal distributions are critical when joining large tables together. To perform a join, matching rows must be located together on the same segment. If data is not distributed on the same join column, the rows needed from one of the tables are dynamically redistributed to the other segments. In some cases a broadcast motion, in which each segment sends its individual rows to all other segments, is performed rather than a redistribution motion, where each segment rehashes the data and sends the rows to the appropriate segments according to the hash key.

Local (Co-located) Joins

Using a hash distribution that evenly distributes table rows across all segments and results in local joins can provide substantial performance gains. When joined rows are on the same segment, much of the processing can be accomplished within the segment instance. These are called local or co-located joins. Local joins minimize data movement; each segment operates independently of the other segments, without network traffic or communications between segments.

To achieve local joins for large tables commonly joined together, distribute the tables on the same column. Local joins require that both sides of a join be distributed on the same columns (and in the same order) and that all columns in the distribution clause are used when joining tables. The distribution columns must also be the same data type—although some values with different data types may appear to have the same representation, they are stored differently and hash to different values, so they are stored on different segments.

Data Skew

Data skew may be caused by uneven data distribution due to the wrong choice of distribution keys or single tuple table insert or copy operations. Present at the table level, data skew, is often the root cause of poor query performance and out of memory conditions. Skewed data affects scan (read) performance, but it also affects all other query execution operations, for instance, joins and group by operations.

It is very important to validate distributions to ensure that data is evenly distributed after the initial load. It is equally important to continue to validate distributions after incremental loads.

The following query shows the number of rows per segment as well as the variance from the minimum and maximum numbers of rows:

```sql
SELECT 'Example Table' AS "Table Name",
   max(c) AS "Max Seg Rows",
   min(c) AS "Min Seg Rows",
   (max(c)-min(c))*100.0/max(c) AS "Percentage Difference Between Max & Min"
FROM (SELECT count(*) c, gp_segment_id FROM facts GROUP BY 2) AS a;
```

The `gp_toolkit` schema has two views that you can use to check for skew.

- The `gp_toolkit.gp_skew_coefficients` view shows data distribution skew by calculating the coefficient of variation (CV) for the data stored on each segment. The `skccoeff` column shows the coefficient of variation (CV), which is calculated as the standard deviation divided by the average. It
takes into account both the average and variability around the average of a data series. The lower the value, the better. Higher values indicate greater data skew.

- The `gp_toolkit.gp_skew_idle_fractions` view shows data distribution skew by calculating the percentage of the system that is idle during a table scan, which is an indicator of computational skew. The `siffraction` column shows the percentage of the system that is idle during a table scan. This is an indicator of uneven data distribution or query processing skew. For example, a value of 0.1 indicates 10% skew, a value of 0.5 indicates 50% skew, and so on. Tables that have more than 10% skew should have their distribution policies evaluated.

### Considerations for Replicated Tables

When you create a replicated table (with the `CREATE TABLE` clause `DISTRIBUTED REPLICATED`), Greenplum Database distributes every table row to every segment instance. Replicated table data is evenly distributed because every segment has the same rows. A query that uses the `gp_segment_id` system column on a replicated table to verify evenly distributed data, will fail because Greenplum Database does not allow queries to reference replicated tables’ system columns.

### Processing Skew

Processing skew results when a disproportionate amount of data flows to, and is processed by, one or a few segments. It is often the culprit behind Greenplum Database performance and stability issues. It can happen with operations such join, sort, aggregation, and various OLAP operations. Processing skew happens in flight while a query is executing and is not as easy to detect as data skew.

If single segments are failing, that is, not all segments on a host, it may be a processing skew issue. Identifying processing skew is currently a manual process. First look for spill files. If there is skew, but not enough to cause spill, it will not become a performance issue. If you determine skew exists, then find the query responsible for the skew. Following are the steps and commands to use. (Change names like the host file name passed to `gpssh` accordingly):

1. Find the OID for the database that is to be monitored for skew processing:

   ```sql
   SELECT oid, datname FROM pg_database;
   ```

   Example output:

<table>
<thead>
<tr>
<th>oid</th>
<th>datname</th>
</tr>
</thead>
<tbody>
<tr>
<td>17088</td>
<td>gpadmin</td>
</tr>
<tr>
<td>10899</td>
<td>postgres</td>
</tr>
<tr>
<td>1</td>
<td>template1</td>
</tr>
<tr>
<td>10898</td>
<td>template0</td>
</tr>
<tr>
<td>38817</td>
<td>pws</td>
</tr>
<tr>
<td>39862</td>
<td>gpperfmon</td>
</tr>
</tbody>
</table>
   (6 rows)

2. Run a `gpssh` command to check file sizes across all of the segment nodes in the system. Replace `<OID>` with the OID of the database from the prior command:

   ```bash
   [gpadmin@mdw kend]$ gpssh -f ~/hosts -e "du -b /data[1-2]/primary/gpseg*/base/<OID>/pgsql_tmp/* | grep -v "du -b" | sort | awk '{ arr[$1] = arr[$1] + $2 ; tot = tot + $2 } END { for ( i in arr ) print "Segment node" i, arr[i], "bytes (" arr[i]/(1024**3) " GB)" ; print "Total", tot, "bytes (" tot/(1024**3) " GB)" )'"
   ```

   Example output:

   ```plaintext
   Segment node[sdw1] 2443370457 bytes (2.27557 GB)
   ```
If there is a *significant and sustained* difference in disk usage, then the queries being executed should be investigated for possible skew (the example output above does not reveal significant skew). In monitoring systems, there will always be some skew, but often it is *transient* and will be *short in duration*.

3. If significant and sustained skew appears, the next task is to identify the offending query.

   The command in the previous step sums up the entire node. This time, find the actual segment directory. You can do this from the master or by logging into the specific node identified in the previous step. Following is an example run from the master.

   This example looks specifically for sort files. Not all spill files or skew situations are caused by sort files, so you will need to customize the command:

   ```bash
   $ gpssh -f ~/hosts -e
   "ls -l /data[1-2]/primary/gpseg*/base/19979/pgsql_tmp/*" | grep -i sort | awk '{sub(/base.*tmp//, ".../", $10); print $1,$6, $10}' | sort -k2 -n
   ```

   Here is output from this command:

   ```plaintext
   [sdw1] 288718848 /data1/primary/gpseg2/.../pgsql_tmp_slice0_sort_17758_0001.0
   291176448 /data2/primary/gpseg5/.../pgsql_tmp_slice0_sort_17764_0001.0
   924581888 /data2/primary/gpseg45/.../pgsql_tmp_slice10_sort_15673_0010.9
   980582400 /data1/primary/gpseg18/.../pgsql_tmp_slice10_sort_29425_0001.0
   986447872 /data2/primary/gpseg35/.../pgsql_tmp_slice10_sort_29602_0001.0
   999620608 /data1/primary/gpseg26/.../pgsql_tmp_slice10_sort_28637_0001.0
   999751680 /data2/primary/gpseg9/.../pgsql_tmp_slice10_sort_3969_0001.0
   1000112128 /data1/primary/gpseg13/.../pgsql_tmp_slice10_sort_24723_0001.0
   1000898560 /data2/primary/gpseg28/.../pgsql_tmp_slice10_sort_28641_0001.0
   [sdw5] 1008009216 /data1/primary/gpseg44/.../pgsql_tmp_slice10_sort_15671_0001.0
   1008566272 /data1/primary/gpseg24/.../pgsql_tmp_slice10_sort_28633_0001.0
   1009451008 /data1/primary/gpseg19/.../pgsql_tmp_slice10_sort_29427_0001.0
   1011187712 /data1/primary/gpseg37/.../pgsql_tmp_slice10_sort_18526_0001.0
   1573741824 /data2/primary/gpseg45/.../pgsql_tmp_slice10_sort_15673_0001.0
   1573741824 /data2/primary/gpseg45/.../pgsql_tmp_slice10_sort_15673_0002.1
   1573741824 /data2/primary/gpseg45/.../pgsql_tmp_slice10_sort_15673_0003.2
   ```
Scanning this output reveals that segment gpseg45 on host sdw8 is the culprit, as its sort files are larger than the others in the output.

4. Log in to the offending node with ssh and become root. Use the lsof command to find the PID for the process that owns one of the sort files:

```
[root@sdw8 ~]# lsof /data2/primary/gpseg45/base/19979/pgsql_tmp/
pqltmplslice10_sort_15673_0002.1
```

<table>
<thead>
<tr>
<th>COMMAND</th>
<th>PID</th>
<th>USER</th>
<th>FD</th>
<th>TYPE</th>
<th>DEVICE</th>
<th>SIZE</th>
<th>NODE</th>
<th>NAME</th>
</tr>
</thead>
<tbody>
<tr>
<td>postgres</td>
<td>15673</td>
<td>gpadmin</td>
<td>11u</td>
<td>REG</td>
<td>8,48</td>
<td>1073741824</td>
<td>64424546751</td>
<td>/data2/primary/gpseg45/base/19979/pgsql_tmp/pgqltmplslice10_sort_15673_0002.1</td>
</tr>
</tbody>
</table>

The PID, 15673, is also part of the file name, but this may not always be the case.

5. Use the ps command with the PID to identify the database and connection information:

```
[root@sdw8 ~]# ps -eaf | grep 15673
```

```
gpadmin 15673 27471 28 12:05 ? 00:12:59 postgres: port 40003,
    sbaskin bdw 172.28.12.250(21813) con699238 seg45 cmd32 slice10 MPPEXEC SELECT
root 29622 29566 0 12:50 pts/16 00:00:00 grep 15673
```

6. On the master, check the pg_log log file for the user in the previous command (sbaskin), connection (con699238), and command (cmd32). The line in the log file with these three values should be the line that contains the query, but occasionally, the command number may differ slightly. For example, the ps output may show cmd32, but in the log file it is cmd34. If the query is still running, the last query for the user and connection is the offending query.

The remedy for processing skew in almost all cases is to rewrite the query. Creating temporary tables can eliminate skew. Temporary tables can be randomly distributed to force a two-stage aggregation.
Inserting, Updating, and Deleting Data

This section provides information about manipulating data and concurrent access in Greenplum Database.

This topic includes the following subtopics:

- About Concurrency Control in Greenplum Database
- Inserting Rows
- Updating Existing Rows
- Deleting Rows
- Working With Transactions
- Global Deadlock Detector
- Vacuuming the Database
- Running Out of Locks

About Concurrency Control in Greenplum Database

Greenplum Database and PostgreSQL do not use locks for concurrency control. They maintain data consistency using a multiversion model, Multiversion Concurrency Control (MVCC). MVCC achieves transaction isolation for each database session, and each query transaction sees a snapshot of data. This ensures the transaction sees consistent data that is not affected by other concurrent transactions.

Because MVCC does not use explicit locks for concurrency control, lock contention is minimized and Greenplum Database maintains reasonable performance in multiuser environments. Locks acquired for querying (reading) data do not conflict with locks acquired for writing data.

Greenplum Database provides multiple lock modes to control concurrent access to data in tables. Most Greenplum Database SQL commands automatically acquire the appropriate locks to ensure that referenced tables are not dropped or modified in incompatible ways while a command executes. For applications that cannot adapt easily to MVCC behavior, you can use the `LOCK` command to acquire explicit locks. However, proper use of MVCC generally provides better performance.

Table 41: Lock Modes in Greenplum Database

<table>
<thead>
<tr>
<th>Lock Mode</th>
<th>Associated SQL Commands</th>
<th>Conflicts With</th>
</tr>
</thead>
<tbody>
<tr>
<td>ACCESS SHARE</td>
<td>SELECT</td>
<td>ACCESS EXCLUSIVE</td>
</tr>
<tr>
<td>ROW SHARE</td>
<td>SELECT FOR SHARE, SELECT... FOR UPDATE</td>
<td>EXCLUSIVE, ACCESS EXCLUSIVE</td>
</tr>
<tr>
<td>ROW EXCLUSIVE</td>
<td>INSERT, COPY</td>
<td>SHARE, SHARE ROW EXCLUSIVE, EXCLUSIVE, ACCESS EXCLUSIVE</td>
</tr>
<tr>
<td>SHARE UPDATE EXCLUSIVE</td>
<td>VACUUM (without FULL), ANALYZE</td>
<td>SHARE UPDATE EXCLUSIVE, SHARE, SHARE ROW EXCLUSIVE, EXCLUSIVE, ACCESS EXCLUSIVE</td>
</tr>
<tr>
<td>SHARE</td>
<td>CREATE INDEX</td>
<td>ROW EXCLUSIVE, SHARE UPDATE EXCLUSIVE, SHARE ROW EXCLUSIVE, EXCLUSIVE, ACCESS EXCLUSIVE</td>
</tr>
</tbody>
</table>

Note: For INSERT, COPY, and CREATE INDEX, the lock mode is SHARE if the table is empty or would become empty after the lock is acquired.
**Lock Mode** | **Associated SQL Commands** | **Conflicts With**
---|---|---
SHARE ROW EXCLUSIVE |  | ROW EXCLUSIVE, SHARE UPDATE EXCLUSIVE, SHARE, SHARE ROW EXCLUSIVE, EXCLUSIVE, ACCESS EXCLUSIVE
EXCLUSIVE | DELETE, UPDATE, SELECT...FOR UPDATE  
See Note. | ROW SHARE, ROW EXCLUSIVE, SHARE UPDATE EXCLUSIVE, SHARE, SHARE ROW EXCLUSIVE, EXCLUSIVE, ACCESS EXCLUSIVE
ACCESS EXCLUSIVE | ALTER TABLE, DROP TABLE, TRUNCATE, REINDEX, CLUSTER, VACUUM FULL | ACCESS SHARE, ROW SHARE, ROW EXCLUSIVE, SHARE UPDATE EXCLUSIVE, SHARE, SHARE ROW EXCLUSIVE, EXCLUSIVE, ACCESS EXCLUSIVE

**Note:** By default, Greenplum Database acquires the more restrictive EXCLUSIVE lock (rather than ROW EXCLUSIVE in PostgreSQL) for UPDATE, DELETE, and SELECT...FOR UPDATE.

When the Global Deadlock Detector is enabled, the lock mode for DELETE, UPDATE, and SELECT...FOR UPDATE operations on heap tables is ROW EXCLUSIVE. See Global Deadlock Detector.

### Inserting Rows

Use the `INSERT` command to create rows in a table. This command requires the table name and a value for each column in the table; you may optionally specify the column names in any order. If you do not specify column names, list the data values in the order of the columns in the table, separated by commas.

For example, to specify the column names and the values to insert:

```
INSERT INTO products (name, price, product_no) VALUES ('Cheese', 9.99, 1);
```

To specify only the values to insert:

```
INSERT INTO products VALUES (1, 'Cheese', 9.99);
```

Usually, the data values are literals (constants), but you can also use scalar expressions. For example:

```
INSERT INTO films SELECT * FROM tmp_films WHERE date_prod < '2016-05-07';
```

You can insert multiple rows in a single command. For example:

```
INSERT INTO products (product_no, name, price) VALUES  
(1, 'Cheese', 9.99),  
(2, 'Bread', 1.99),  
(3, 'Milk', 2.99);
```

To insert data into a partitioned table, you specify the root partitioned table, the table created with the `CREATE TABLE` command. You also can specify a leaf child table of the partitioned table in an `INSERT` command. An error is returned if the data is not valid for the specified leaf child table. Specifying a child table that is not a leaf child table in the `INSERT` command is not supported.

To insert large amounts of data, use external tables or the `COPY` command. These load mechanisms are more efficient than `INSERT` for inserting large quantities of rows. See Loading and Unloading Data for more information about bulk data loading.
The storage model of append-optimized tables is optimized for bulk data loading. Greenplum does not recommend single row `INSERT` statements for append-optimized tables. For append-optimized tables, Greenplum Database supports a maximum of 127 concurrent `INSERT` transactions into a single append-optimized table.

**Updating Existing Rows**

The `UPDATE` command updates rows in a table. You can update all rows, a subset of all rows, or individual rows in a table. You can update each column separately without affecting other columns.

To perform an update, you need:

- The name of the table and columns to update
- The new values of the columns
- One or more conditions specifying the row or rows to be updated.

For example, the following command updates all products that have a price of 5 to have a price of 10:

```
UPDATE products SET price = 10 WHERE price = 5;
```

Using `UPDATE` in Greenplum Database has the following restrictions:

- While GPORCA supports updates to Greenplum distribution key columns, the Postgres Planner does not.
- If mirrors are enabled, you cannot use `STABLE` or `VOLATILE` functions in an `UPDATE` statement.
- Greenplum Database partitioning columns cannot be updated.

**Deleting Rows**

The `DELETE` command deletes rows from a table. Specify a `WHERE` clause to delete rows that match certain criteria. If you do not specify a `WHERE` clause, all rows in the table are deleted. The result is a valid, but empty, table. For example, to remove all rows from the products table that have a price of 10:

```
DELETE FROM products WHERE price = 10;
```

To delete all rows from a table:

```
DELETE FROM products;
```

Using `DELETE` in Greenplum Database has similar restrictions to using `UPDATE`:

- If mirrors are enabled, you cannot use `STABLE` or `VOLATILE` functions in an `UPDATE` statement.

**Truncating a Table**

Use the `TRUNCATE` command to quickly remove all rows in a table. For example:

```
TRUNCATE mytable;
```

This command empties a table of all rows in one operation. Note that `TRUNCATE` does not scan the table, therefore it does not process inherited child tables or `ON DELETE` rewrite rules. The command truncates only rows in the named table.

**Working With Transactions**

Transactions allow you to bundle multiple SQL statements in one all-or-nothing operation.

The following are the Greenplum Database SQL transaction commands:
• BEGIN or START TRANSACTION starts a transaction block.
• END or COMMIT commits the results of a transaction.
• ROLLBACK abandons a transaction without making any changes.
• SAVEPOINT marks a place in a transaction and enables partial rollback. You can roll back commands executed after a savepoint while maintaining commands executed before the savepoint.
• ROLLBACK TO SAVEPOINT rolls back a transaction to a savepoint.
• RELEASE SAVEPOINT destroys a savepoint within a transaction.

Transaction Isolation Levels
Greenplum Database accepts the standard SQL transaction levels as follows:
• READ UNCOMMITTED and READ COMMITTED behave like the standard READ COMMITTED.
• REPEATABLE READ and SERIALIZABLE behave like REPEATABLE READ.

The following information describes the behavior of the Greenplum transaction levels.

Read Uncommitted and Read Committed
Greenplum Database does not allow any command to see an uncommitted update in another concurrent transaction, so READ UNCOMMITTED behaves the same as READ COMMITTED. READ COMMITTED provides fast, simple, partial transaction isolation. SELECT, UPDATE, and DELETE commands operate on a snapshot of the database taken when the query started.

A SELECT query:
• Sees data committed before the query starts.
• Sees updates executed within the transaction.
• Does not see uncommitted data outside the transaction.
• Can possibly see changes that concurrent transactions made if the concurrent transaction is committed after the initial read in its own transaction.

Successive SELECT queries in the same transaction can see different data if other concurrent transactions commit changes between the successive queries. UPDATE and DELETE commands find only rows committed before the commands started.

READ COMMITTED transaction isolation allows concurrent transactions to modify or lock a row before UPDATE or DELETE find the row. READ COMMITTED transaction isolation may be inadequate for applications that perform complex queries and updates and require a consistent view of the database.

Repeatable Read and Serializable
SERIALIZABLE transaction isolation, as defined by the SQL standard, ensures that transactions that run concurrently produce the same results as if they were run one after another. If you specify SERIALIZABLE Greenplum Database falls back to REPEATABLE READ. REPEATABLE READ transactions prevent dirty reads, non-repeatable reads, and phantom reads without expensive locking, but Greenplum Database does not detect all serializability interactions that can occur during concurrent transaction execution.
Concurrent transactions should be examined to identify interactions that are not prevented by disallowing concurrent updates of the same data. You can prevent these interactions by using explicit table locks or by requiring the conflicting transactions to update a dummy row introduced to represent the conflict.

With REPEATABLE READ transactions, a SELECT query:
• Sees a snapshot of the data as of the start of the transaction (not as of the start of the current query within the transaction).
• Sees only data committed before the query starts.
• Sees updates executed within the transaction.
• Does not see uncommitted data outside the transaction.
• Does not see changes that concurrent transactions make.
• Successive SELECT commands within a single transaction always see the same data.
• UPDATE, DELETE, SELECT FOR UPDATE, and SELECT FOR SHARE commands find only rows committed before the command started. If a concurrent transaction has updated, deleted, or locked a target row, the REPEATABLE READ transaction waits for the concurrent transaction to commit or roll back the change. If the concurrent transaction commits the change, the REPEATABLE READ transaction rolls back. If the concurrent transaction rolls back its change, the REPEATABLE READ transaction can commit its changes.

The default transaction isolation level in Greenplum Database is READ COMMITTED. To change the isolation level for a transaction, declare the isolation level when you BEGIN the transaction or use the SET TRANSACTION command after the transaction starts.

Global Deadlock Detector

The Greenplum Database Global Deadlock Detector background worker process collects lock information on all segments and uses a directed algorithm to detect the existence of local and global deadlocks. This algorithm allows Greenplum Database to relax concurrent update and delete restrictions on heap tables. (Greenplum Database still employs table-level locking on AO/CO tables, restricting concurrent UPDATE, DELETE, and SELECT...FOR UPDATE operations.)

By default, the Global Deadlock Detector is disabled and Greenplum Database executes the concurrent update and delete operations on a heap table serially. You can enable these concurrent updates and have the Global Deadlock Detector determine when a deadlock exists by setting the server configuration parameter gp_enable_global_deadlock_detector.

When the Global Deadlock Detector is enabled, the background worker process is automatically started on the master host when you start Greenplum Database. You configure the interval at which the Global Deadlock Detector collects and analyzes lock waiting data via the gp_global_deadlock_detector_period server configuration parameter.

If the Global Deadlock Detector determines that deadlock exists, it breaks the deadlock by cancelling one or more backend processes associated with the youngest transaction(s) involved.

When the Global Deadlock Detector determines a deadlock exists for the following types of transactions, only one of the transactions will succeed. The other transactions will fail with an error indicating that concurrent updates to the same row is not allowed.

• Concurrent transactions on the same row of a heap table where the first transaction is an update operation and a later transaction executes an update or delete and the query plan contains a motion operator.
• Concurrent update transactions on the same distribution key of a heap table that are executed by the Postgres Planner.
• Concurrent update transactions on the same row of a hash table that are executed by the GPORCA optimizer.

Note: Greenplum Database uses the interval specified in the deadlock_timeout server configuration parameter for local deadlock detection. Because the local and global deadlock detection algorithms differ, the cancelled process(es) may differ depending upon which detector (local or global) Greenplum Database triggers first.

Note: If the lock_timeout server configuration parameter is turned on and set to a value smaller than deadlock_timeout and gp_global_deadlock_detector_period, Greenplum Database will abort a statement before it would ever trigger a deadlock check in that session.

To view lock waiting information for all segments, run the gp_dist_wait_status() user-defined function. You can use the output of this function to determine which transactions are waiting on locks, which transactions are holding locks, the lock types and mode, the waiter and holder session identifiers,
and which segments are executing the transactions. Sample output of the `gp_dist_wait_status()` function follows:

```sql
SELECT * FROM pg_catalog.gp_dist_wait_status();
-[/ RECORD 1 ]-------------------
| segid  | 0 |
| waiter_dxid | 11 |
| holder_dxid | 12 |
| holdTillEndXact | t |
| waiter_lpid | 31249 |
| holder_lpid | 31458 |
| waiter_lockmode | ShareLock |
| waiter_locktype | transactionid |
| waiter_sessionid | 8 |
| holder_sessionid | 9 |
-[/ RECORD 2 ]-------------------
| segid  | 1 |
| waiter_dxid | 12 |
| holder_dxid | 11 |
| holdTillEndXact | t |
| waiter_lpid | 31467 |
| holder_lpid | 31250 |
| waiter_lockmode | ShareLock |
| waiter_locktype | transactionid |
| waiter_sessionid | 9 |
| holder_sessionid | 8 |
```

When it cancels a transaction to break a deadlock, the Global Deadlock Detector reports the following error message:

```
ERROR:  canceling statement due to user request: "cancelled by global deadlock detector"
```

### Global Deadlock Detector UPDATE and DELETE Compatibility

The Global Deadlock Detector can manage concurrent updates for these types of `UPDATE` and `DELETE` commands on heap tables:

- **Simple UPDATE** of a single table. Update a non-distribution key with the Postgres Planner. The command does not contain a `FROM` clause, or a sub-query in the `WHERE` clause.

  ```sql
  UPDATE t SET c2 = c2 + 1 WHERE c1 > 10;
  ```

- **Simple DELETE** of a single table. The command does not contain a sub-query in the `FROM` or `WHERE` clauses.

  ```sql
  DELETE FROM t WHERE c1 > 10;
  ```

- **Split UPDATE**. For the Postgres Planner, the `UPDATE` command updates a distribution key.

  ```sql
  UPDATE t SET c = c + 1; -- c is a distribution key
  ```

  For GPORCA, the `UPDATE` command updates a distribution key or references a distribution key.

  ```sql
  UPDATE t SET b = b + 1 WHERE c = 10; -- c is a distribution key
  ```

- **Complex UPDATE**. The `UPDATE` command includes multiple table joins.

  ```sql
  UPDATE t1 SET c = t1.c+1 FROM t2 WHERE t1.c = t2.c;
  ```
Or the command contains a sub-query in the WHERE clause.

```
UPDATE t SET c = c + 1 WHERE c > ALL(SELECT * FROM t1);
```

- **Complex DELETE.** A complex DELETE command is similar to a complex UPDATE, and involves multiple table joins or a sub-query.

```
DELETE FROM t USING t1 WHERE t.c > t1.c;
```

The following table shows the concurrent UPDATE or DELETE commands that are managed by the Global Deadlock Detector. For example, concurrent simple UPDATE commands on the same table row are managed by the Global Deadlock Detector. For a concurrent complex UPDATE and a simple UPDATE, only one UPDATE is performed, and an error is returned for the other UPDATE.

**Table 42: Concurrent Updates and Deletes Managed by Global Deadlock Detector**

</tbody>
</table>

**Vacuuming the Database**

Deleted or updated data rows occupy physical space on disk even though new transactions cannot see them. Periodically running the VACUUM command removes these expired rows. For example:

```
VACUUM mytable;
```

The VACUUM command collects table-level statistics such as the number of rows and pages. Vacuum all tables after loading data, including append-optimized tables. For information about recommended routine vacuum operations, see [Routine Vacuum and Analyze](#).

**Important:** The VACUUM, VACUUM FULL, and VACUUM ANALYZE commands should be used to maintain the data in a Greenplum database especially if updates and deletes are frequently performed on your database data. See the VACUUM command in the [Greenplum Database Reference Guide](#) for information about using the command.

**Running Out of Locks**

Greenplum Database can potentially run out of locks when a database operation accesses multiple tables in a single transaction. Backup and restore are examples of such operations.

When Greenplum Database runs out of locks, the error message that you may observe references a shared memory error:

```
... "WARNING","53200","out of shared memory","","LOCK TABLE ...
... "ERROR","53200","out of shared memory","","You might need to increase max_locks_per_transaction.",","LOCK TABLE ...
```
**Note:** "shared memory" in this context refers to the shared memory of the internal object: the lock slots. "Out of shared memory" does *not* refer to exhaustion of system- or Greenplum-level memory resources.

As the hint describes, consider increasing the `max_locks_per_transaction` server configuration parameter when you encounter this error.
Querying Data

This topic provides information about using SQL in Greenplum databases.

You enter SQL statements called queries to view, change, and analyze data in a database using the `psql` interactive SQL client and other client tools.

About Greenplum Query Processing

This topic provides an overview of how Greenplum Database processes queries. Understanding this process can be useful when writing and tuning queries.

Users issue queries to Greenplum Database as they would to any database management system. They connect to the database instance on the Greenplum master host using a client application such as `psql` and submit SQL statements.

Understanding Query Planning and Dispatch

The master receives, parses, and optimizes the query. The resulting query plan is either parallel or targeted. The master dispatches parallel query plans to all segments, as shown in Figure 21: Dispatching the Parallel Query Plan. The master dispatches targeted query plans to a single segment, as shown in Figure 22: Dispatching a Targeted Query Plan. Each segment is responsible for executing local database operations on its own set of data.

Most database operations—such as table scans, joins, aggregations, and sorts—execute across all segments in parallel. Each operation is performed on a segment database independent of the data stored in the other segment databases.

Figure 21: Dispatching the Parallel Query Plan
Certain queries may access only data on a single segment, such as single-row `INSERT`, `UPDATE`, `DELETE`, or `SELECT` operations or queries that filter on the table distribution key column(s). In queries such as these, the query plan is not dispatched to all segments, but is targeted at the segment that contains the affected or relevant row(s).

**Figure 22: Dispatching a Targeted Query Plan**

**Understanding Greenplum Query Plans**

A query plan is the set of operations Greenplum Database will perform to produce the answer to a query. Each node or step in the plan represents a database operation such as a table scan, join, aggregation, or sort. Plans are read and executed from bottom to top.

In addition to common database operations such as table scans, joins, and so on, Greenplum Database has an additional operation type called *motion*. A motion operation involves moving tuples between the segments during query processing. Note that not every query requires a motion. For example, a targeted query plan does not require data to move across the interconnect.

To achieve maximum parallelism during query execution, Greenplum divides the work of the query plan into *slices*. A slice is a portion of the plan that segments can work on independently. A query plan is sliced wherever a *motion* operation occurs in the plan, with one slice on each side of the motion.

For example, consider the following simple query involving a join between two tables:

```sql
SELECT customer, amount
FROM sales JOIN customer USING (cust_id)
WHERE dateCol = '04-30-2016';
```

**Figure 23: Query Slice Plan** shows the query plan. Each segment receives a copy of the query plan and works on it in parallel.

The query plan for this example has a *redistribute motion* that moves tuples between the segments to complete the join. The redistribute motion is necessary because the customer table is distributed across the segments by `cust_id`, but the sales table is distributed across the segments by `sale_id`. To perform
the join, the sales tuples must be redistributed by cust_id. The plan is sliced on either side of the redistribute motion, creating slice 1 and slice 2.

This query plan has another type of motion operation called a gather motion. A gather motion is when the segments send results back up to the master for presentation to the client. Because a query plan is always sliced wherever a motion occurs, this plan also has an implicit slice at the very top of the plan (slice 3). Not all query plans involve a gather motion. For example, a CREATE TABLE x AS SELECT... statement would not have a gather motion because tuples are sent to the newly created table, not to the master.

Figure 23: Query Slice Plan

Understanding Parallel Query Execution

Greenplum creates a number of database processes to handle the work of a query. On the master, the query worker process is called the query dispatcher (QD). The QD is responsible for creating and dispatching the query plan. It also accumulates and presents the final results. On the segments, a query worker process is called a query executor (QE). A QE is responsible for completing its portion of work and communicating its intermediate results to the other worker processes.

There is at least one worker process assigned to each slice of the query plan. A worker process works on its assigned portion of the query plan independently. During query execution, each segment will have a number of processes working on the query in parallel.

Related processes that are working on the same slice of the query plan but on different segments are called gangs. As a portion of work is completed, tuples flow up the query plan from one gang of processes
to the next. This inter-process communication between the segments is referred to as the *interconnect* component of Greenplum Database.

*Figure 24: Query Worker Processes* shows the query worker processes on the master and two segment instances for the query plan illustrated in *Figure 23: Query Slice Plan.*

---

### About GPORCA

In Greenplum Database, the default GPORCA optimizer co-exists with the Postgres Planner.

These sections describe GPORCA functionality and usage:

- Overview of GPORCA
- Enabling and Disabling GPORCA
- Considerations when Using GPORCA
- GPORCA Features and Enhancements
- Changed Behavior with the GPORCA
- GPORCA Limitations
- Determining the Query Optimizer that is Used
- About Uniform Multi-level Partitioned Tables

### Overview of GPORCA

GPORCA extends the planning and optimization capabilities of the Postgres Planner. GPORCA is extensible and achieves better optimization in multi-core architecture environments. Greenplum Database uses GPORCA by default to generate an execution plan for a query when possible.

GPORCA also enhances Greenplum Database query performance tuning in the following areas:

- Queries against partitioned tables
- Queries that contain a common table expression (CTE)
- Queries that contain subqueries
In Greenplum Database, GPORCA co-exists with the Postgres Planner. By default, Greenplum Database uses GPORCA. If GPORCA cannot be used, then the Postgres Planner is used.

The following figure shows how GPORCA fits into the query planning architecture.

Note: All Postgres Planner server configuration parameters are ignored by GPORCA. However, if Greenplum Database falls back to the Postgres Planner, the planner server configuration parameters will impact the query plan generation. For a list of Postgres Planner server configuration parameters, see Query Tuning Parameters.

Enabling and Disabling GPORCA

By default, Greenplum Database uses GPORCA instead of the Postgres Planner. Server configuration parameters enable or disable GPORCA.

Although GPORCA is on by default, you can configure GPORCA usage at the system, database, session, or query level using the optimizer parameter. Refer to one of the following sections if you want to change the default behavior:

• Enabling GPORCA for a System
• Enabling GPORCA for a Database
• Enabling GPORCA for a Session or a Query

Note: You can disable the ability to enable or disable GPORCA with the server configuration parameter optimizer_control. For information about the server configuration parameters, see the Greenplum Database Reference Guide.

Enabling GPORCA for a System

Set the server configuration parameter optimizer for the Greenplum Database system.

1. Log into the Greenplum Database master host as gpadmin, the Greenplum Database administrator.
2. Set the values of the server configuration parameters. These Greenplum Database gpconfig utility commands sets the value of the parameters to on:

   $ gpconfig -c optimizer -v on --masteronly
3. Restart Greenplum Database. This Greenplum Database gpstop utility command reloads the postgresql.conf files of the master and segments without shutting down Greenplum Database.

   gpstop -u

**Enabling GPORCA for a Database**

Set the server configuration parameter `optimizer` for individual Greenplum databases with the `ALTER DATABASE` command. For example, this command enables GPORCA for the database `test_db`.

> ALTER DATABASE test_db SET OPTIMIZER = ON ;

**Enabling GPORCA for a Session or a Query**

You can use the `SET` command to set `optimizer` server configuration parameter for a session. For example, after you use the `psql` utility to connect to Greenplum Database, this `SET` command enables GPORCA:

> set optimizer = on ;

To set the parameter for a specific query, include the `SET` command prior to running the query.

**Collecting Root Partition Statistics**

For a partitioned table, GPORCA uses statistics of the table root partition to generate query plans. These statistics are used for determining the join order, for splitting and joining aggregate nodes, and for costing the query steps. In contrast, the Postgres Planner uses the statistics of each leaf partition.

If you execute queries on partitioned tables, you should collect statistics on the root partition and periodically update those statistics to ensure that GPORCA can generate optimal query plans. If the root partition statistics are not up-to-date or do not exist, GPORCA still performs dynamic partition elimination for queries against the table. However, the query plan might not be optimal.

**Running ANALYZE**

By default, running the `ANALYZE` command on the root partition of a partitioned table samples the leaf partition data in the table, and stores the statistics for the root partition. `ANALYZE` collects statistics on the root and leaf partitions, including HyperLogLog (HLL) statistics on the leaf partitions. `ANALYZE ROOTPARTITION` collects statistics only on the root partition. The server configuration parameter `optimizer_analyze_root_partition` controls whether the `ROOTPARTITION` keyword is required to collect root statistics for the root partition of a partitioned table. See the `ANALYZE` command for information about collecting statistics on partitioned tables.

Keep in mind that `ANALYZE` always scans the entire table before updating the root partition statistics. If your table is very large, this operation can take a significant amount of time. `ANALYZE ROOTPARTITION` also uses an `ACCESS SHARE` lock that prevents certain operations, such as `TRUNCATE` and `VACUUM` operations, during execution. For these reasons, you should schedule `ANALYZE` operations periodically, or when there are significant changes to leaf partition data.

Follow these best practices for running `ANALYZE` or `ANALYZE_ROOTPARTITION` on partitioned tables in your system:

- Run `ANALYZE <root_partition>` on a new partitioned table after adding initial data. Run `ANALYZE <leaf_partition>` on a new leaf partition or a leaf partition where data has changed. By default, running the command on a leaf partition updates the root partition statistics if the other leaf partitions have statistics.
- Update root partition statistics when you observe query performance regression in `EXPLAIN` plans against the table, or after significant changes to leaf partition data. For example, if you add a new leaf partition at some point after generating root partition statistics, consider running `ANALYZE` or `ANALYZE_ROOTPARTITION` on the new leaf partition.
ROOTPARTITION to update root partition statistics with the new tuples inserted from the new leaf partition.

- For very large tables, run ANALYZE or ANALYZE ROOTPARTITION only weekly, or at some interval longer than daily.
- Avoid running ANALYZE with no arguments, because doing so executes the command on all database tables including partitioned tables. With large databases, these global ANALYZE operations are difficult to monitor, and it can be difficult to predict the time needed for completion.
- Consider running multiple ANALYZE <table_name> or ANALYZE ROOTPARTITION <table_name> operations in parallel to speed the operation of statistics collection, if your I/O throughput can support the load.
- You can also use the Greenplum Database utility analyzedb to update table statistics. Using analyzedb ensures that tables that were previously analyzied are not re-analyzed if no modifications were made to the leaf partition.

**GPORCA and Leaf Partition Statistics**

Although creating and maintaining root partition statistics is crucial for GPORCA query performance with partitioned tables, maintaining leaf partition statistics is also important. If GPORCA cannot generate a plan for a query against a partitioned table, then the Postgres Planner is used and leaf partition statistics are needed to produce the optimal plan for that query.

GPORCA itself also uses leaf partition statistics for any queries that access leaf partitions directly, instead of using the root partition with predicates to eliminate partitions. For example, if you know which partitions hold necessary tuples for a query, you can directly query the leaf partition table itself; in this case GPORCA uses the leaf partition statistics.

**Disabling Automatic Root Partition Statistics Collection**

If you do not intend to execute queries on partitioned tables with GPORCA (setting the server configuration parameter optimizer to off), then you can disable the automatic collection of statistics on the root partition of the partitioned table. The server configuration parameter optimizer_analyze_root_partition controls whether the ROOTPARTITION keyword is required to collect root statistics for the root partition of a partitioned table. The default setting for the parameter is on, the ANALYZE command can collect root partition statistics without the ROOTPARTITION keyword. You can disable automatic collection of root partition statistics by setting the parameter to off. When the value is off, you must run ANALYZE ROOTPARTITION to collect root partition statistics.

1. Log into the Greenplum Database master host as gpadmin, the Greenplum Database administrator.
2. Set the values of the server configuration parameters. These Greenplum Database gpconfig utility commands sets the value of the parameters to off:

   ```
   $ gpconfig -c optimizer_analyze_root_partition -v off --masteronly
   ```

3. Restart Greenplum Database. This Greenplum Database gpstop utility command reloads the postgresql.conf files of the master and segments without shutting down Greenplum Database.

   ```
   gpstop -u
   ```

**Considerations when Using GPORCA**

To execute queries optimally with GPORCA, query criteria to consider.

Ensure the following criteria are met:

- The table does not contain multi-column partition keys.
- The multi-level partitioned table is a uniform multi-level partitioned table. See About Uniform Multi-level Partitioned Tables.
- The server configuration parameter `optimizer_enable_master_only_queries` is set to on when running against master only tables such as the system table `pg_attribute`. For information about the parameter, see the *Greenplum Database Reference Guide*.

  **Note:** Enabling this parameter decreases performance of short running catalog queries. To avoid this issue, set this parameter only for a session or a query.

- Statistics have been collected on the root partition of a partitioned table.

  If the partitioned table contains more than 20,000 partitions, consider a redesign of the table schema.

These server configuration parameters affect GPORCA query processing.

- `optimizer_cce_inlining_bound` controls the amount of inlining performed for common table expression (CTE) queries (queries that contain a WHERE clause).
- `optimizer_force_multistage_agg` forces GPORCA to choose a multi-stage aggregate plan for a scalar distinct qualified aggregate. When the value is off (the default), GPORCA chooses between a one-stage and two-stage aggregate plan based on cost.
- `optimizer_force_three_stage_scalar_dqa` forces GPORCA to choose a plan with multistage aggregates when such a plan alternative is generated.
- `optimizer_join_order` sets the query optimization level for join ordering by specifying which types of join ordering alternatives to evaluate.
- `optimizer_join_order_threshold` specifies the maximum number of join children for which GPORCA uses the dynamic programming-based join ordering algorithm.
- `optimizer_nestloop_factor` controls nested loop join cost factor to apply to during query optimization.
- `optimizer_parallel_union` controls the amount of parallelization that occurs for queries that contain a UNION or UNION ALL clause. When the value is on, GPORCA can generate a query plan the child operations of a UNION or UNION ALL operation execute in parallel on segment instances.
- `optimizer_sort_factor` controls the cost factor that GPORCA applies to sorting operations during query optimization. The cost factor can be adjusted for queries when data skew is present.
- `gp_enable_relsize_collection` controls how GPORCA (and the Postgres Planner) handle a table without statistics. By default, GPORCA uses a default value to estimate the number of rows if statistics are not available. When this value is on, GPORCA uses the estimated size of a table if there are no statistics for the table.

  This parameter is ignored for a root partition of a partitioned table. If the root partition does not have statistics, GPORCA always uses the default value. You can use `ANALYZE ROOTPARTITION` to collect statistics on the root partition. See `ANALYZE`.

These server configuration parameters control the display and logging of information.

- `optimizer_print_missing_stats` controls the display of column information about columns with missing statistics for a query (default is true)
- `optimizer_print_optimization_stats` controls the logging of GPORCA query optimization metrics for a query (default is off)

For information about the parameters, see the *Greenplum Database Reference Guide*.

GPORCA generates minidumps to describe the optimization context for a given query. The minidump files are used by Pivotal support to analyze Greenplum Database issues. The information in the file is not in a format that can be easily used for debugging or troubleshooting. The minidump file is located under the master data directory and uses the following naming format:

`Minidump_date_time.mdp`

For information about the minidump file, see the server configuration parameter `optimizer_minidump` in the *Greenplum Database Reference Guide*.

When the `EXPLAIN ANALYZE` command uses GPORCA, the `EXPLAIN` plan shows only the number of partitions that are being eliminated. The scanned partitions are not shown. To show
the name of the scanned partitions in the segment logs set the server configuration parameter `gp_log_dynamic_partition_pruning` to `on`. This example `SET` command enables the parameter.

```
SET gp_log_dynamic_partition_pruning = on;
```

### GPORCA Features and Enhancements

GPORCA, the Greenplum next generation query optimizer, includes enhancements for specific types of queries and operations:

- Queries Against Partitioned Tables
- Queries that Contain Subqueries
- Queries that Contain Common Table Expressions
- DML Operation Enhancements with GPORCA

GPORCA also includes these optimization enhancements:

- Improved join ordering
- Join-Aggregate reordering
- Sort order optimization
- Data skew estimates included in query optimization

### Queries Against Partitioned Tables

GPORCA includes these enhancements for queries against partitioned tables:

- Partition elimination is improved.
- Uniform multi-level partitioned tables are supported. For information about uniform multi-level partitioned tables, see [About Uniform Multi-level Partitioned Tables](#).
- Query plan can contain the `Partition selector` operator.
- Partitions are not enumerated in `EXPLAIN` plans.

For queries that involve static partition selection where the partitioning key is compared to a constant, GPORCA lists the number of partitions to be scanned in the `EXPLAIN` output under the Partition Selector operator. This example Partition Selector operator shows the filter and number of partitions selected:

```
Partition Selector for Part_Table (dynamic scan id: 1)
  Filter: a > 10
  Partitions selected: 1 (out of 3)
```

For queries that involve dynamic partition selection where the partitioning key is compared to a variable, the number of partitions that are scanned will be known only during query execution. The partitions selected are not shown in the `EXPLAIN` output.

- Plan size is independent of number of partitions.
- Out of memory errors caused by number of partitions are reduced.

This example `CREATE TABLE` command creates a range partitioned table.

```
CREATE TABLE sales(order_id int, item_id int, amount numeric(15,2),
  date date, yr_qtr int)
  range partitioned by yr_qtr;
```

GPORCA improves on these types of queries against partitioned tables:

- Full table scan. Partitions are not enumerated in plans.

```
SELECT * FROM sales;
```
• Query with a constant filter predicate. Partition elimination is performed.

```
SELECT * FROM sales WHERE yr_qtr = 201501;
```

• Range selection. Partition elimination is performed.

```
SELECT * FROM sales WHERE yr_qtr BETWEEN 201601 AND 201704;
```

• Joins involving partitioned tables. In this example, the partitioned dimension table `date_dim` is joined with fact table `catalog_sales`:

```
SELECT * FROM catalog_sales
WHERE date_id IN (SELECT id FROM date_dim WHERE month=12);
```

### Queries that Contain Subqueries

GPORCA handles subqueries more efficiently. A subquery is query that is nested inside an outer query block. In the following query, the `SELECT` in the `WHERE` clause is a subquery.

```
SELECT * FROM part
WHERE price > (SELECT avg(price) FROM part);
```

GPORCA also handles queries that contain a correlated subquery (CSQ) more efficiently. A correlated subquery is a subquery that uses values from the outer query. In the following query, the `price` column is used in both the outer query and the subquery.

```
SELECT * FROM part p1
WHERE price > (SELECT avg(price) FROM part p2
HERE p2.brand = p1.brand);
```

GPORCA generates more efficient plans for the following types of subqueries:

• CSQ in the `SELECT` list.

```
SELECT *
(SELECT min(price) FROM part p2 WHERE p1.brand = p2.brand)
AS foo
FROM part p1;
```

• CSQ in disjunctive (OR) filters.

```
SELECT FROM part p1 WHERE p_size > 40 OR
p_retailprice >
(SELECT avg(p_retailprice)
FROM part p2
WHERE p2.p_brand = p1.p_brand)
```

• Nested CSQ with skip level correlations

```
SELECT * FROM part p1 WHERE p1.p_partkey
IN (SELECT p_partkey FROM part p2 WHERE p2.p_retailprice =
(SELECT min(p_retailprice)
FROM part p3
WHERE p3.p_brand = p1.p_brand)
);
```

**Note:** Nested CSQ with skip level correlations are not supported by the Postgres Planner.

• CSQ with aggregate and inequality. This example contains a CSQ with an inequality.

```
SELECT * FROM part p1 WHERE p1.p_retailprice =
```
(SELECT min(p_retailprice) FROM part p2 WHERE p2.p_brand <> p1.p_brand);

- CSQ that must return one row.

SELECT p_partkey,
  (SELECT p_retailprice FROM part p2 WHERE p2.p_brand = p1.p_brand )
FROM part p1;

**Queries that Contain Common Table Expressions**

GPORCA handles queries that contain the WITH clause. The WITH clause, also known as a common table expression (CTE), generates temporary tables that exist only for the query. This example query contains a CTE.

```sql
WITH v AS (SELECT a, sum(b) as s FROM T where c < 10 GROUP BY a)
SELECT *FROM  v AS v1 ,  v AS v2
WHERE v1.a <> v2.a AND v1.s < v2.s;
```

As part of query optimization, GPORCA can push down predicates into a CTE. For example query, GPORCA pushes the equality predicates to the CTE.

```sql
WITH v AS (SELECT a, sum(b) as s FROM T GROUP BY a)
SELECT *
FROM v as v1, v as v2, v as v3
WHERE v1.a < v2.a 
  AND v1.s < v3.s
  AND v1.a = 10
  AND v2.a = 20
  AND v3.a = 30;
```

GPORCA can handle these types of CTEs:

- CTE that defines one or multiple tables. In this query, the CTE defines two tables.

```sql
WITH cte1 AS (SELECT a, sum(b) as s FROM T 
  where c < 10 GROUP BY a),
  cte2 AS (SELECT a, s FROM cte1 where s > 1000)
SELECT *
FROM cte1 as v1, cte2 as v2, cte2 as v3
WHERE v1.a < v2.a AND v1.s < v3.s;
```

- Nested CTEs.

```sql
WITH v AS (WITH w AS (SELECT a, b FROM foo 
  WHERE b < 5)
  SELECT w1.a, w2.b
  FROM w AS w1, w AS w2
  WHERE w1.a = w2.a AND w1.a > 2)
SELECT v1.a, v2.a, v2.b
FROM v as v1, v2.a, v2.b
WHERE v1.a < v2.a;
```

**DML Operation Enhancements with GPORCA**

GPORCA contains enhancements for DML operations such as **INSERT**, **UPDATE**, and **DELETE**.

- A DML node in a query plan is a query plan operator.
  - Can appear anywhere in the plan, as a regular node (top slice only for now)
  - Can have consumers
  - **UPDATE** operations use the query plan operator **Split** and supports these operations:
• UPDATE operations on the table distribution key columns.
• UPDATE operations on the table on the partition key column.

This example plan shows the Split operator.

QUERY PLAN
--------------------------------------------------------------
Update  (cost=0.00..5.46 rows=1 width=1)
   ->  Redistribute Motion 2:2  (slice1; segments: 2)
       Hash Key: a
       ->  Result  (cost=0.00..3.23 rows=1 width=48)
           ->  Split  (cost=0.00..2.13 rows=1 width=40)
               ->  Result  (cost=0.00..1.05 rows=1 width=40)
               ->  Seq Scan on dmltest

• New query plan operator Assert is used for constraints checking.

This example plan shows the Assert operator.

QUERY PLAN
------------------------------------------------------------
Insert  (cost=0.00..4.61 rows=3 width=8)
   ->  Assert  (cost=0.00..3.37 rows=3 width=24)
       Assert Cond: (dmlsource.a > 2) IS DISTINCT FROM false
       ->  Assert  (cost=0.00..2.25 rows=3 width=24)
           Assert Cond: NOT dmlsource.b IS NULL
           ->  Result  (cost=0.00..1.14 rows=3 width=24)
           ->  Seq Scan on dmlsource

Changed Behavior with the GPORCA

There are changes to Greenplum Database behavior with the GPORCA optimizer enabled (the default) as compared to the Postgres Planner.

• UPDATE operations on distribution keys are allowed.
• UPDATE operations on partitioned keys are allowed.
• Queries against uniform partitioned tables are supported.
• Queries against partitioned tables that are altered to use an external table as a leaf child partition fall back to the Postgres Planner.
• Except for INSERT, DML operations directly on partition (child table) of a partitioned table are not supported.

For the INSERT command, you can specify a leaf child table of the partitioned table to insert data into a partitioned table. An error is returned if the data is not valid for the specified leaf child table. Specifying a child table that is not a leaf child table is not supported.

• The command CREATE TABLE AS distributes table data randomly if the DISTRIBUTED BY clause is not specified and no primary or unique keys are specified.
• Non-deterministic updates not allowed. The following UPDATE command returns an error.

update r set b = r.b + 1 from s where r.a in (select a from s);

• Statistics are required on the root table of a partitioned table. The ANALYZE command generates statistics on both root and individual partition tables (leaf child tables). See the ROOTPARTITION clause for ANALYZE command.
• Additional Result nodes in the query plan:
  • Query plan Assert operator.
  • Query plan Partition selector operator.
  • Query plan Split operator.
• When running `EXPLAIN`, the query plan generated by GPORCA is different than the plan generated by the Postgres Planner.
• Greenplum Database adds the log file message *Planner produced plan when GPORCA is enabled* and Greenplum Database falls back to the Postgres Planner to generate the query plan.
• Greenplum Database issues a warning when statistics are missing from one or more table columns. When executing an SQL command with GPORCA, Greenplum Database issues a warning if the command performance could be improved by collecting statistics on a column or set of columns referenced by the command. The warning is issued on the command line and information is added to the Greenplum Database log file. For information about collecting statistics on table columns, see the `ANALYZE` command in the *Greenplum Database Reference Guide*.

**GPORCA Limitations**

There are limitations in Greenplum Database when using the default GPORCA optimizer. GPORCA and the Postgres Planner currently coexist in Greenplum Database because GPORCA does not support all Greenplum Database features.

This section describes the limitations.

• **Unsupported SQL Query Features**
• **Performance Regressions**

**Unsupported SQL Query Features**

Certain query features are not supported with the default GPORCA optimizer. When an unsupported query is executed, Greenplum logs this notice along with the query text:

```
Feature not supported by the Pivotal Query Optimizer: UTILITY command
```

These features are unsupported when GPORCA is enabled (the default):

• Prepared statements that have parameterized values.
• Indexed expressions (an index defined as expression based on one or more columns of the table)
• SP-GiST indexing method. GPORCA supports only B-tree, bitmap, GIN, and GiST indexes. GPORCA ignores indexes created with unsupported methods.
• External parameters
• These types of partitioned tables:
  • Non-uniform partitioned tables.
  • Partitioned tables that have been altered to use an external table as a leaf child partition.
• SortMergeJoin (SMJ).
• Ordered aggregations.
• These analytics extensions:
  • CUBE
  • Multiple grouping sets
• These scalar operators:
  • ROW
  • ROWCOMPARE
  • FIELDSELECT
• Aggregate functions that take set operators as input arguments.
• `percentile_*` window functions (ordered-set aggregate functions).
• Inverse distribution functions.
• Queries that execute functions that are defined with the `ON MASTER` or `ON ALL SEGMENTS` attribute.
• Queries that contain UNICODE characters in metadata names, such as table names, and the characters are not compatible with the host system locale.
• SELECT, UPDATE, and DELETE commands where a table name is qualified by the ONLY keyword.
• Per-column collation. GPORCA supports collation only when all columns in the query use the same collation. If columns in the query use different collations, then Greenplum uses the Postgres Planner.

**Performance Regressions**
The following features are known performance regressions that occur with GPORCA enabled:
• Short running queries - For GPORCA, short running queries might encounter additional overhead due to GPORCA enhancements for determining an optimal query execution plan.
• ANALYZE - For GPORCA, the ANALYZE command generates root partition statistics for partitioned tables. For the Postgres Planner, these statistics are not generated.
• DML operations - For GPORCA, DML enhancements including the support of updates on partition and distribution keys might require additional overhead.

Also, enhanced functionality of the features from previous versions could result in additional time required when GPORCA executes SQL statements with the features.

**Determining the Query Optimizer that is Used**
When GPORCA is enabled (the default), you can determine if Greenplum Database is using GPORCA or is falling back to the Postgres Planner.

You can examine the `EXPLAIN` query plan for the query determine which query optimizer was used by Greenplum Database to execute the query:
• When GPORCA generates the query plan, the setting `optimizer=on` and GPORCA version are displayed at the end of the query plan. For example.

<table>
<thead>
<tr>
<th>Settings: optimizer=on</th>
<th>Optimizer status: Pivotal Optimizer (GPORCA) version 1.584</th>
</tr>
</thead>
</table>

When Greenplum Database falls back to the Postgres Planner to generate the plan, the setting `optimizer=on` and Postgres query optimizer are displayed at the end of the query plan. For example.

<table>
<thead>
<tr>
<th>Settings: optimizer=on</th>
<th>Optimizer status: Postgres query optimizer</th>
</tr>
</thead>
</table>

When the server configuration parameter OPTIMIZER is off, these lines are displayed at the end of a query plan.

<table>
<thead>
<tr>
<th>Settings: optimizer=off</th>
<th>Optimizer status: Postgres query optimizer</th>
</tr>
</thead>
</table>

• These plan items appear only in the `EXPLAIN` plan output generated by GPORCA. The items are not supported in a Postgres Planner query plan.
• Assert operator
• Sequence operator
• DynamicIndexScan
• DynamicSeqScan
• When a query against a partitioned table is generated by GPORCA, the `EXPLAIN` plan displays only the number of partitions that are being eliminated is listed. The scanned partitions are not shown. The `EXPLAIN` plan generated by the Postgres Planner lists the scanned partitions.

The log file contains messages that indicate which query optimizer was used. If Greenplum Database falls back to the Postgres Planner, a message with NOTICE information is added to the log file that indicates the unsupported feature. Also, the label Planner produced plan: appears before the query in the query execution log message when Greenplum Database falls back to the Postgres optimizer.
**Note:** You can configure Greenplum Database to display log messages on the psql command line by setting the Greenplum Database server configuration parameter `client_min_messages` to `LOG`. See the Greenplum Database Reference Guide for information about the parameter.

**Examples**

This example shows the differences for a query that is run against partitioned tables when GPORCA is enabled.

This `CREATE TABLE` statement creates a table with single level partitions:

```sql
CREATE TABLE sales (trans_id int, date date,
    amount decimal(9,2), region text)
DISTRIBUTED BY (trans_id)
PARTITION BY RANGE (date)
    (START (date '20160101')
        INCLUSIVE END (date '20170101')
        EXCLUSIVE EVERY (INTERVAL '1 month'),
    DEFAULT PARTITION outlying_dates )#
```

This query against the table is supported by GPORCA and does not generate errors in the log file:

```sql
select * from sales ;
```

The `EXPLAIN` plan output lists only the number of selected partitions.

```
->  Partition Selector for sales (dynamic scan id: 1)  (cost=10.00..100.00
    rows=50 width=4)
    Partitions selected:  13 (out of 13)
```

If a query against a partitioned table is not supported by GPORCA, Greenplum Database falls back to the Postgres Planner. The `EXPLAIN` plan generated by the Postgres Planner lists the selected partitions. This example shows a part of the explain plan that lists some selected partitions.

```
->  Append  (cost=0.00..0.00 rows=26 width=53)
    ->  Seq Scan on sales2_1_prt_7_2_prt_usa sales2  (cost=0.00..0.00
        rows=1 width=53)
    ->  Seq Scan on sales2_1_prt_7_2_prt_asia sales2  (cost=0.00..0.00
        rows=1 width=53)
    ...
```

This example shows the log output when the Greenplum Database falls back to the Postgres Planner from GPORCA.

When this query is run, Greenplum Database falls back to the Postgres Planner.

```sql
explain select * from pg_class;
```

A message is added to the log file. The message contains this `NOTICE` information that indicates the reason GPORCA did not execute the query:

```
NOTICE,""Feature not supported: Queries on master-only tables"
```

**About Uniform Multi-level Partitioned Tables**

GPORCA supports queries on a multi-level partitioned (MLP) table if the MLP table is a *uniform partitioned table*. A multi-level partitioned table is a partitioned table that was created with the `SUBPARTITION` clause. A uniform partitioned table must meet these requirements.
• The partitioned table structure is uniform. Each partition node at the same level must have the same hierarchical structure.
• The partition key constraints must be consistent and uniform. At each subpartition level, the sets of constraints on the child tables created for each branch must match.

You can display information about partitioned tables in several ways, including displaying information from these sources:
• The `pg_partitions` system view contains information on the structure of a partitioned table.
• The `pg_constraint` system catalog table contains information on table constraints.
• The `psql` meta command `\d+ tablename` displays the table constraints for child leaf tables of a partitioned table.

**Example**

This `CREATE TABLE` command creates a uniform partitioned table.

```sql
CREATE TABLE mlp (id int, year int, month int, day int, region text)
  DISTRIBUTED BY (id)
  PARTITION BY RANGE (year)
    SUBPARTITION BY LIST (region)
    SUBPARTITION TEMPLATE (
        SUBPARTITION usa VALUES ('usa'),
        SUBPARTITION europe VALUES ('europe'),
        SUBPARTITION asia VALUES ('asia'))
  (START (2006) END (2016) EVERY (5));
```

These are child tables and the partition hierarchy that are created for the table `mlp`. This hierarchy consists of one subpartition level that contains two branches.

```plaintext
mlp_1_prt_11
  mlp_1_prt_11_2_prt_usa
  mlp_1_prt_11_2_prt_europe
  mlp_1_prt_11_2_prt_asia

mlp_1_prt_21
  mlp_1_prt_21_2_prt_usa
  mlp_1_prt_21_2_prt_europe
  mlp_1_prt_21_2_prt_asia
```

The hierarchy of the table is uniform, each partition contains a set of three child tables (subpartitions). The constraints for the region subpartitions are uniform, the set of constraints on the child tables for the branch table `mlp_1_prt_11` are the same as the constraints on the child tables for the branch table `mlp_1_prt_21`.

As a quick check, this query displays the constraints for the partitions.

```sql
WITH tbl AS (SELECT oid, partitionlevel AS level, partitiontablename AS part
  FROM pg_partitions, pg_class
  WHERE tablename = 'mlp' AND partitiontablename=relname
    AND partitionlevel=1 )
SELECT tbl.part, consrc
  FROM tbl, pg_constraint
  WHERE tbl.oid = conrelid ORDER BY consrc;
```

**Note:** You will need modify the query for more complex partitioned tables. For example, the query does not account for table names in different schemas.
The `consrc` column displays constraints on the subpartitions. The set of region constraints for the subpartitions in `mlp_1_prt_1` match the constraints for the subpartitions in `mlp_1_prt_2`. The constraints for `year` are inherited from the parent branch tables.

<table>
<thead>
<tr>
<th>part</th>
<th>consrc</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>mlp_1_prt_2_prt_asia</code></td>
<td><code>(region = 'asia':text)</code></td>
</tr>
<tr>
<td><code>mlp_1_prt_1_prt_asia</code></td>
<td><code>(region = 'asia':text)</code></td>
</tr>
<tr>
<td><code>mlp_1_prt_2_prt_europe</code></td>
<td><code>(region = 'europe':text)</code></td>
</tr>
<tr>
<td><code>mlp_1_prt_1_prt_europe</code></td>
<td><code>(region = 'europe':text)</code></td>
</tr>
<tr>
<td><code>mlp_1_prt_1_prt_usa</code></td>
<td><code>(region = 'usa':text)</code></td>
</tr>
<tr>
<td><code>mlp_1_prt_2_prt_usa</code></td>
<td><code>(region = 'usa':text)</code></td>
</tr>
<tr>
<td><code>mlp_1_prt_1_prt_asia</code></td>
<td><code>((year &gt;= 2006) AND (year &lt; 2011))</code></td>
</tr>
<tr>
<td><code>mlp_1_prt_1_prt_usa</code></td>
<td><code>((year &gt;= 2006) AND (year &lt; 2011))</code></td>
</tr>
<tr>
<td><code>mlp_1_prt_1_prt_europe</code></td>
<td><code>((year &gt;= 2006) AND (year &lt; 2011))</code></td>
</tr>
<tr>
<td><code>mlp_1_prt_2_prt_usa</code></td>
<td><code>((year &gt;= 2011) AND (year &lt; 2016))</code></td>
</tr>
<tr>
<td><code>mlp_1_prt_2_prt_asia</code></td>
<td><code>((year &gt;= 2011) AND (year &lt; 2016))</code></td>
</tr>
<tr>
<td><code>mlp_1_prt_2_prt_europe</code></td>
<td><code>((year &gt;= 2011) AND (year &lt; 2016))</code></td>
</tr>
</tbody>
</table>

If you add a default partition to the example partitioned table with this command:

```
ALTER TABLE mlp ADD DEFAULT PARTITION def
```

The partitioned table remains a uniform partitioned table. The branch created for default partition contains three child tables and the set of constraints on the child tables match the existing sets of child table constraints.

In the above example, if you drop the subpartition `mlp_1_prt_21_prt_asia` and add another subpartition for the region `canada`, the constraints are no longer uniform.

```
ALTER TABLE mlp ALTER PARTITION FOR (RANK(2)) DROP PARTITION asia;
ALTER TABLE mlp ALTER PARTITION FOR (RANK(2)) ADD PARTITION canada VALUES ('canada');
```

Also, if you add a partition `canada` under `mlp_1_prt_21`, the partitioning hierarchy is not uniform.

However, if you add the subpartition `canada` to both `mlp_1_prt_21` and `mlp_1_prt_11` the of the original partitioned table, it remains a uniform partitioned table.

**Note:** Only the constraints on the sets of partitions at a partition level must be the same. The names of the partitions can be different.

**Defining Queries**

Greenplum Database is based on the PostgreSQL implementation of the SQL standard. This topic describes how to construct SQL queries in Greenplum Database.

- **SQL Lexicon**
- **SQL Value Expressions**

**SQL Lexicon**

SQL is a standard language for accessing databases. The language consists of elements that enable data storage, retrieval, analysis, viewing, manipulation, and so on. You use SQL commands to construct queries and commands that the Greenplum Database engine understands. SQL queries consist of a sequence of commands. Commands consist of a sequence of valid tokens in correct syntax order, terminated by a semicolon (`;`).
For more information about SQL commands, see SQL Command Reference in the Greenplum Database Reference Guide.

Greenplum Database uses PostgreSQL's structure and syntax, with some exceptions. For more information about SQL rules and concepts in PostgreSQL, see "SQL Syntax" in the PostgreSQL documentation.

**SQL Value Expressions**

SQL value expressions consist of one or more values, symbols, operators, SQL functions, and data. The expressions compare data or perform calculations and return a value as the result. Calculations include logical, arithmetic, and set operations.

The following are value expressions:

- An aggregate expression
- An array constructor
- A column reference
- A constant or literal value
- A correlated subquery
- A field selection expression
- A function call
- A new column value in an INSERT or UPDATE
- An operator invocation column reference
- A positional parameter reference, in the body of a function definition or prepared statement
- A row constructor
- A subquery
- A search condition in a WHERE clause
- A target list of a SELECT command
- A type cast
- A value expression in parentheses, useful to group sub-expressions and override precedence
- A window expression

SQL constructs such as functions and operators are expressions but do not follow any general syntax rules. For more information about these constructs, see Using Functions and Operators.

**Column References**

A column reference has the form:

```
correlation.columnname
```

Here, correlation is the name of a table (possibly qualified with a schema name) or an alias for a table defined with a FROM clause or one of the keywords NEW or OLD. NEW and OLD can appear only in rewrite rules, but you can use other correlation names in any SQL statement. If the column name is unique across all tables in the query, you can omit the "correlation." part of the column reference.

**Positional Parameters**

Positional parameters are arguments to SQL statements or functions that you reference by their positions in a series of arguments. For example, $1 refers to the first argument, $2 to the second argument, and so on. The values of positional parameters are set from arguments external to the SQL statement or supplied when SQL functions are invoked. Some client libraries support specifying data values separately from the
SQL command, in which case parameters refer to the out-of-line data values. A parameter reference has the form:

\$number

For example:

```
CREATE FUNCTION dept(text) RETURNS dept
    AS $\$ SELECT * FROM dept WHERE name = $1 $\$
    LANGUAGE SQL;
```

Here, the $1 references the value of the first function argument whenever the function is invoked.

**Subscripts**

If an expression yields a value of an array type, you can extract a specific element of the array value as follows:

```
expression[subscript]
```

You can extract multiple adjacent elements, called an array slice, as follows (including the brackets):

```
expression[lower_subscript:upper_subscript]
```

Each subscript is an expression and yields an integer value.

Array expressions usually must be in parentheses, but you can omit the parentheses when the expression to be subscripted is a column reference or positional parameter. You can concatenate multiple subscripts when the original array is multidimensional. For example (including the parentheses):

```
mytable.arraycolumn[4]
```

```
mytable.two_d_column[17][34]
```

```
$1[10:42]
```

```
(arrayfunction(a,b))[42]
```

**Field Selection**

If an expression yields a value of a composite type (row type), you can extract a specific field of the row as follows:

```
expression.fieldname
```

The row expression usually must be in parentheses, but you can omit these parentheses when the expression to be selected from is a table reference or positional parameter. For example:

```
mytable.mycolumn
```

```
$1.somecolumn
```

```
(rowfunction(a,b)).col3
```

A qualified column reference is a special case of field selection syntax.
**Operator Invocations**

Operator invocations have the following possible syntaxes:

- `expression operator expression` (binary infix operator)
- `operator expression` (unary prefix operator)
- `expression operator` (unary postfix operator)

Where `operator` is an operator token, one of the key words **AND**, **OR**, or **NOT**, or qualified operator name in the form:

```
OPERATOR(schema.operatorsname)
```

Available operators and whether they are unary or binary depends on the operators that the system or user defines. For more information about built-in operators, see *Built-in Functions and Operators*.

**Function Calls**

The syntax for a function call is the name of a function (possibly qualified with a schema name), followed by its argument list enclosed in parentheses:

```
function ([expression [, expression ... ]])
```

For example, the following function call computes the square root of 2:

```
sqrt(2)
```

See *Summary of Built-in Functions* in the *Greenplum Database Reference Guide* for lists of the built-in functions by category. You can add custom functions, too.

**Aggregate Expressions**

An aggregate expression applies an aggregate function across the rows that a query selects. An aggregate function performs a calculation on a set of values and returns a single value, such as the sum or average of the set of values. The syntax of an aggregate expression is one of the following:

- `aggregate_name(expression [, ... ]) [ FILTER ( WHERE filter_clause ) ]` — operates across all input rows for which the expected result value is non-null. **ALL** is the default.
- `aggregate_name(ALL expression [, ... ]) [ FILTER ( WHERE filter_clause ) ]` — operates identically to the first form because **ALL** is the default.
- `aggregate_name(DISTINCT expression [, ... ]) [ FILTER ( WHERE filter_clause ) ]` — operates across all distinct non-null values of input rows.
- `aggregate_name(*) [ FILTER ( WHERE filter_clause ) ]` — operates on all rows with values both null and non-null. Generally, this form is most useful for the `count(*)` aggregate function.

Where `aggregate_name` is a previously defined aggregate (possibly schema-qualified) and `expression` is any value expression that does not contain an aggregate expression.

For example, `count(*)` yields the total number of input rows, `count(f1)` yields the number of input rows in which `f1` is non-null, and `count(distinct f1)` yields the number of distinct non-null values of `f1`.

If `FILTER` is specified, then only the input rows for which the `filter_clause` evaluates to true are fed to the aggregate function; other rows are discarded. For example:

```
SELECT count(*) AS unfiltered,
```
count(*) FILTER (WHERE i < 5) AS filtered
FROM generate_series(1,10) AS s(i);

<table>
<thead>
<tr>
<th>unfiltered</th>
<th>filtered</th>
</tr>
</thead>
<tbody>
<tr>
<td>10</td>
<td>4</td>
</tr>
</tbody>
</table>

For predefined aggregate functions, see Built-in Functions and Operators. You can also add custom aggregate functions.

Greenplum Database provides the MEDIAN aggregate function, which returns the fiftieth percentile of the PERCENTILE_CONT result and special aggregate expressions for inverse distribution functions as follows:

\[
\text{PERCENTILE\_CONT(\_percentage\_) WITHIN GROUP (ORDER BY \_expression\_)}
\]

\[
\text{PERCENTILE\_DISC(\_percentage\_) WITHIN GROUP (ORDER BY \_expression\_)}
\]

Currently you can use only these two expressions with the keyword WITHIN GROUP.

**Limitations of Aggregate Expressions**

The following are current limitations of the aggregate expressions:

- Greenplum Database does not support the following keywords: all, distinct, and over. See Table 47: Advanced Aggregate Functions for more details.
- An aggregate expression can appear only in the result list or having clause of a select command. It is forbidden in other clauses, such as where, because those clauses are logically evaluated before the results of aggregates form. This restriction applies to the query level to which the aggregate belongs.
- When an aggregate expression appears in a subquery, the aggregate is normally evaluated over the rows of the subquery. If the aggregate's arguments (and filter clause if any) contain only outer-level variables, the aggregate belongs to the nearest such outer level and evaluates over the rows of that query. The aggregate expression as a whole is then an outer reference for the subquery in which it appears, and the aggregate expression acts as a constant over any one evaluation of that subquery. The restriction about appearing only in the result list or having clause applies with respect to the query level at which the aggregate appears. See Scalar Subqueries and Table 45: Built-in functions and operators.
- Greenplum Database does not support specifying an aggregate function as an argument to another aggregate function.
- Greenplum Database does not support specifying a window function as an argument to an aggregate function.

**Window Expressions**

Window expressions allow application developers to more easily compose complex online analytical processing (OLAP) queries using standard SQL commands. For example, with window expressions, users can calculate moving averages or sums over various intervals, reset aggregations and ranks as selected column values change, and express complex ratios in simple terms.

A window expression represents the application of a window function to a window frame, which is defined with an OVER() clause. This is comparable to the type of calculation that can be done with an aggregate function and a GROUP BY clause. Unlike aggregate functions, which return a single result value for each group of rows, window functions return a result value for every row, but that value is calculated with respect to the set of rows in the window frame to which the row belongs. The OVER() clause allows dividing the rows into partitions and then further restricting the window frame by specifying which rows preceding or following the current row within its partition to include in the calculation.

Greenplum Database does not support specifying a window function as an argument to another window function.
The syntax of a window expression is:

\[
\text{window_function} \ (\ [\text{expression} \ [, \ ...]\ ] \ ) \ [\ \text{FILTER} \ (\ \text{WHERE} \ \text{filter\_clause} \ ) \ ] \\
\text{OVER} \ (\ \text{window\_specification} \ )
\]

Where \text{window\_function} is one of the functions listed in Table 46: Window functions or a user-defined window function, \text{expression} is any value expression that does not contain a window expression, and \text{window\_specification} is:

\[[\text{window\_name}] \\
[\text{PARTITION BY} \ \text{expression} \ [, \ ...]] \\
[[\text{ORDER BY} \ \text{expression} \ [\text{ASC} \ | \ \text{DESC} \ | \ \text{USING} \ \text{operator}] \ [\text{NULLS} \ \{\text{FIRST} \ | \ \text{LAST}\}] \\
[, \ ...] \\
\{\text{RANGE} \ | \ \text{ROWS}\} \\
\{\text{UNBOUNDED} \ \text{PRECEDING} \\
\text{expression} \ \text{PRECEDING} \\
\text{CURRENT} \ \text{ROW} \\
\text{expression} \ \text{FOLLOWING} \\
\text{UNBOUNDED} \ \text{FOLLOWING} \}]]

and where \text{window\_frame\_bound} can be one of:

- UNBOUNDED PRECEDING
- expression PRECEDING
- CURRENT ROW
- expression FOLLOWING
- UNBOUNDED FOLLOWING

A window expression can appear only in the select list of a \text{SELECT} command. For example:

\[
\text{SELECT} \ \text{count(*) OVER(PARTITION BY customer\_id), * FROM sales;}
\]

If \text{FILTER} is specified, then only the input rows for which the \text{filter\_clause} evaluates to true are fed to the window function; other rows are discarded. In a window expression, a \text{FILTER} clause can be used only with a \text{window\_function} that is an aggregate function.

In a window expression, the expression must contain an \text{OVER} clause. The \text{OVER} clause specifies the window frame—the rows to be processed by the window function. This syntactically distinguishes the function from a regular or aggregate function.

In a window aggregate function that is used in a window expression, Greenplum Database does not support a \text{DISTINCT} clause with multiple input expressions.

A window specification has the following characteristics:

- The \text{PARTITION BY} clause defines the window partitions to which the window function is applied. If omitted, the entire result set is treated as one partition.
- The \text{ORDER BY} clause defines the expression(s) for sorting rows within a window partition. The \text{ORDER BY} clause of a window specification is separate and distinct from the \text{ORDER BY} clause of a regular query expression. The \text{ORDER BY} clause is required for the window functions that calculate rankings, as it identifies the measure(s) for the ranking values. For OLAP aggregations, the \text{ORDER BY} clause is required to use window frames (the \text{ROWS} or \text{RANGE} clause).

Note: Columns of data types without a coherent ordering, such as \text{time}, are not good candidates for use in the \text{ORDER BY} clause of a window specification. \text{Time}, with or without a specified time zone, lacks a coherent ordering because addition and subtraction do not have the expected effects. For example, the following is not generally true: \text{x::time < x::time + '2 hour'::interval}

- The \text{ROWS} or \text{RANGE} clause defines a window frame for aggregate (non-ranking) window functions. A window frame defines a set of rows within a window partition. When a window frame is defined, the window function computes on the contents of this moving frame rather than the fixed contents of the entire window partition. Window frames are row-based (\text{ROWS}) or value-based (\text{RANGE}).
Window Examples

The following examples demonstrate using window functions with partitions and window frames.

Example 1 – Aggregate Window Function Over a Partition

The `PARTITION BY` list in the `OVER` clause divides the rows into groups, or partitions, that have the same values as the specified expressions.

This example compares employees’ salaries with the average salaries for their departments:

```
SELECT depname, empno, salary, avg(salary) OVER(PARTITION BY depname)
FROM empsalary;
```

```
| depname  | empno | salary |          avg         |
|-----------+-------+--------+----------------------|
| develop   |     9 |   4500 | 5020.0000000000000000 |
| develop   |    10 |   5200 | 5020.0000000000000000 |
| develop   |    11 |   5200 | 5020.0000000000000000 |
| develop   |     7 |   4200 | 5020.0000000000000000 |
| develop   |     8 |   6000 | 5020.0000000000000000 |
| personnel |     5 |   3500 | 3700.0000000000000000 |
| personnel |     2 |   3900 | 3700.0000000000000000 |
| sales     |     1 |   5000 | 4866.6666666666666667 |
| sales     |     3 |   4800 | 4866.6666666666666667 |
| sales     |     4 |   4800 | 4866.6666666666666667 |
```

(10 rows)

The first three output columns come from the table `empsalary`, and there is one output row for each row in the table. The fourth column is the average calculated on all rows that have the same `depname` value as the current row. Rows that share the same `depname` value constitute a partition, and there are three partitions in this example. The `avg` function is the same as the regular `avg` aggregate function, but the `OVER` clause causes it to be applied as a window function.

You can also put the window specification in a `WINDOW` clause and reference it in the select list. This example is equivalent to the previous query:

```
SELECT depname, empno, salary, avg(salary) OVER(mywindow)
FROM empsalary
WINDOW mywindow AS (PARTITION BY depname);
```

Defining a named `window` is useful when the select list has multiple window functions using the same window specification.

Example 2 – Ranking Window Function With an ORDER BY Clause

An `ORDER BY` clause within the `OVER` clause controls the order in which rows are processed by window functions. The `ORDER BY` list for the window function does not have to match the output order of the query. This example uses the `rank()` window function to rank employees’ salaries within their departments:

```
SELECT depname, empno, salary, rank() OVER (PARTITION BY depname ORDER BY salary DESC)
FROM empsalary;
```

```
| depname  | empno | salary | rank |
|-----------+-------+--------+------|
| develop   |     8 |   6000 |    1 |
| develop   |    11 |   5200 |    2 |
| develop   |    10 |   5200 |    2 |
| develop   |     9 |   4500 |    4 |
| develop   |     7 |   4200 |    5 |
| personnel |     2 |   3900 |    1 |
```
Example 3 – Aggregate Function over a Row Window Frame

A `RANGE` or `ROWS` clause defines the window frame—a set of rows within a partition—that the window function includes in the calculation. `ROWS` specifies a physical set of rows to process, for example all rows from the beginning of the partition to the current row.

This example calculates a running total of employee’s salaries by department using the `sum()` function to total rows from the start of the partition to the current row:

```sql
SELECT depname, empno, salary,
       sum(salary) OVER (PARTITION BY depname ORDER BY salary
                       ROWS between UNBOUNDED PRECEDING AND CURRENT ROW)
FROM empsalary ORDER BY depname, sum;
```

<table>
<thead>
<tr>
<th>depname</th>
<th>empno</th>
<th>salary</th>
<th>sum</th>
</tr>
</thead>
<tbody>
<tr>
<td>develop</td>
<td>7</td>
<td>4200</td>
<td>4200</td>
</tr>
<tr>
<td>develop</td>
<td>9</td>
<td>4500</td>
<td>8700</td>
</tr>
<tr>
<td>develop</td>
<td>11</td>
<td>5200</td>
<td>13900</td>
</tr>
<tr>
<td>develop</td>
<td>10</td>
<td>5200</td>
<td>19100</td>
</tr>
<tr>
<td>develop</td>
<td>8</td>
<td>6000</td>
<td>25100</td>
</tr>
<tr>
<td>personnel</td>
<td>5</td>
<td>3500</td>
<td>3500</td>
</tr>
<tr>
<td>personnel</td>
<td>2</td>
<td>3900</td>
<td>7400</td>
</tr>
<tr>
<td>sales</td>
<td>4</td>
<td>4800</td>
<td>4800</td>
</tr>
<tr>
<td>sales</td>
<td>3</td>
<td>4800</td>
<td>9600</td>
</tr>
<tr>
<td>sales</td>
<td>1</td>
<td>5000</td>
<td>14600</td>
</tr>
</tbody>
</table>
```

Example 4 – Aggregate Function for a Range Window Frame

`RANGE` specifies logical values based on values of the `ORDER BY` expression in the `OVER` clause. This example demonstrates the difference between `ROWS` and `RANGE`. The frame contains all rows with salary values less than or equal to the current row. Unlike the previous example, for employees with the same salary, the sum is the same and includes the salaries of all of those employees.

```sql
SELECT depname, empno, salary,
       sum(salary) OVER (PARTITION BY depname ORDER BY salary
                       RANGE between UNBOUNDED PRECEDING AND CURRENT ROW)
FROM empsalary ORDER BY depname, sum;
```

<table>
<thead>
<tr>
<th>depname</th>
<th>empno</th>
<th>salary</th>
<th>sum</th>
</tr>
</thead>
<tbody>
<tr>
<td>develop</td>

**Type Casts**

A type cast specifies a conversion from one data type to another. A cast applied to a value expression of a known type is a run-time type conversion. The cast succeeds only if a suitable type conversion is defined. This differs from the use of casts with constants. A cast applied to a string literal represents the initial assignment of a type to a literal constant value, so it succeeds for any type if the contents of the string literal are acceptable input syntax for the data type.

Greenplum Database supports three types of casts applied to a value expression:

- **Explicit cast** - Greenplum Database applies a cast when you explicitly specify a cast between two data types. Greenplum Database accepts two equivalent syntaxes for explicit type casts:

  ```
  CAST ( expression AS type )
  expression::type
  ```

  The `CAST` syntax conforms to SQL; the syntax using `::` is historical PostgreSQL usage.

- **Assignment cast** - Greenplum Database implicitly invokes a cast in assignment contexts, when assigning a value to a column of the target data type. For example, a `CREATE CAST` command with the `AS ASSIGNMENT` clause creates a cast that is applied implicitly in the assignment context. This example assignment cast assumes that `tbl1.f1` is a column of type `text`. The `INSERT` command is allowed because the value is implicitly cast from the `integer` to `text` type.

  ```
  INSERT INTO tbl1 (f1) VALUES (42);
  ```

- **Implicit cast** - Greenplum Database implicitly invokes a cast in assignment or expression contexts. For example, a `CREATE CAST` command with the `AS IMPLICIT` clause creates an implicit cast, a cast that is applied implicitly in both the assignment and expression context. This example implicit cast assumes that `tbl1.c1` is a column of type `int`. For the calculation in the predicate, the value of `c1` is implicitly cast from `int` to a `decimal` type.

  ```
  SELECT * FROM tbl1 WHERE tbl1.c2 = (4.3 + tbl1.c1) ;
  ```

You can usually omit an explicit type cast if there is no ambiguity about the type a value expression must produce (for example, when it is assigned to a table column); the system automatically applies a type cast. Greenplum Database implicitly applies casts only to casts defined with a cast context of assignment or explicit in the system catalogs. Other casts must be invoked with explicit casting syntax to prevent unexpected conversions from being applied without the user's knowledge.

You can display cast information with the `psql` meta-command `\dC`. Cast information is stored in the catalog table `pg_cast`, and type information is stored in the catalog table `pg_type`.

**Scalar Subqueries**

A scalar subquery is a `SELECT` query in parentheses that returns exactly one row with one column. Do not use a `SELECT` query that returns multiple rows or columns as a scalar subquery. The query runs and uses the returned value in the surrounding value expression. A correlated scalar subquery contains references to the outer query block.

**Correlated Subqueries**

A correlated subquery (CSQ) is a `SELECT` query with a `WHERE` clause or target list that contains references to the parent outer clause. CSQs efficiently express results in terms of results of another query. Greenplum Database supports correlated subqueries that provide compatibility with many existing applications. A CSQ is a scalar or table subquery, depending on whether it returns one or multiple rows. Greenplum Database does not support correlated subqueries with skip-level correlations.
Correlated Subquery Examples

Example 1 – Scalar correlated subquery

```sql
SELECT * FROM t1 WHERE t1.x > (SELECT MAX(t2.x) FROM t2 WHERE t2.y = t1.y);
```

Example 2 – Correlated EXISTS subquery

```sql
SELECT * FROM t1 WHERE EXISTS (SELECT 1 FROM t2 WHERE t2.x = t1.x);
```

Greenplum Database uses one of the following methods to run CSQs:

- Unnest the CSQ into join operations – This method is most efficient, and it is how Greenplum Database runs most CSQs, including queries from the TPC-H benchmark.
- Run the CSQ on every row of the outer query – This method is relatively inefficient, and it is how Greenplum Database runs queries that contain CSQs in the `SELECT` list or are connected by `OR` conditions.

The following examples illustrate how to rewrite some of these types of queries to improve performance.

Example 3 - CSQ in the Select List

**Original Query**

```sql
SELECT T1.a, 
      (SELECT COUNT(DISTINCT T2.z) FROM t2 WHERE t1.x = t2.y) dt2 
FROM t1;
```

Rewrite this query to perform an inner join with `t1` first and then perform a left join with `t1` again. The rewrite applies for only an equijoin in the correlated condition.

**Rewritten Query**

```sql
SELECT t1.a, dt2 FROM t1 
  LEFT JOIN 
    (SELECT t2.y AS csq_y, COUNT(DISTINCT t2.z) AS dt2 
     FROM t1, t2 WHERE t1.x = t2.y 
     GROUP BY t1.x) 
  ON (t1.x = csq_y);
```

Example 4 - CSQs connected by OR Clauses

**Original Query**

```sql
SELECT * FROM t1 
WHERE 
x > (SELECT COUNT(*) FROM t2 WHERE t1.x = t2.x) 
OR x < (SELECT COUNT(*) FROM t3 WHERE t1.y = t3.y)
```

Rewrite this query to separate it into two parts with a union on the `OR` conditions.

**Rewritten Query**

```sql
SELECT * FROM t1 
WHERE x > (SELECT count(*) FROM t2 WHERE t1.x = t2.x) 
UNION 
SELECT * FROM t1
```
WHERE \( x < (\text{SELECT count(*) FROM t3 WHERE t1.y = t3.y}) \)

To view the query plan, use `EXPLAIN SELECT` or `EXPLAIN ANALYZE SELECT`. Subplan nodes in the query plan indicate that the query will run on every row of the outer query, and the query is a candidate for rewriting. For more information about these statements, see *Query Profiling*.

### Array Constructors

An array constructor is an expression that builds an array value from values for its member elements. A simple array constructor consists of the key word `ARRAY`, a left square bracket `[]`, one or more expressions separated by commas for the array element values, and a right square bracket `]`. For example,

```sql
SELECT ARRAY[1,2,3+4];
array
--------
{1,2,7}
```

The array element type is the common type of its member expressions, determined using the same rules as for `UNION` or `CASE` constructs.

You can build multidimensional array values by nesting array constructors. In the inner constructors, you can omit the keyword `ARRAY`. For example, the following two `SELECT` statements produce the same result:

```sql
SELECT ARRAY[ARRAY[1,2], ARRAY[3,4]];  
SELECT ARRAY[[1,2],[3,4]];
array
----------
{{1,2},{3,4}}
```

Since multidimensional arrays must be rectangular, inner constructors at the same level must produce sub-arrays of identical dimensions.

Multidimensional array constructor elements are not limited to a sub-`ARRAY` construct; they are anything that produces an array of the proper kind. For example:

```sql
CREATE TABLE arr(f1 int[], f2 int[]);
INSERT INTO arr VALUES (ARRAY[[1,2],[3,4]], ARRAY[[5,6],[7,8]]);
SELECT ARRAY[f1, f2, '((9,10),(11,12))':int[]] FROM arr;
array
---------------------
{{{1,2},{3,4}},{{5,6},{7,8}},{{9,10},{11,12}}}
```

You can construct an array from the results of a subquery. Write the array constructor with the keyword `ARRAY` followed by a subquery in parentheses. For example:

```sql
SELECT ARRAY(SELECT oid FROM pg_proc WHERE proname LIKE 'bytea%');
?column?
--------------------------------
```

The subquery must return a single column. The resulting one-dimensional array has an element for each row in the subquery result, with an element type matching that of the subquery's output column. The subscripts of an array value built with `ARRAY` always begin with 1.
**Row Constructors**

A row constructor is an expression that builds a row value (also called a composite value) from values for its member fields. For example,

```sql
SELECT ROW(1,2.5,'this is a test');
```

Row constructors have the syntax `rowvalue.*`, which expands to a list of the elements of the row value, as when you use the syntax `.*` at the top level of a `SELECT` list. For example, if table `t` has columns `f1` and `f2`, the following queries are the same:

```sql
SELECT ROW(t.*, 42) FROM t;
SELECT ROW(t.f1, t.f2, 42) FROM t;
```

By default, the value created by a `ROW` expression has an anonymous record type. If necessary, it can be cast to a named composite type — either the row type of a table, or a composite type created with `CREATE TYPE AS`. To avoid ambiguity, you can explicitly cast the value if necessary. For example:

```sql
CREATE TABLE mytable(f1 int, f2 float, f3 text);
CREATE FUNCTION getf1(mytable) RETURNS int AS 'SELECT $1.f1'
LANGUAGE SQL;
```

In the following query, you do not need to cast the value because there is only one `getf1()` function and therefore no ambiguity:

```sql
SELECT getf1(ROW(1,2.5,'this is a test'));
```

```plaintext
getf1
-------
  1
```

```sql
CREATE TYPE myrowtype AS (f1 int, f2 text, f3 numeric);
CREATE FUNCTION getf1(myrowtype) RETURNS int AS 'SELECT $1.f1'
LANGUAGE SQL;
```

Now we need a cast to indicate which function to call:

```sql
SELECT getf1(ROW(1,2.5,'this is a test')::mytable);
```

```plaintext
ERROR:  function getf1(record) is not unique
```

```sql
SELECT getf1(CAST(ROW(11,'this is a test',2.5) AS myrowtype));
```

```plaintext
getf1
-------
  11
```

You can use row constructors to build composite values to be stored in a composite-type table column or to be passed to a function that accepts a composite parameter.

**Expression Evaluation Rules**

The order of evaluation of subexpressions is undefined. The inputs of an operator or function are not necessarily evaluated left-to-right or in any other fixed order.
If you can determine the result of an expression by evaluating only some parts of the expression, then other subexpressions might not be evaluated at all. For example, in the following expression:

```sql
SELECT true OR somefunc();
```

`somefunc()` would probably not be called at all. The same is true in the following expression:

```sql
SELECT somefunc() OR true;
```

This is not the same as the left-to-right evaluation order that Boolean operators enforce in some programming languages.

Do not use functions with side effects as part of complex expressions, especially in `WHERE` and `HAVING` clauses, because those clauses are extensively reprocessed when developing an execution plan. Boolean expressions (AND/OR/NOT combinations) in those clauses can be reorganized in any manner that Boolean algebra laws allow.

Use a `CASE` construct to force evaluation order. The following example is an untrustworthy way to avoid division by zero in a `WHERE` clause:

```sql
SELECT ... WHERE x <> 0 AND y/x > 1.5;
```

The following example shows a trustworthy evaluation order:

```sql
SELECT ... WHERE CASE WHEN x <> 0 THEN y/x > 1.5 ELSE false END;
```

This `CASE` construct usage defeats optimization attempts; use it only when necessary.

**WITH Queries (Common Table Expressions)**

The `WITH` clause provides a way to use subqueries or perform a data modifying operation in a larger `SELECT` query. You can also use the `WITH` clause in an `INSERT`, `UPDATE`, or `DELETE` command.

See **SELECT in a WITH Clause** for information about using `SELECT` in a `WITH` clause.

See **Data-Modifying Statements in a WITH clause**, for information about using `INSERT`, `UPDATE`, or `DELETE` in a `WITH` clause.

*Note:* These are limitations for using a `WITH` clause.

- For a `SELECT` command that includes a `WITH` clause, the clause can contain at most a single clause that modifies table data (`INSERT`, `UPDATE`, or `DELETE`) command.
- For a data-modifying command (`INSERT`, `UPDATE`, or `DELETE`) that includes a `WITH` clause, the clause can only contain a `SELECT` command, the `WITH` clause cannot contain a data-modifying command.

By default, the `RECURSIVE` keyword for the `WITH` clause is **enabled**. `RECURSIVE` can be disabled by setting the server configuration parameter `gp_recursive_cte` to false.

**SELECT in a WITH Clause**

The subqueries, which are often referred to as Common Table Expressions or CTEs, can be thought of as defining temporary tables that exist just for the query. These examples show the `WITH` clause being used with a `SELECT` command. The example `WITH` clauses can be used the same way with `INSERT`, `UPDATE`, or `DELETE`. In each case, the `WITH` clause effectively provides temporary tables that can be referred to in the main command.

A `SELECT` command in the `WITH` clause is evaluated only once per execution of the parent query, even if it is referred to more than once by the parent query or sibling `WITH` clauses. Thus, expensive calculations that are needed in multiple places can be placed within a `WITH` clause to avoid redundant work. Another
possible application is to prevent unwanted multiple evaluations of functions with side-effects. However, the other side of this coin is that the optimizer is less able to push restrictions from the parent query down into a WITH query than an ordinary sub-query. The WITH query will generally be evaluated as written, without suppression of rows that the parent query might discard afterwards. However, evaluation might stop early if the references to the query demand only a limited number of rows.

One use of this feature is to break down complicated queries into simpler parts. This example query displays per-product sales totals in only the top sales regions:

```sql
WITH regional_sales AS (
    SELECT region, SUM(amount) AS total_sales
    FROM orders
    GROUP BY region
), top_regions AS (
    SELECT region
    FROM regional_sales
    WHERE total_sales > (SELECT SUM(total_sales)/10 FROM regional_sales)
)
SELECT region,
    product,
    SUM(quantity) AS product_units,
    SUM(amount) AS product_sales
FROM orders
WHERE region IN (SELECT region FROM top_regions)
GROUP BY region, product;
```

The query could have been written without the WITH clause, but would have required two levels of nested sub-SELECTs. It is easier to follow with the WITH clause.

When the optional RECURSIVE keyword is enabled, the WITH clause can accomplish things not otherwise possible in standard SQL. Using RECURSIVE, a query in the WITH clause can refer to its own output. This is a simple example that computes the sum of integers from 1 through 100:

```sql
WITH RECURSIVE t(n) AS (
    VALUES (1)
    UNION ALL
    SELECT n+1 FROM t WHERE n < 100
)
SELECT sum(n) FROM t;
```

The general form of a recursive WITH clause (a WITH clause that uses a the RECURSIVE keyword) is a non-recursive term, followed by a UNION (or UNION ALL), and then a recursive term, where only the recursive term can contain a reference to the query output.

```
non_recursive_term UNION [ ALL ] recursive_term
```

A recursive WITH query that contains a UNION [ ALL ] is executed as follows:

1. Evaluate the non-recursive term. For UNION (but not UNION ALL), discard duplicate rows. Include all remaining rows in the result of the recursive query, and also place them in a temporary working table.
2. As long as the working table is not empty, repeat these steps:
   a. Evaluate the recursive term, substituting the current contents of the working table for the recursive self-reference. For UNION (but not UNION ALL), discard duplicate rows and rows that duplicate any previous result row. Include all remaining rows in the result of the recursive query, and also place them in a temporary intermediate table.
   b. Replace the contents of the working table with the contents of the intermediate table, then empty the intermediate table.

   **Note:** Strictly speaking, the process is iteration not recursion, but RECURSIVE is the terminology chosen by the SQL standards committee.
Recursive WITH queries are typically used to deal with hierarchical or tree-structured data. An example is this query to find all the direct and indirect sub-parts of a product, given only a table that shows immediate inclusions:

```sql
WITH RECURSIVE included_parts(sub_part, part, quantity) AS (
    SELECT sub_part, part, quantity FROM parts WHERE part = 'our_product'
    UNION ALL
    SELECT p.sub_part, p.part, p.quantity
    FROM included_parts pr, parts p
    WHERE p.part = pr.sub_part
)
SELECT sub_part, SUM(quantity) as total_quantity
FROM included_parts
GROUP BY sub_part;
```

When working with recursive WITH queries, you must ensure that the recursive part of the query eventually returns no tuples, or else the query loops indefinitely. In the example that computes the sum of integers, the working table contains a single row in each step, and it takes on the values from 1 through 100 in successive steps. In the 100th step, there is no output because of the WHERE clause, and the query terminates.

For some queries, using UNION instead of UNION ALL can ensure that the recursive part of the query eventually returns no tuples by discarding rows that duplicate previous output rows. However, often a cycle does not involve output rows that are complete duplicates: it might be sufficient to check just one or a few fields to see if the same point has been reached before. The standard method for handling such situations is to compute an array of the visited values. For example, consider the following query that searches a table graph using a link field:

```sql
WITH RECURSIVE search_graph(id, link, data, depth) AS (
    SELECT g.id, g.link, g.data, 1
    FROM graph g
    UNION ALL
    SELECT g.id, g.link, g.data, sg.depth + 1
    FROM graph g, search_graph sg
    WHERE g.id = sg.link
)
SELECT * FROM search_graph;
```

This query loops if the link relationships contain cycles. Because the query requires a depth output, changing UNION ALL to UNION does not eliminate the looping. Instead the query needs to recognize whether it has reached the same row again while following a particular path of links. This modified query adds two columns, path and cycle, to the loop-prone query:

```sql
WITH RECURSIVE search_graph(id, link, data, depth, path, cycle) AS (
    SELECT g.id, g.link, g.data, 1,  
    ARRAY[g.id],
    false
    FROM graph g
    UNION ALL
    SELECT g.id, g.link, g.data, sg.depth + 1,  
    path || g.id,
    g.id = ANY(path)
    FROM graph g, search_graph sg
    WHERE g.id = sg.link AND NOT cycle
)
SELECT * FROM search_graph;
```

Aside from detecting cycles, the array value of path is useful in its own right since it represents the path taken to reach any particular row.
In the general case where more than one field needs to be checked to recognize a cycle, an array of rows can be used. For example, if we needed to compare fields $f_1$ and $f_2$:

```sql
WITH RECURSIVE search_graph(id, link, data, depth, path, cycle) AS (
    SELECT g.id, g.link, g.data, 1,
    ARRAY[ROW(g.f1, g.f2)],
    false
    FROM graph g
    UNION ALL
    SELECT g.id, g.link, g.data, sg.depth + 1,
    path || ROW(g.f1, g.f2),
    ROW(g.f1, g.f2) = ANY(path)
    FROM graph g, search_graph sg
    WHERE g.id = sg.link AND NOT cycle
) SELECT * FROM search_graph;
```

**Tip:** Omit the `ROW()` syntax in the case where only one field needs to be checked to recognize a cycle. This uses a simple array rather than a composite-type array, gaining efficiency.

**Tip:** The recursive query evaluation algorithm produces its output in breadth-first search order. You can display the results in depth-first search order by making the outer query `ORDER BY` a path column constructed in this way.

A helpful technique for testing a query when you are not certain if it might loop indefinitely is to place a `LIMIT` in the parent query. For example, this query would loop forever without the `LIMIT` clause:

```sql
WITH RECURSIVE t(n) AS (
    SELECT 1
    UNION ALL
    SELECT n+1 FROM t
) SELECT n FROM t LIMIT 100;
```

The technique works because the recursive `WITH` implementation evaluates only as many rows of a `WITH` query as are actually fetched by the parent query. Using this technique in production is not recommended, because other systems might work differently. Also, the technique might not work if the outer query sorts the recursive `WITH` results or join the results to another table.

### Data-Modifying Statements in a `WITH` clause

For a `SELECT` command, you can use the data-modifying commands `INSERT`, `UPDATE`, or `DELETE` in a `WITH` clause. This allows you to perform several different operations in the same query.

A data-modifying statement in a `WITH` clause is executed exactly once, and always to completion, independently of whether the primary query reads all (or indeed any) of the output. This is different from the rule when using `SELECT` in a `WITH` clause, the execution of a `SELECT` continues only as long as the primary query demands its output.

This simple CTE query deletes rows from `products`. The `DELETE` in the `WITH` clause deletes the specified rows from `products`, returning their contents by means of its `RETURNING` clause.

```sql
WITH deleted_rows AS (
    DELETE FROM products
    WHERE
      "date" >= '2010-10-01' AND
      "date" < '2010-11-01'
    RETURNING *
) SELECT * FROM deleted_rows;
```
Data-modifying statements in a WITH clause must have RETURNING clauses, as shown in the previous example. It is the output of the RETURNING clause, not the target table of the data-modifying statement, that forms the temporary table that can be referred to by the rest of the query. If a data-modifying statement in a WITH lacks a RETURNING clause, an error is returned.

If the optional RECURSIVE keyword is enabled, recursive self-references in data-modifying statements are not allowed. In some cases it is possible to work around this limitation by referring to the output of a recursive WITH. For example, this query would remove all direct and indirect subparts of a product.

```sql
WITH RECURSIVE included_parts(sub_part, part) AS (
    SELECT sub_part, part FROM parts WHERE part = 'our_product'
    UNION ALL
    SELECT p.sub_part, p.part
    FROM included_parts pr, parts p
    WHERE p.part = pr.sub_part
)
DELETE FROM parts
WHERE part IN (SELECT part FROM included_parts);
```

The sub-statements in a WITH clause are executed concurrently with each other and with the main query. Therefore, when using a data-modifying statement in a WITH, the statement is executed in a snapshot. The effects of the statement are not visible on the target tables. The RETURNING data is the only way to communicate changes between different WITH sub-statements and the main query. In this example, the outer SELECT returns the original prices before the action of the UPDATE in the WITH clause.

```sql
WITH t AS (
    UPDATE products SET price = price * 1.05
    RETURNING *
)
SELECT * FROM products;
```

In this example the outer SELECT returns the updated data.

```sql
WITH t AS (
    UPDATE products SET price = price * 1.05
    RETURNING *
)
SELECT * FROM t;
```

Updating the same row twice in a single statement is not supported. The effects of such a statement will not be predictable. Only one of the modifications takes place, but it is not easy (and sometimes not possible) to predict which modification occurs.

Any table used as the target of a data-modifying statement in a WITH clause must not have a conditional rule, or an ALSO rule, or an INSTEAD rule that expands to multiple statements.

### Using Functions and Operators

Description of user-defined and built-in functions and operators in Greenplum Database.

- *Using Functions in Greenplum Database*
- *User-Defined Functions*
- *Built-in Functions and Operators*
- *Window Functions*
- *Advanced Aggregate Functions*

#### Using Functions in Greenplum Database

When you invoke a function in Greenplum Database, function attributes control the execution of the function. The volatility attributes (IMMUTABLE, STABLE, VOLATILE) and the EXECUTE ON attributes...
control two different aspects of function execution. In general, volatility indicates when the function is executed, and `EXECUTE ON` indicates where it is executed. The volatility attributes are PostgreSQL based attributes, the `EXECUTE ON` attributes are Greenplum Database attributes.

For example, a function defined with the `IMMUTABLE` attribute can be executed at query planning time, while a function with the `VOLATILE` attribute must be executed for every row in the query. A function with the `EXECUTE ON MASTER` attribute executes only on the master instance, and a function with the `EXECUTE ON ALL SEGMENTS` attribute executes on all primary segment instances (not the master).

These tables summarize what Greenplum Database assumes about function execution based on the attribute.

### Table 43: Function Volatility Attributes in Greenplum Database

<table>
<thead>
<tr>
<th>Function Attribute</th>
<th>Greenplum Support</th>
<th>Description</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>IMMUTABLE</td>
<td>Yes</td>
<td>Relies only on information directly in its argument list. Given the same argument values, always returns the same result.</td>
<td>Results depend on database lookups or parameter values. current_timestamp family of functions is STABLE; values do not change within an execution.</td>
</tr>
<tr>
<td>STABLE</td>
<td>Yes, in most cases</td>
<td>Within a single table scan, returns the same result for same argument values, but results change across SQL statements.</td>
<td></td>
</tr>
</tbody>
</table>
| VOLATILE           | Restricted        | Function values can change within a single table scan. For example: `random()`, `timeofday()`. This is the default attribute. | Any function with side effects is volatile, even if its result is predictable. For example: `setval()`.

### Table 44: Function `EXECUTE ON` attributes in Greenplum Database

<table>
<thead>
<tr>
<th>Function Attribute</th>
<th>Description</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>EXECUTE ON ANY</code></td>
<td>Indicates that the function can be executed on the master, or any segment instance, and it returns the same result regardless of where it executes. This is the default attribute.</td>
<td>Greenplum Database determines where the function executes.</td>
</tr>
<tr>
<td><code>EXECUTE ON MASTER</code></td>
<td>Indicates that the function must be executed on the master instance.</td>
<td>Specify this attribute if the user-defined function executes queries to access tables.</td>
</tr>
<tr>
<td><code>EXECUTE ON ALL SEGMENTS</code></td>
<td>Indicates that for each invocation, the function must be executed on all primary segment instances, but not the master.</td>
<td></td>
</tr>
</tbody>
</table>

You can display the function volatility and `EXECUTE ON` attribute information with the `psql \df+ function` command.

Refer to the PostgreSQL Function Volatility Categories documentation for additional information about the Greenplum Database function volatility classifications.

For more information about `EXECUTE ON` attributes, see `CREATE FUNCTION`.

In Greenplum Database, data is divided up across segments — each segment is a distinct PostgreSQL database. To prevent inconsistent or unexpected results, do not execute functions classified as **VOLATILE** at the segment level if they contain SQL commands or modify the database in any way. For example, functions such as `setval()` are not allowed to execute on distributed data in Greenplum Database because they can cause inconsistent data between segment instances.

A function can execute read-only queries on replicated tables (**DISTRIBUTED REPLICATED**) on the segments, but any SQL command that modifies data must execute on the master instance.

**Note**: The hidden system columns (`ctid`, `cmin`, `cmax`, `xmin`, `xmax`, and `gp_segment_id`) cannot be referenced in user queries on replicated tables because they have no single, unambiguous value. Greenplum Database returns a column does not exist error for the query.

To ensure data consistency, you can safely use **VOLATILE** and **STABLE** functions in statements that are evaluated on and run from the master. For example, the following statements run on the master (statements without a `FROM` clause):

```sql
SELECT setval('myseq', 201);
SELECT foo();
```

If a statement has a `FROM` clause containing a distributed table and the function in the `FROM` clause returns a set of rows, the statement can run on the segments:

```sql
SELECT * from foo();
```

Greenplum Database does not support functions that return a table reference (**rangeFuncs**) or functions that use the **refCursor** data type.

**Function Volatility and Plan Caching**

There is relatively little difference between the **STABLE** and **IMMUTABLE** function volatility categories for simple interactive queries that are planned and immediately executed. It does not matter much whether a function is executed once during planning or once during query execution start up. But there is a big difference when you save the plan and reuse it later. If you mislabel a function **IMMUTABLE**, Greenplum Database may prematurely fold it to a constant during planning, possibly reusing a stale value during subsequent execution of the plan. You may run into this hazard when using **PREPARED** statements, or when using languages such as PL/pgSQL that cache plans.

**User-Defined Functions**

Greenplum Database supports user-defined functions. See **Extending SQL** in the PostgreSQL documentation for more information.

Use the `CREATE FUNCTION` statement to register user-defined functions that are used as described in **Using Functions in Greenplum Database**. By default, user-defined functions are declared as **VOLATILE**, so if your user-defined function is **IMMUTABLE** or **STABLE**, you must specify the correct volatility level when you register your function.

By default, user-defined functions are declared as **EXECUTE ON ANY**. A function that executes queries to access tables is supported only when the function executes on the master instance, except that a function can execute `SELECT` commands that access only replicated tables on the segment instances. A function that accesses hash-distributed or randomly distributed tables must be defined with the **EXECUTE ON MASTER** attribute. Otherwise, the function might return incorrect results when the function is used in a complicated query. Without the attribute, planner optimization might determine it would be beneficial to push the function invocation to segment instances.

When you create user-defined functions, avoid using fatal errors or destructive calls. Greenplum Database may respond to such errors with a sudden shutdown or restart.
In Greenplum Database, the shared library files for user-created functions must reside in the same library path location on every host in the Greenplum Database array (masters, segments, and mirrors).

You can also create and execute anonymous code blocks that are written in a Greenplum Database procedural language such as PL/pgSQL. The anonymous blocks run as transient anonymous functions. For information about creating and executing anonymous blocks, see the `do` command.

### Built-in Functions and Operators

The following table lists the categories of built-in functions and operators supported by PostgreSQL. All functions and operators are supported in Greenplum Database as in PostgreSQL with the exception of `STABLE` and `VOLATILE` functions, which are subject to the restrictions noted in Using Functions in Greenplum Database. See the Functions and Operators section of the PostgreSQL documentation for more information about these built-in functions and operators.

Greenplum Database includes JSON processing functions that manipulate values the `json` data type. For information about JSON data, see Working with JSON Data.

<td>PERCENT_RANK () OVER ([PARTITION BY expr] ORDER BY expr)</td>
<td>Calculates the rank of a hypothetical row R minus 1, divided by 1 less than the number of rows being evaluated (within a window partition).</td>
</tr>
<tr>
<td>rank()</td>
<td>bigint</td>
<td>RANK () OVER ([PARTITION BY expr] ORDER BY expr)</td>
<td>Calculates the rank of a row in an ordered group of values. Rows with equal values for the ranking criteria receive the same rank. The number of tied rows are added to the rank number to calculate the next rank value. Ranks may not be consecutive numbers in this case.</td>
</tr>
<tr>
<td>row_number()</td>
<td>bigint</td>
<td>ROW_NUMBER () OVER ([PARTITION BY expr] ORDER BY expr)</td>
<td>Assigns a unique number to each row to which it is applied (either each row in a window partition or each row of the query).</td>
</tr>
</tbody>
</table>

**Advanced Aggregate Functions**

The following built-in advanced aggregate functions are Greenplum extensions of the PostgreSQL database. These functions are immutable.

**Note:** The Greenplum MADlib Extension for Analytics provides additional advanced functions to perform statistical analysis and machine learning with Greenplum Database data. See Greenplum MADlib Extension for Analytics in the Greenplum Database Reference Guide.

**Table 47: Advanced Aggregate Functions**

<table>
<thead>
<tr>

<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>MEDIAN (expr)</td>
<td>timestamp, timestamptz, interval, float</td>
<td>MEDIAN (expression)</td>
<td>Can take a two-dimensional array as input. Treats such arrays as matrices.</td>
</tr>
</tbody>
</table>

*Example:*

```sql
SELECT departmzent_id, MEDIAN(salary) FROM employees GROUP BY department_id;
```
### Function

<table>
<thead>
<tr>
<th>Function</th>
<th>Return Type</th>
<th>Full Syntax</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sum(array[])</td>
<td>smallint[], int[], bigint[], float[]</td>
<td>sum(array[[1,2],[3,4]])</td>
<td>Performs matrix summation. Can take as input a two-dimensional array that is treated as a matrix.</td>
</tr>
<tr>
<td>pivot_sum</td>
<td>int[], bigint[], float[]</td>
<td>pivot_sum( array['A1','A2'], attr, value)</td>
<td>A pivot aggregation using sum to resolve duplicate entries.</td>
</tr>
<tr>
<td>unnest (array[])</td>
<td>set of anyelement</td>
<td>unnest( array['one', 'row', 'per', 'item'])</td>
<td>Transforms a one dimensional array into rows. Returns a set of anyelement, a polymorphic pseudo-type in PostgreSQL.</td>
</tr>
</tbody>
</table>

#### Working with JSON Data

Greenplum Database supports the json and jsonb data types that store JSON (JavaScript Object Notation) data.

Greenplum Database supports JSON as specified in the [RFC 7159](https://tools.ietf.org/html/rfc7159) document and enforces data validity according to the JSON rules. There are also JSON-specific functions and operators available for the json and jsonb data types. See [JSON Functions and Operators](#).

This section contains the following topics:
- About JSON Data
- JSON Input and Output Syntax
- Designing JSON documents
- jsonb Containment and Existence
- jsonb Indexing
- JSON Functions and Operators

### About JSON Data

Greenplum Database supports two JSON data types: json and jsonb. They accept almost identical sets of values as input. The major difference is one of efficiency.

- The json data type stores an exact copy of the input text. This requires JSON processing functions to reparse json data on each execution. The json data type does not alter the input text.
- Semantically-insignificant white space between tokens is retained, as well as the order of keys within JSON objects.
- All key/value pairs are kept even if a JSON object contains duplicate keys. For duplicate keys, JSON processing functions consider the last value as the operative one.
- The jsonb data type stores a decomposed binary format of the input text. The conversion overhead makes data input slightly slower than the json data type. However, The JSON processing functions are significantly faster because reparsing jsonb data is not required. The json data type alters the input text.
  - White space is not preserved.
  - The order of object keys is not preserved.
  - Duplicate object keys are not kept. If the input includes duplicate keys, only the last value is kept.

The jsonb data type supports indexing. See \jsonb Indexing.\n
In general, JSON data should be stored as the jsonb data type unless there are specialized needs, such as legacy assumptions about ordering of object keys.

### About Unicode Characters in JSON Data

The RFC 7159 document permits JSON strings to contain Unicode escape sequences denoted by \uXXXX. However, Greenplum Database allows only one character set encoding per database. It is not possible for the json data type to conform rigidly to the JSON specification unless the database encoding is UTF8. Attempts to include characters that cannot be represented in the database encoding will fail. Characters that can be represented in the database encoding, but not in UTF8, are allowed.

- The Greenplum Database input function for the json data type allows Unicode escapes regardless of the database encoding and checks Unicode escapes only for syntactic correctness (a \u followed by four hex digits).
- The Greenplum Database input function for the jsonb data type is more strict. It does not allow Unicode escapes for non-ASCII characters (those above U+007F) unless the database encoding is UTF8. It also rejects \u0000, which cannot be represented in the Greenplum Database text type, and it requires that any use of Unicode surrogate pairs to designate characters outside the Unicode Basic Multilingual Plane be correct. Valid Unicode escapes, except for \u0000, are converted to the equivalent ASCII or UTF8 character for storage; this includes folding surrogate pairs into a single character.

\Note: Many of the JSON processing functions described in JSON Functions and Operators convert Unicode escapes to regular characters. The functions throw an error for characters that cannot be represented in the database encoding. You should avoid mixing Unicode escapes in JSON with a non-UTF8 database encoding, if possible.

### Mapping JSON Data Types to Greenplum Data Types

When converting JSON text input into jsonb data, the primitive data types described by RFC 7159 are effectively mapped onto native Greenplum Database data types, as shown in the following table.

**Table 48: JSON Primitive Types and Corresponding Greenplum Database Data Types**

<table>
<thead>
<tr>
<th>JSON primitive data type</th>
<th>Greenplum Database data type</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>string</td>
<td>text</td>
<td>\u0000 is not allowed. Non-ASCII Unicode escapes are allowed only if database encoding is UTF8</td>
</tr>
<tr>
<td>number</td>
<td>numeric</td>
<td>NaN and infinity values are disallowed</td>
</tr>
<tr>
<td>JSON primitive data type</td>
<td>Greenplum Database data type</td>
<td>Notes</td>
</tr>
<tr>
<td>-------------------------</td>
<td>-----------------------------</td>
<td>-------</td>
</tr>
<tr>
<td>boolean</td>
<td>boolean</td>
<td>Only lowercase true and false spellings are accepted</td>
</tr>
<tr>
<td>null</td>
<td>(none)</td>
<td>The JSON null primitive type is different than the SQL NULL.</td>
</tr>
</tbody>
</table>

There are some minor constraints on what constitutes valid jsonb data that do not apply to the json data type, nor to JSON in the abstract, corresponding to limits on what can be represented by the underlying data type. Notably, when converting data to the jsonb data type, numbers that are outside the range of the Greenplum Database numeric data type are rejected, while the json data type does not reject such numbers.

Such implementation-defined restrictions are permitted by RFC 7159. However, in practice such problems might occur in other implementations, as it is common to represent the JSON number primitive type as IEEE 754 double precision floating point (which RFC 7159 explicitly anticipates and allows for).

When using JSON as an interchange format with other systems, be aware of the possibility of losing numeric precision compared to data originally stored by Greenplum Database.

Also, as noted in the previous table, there are some minor restrictions on the input format of JSON primitive types that do not apply to the corresponding Greenplum Database data types.

### JSON Input and Output Syntax

The input and output syntax for the json data type is as specified in RFC 7159.

The following are all valid json expressions:

```sql
-- Simple scalar/primitive value
-- Primitive values can be numbers, quoted strings, true, false, or null
SELECT '5'::json;

-- Array of zero or more elements (elements need not be of same type)
SELECT '[[1, 2, "foo", null]]'::json;

-- Object containing pairs of keys and values
-- Note that object keys must always be quoted strings
SELECT '{"bar": "baz", "balance": 7.77, "active": false}'::json;

-- Arrays and objects can be nested arbitrarily
SELECT '{"foo": [true, "bar"], "tags": {"a": 1, "b": null}}'::json;
```

As previously stated, when a JSON value is input and then printed without any additional processing, the json data type outputs the same text that was input, while the jsonb data type does not preserve semantically-insignificant details such as whitespace. For example, note the differences here:

```sql
SELECT '{"bar": "baz", "balance": 7.77, "active":false}'::json;
json
--------------------------------------------------
{"bar": "baz", "balance": 7.77, "active":false}
(1 row)

SELECT '{"bar": "baz", "balance": 7.77, "active":false}'::jsonb;
jsonb
--------------------------------------------------
{"bar": "baz", "active":false, "balance":7.77}
(1 row)
```
One semantically-insignificant detail worth noting is that with the \texttt{jsonb} data type, numbers will be printed according to the behavior of the underlying numeric type. In practice, this means that numbers entered with \texttt{E} notation will be printed without it, for example:

\begin{verbatim}
SELECT '{"reading": 1.230e-5}':::json, '{"reading": 1.230e-5}':::jsonb;
\end{verbatim}

\begin{verbatim}
json          |          jsonb
-----------------------+-------------------------
{"reading": 1.230e-5} | {"reading": 0.00001230}
(1 row)
\end{verbatim}

However, the \texttt{jsonb} data type preserves trailing fractional zeroes, as seen in previous example, even though those are semantically insignificant for purposes such as equality checks.

### Designing JSON documents

Representing data as JSON can be considerably more flexible than the traditional relational data model, which is compelling in environments where requirements are fluid. It is quite possible for both approaches to co-exist and complement each other within the same application. However, even for applications where maximal flexibility is desired, it is still recommended that JSON documents have a somewhat fixed structure. The structure is typically unenforced (though enforcing some business rules declaratively is possible), but having a predictable structure makes it easier to write queries that usefully summarize a set of JSON documents (datums) in a table.

JSON data is subject to the same concurrency-control considerations as any other data type when stored in a table. Although storing large documents is practicable, keep in mind that any update acquires a row-level lock on the whole row. Consider limiting JSON documents to a manageable size in order to decrease lock contention among updating transactions. Ideally, JSON documents should each represent an atomic datum that business rules dictate cannot reasonably be further subdivided into smaller datums that could be modified independently.

### jsonb Containment and Existence

Testing \textit{containment} is an important capability of \texttt{jsonb}. There is no parallel set of facilities for the \texttt{json} type. Containment tests whether one \texttt{jsonb} document has contained within it another one. These examples return true except as noted:

\begin{verbatim}
-- Simple scalar/primitive values contain only the identical value:
SELECT '"foo"':::jsonb @> '"foo"':::jsonb;

-- The array on the right side is contained within the one on the left:
SELECT '[[1, 2, 3]]':::jsonb @> '[1, 3]':::jsonb;

-- Order of array elements is not significant, so this is also true:
SELECT '[[1, 2, 3]]':::jsonb @> '[3, 1]':::jsonb;

-- Duplicate array elements don't matter either:
SELECT '[[1, 2, 3]]':::jsonb @> '[1, 2, 2]':::jsonb;

-- The object with a single pair on the right side is contained
-- within the object on the left side:
SELECT '{"product": "Greenplum", "version": "6.0.0", "jsonb":true}':::jsonb
@> '{"version":"6.0.0"}':::jsonb;

-- The array on the right side is \textbf{not} considered contained within the
-- array on the left, even though a similar array is nested within it:
SELECT '[[1, 2, [1, 3]]]':::jsonb @> '[1, 3]':::jsonb; -- yields false

-- But with a layer of nesting, it is contained:
SELECT '[[1, 2, [1, 3]]]':::jsonb @> '[[1, 3]]':::jsonb;
\end{verbatim}
-- Similarly, containment is not reported here:
SELECT '{"foo": {"bar": "baz", "zig": "zag"}}':::jsonb @> '{"bar": "baz"}':::jsonb; -- yields false

-- But with a layer of nesting, it is contained:
SELECT '{"foo": {"bar": "baz", "zig": "zag"}}':::jsonb @> '{"foo": {"bar": "baz"}}':::jsonb;

The general principle is that the contained object must match the containing object as to structure and data contents, possibly after discarding some non-matching array elements or object key/value pairs from the containing object. For containment, the order of array elements is not significant when doing a containment match, and duplicate array elements are effectively considered only once.

As an exception to the general principle that the structures must match, an array may contain a primitive value:

-- This array contains the primitive string value:
SELECT '["foo", "bar"]':::jsonb @> '"bar"':::jsonb;

-- This exception is not reciprocal -- non-containment is reported here:
SELECT '"bar"':::jsonb @> '["bar"]':::jsonb; -- yields false

`jsonb` also has an `existence` operator, which is a variation on the theme of containment: it tests whether a string (given as a text value) appears as an object key or array element at the top level of the `jsonb` value. These examples return true except as noted:

-- String exists as array element:
SELECT '["foo", "bar", "baz"]':::jsonb ? 'bar';

-- String exists as object key:
SELECT '{"foo": "bar"}':::jsonb ? 'foo';

-- Object values are not considered:
SELECT '{"foo": "bar"}':::jsonb ? 'bar'; -- yields false

-- As with containment, existence must match at the top level:
SELECT '{"foo": {"bar": "baz"}}':::jsonb ? 'bar'; -- yields false

-- A string is considered to exist if it matches a primitive JSON string:
SELECT '"foo"':::jsonb ? 'foo';

JSON objects are better suited than arrays for testing containment or existence when there are many keys or elements involved, because unlike arrays they are internally optimized for searching, and do not need to be searched linearly.

The various containment and existence operators, along with all other JSON operators and functions are documented in `JSON Functions and Operators`.

Because JSON containment is nested, an appropriate query can skip explicit selection of sub-objects. As an example, suppose that we have a doc column containing objects at the top level, with most objects containing tags fields that contain arrays of sub-objects. This query finds entries in which sub-objects containing both "term":"paris" and "term":"food" appear, while ignoring any such keys outside the tags array:

```
SELECT doc->'site_name' FROM websites
  WHERE doc @> '{"tags":[{"term":"paris"}, {"term":"food"}]}';
```

The query with this predicate could accomplish the same thing.

```
SELECT doc->'site_name' FROM websites
  WHERE doc->'tags' @> '[{"term":"paris"}, {"term":"food"}];
```
However, the second approach is less flexible and is often less efficient as well. On the other hand, the JSON existence operator is not nested: it will only look for the specified key or array element at top level of the JSON value.

**jsonb Indexing**

The Greenplum Database **jsonb** data type, supports GIN, btree, and hash indexes.

- **GIN Indexes on jsonb Data**
- **Btree and Hash Indexes on jsonb Data**

**GIN Indexes on jsonb Data**

GIN indexes can be used to efficiently search for keys or key/value pairs occurring within a large number of **jsonb** documents (datums). Two GIN operator classes are provided, offering different performance and flexibility trade-offs.

The default GIN operator class for **jsonb** supports queries with the `@>`, `?`, `?&` and `?|` operators. (For details of the semantics that these operators implement, see the table **Table 50: jsonb Operators**.) An example of creating an index with this operator class is:

```sql
CREATE INDEX idxgin ON api USING gin (jdoc);
```

The non-default GIN operator class **jsonb_path_ops** supports indexing the `@>` operator only. An example of creating an index with this operator class is:

```sql
CREATE INDEX idxginp ON api USING gin (jdoc jsonb_path_ops);
```

Consider the example of a table that stores JSON documents retrieved from a third-party web service, with a documented schema definition. This is a typical document:

```json
{
  "guid": "9c36ad1-7fb5-4d5b-83b4-90356a46061a",
  "name": "Angela Barton",
  "is_active": true,
  "company": "Magnafone",
  "address": "178 Howard Place, Gulf, Washington, 702",
  "registered": "2009-11-07T08:53:22 +08:00",
  "latitude": 19.793713,
  "longitude": 86.513373,
  "tags": ["enim","aliquip","qui"]
}
```

The JSON documents are stored a table named **api**, in a **jsonb** column named **jdoc**. If a GIN index is created on this column, queries like the following can make use of the index:

```sql
-- Find documents in which the key "company" has value "Magnafone"
SELECT jdoc->'guid', jdoc->'name' FROM api WHERE jdoc @> '{"company": "Magnafone"}';
```

However, the index could not be used for queries like the following. The operator `?` is indexable, however, the comparison is not applied directly to the indexed column **jdoc**:

```sql
-- Find documents in which the key "tags" contains key or array element "qui"
SELECT jdoc->'guid', jdoc->'name' FROM api WHERE jdoc -> 'tags' ? 'qui';
```
With appropriate use of expression indexes, the above query can use an index. If querying for particular items within the `tags` key is common, defining an index like this might be worthwhile:

```sql
CREATE INDEX idxgintags ON api USING gin ((jdoc -> 'tags'));
```

Now, the `WHERE` clause `jdoc -> 'tags' ? 'qui'` is recognized as an application of the indexable operator `?` to the indexed expression `jdoc -> 'tags'`. For information about expression indexes, see `Indexes on Expressions`.

Another approach to querying JSON documents is to exploit containment, for example:

```sql
-- Find documents in which the key "tags" contains array element "qui"
SELECT jdoc->'guid', jdoc->'name' FROM api WHERE jdoc @> '"tags": ["qui"]';
```

A simple GIN index on the `jdoc` column can support this query. However, the index will store copies of every key and value in the `jdoc` column, whereas the expression index of the previous example stores only data found under the `tags` key. While the simple-index approach is far more flexible (since it supports queries about any key), targeted expression indexes are likely to be smaller and faster to search than a simple index.

Although the `jsonb_path_ops` operator class supports only queries with the `@>` operator, it has performance advantages over the default operator class `jsonb_ops`. A `jsonb_path_ops` index is usually much smaller than a `jsonb_ops` index over the same data, and the specificity of searches is better, particularly when queries contain keys that appear frequently in the data. Therefore search operations typically perform better than with the default operator class.

The technical difference between a `jsonb_ops` and a `jsonb_path_ops` GIN index is that the former creates independent index items for each key and value in the data, while the latter creates index items only for each value in the data.

**Note:** For this discussion, the term `value` includes array elements, though JSON terminology sometimes considers array elements distinct from values within objects.

Basically, each `jsonb_path_ops` index item is a hash of the value and the key(s) leading to it; for example to index `{"foo": {"bar": "baz"}}`, a single index item would be created incorporating all three of `foo`, `bar`, and `baz` into the hash value. Thus a containment query looking for this structure would result in an extremely specific index search; but there is no way at all to find out whether `foo` appears as a key. On the other hand, a `jsonb_ops` index would create three index items representing `foo`, `bar`, and `baz` separately; then to do the containment query, it would look for rows containing all three of these items. While GIN indexes can perform such an AND search fairly efficiently, it will still be less specific and slower than the equivalent `jsonb_path_ops` search, especially if there are a very large number of rows containing any single one of the three index items.

A disadvantage of the `jsonb_path_ops` approach is that it produces no index entries for JSON structures not containing any values, such as `{"a": {}}`. If a search for documents containing such a structure is requested, it will require a full-index scan, which is quite slow. `jsonb_path_ops` is ill-suited for applications that often perform such searches.

**Btree and Hash Indexes on jsonb Data**

`jsonb` also supports `btree` and `hash` indexes. These are usually useful only when it is important to check the equality of complete JSON documents.

For completeness the `btree` ordering for `jsonb` datums is:

- Object > Array > Boolean > Number > String > Null
- Object with n pairs > object with n - 1 pairs
- Array with n elements > array with n - 1 elements
- Objects with equal numbers of pairs are compared in the order:
Object keys are compared in their storage order. In particular, since shorter keys are stored before longer keys, this can lead to orderings that might not be intuitive, such as:

```
{ "aa": 1, "c": 1} > {"b": 1, "d": 1}
```

Similarly, arrays with equal numbers of elements are compared in the order:

```
element-1, element-2 ...
```

Primitive JSON values are compared using the same comparison rules as for the underlying Greenplum Database data type. Strings are compared using the default database collation.

**JSON Functions and Operators**

Greenplum Database includes built-in functions and operators that create and manipulate JSON data.

- **JSON Operators**
- **JSON Creation Functions**
- **JSON Aggregate Functions**
- **JSON Processing Functions**

**Note:** For `json` data type values, all key/value pairs are kept even if a JSON object contains duplicate keys. For duplicate keys, JSON processing functions consider the last value as the operative one. For the `jsonb` data type, duplicate object keys are not kept. If the input includes duplicate keys, only the last value is kept. See About JSON Data.

**JSON Operators**

This table describes the operators that are available for use with the `json` and `jsonb` data types.

<table>
<thead>
<tr>
<th>Operator</th>
<th>Right Operand Type</th>
<th>Description</th>
<th>Example</th>
<th>Example Result</th>
</tr>
</thead>
</table>
| `->`     | `int`              | Get the JSON array element (indexed from zero). | '[["a":"foo"],
{"b":"bar"},
{"c":"baz"}]:json->2 |
| `->`     | `text`             | Get the JSON object field by key. | '{"a":
{"b":"foo"}}':json->'a' |
| `->>`    | `int`              | Get the JSON array element as text. | '[1,2,3]':json->>2 |
| `->>`    | `text`             | Get the JSON object field as text. | '{"a":1,"b":2}':json->>'b' |
| `#>`     | `text[]`           | Get the JSON object at specified path. | '{"a": {"b":{"c":"foo"}}}':json#>{a,b} |
| `#>>`    | `text[]`           | Get the JSON object at specified path as text. | '{"a":[1,2,3],"b": [4,5,6]}':json#>>>{a,2}' |

**Note:** There are parallel variants of these operators for both the `json` and `jsonb` data types. The field, element, and path extraction operators return the same data type as their left-hand input (either `json` or `jsonb`), except for those specified as returning `text`, which coerce the value to
The field, element, and path extraction operators return NULL, rather than failing, if the JSON input does not have the right structure to match the request; for example if no such element exists.

Operators that require the jsonb data type as the left operand are described in the following table. Many of these operators can be indexed by jsonb operator classes. For a full description of jsonb containment and existence semantics, see jsonb Containment and Existence. For information about how these operators can be used to effectively index jsonb data, see jsonb Indexing.

Table 50: jsonb Operators

<table>
<thead>
<tr>
<th>Operator</th>
<th>Right Operand Type</th>
<th>Description</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>@&gt;</td>
<td>jsonb</td>
<td>Does the left JSON value contain within it the right value?</td>
<td>'{&quot;a&quot;:1, &quot;b&quot;:2} '::jsonb @&gt; '{&quot;b&quot;:2} '::jsonb</td>
</tr>
<tr>
<td>&lt;@</td>
<td>jsonb</td>
<td>Is the left JSON value contained within the right value?</td>
<td>'{&quot;b&quot;:2} '::jsonb &lt;@ '{&quot;a&quot;:1, &quot;b&quot;:2} '::jsonb</td>
</tr>
<tr>
<td>?</td>
<td>text</td>
<td>Does the key/element string exist within the JSON value?</td>
<td>'{&quot;a&quot;:1, &quot;b&quot;:2} '::jsonb ? 'b'</td>
</tr>
<tr>
<td>?</td>
<td></td>
<td>text[]</td>
<td>Do any of these key/element strings exist?</td>
</tr>
<tr>
<td>?&amp;</td>
<td>text[]</td>
<td>Do all of these key/element strings exist?</td>
<td>'{&quot;a&quot;, &quot;b&quot;] '::jsonb ?&amp; array['a', 'b']</td>
</tr>
</tbody>
</table>

The standard comparison operators in the following table are available only for the jsonb data type, not for the json data type. They follow the ordering rules for B-tree operations described in jsonb Indexing.

Table 51: jsonb Comparison Operators

<table>
<thead>
<tr>
<th>Operator</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt;</td>
<td>less than</td>
</tr>
<tr>
<td>&gt;</td>
<td>greater than</td>
</tr>
<tr>
<td>&lt;=</td>
<td>less than or equal to</td>
</tr>
<tr>
<td>&gt;=</td>
<td>greater than or equal to</td>
</tr>
<tr>
<td>=</td>
<td>equal</td>
</tr>
<tr>
<td>&lt;&gt; or !=</td>
<td>not equal</td>
</tr>
</tbody>
</table>

**Note:** The != operator is converted to <> in the parser stage. It is not possible to implement != and <> operators that do different things.

**JSON Creation Functions**

This table describes the functions that create json data type values. (Currently, there are no equivalent functions for jsonb, but you can cast the result of one of these functions to jsonb.)
<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
<th>Example</th>
<th>Example Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>to_json(anyelement)</td>
<td>Returns the value as a JSON object. Arrays and composites are processed recursively and are converted to arrays and objects. If the input contains a cast from the type to json, the cast function is used to perform the conversion; otherwise, a JSON scalar value is produced. For any scalar type other than a number, a Boolean, or a null value, the text representation will be used, properly quoted and escaped so that it is a valid JSON string.</td>
<td>to_json('Fred said &quot;Hi.&quot;':text)</td>
<td>&quot;Fred said &quot;Hi.&quot;&quot;</td>
</tr>
<tr>
<td>array_to_json(anyarray [, pretty_bool])</td>
<td>Returns the array as a JSON array. A multidimensional array becomes a JSON array of arrays. Line feeds will be added between dimension-1 elements if pretty_bool is true.</td>
<td>array_to_json('{{1,5}, {99,100}}':int[])</td>
<td>[[1,5],[99,100]]</td>
</tr>
<tr>
<td>row_to_json(record [, pretty_bool])</td>
<td>Returns the row as a JSON object. Line feeds will be added between level-1 elements if pretty_bool is true.</td>
<td>row_to_json(row(1,'foo'))</td>
<td>{&quot;f1&quot;:1,&quot;f2&quot;:&quot;foo&quot;}</td>
</tr>
<tr>
<td>json_build_array(VARIADIC &quot;any&quot;)</td>
<td>Builds a possibly-heterogeneously-typed JSON array out of a VARIADIC argument list.</td>
<td>json_build_array(1,2,'3',4,5)</td>
<td>[1, 2, &quot;3&quot;, 4, 5]</td>
</tr>
<tr>
<td>json_build_object(VARIADIC &quot;any&quot;)</td>
<td>Builds a JSON object out of a VARIADIC argument list. The argument list is taken in order and converted to a set of key/value pairs.</td>
<td>json_build_object('foo',1,'bar'=&gt;2)</td>
<td>{&quot;foo&quot;: 1, &quot;bar&quot;: 2}</td>
</tr>
<tr>
<td>Function</td>
<td>Description</td>
<td>Example</td>
<td>Example Result</td>
</tr>
<tr>
<td>----------</td>
<td>-------------</td>
<td>---------</td>
<td>----------------</td>
</tr>
<tr>
<td>json_object(text[])</td>
<td>Builds a JSON object out of a text array. The array must be either a one or a two dimensional array. The one dimensional array must have an even number of elements. The elements are taken as key/value pairs. For a two dimensional array, each inner array must have exactly two elements, which are taken as a key/value pair.</td>
<td>json_object('{a, 1, b, &quot;def&quot;, c, 3.5}')</td>
<td>{&quot;a&quot;: &quot;1&quot;, &quot;b&quot;: &quot;def&quot;, &quot;c&quot;: &quot;3.5&quot;}</td>
</tr>
<tr>
<td>json_object(keys text[], values text[])</td>
<td>Builds a JSON object out of a text array. This form of json_object takes keys and values pairwise from two separate arrays. In all other respects it is identical to the one-argument form.</td>
<td>json_object('{a, b}', '{1,2}')</td>
<td>{&quot;a&quot;: &quot;1&quot;, &quot;b&quot;: &quot;2&quot;}</td>
</tr>
</tbody>
</table>

Note: array_to_json and row_to_json have the same behavior as to_json except for offering a pretty-printing option. The behavior described for to_json likewise applies to each individual value converted by the other JSON creation functions.

Note: The hstore module contains functions that cast from hstore to json, so that hstore values converted via the JSON creation functions will be represented as JSON objects, not as primitive string values.

**JSON Aggregate Functions**

This table shows the functions that aggregate records to an array of JSON objects and pairs of values to a JSON object.

**Table 53: JSON Aggregate Functions**

<table>
<thead>
<tr>
<th>Function</th>
<th>Argument Types</th>
<th>Return Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>json_agg(record)</td>
<td>record</td>
<td>json</td>
<td>Aggregates records as a JSON array of objects.</td>
</tr>
<tr>
<td>json_object_agg(name, value)</td>
<td>(&quot;any&quot;, &quot;any&quot;)</td>
<td>json</td>
<td>Aggregates name/value pairs as a JSON object.</td>
</tr>
</tbody>
</table>

**JSON Processing Functions**

This table shows the functions that are available for processing json and jsonb values.

Many of these processing functions and operators convert Unicode escapes in JSON strings to the appropriate single character. This is not an issue if the input data type is jsonb, because the conversion
was already done. However, for \textit{json} data type input, this might result in an error being thrown. See \textit{About JSON Data}.

### Table 54: JSON Processing Functions

<table>
<thead>
<tr>
<th>Function</th>
<th>Return Type</th>
<th>Description</th>
<th>Example</th>
<th>Example Result</th>
</tr>
</thead>
</table>
| \texttt{json\_array\_length(json)} | int         | Returns the number of elements in the outermost JSON array.                 | \texttt{json\_array\_length('[1,2,3,
|                                 |             |                                                                             | "f1":1,"f2":
|                                 |             |                                                                             | [5,6]),4]')}                                      | 5              |
| \texttt{json\_array\_length(jsonb)} | int         |                                                                             |                                              |                |
| \texttt{json\_each(json)}       | setof key text, value json | Expands the outermost JSON object into a set of key/value pairs.          | \texttt{select * from json\_each('"a":"foo",
|                                 |             |                                                                             | "b":"bar"')}                                     | key | value  |
|                                 |             |                                                                             |                                             | a   | "foo"   |
|                                 |             |                                                                             |                                             | b   | "bar"   |
| \texttt{json\_each\_text(json)} | setof key text | Expands the outermost JSON object into a set of key/value pairs. The returned values will be of type \texttt{text}. | \texttt{select * from json\_each\_text('"a":"foo",
|                                 |             |                                                                             | "b":"bar"')}                                     | key | value  |
|                                 |             |                                                                             |                                             | a   | foo     |
|                                 |             |                                                                             |                                             | b   | bar     |
| \texttt{json\_extract\_path(from_json json, VARIADIC path\_elems text[])} | json | Returns the JSON value pointed to by \texttt{path\_elems} (equivalent to \#> operator). | \texttt{json\_extract\_path('"f2":
|                                 |             |                                                                             | "f3":1,"f4":
|                                 |             |                                                                             | "f5":99,"f6":"foo"')}                               | "f5":99,"f6":"foo" |
| \texttt{json\_extract\_path\_text(from_json json, VARIADIC path\_elems text[])} | text | Returns the JSON value pointed to by \texttt{path\_elems} as \texttt{text}. Equivalent to \#>> operator. | \texttt{json\_extract\_path\_text('"f2":
|                                 |             |                                                                             | "f3":1,"f4":
<p>|                                 |             |                                                                             | &quot;f5&quot;:99,&quot;f6&quot;:&quot;foo&quot;')}                               | foo  |
| \texttt{json_extract_path_text(jsonb, VARIADIC path_elems text[])} | text |                                                                             |                                              |                |</p>

### Working with XML Data

Greenplum Database supports the `xml` data type that stores XML data.

The `xml` data type checks the input values for well-formedness, providing an advantage over simply storing XML data in a text field. Additionally, support functions allow you to perform type-safe operations on this data; refer to `XML Function Reference`, below.

The `xml` type can store well-formed "documents", as defined by the XML standard, as well as "content" fragments, which are defined by reference to the more permissive `document node` of the XQuery and
XPath model. Roughly, this means that content fragments can have more than one top-level element or character node. The expression `xmlvalue IS DOCUMENT` can be used to evaluate whether a particular `xml` value is a full document or only a content fragment.

This section contains the following topics:

- Creating XML Values
- Encoding Handling
- Accessing XML Values
- Processing XML
- Mapping Tables to XML
- Using XML Functions and Expressions

**Creating XML Values**

To produce a value of type `xml` from character data, use the function `xmlparse`:

```
xmlparse ( { DOCUMENT | CONTENT } value)
```

For example:

```
XMLPARSE (DOCUMENT '<?xml version="1.0"?><book><title>Manual</title><chapter>...</chapter></book>')
XMLPARSE (CONTENT 'abc<foo>bar</foo><bar>foo</bar>')
```

The above method converts character strings into XML values according to the SQL standard, but you can also use Greenplum Database syntax like the following:

```
xm '<foo>bar</foo>'
'<foo>bar</foo>':::xml
```

The `xml` type does not validate input values against a document type declaration (DTD), even when the input value specifies a DTD. There is also currently no built-in support for validating against other XML schema languages such as XML schema.

The inverse operation, producing a character string value from `xml`, uses the function `xmlserialize`:

```
xmserialize ( { DOCUMENT | CONTENT } value AS type )
```

`type` can be `character`, `character varying`, or `text` (or an alias for one of those). Again, according to the SQL standard, this is the only way to convert between type `xml` and character types, but Greenplum Database also allows you to simply cast the value.

When a character string value is cast to or from type `xml` without going through `XMLPARSE` or `XMLSERIALIZE`, respectively, the choice of `DOCUMENT` versus `CONTENT` is determined by the `XML OPTION` session configuration parameter, which can be set using the standard command:

```
SET XML OPTION { DOCUMENT | CONTENT };
```

or simply like Greenplum Database:

```
SET XML OPTION TO { DOCUMENT | CONTENT };
```

The default is `CONTENT`, so all forms of XML data are allowed.

**Encoding Handling**

Be careful when dealing with multiple character encodings on the client, server, and in the XML data passed through them. When using the text mode to pass queries to the server and query results to the
client (which is the normal mode), Greenplum Database converts all character data passed between the client and the server, and vice versa, to the character encoding of the respective endpoint; see Character Set Support. This includes string representations of XML values, such as in the above examples. Ordinarily, this means that encoding declarations contained in XML data can become invalid, as the character data is converted to other encodings while travelling between client and server, because the embedded encoding declaration is not changed. To cope with this behavior, encoding declarations contained in character strings presented for input to the xml type are ignored, and content is assumed to be in the current server encoding. Consequently, for correct processing, character strings of XML data must be sent from the client in the current client encoding. It is the responsibility of the client to either convert documents to the current client encoding before sending them to the server, or to adjust the client encoding appropriately. On output, values of type xml will not have an encoding declaration, and clients should assume all data is in the current client encoding.

When using binary mode to pass query parameters to the server and query results back to the client, no character set conversion is performed, so the situation is different. In this case, an encoding declaration in the XML data will be observed, and if it is absent, the data will be assumed to be in UTF-8 (as required by the XML standard; note that Greenplum Database does not support UTF-16). On output, data will have an encoding declaration specifying the client encoding, unless the client encoding is UTF-8, in which case it will be omitted.

Note:
Processing XML data with Greenplum Database will be less error-prone and more efficient if the XML data encoding, client encoding, and server encoding are the same. Because XML data is internally processed in UTF-8, computations will be most efficient if the server encoding is also UTF-8.

Accessing XML Values

The xml data type is unusual in that it does not provide any comparison operators. This is because there is no well-defined and universally useful comparison algorithm for XML data. One consequence of this is that you cannot retrieve rows by comparing an xml column against a search value. XML values should therefore typically be accompanied by a separate key field such as an ID. An alternative solution for comparing XML values is to convert them to character strings first, but note that character string comparison has little to do with a useful XML comparison method.

Because there are no comparison operators for the xml data type, it is not possible to create an index directly on a column of this type. If speedy searches in XML data are desired, possible workarounds include casting the expression to a character string type and indexing that, or indexing an XPath expression. Of course, the actual query would have to be adjusted to search by the indexed expression.

Processing XML

To process values of data type xml, Greenplum Database offers the functions xpath and xpath_exists, which evaluate XPath 1.0 expressions.

\[
\text{xpath}(\text{xpath}, \text{xml}[, \text{nsarray}])
\]

The function xpath evaluates the XPath expression xpath (a text value) against the XML value xml. It returns an array of XML values corresponding to the node set produced by the XPath expression.

The second argument must be a well formed XML document. In particular, it must have a single root node element.

The optional third argument of the function is an array of namespace mappings. This array should be a two-dimensional text array with the length of the second axis being equal to 2 (i.e., it should be an array of arrays, each of which consists of exactly 2 elements). The first element of each array entry is the namespace name (alias), the second the namespace URI. It is not required that aliases provided in
this array be the same as those being used in the XML document itself (in other words, both in the XML
document and in the xpath function context, aliases are local).

Example:

```
                   ARRAY[ARRAY['my', 'http://example.com']]);
```

```
xpath
--------
{test}
(1 row)
```

To deal with default (anonymous) namespaces, do something like this:

```
SELECT xpath('//mydefns:b/text()', '<a xmlns="http://example.com"><b>test</b></a>',
                    ARRAY[ARRAY['mydefns', 'http://example.com']]);
```

```
xpath
--------
{test}
(1 row)
```

```
xpath_exists(xpath, xml [, nsarray])
```

The function xpath_exists is a specialized form of the xpath function. Instead of returning the
individual XML values that satisfy the XPath, this function returns a Boolean indicating whether the query
was satisfied or not. This function is equivalent to the standard XMLEXISTS predicate, except that it also
offers support for a namespace mapping argument.

Example:

```
                        ARRAY[ARRAY['my', 'http://example.com']]);
```

```
xpath_exists
------------
t
(1 row)
```

**Mapping Tables to XML**

The following functions map the contents of relational tables to XML values. They can be thought of as
XML export functionality:

```
table_to_xml(tbl regclass, nulls boolean, tableforest boolean, targetns text)
query_to_xml(query text, nulls boolean, tableforest boolean, targetns text)
cursor_to_xml(cursor refcursor, count int, nulls boolean, tableforest boolean, targetns text)
```

The return type of each function is xml.

table_to_xml maps the content of the named table, passed as parameter tbl. The regclass type
accepts strings identifying tables using the usual notation, including optional schema qualifications and
double quotes. query_to_xml executes the query whose text is passed as parameter query and maps
the result set. cursor_to_xml fetches the indicated number of rows from the cursor specified by the
parameter cursor. This variant is recommended if large tables have to be mapped, because the result value is built up in memory by each function.

If `tableforest` is false, then the resulting XML document looks like this:

```xml
<tablename>
  <row>
    <columnname1>data</columnname1>
    <columnname2>data</columnname2>
  </row>
  ...
</tablename>

If `tableforest` is true, the result is an XML content fragment that looks like this:

```xml
<tablename>
  <columnname1>data</columnname1>
  <columnname2>data</columnname2>
</tablename>
<tablename>
  ...
</tablename>

If no table name is available, that is, when mapping a query or a cursor, the string `table` is used in the first format, `row` in the second format.

The choice between these formats is up to the user. The first format is a proper XML document, which will be important in many applications. The second format tends to be more useful in the `cursor_to_xml` function if the result values are to be later reassembled into one document. The functions for producing XML content discussed above, in particular `xmlelement`, can be used to alter the results as desired.

The data values are mapped in the same way as described for the function `xmlelement`, above.

The parameter `nulls` determines whether null values should be included in the output. If true, null values in columns are represented as:

```xml
<columnname xsi:nil="true"/>
```

where `xsi` is the XML namespace prefix for XML schema Instance. An appropriate namespace declaration will be added to the result value. If false, columns containing null values are simply omitted from the output.

The parameter `targetns` specifies the desired XML namespace of the result. If no particular namespace is wanted, an empty string should be passed.

The following functions return XML schema documents describing the mappings performed by the corresponding functions above:

```c
able_to_xmlschema(tbl regclass, nulls boolean, tableforest boolean, targetns text)
query_to_xmlschema(query text, nulls boolean, tableforest boolean, targetns text)
cursor_to_xmlschema(cursor refcursor, nulls boolean, tableforest boolean, targetns text)
```
It is essential that the same parameters are passed in order to obtain matching XML data mappings and XML schema documents.

The following functions produce XML data mappings and the corresponding XML schema in one document (or forest), linked together. They can be useful where self-contained and self-describing results are desired:

```sql
table_to_xml_and_xmlschema(tbl regclass, nulls boolean, tableforest boolean, targetns text)
query_to_xml_and_xmlschema(query text, nulls boolean, tableforest boolean, targetns text)
```

In addition, the following functions are available to produce analogous mappings of entire schemas or the entire current database:

```sql
schema_to_xml(schema name, nulls boolean, tableforest boolean, targetns text)
schema_to_xmlschema(schema name, nulls boolean, tableforest boolean, targetns text)
schema_to_xml_and_xmlschema(schema name, nulls boolean, tableforest boolean, targetns text)

database_to_xml(nulls boolean, tableforest boolean, targetns text)
database_to_xmlschema(nulls boolean, tableforest boolean, targetns text)
database_to_xml_and_xmlschema(nulls boolean, tableforest boolean, targetns text)
```

Note that these potentially produce large amounts of data, which needs to be built up in memory. When requesting content mappings of large schemas or databases, consider mapping the tables separately instead, possibly even through a cursor.

The result of a schema content mapping looks like this:

```
<schemaname>
  table1-mapping
  table2-mapping
  ...
</schemaname>
```

where the format of a table mapping depends on the `tableforest` parameter, as explained above.

The result of a database content mapping looks like this:

```
<dbname>
  <schema1name>
    ...
  </schema1name>
  ...
  <schema1name>
    ...
  </schema1name>
  <schema2name>
    ...
  </schema2name>
  ...
</dbname>
```

where the schema mapping is as above.
The example below demonstrates using the output produced by these functions. The example shows an XSLT stylesheet that converts the output of `table_to_xml_and_xmlschema` to an HTML document containing a tabular rendition of the table data. In a similar manner, the results from these functions can be converted into other XML-based formats.

```xml
<?xml version="1.0"?>
<xsl:stylesheet version="1.0"
    xmlns:xsl="http://www.w3.org/1999/XSL/Transform"
    xmlns:xsd="http://www.w3.org/2001/XMLSchema"
    xmlns="http://www.w3.org/1999/xhtml">

<xsl:output method="xml"
    doctype-system="http://www.w3.org/TR/xhtml1/DTD/xhtml1-strict.dtd"
    doctype-public="-//W3C/DTD XHTML 1.0 Strict//EN"
    indent="yes"/>

<xsl:template match="/*">
    <xsl:variable name="schema" select="//xsd:schema"/>
    <xsl:variable name="tabletypename"
        select="$schema/xsd:element[@name=name(current())]/@type"/>
    <xsl:variable name="rowtypename"
        select="$schema/xsd:complexType[@name=$tabletypename]/xsd:sequence/xsd:element[@name='row']/@type"/>

    <html>
        <head>
            <title><xsl:value-of select="name(current())"/></title>
        </head>
        <body>
            <table>
                <tr>
                    <xsl:for-each select="$schema/xsd:complexType[@name=$rowtypename]/xsd:sequence/xsd:element/@name">
                        <th><xsl:value-of select="."/></th>
                    </xsl:for-each>
                </tr>
                <xsl:for-each select="row">
                    <tr>
                        <xsl:for-each select="*">
                            <td><xsl:value-of select="."/></td>
                        </xsl:for-each>
                    </tr>
                </xsl:for-each>
            </table>
        </body>
    </html>
</xsl:template>
</xsl:stylesheet>
```

**XML Function Reference**

The functions described in this section operate on values of type `xml`. The section `XML Predicates` also contains information about the `xml` functions and function-like expressions.

**Function:**

`xmlcomment`
Greenplum Database Administrator Guide

Release Notes

Synopsis:
xmlcomment(text)
The function xmlcomment creates an XML value containing an XML comment with the specified text
as content. The text cannot contain "--" or end with a "-" so that the resulting construct is a valid XML
comment. If the argument is null, the result is null.
Example:
SELECT xmlcomment('hello');
xmlcomment
-------------<!--hello-->
Function:
xmlconcat
Synopsis:
xmlconcat(xml[, …])
The function xmlconcat concatenates a list of individual XML values to create a single value containing
an XML content fragment. Null values are omitted; the result is only null if there are no nonnull arguments.
Example:
SELECT xmlconcat('<abc/>', '<bar>foo</bar>');
xmlconcat
---------------------<abc/><bar>foo</bar>
XML declarations, if present, are combined as follows:
•
•
•
•

If all argument values have the same XML version declaration, that version is used in the result, else no
version is used.
If all argument values have the standalone declaration value "yes", then that value is used in the result.
If all argument values have a standalone declaration value and at least one is "no", then that is used in
the result. Otherwise, the result will have no standalone declaration.
If the result is determined to require a standalone declaration but no version declaration, a version
declaration with version 1.0 will be used because XML requires an XML declaration to contain a version
declaration.

Encoding declarations are ignored and removed in all cases.
Example:
SELECT xmlconcat('<?xml version="1.1"?><foo/>', '<?xml version="1.1"
standalone="no"?><bar/>');
xmlconcat
----------------------------------<?xml version="1.1"?><foo/><bar/>
Function:
xmlelement

388


Synopsis:

```sql
xmlelement(name name [, xmlattributes(value [AS attname] [, ... ])] [,
content, ...])
```

The `xmlelement` expression produces an XML element with the given name, attributes, and content.

Examples:

```
SELECT xmlelement(name foo);

  xmlelement
  -----------
  <foo/>

SELECT xmlelement(name foo, xmlattributes('xyz' as bar));

  xmlelement
  -----------
  <foo bar="xyz"/>

SELECT xmlelement(name foo, xmlattributes(current_date as bar), 'cont',
'ent');

  xmlelement
  ---------------------
  <foo bar="2017-01-26">content</foo>
```

Element and attribute names that are not valid XML names are escaped by replacing the offending characters by the sequence `_xHHHH_`, where `HHHH` is the character's Unicode codepoint in hexadecimal notation. For example:

```
SELECT xmlelement(name "foo$bar", xmlattributes('xyz' as "a&b"));

  xmlelement
  ---------------------------
  <foo_x0024_bar a_x0026_b="xyz"/>
```

An explicit attribute name need not be specified if the attribute value is a column reference, in which case the column's name will be used as the attribute name by default. In other cases, the attribute must be given an explicit name. So this example is valid:

```
CREATE TABLE test (a xml, b xml);
SELECT xmlelement(name test, xmlattributes(a, b)) FROM test;
```

But these are not:

```
SELECT xmlelement(name test, xmlattributes('constant'), a, b) FROM test;
SELECT xmlelement(name test, xmlattributes(func(a, b))) FROM test;
```

Element content, if specified, will be formatted according to its data type. If the content is itself of type `xml`, complex XML documents can be constructed. For example:

```
SELECT xmlelement(name foo, xmlattributes('xyz' as bar),
xmlelement(name abc),
xmlcomment('test'),
xmlelement(name xyz));

  xmlelement
  -------------------------------------
```
Content of other types will be formatted into valid XML character data. This means in particular that the characters <,>, and & will be converted to entities. Binary data (data type bytea) will be represented in base64 or hex encoding, depending on the setting of the configuration parameter xmlbinary. The particular behavior for individual data types is expected to evolve in order to align the SQL and Greenplum Database data types with the XML schema specification, at which point a more precise description will appear.

**Function:**
xmlforest

**Synopsis:**

```sql
xmlforest(content [AS name] [, ...])
```

The `xmlforest` expression produces an XML forest (sequence) of elements using the given names and content.

**Examples:**

```sql
SELECT xmlforest('abc' AS foo, 123 AS bar);
```

```
<foo>abc</foo><bar>123</bar>
```

```sql
SELECT xmlforest(table_name, column_name)
FROM information_schema.columns
WHERE table_schema = 'pg_catalog';
```

```
<table_name>pg_authid</table_name><column_name>rolname</column_name>
<table_name>pg_authid</table_name><column_name>rolsuper</column_name>
```

As seen in the second example, the element name can be omitted if the content value is a column reference, in which case the column name is used by default. Otherwise, a name must be specified.

Element names that are not valid XML names are escaped as shown for `xmlelement` above. Similarly, content data is escaped to make valid XML content, unless it is already of type `xml`.

Note that XML forests are not valid XML documents if they consist of more than one element, so it might be useful to wrap `xmlforest` expressions in `xmlelement`.

**Function:**
xmlpi

**Synopsis:**

```sql
xmlpi(name target [, content])
```

The `xmlpi` expression creates an XML processing instruction. The content, if present, must not contain the character sequence `?>`.

**Example:**

```sql
SELECT xmlpi(name php, 'echo "hello world";');
```

```
<?php echo "hello world";?>
```
<?php echo "hello world";?>

**Function:**

xmlroot

**Synopsis:**

xmlroot(xml, version text | no value [, standalone yes|no|no value])

The `xmlroot` expression alters the properties of the root node of an XML value. If a version is specified, it replaces the value in the root node's version declaration; if a standalone setting is specified, it replaces the value in the root node's standalone declaration.

```sql
SELECT xmlroot(xmlparse(document '<?xml version="1.1"?><content>abc</content>'),
    version '1.0', standalone yes);
```

```xml
<?xml version="1.0" standalone="yes"?><content>abc</content>
```

**Function:**

xmlagg

xmlagg (xml)

The function `xmlagg` is, unlike the other functions described here, an aggregate function. It concatenates the input values to the aggregate function call, much like `xmlconcat` does, except that concatenation occurs across rows rather than across expressions in a single row. See *Using Functions and Operators* for additional information about aggregate functions.

**Example:**

```sql
CREATE TABLE test (y int, x xml);
INSERT INTO test VALUES (1, '<foo>abc</foo>');
INSERT INTO test VALUES (2, '<bar/>');
SELECT xmlagg(x) FROM test;
```

```xml
<foo>abc</foo><bar/>
```

To determine the order of the concatenation, an `ORDER BY` clause may be added to the aggregate call. For example:

```sql
SELECT xmlagg(x ORDER BY y DESC) FROM test;
```

```xml
<bar/><foo>abc</foo>
```

The following non-standard approach used to be recommended in previous versions, and may still be useful in specific cases:

```sql
SELECT xmlagg(x) FROM (SELECT * FROM test ORDER BY y DESC) AS tab;
```

```xml
<bar/><foo>abc</foo>
```
XML Predicates

The expressions described in this section check properties of xml values.

Expression:

IS DOCUMENT

Synopsis:

xml IS DOCUMENT

The expression IS DOCUMENT returns true if the argument XML value is a proper XML document, false if it is not (that is, it is a content fragment), or null if the argument is null.

Expression:

XMLEXISTS

Synopsis:

XMLEXISTS(text PASSING [BY REF] xml [BY REF])

The function xmlexists returns true if the XPath expression in the first argument returns any nodes, and false otherwise. (If either argument is null, the result is null.)

Example:

SELECT xmlexists('//town[text()] = ''Toronto'']' PASSING BY REF '<towns><town>Toronto</town><town>Ottawa</town></towns>');

xmlexists

----------------

1 row

The BY REF clauses have no effect in Greenplum Database, but are allowed for SQL conformance and compatibility with other implementations. Per SQL standard, the first BY REF is required, the second is optional. Also note that the SQL standard specifies the xmlexists construct to take an XQuery expression as first argument, but Greenplum Database currently only supports XPath, which is a subset of XQuery.

Expression:

xml_is_well_formed

Synopsis:

xml_is_well_formed(text)
xml_is_well_formed_document (text)
xml_is_well_formed_content (text)

These functions check whether a text string is well-formed XML, returning a Boolean result. xml_is_well_formed_document checks for a well-formed document, while xml_is_well_formed_content checks for well-formed content. xml_is_well_formed does the former if the xml:option configuration parameter is set to DOCUMENT, or the latter if it is set to CONTENT. This means that xml_is_well_formed is useful for seeing whether a simple cast to type xml will succeed, whereas the other two functions are useful for seeing whether the corresponding variants of XMLPARSE will succeed.
Examples:

```sql
SET xmloption TO DOCUMENT;
SELECT xml_is_well_formed('<>');
  xml_is_well_formed
-----------
  f
(1 row)

SELECT xml_is_well_formed('<abc/>');
  xml_is_well_formed
----------
  t
(1 row)

SET xmloption TO CONTENT;
SELECT xml_is_well_formed('abc');
  xml_is_well_formed
----------
  t
(1 row)

SELECT xml_is_well_formed_document('<pg:foo xmlns:pg="http://postgresql.org/stuff">bar</pg:foo>');</n
  xml_is_well_formed_document
-----------------------------
  t
(1 row)

SELECT xml_is_well_formed_document('<pg:foo xmlns:pg="http://postgresql.org/stuff">bar</my:foo>');</n
  xml_is_well_formed_document
-----------------------------
  f
(1 row)
```

The last example shows that the checks include whether namespaces are correctly matched.

**Using Full Text Search**

Greenplum Database provides data types, functions, operators, index types, and configurations for querying natural language documents.

**About Full Text Search**

This topic provides an overview of Greenplum Database full text search, basic text search expressions, configuring, and customizing text search. Greenplum Database full text search is compared with Pivotal GPText.

This section contains the following subtopics:

- What is a Document?
- Basic Text Matching
- Configurations
- Comparing Greenplum Database Text Search with Pivotal GPText

Full Text Searching (or just "text search") provides the capability to identify natural-language documents that satisfy a query, and optionally to rank them by relevance to the query. The most common type of search is to find all documents containing given query terms and return them in order of their similarity to the query.
Greenplum Database provides a data type `tsvector` to store preprocessed documents, and a data type `tsquery` to store processed queries (Text Search Data Types). There are many functions and operators available for these data types (Text Search Functions and Operators), the most important of which is the match operator `@@`, which we introduce in Basic Text Matching. Full text searches can be accelerated using indexes (GiST and GIN Indexes for Text Search).

Notions of query and similarity are very flexible and depend on the specific application. The simplest search considers query as a set of words and similarity as the frequency of query words in the document.

Greenplum Database supports the standard text matching operators `~`, `~*`, `LIKE`, and `ILIKE` for textual data types, but these operators lack many essential properties required for searching documents:

- There is no linguistic support, even for English. Regular expressions are not sufficient because they cannot easily handle derived words, e.g., `satisfies` and `satisfy`. You might miss documents that contain `satisfies`, although you probably would like to find them when searching for `satisfy`. It is possible to use `OR` to search for multiple derived forms, but this is tedious and error-prone (some words can have several thousand derivatives).
- They provide no ordering (ranking) of search results, which makes them ineffective when thousands of matching documents are found.
- They tend to be slow because there is no index support, so they must process all documents for every search.

Full text indexing allows documents to be preprocessed and an index saved for later rapid searching. Preprocessing includes:

- Parsing documents into tokens. It is useful to identify various classes of tokens, e.g., numbers, words, complex words, email addresses, so that they can be processed differently. In principle token classes depend on the specific application, but for most purposes it is adequate to use a predefined set of classes. Greenplum Database uses a parser to perform this step. A standard parser is provided, and custom parsers can be created for specific needs.
- Converting tokens into lexemes. A lexeme is a string, just like a token, but it has been normalized so that different forms of the same word are made alike. For example, normalization almost always includes folding upper-case letters to lower-case, and often involves removal of suffixes (such as `s` or `es` in English). This allows searches to find variant forms of the same word, without tediously entering all the possible variants. Also, this step typically eliminates stop words, which are words that are so common that they are useless for searching. (In short, then, tokens are raw fragments of the document text, while lexemes are words that are believed useful for indexing and searching.) Greenplum Database uses dictionaries to perform this step. Various standard dictionaries are provided, and custom ones can be created for specific needs.
- Storing preprocessed documents optimized for searching. For example, each document can be represented as a sorted array of normalized lexemes. Along with the lexemes it is often desirable to store positional information to use for proximity ranking, so that a document that contains a more "dense" region of query words is assigned a higher rank than one with scattered query words.

Dictionaries allow fine-grained control over how tokens are normalized. With appropriate dictionaries, you can:

- Define stop words that should not be indexed.
- Map synonyms to a single word using Ispell.
- Map phrases to a single word using a thesaurus.
- Map different variations of a word to a canonical form using an Ispell dictionary.
- Map different variations of a word to a canonical form using Snowball stemmer rules.

What is a Document?

A document is the unit of searching in a full text search system; for example, a magazine article or email message. The text search engine must be able to parse documents and store associations of lexemes (key words) with their parent document. Later, these associations are used to search for documents that contain query words.
For searches within Greenplum Database, a document is normally a textual field within a row of a database table, or possibly a combination (concatenation) of such fields, perhaps stored in several tables or obtained dynamically. In other words, a document can be constructed from different parts for indexing and it might not be stored anywhere as a whole. For example:

```sql
SELECT title || ' ' || author || ' ' || abstract || ' ' || body AS document
FROM messages
WHERE mid = 12;
```

```sql
SELECT m.title || ' ' || m.author || ' ' || m.abstract || ' ' || d.body AS document
FROM messages m, docs d
WHERE mid = did AND mid = 12;
```

**Note:**
Actually, in these example queries, `coalesce` should be used to prevent a single `NULL` attribute from causing a `NULL` result for the whole document.

Another possibility is to store the documents as simple text files in the file system. In this case, the database can be used to store the full text index and to execute searches, and some unique identifier can be used to retrieve the document from the file system. However, retrieving files from outside the database requires superuser permissions or special function support, so this is usually less convenient than keeping all the data inside Greenplum Database. Also, keeping everything inside the database allows easy access to document metadata to assist in indexing and display.

For text search purposes, each document must be reduced to the preprocessed `tsvector` format. Searching and ranking are performed entirely on the `tsvector` representation of a document — the original text need only be retrieved when the document has been selected for display to a user. We therefore often speak of the `tsvector` as being the document, but of course it is only a compact representation of the full document.

### Basic Text Matching

Full text searching in Greenplum Database is based on the match operator `@@`, which returns `true` if a `tsvector` (document) matches a `tsquery` (query). It does not matter which data type is written first:

```sql
SELECT 'a fat cat sat on a mat and ate a fat rat':tsquery @@ 'cat & rat':tsquery;
?column?
--------
t
```

```sql
SELECT 'fat & cow':tsquery @@ 'a fat cat sat on a mat and ate a fat rat':tsvector;
?column?
--------
F
```

As the above example suggests, a `tsquery` is not just raw text, any more than a `tsvector` is. A `tsquery` contains search terms, which must be already-normalized lexemes, and may combine multiple terms using AND, OR, and NOT operators. (For details see.) There are functions `to_tsquery` and `plainto_tsquery` that are helpful in converting user-written text into a proper `tsquery`, for example by normalizing words appearing in the text. Similarly, `to_tsvector` is used to parse and normalize a document string. So in practice a text search match would look more like this:

```sql
SELECT to_tsvector('fat cats ate fat rats') @@ to_tsquery('fat & rat');
?column?
--------

Observe that this match would not succeed if written as

```sql
SELECT 'fat cats ate fat rats'::tsvector @@ to_tsquery('fat & rat');
```

since here no normalization of the word rats will occur. The elements of a tsvector are lexemes, which are assumed already normalized, so rats does not match rat.

The @@ operator also supports text input, allowing explicit conversion of a text string to tsvector or tsquery to be skipped in simple cases. The variants available are:

```sql
tsvector @@ tsquery
tsquery  @@ tsvector
text @@ tsquery
text @@ text
```

The first two of these we saw already. The form `text @@ tsquery` is equivalent to `to_tsvector(x) @@ y`. The form `text @@ text` is equivalent to `to_tsvector(x) @@ plainto_tsquery(y).

### Configurations

The above are all simple text search examples. As mentioned before, full text search functionality includes the ability to do many more things: skip indexing certain words (stop words), process synonyms, and use sophisticated parsing, e.g., parse based on more than just white space. This functionality is controlled by text search configurations. Greenplum Database comes with predefined configurations for many languages, and you can easily create your own configurations. (psql's `\df` command shows all available configurations.)

During installation an appropriate configuration is selected and `default_text_search_config` is set accordingly in `postgresql.conf`. If you are using the same text search configuration for the entire cluster you can use the value in `postgresql.conf`. To use different configurations throughout the cluster but the same configuration within any one database, use `ALTER DATABASE ... SET`. Otherwise, you can set `default_text_search_config` in each session.

Each text search function that depends on a configuration has an optional `regconfig` argument, so that the configuration to use can be specified explicitly. `default_text_search_config` is used only when this argument is omitted.

To make it easier to build custom text search configurations, a configuration is built up from simpler database objects. Greenplum Database’s text search facility provides four types of configuration-related database objects:

- **Text search parsers** break documents into tokens and classify each token (for example, as words or numbers).
- **Text search dictionaries** convert tokens to normalized form and reject stop words.
- **Text search templates** provide the functions underlying dictionaries. (A dictionary simply specifies a template and a set of parameters for the template.)
- **Text search configurations** select a parser and a set of dictionaries to use to normalize the tokens produced by the parser.

Text search parsers and templates are built from low-level C functions; therefore it requires C programming ability to develop new ones, and superuser privileges to install one into a database. (There are examples of add-on parsers and templates in the `contrib/` area of the Greenplum Database distribution.) Since dictionaries and configurations just parameterize and connect together some underlying parsers and templates, no special privilege is needed to create a new dictionary or configuration. Examples of creating custom dictionaries and configurations appear later in this chapter.
Comparing Greenplum Database Text Search with Pivotal GPText

Greenplum Database text search is PostgreSQL text search ported to the Greenplum Database MPP platform. Pivotal also offers Pivotal GPText, which integrates Greenplum Database with the Apache Solr text search platform. GPText installs an Apache Solr cluster alongside your Greenplum Database cluster and provides Greenplum Database functions you can use to create Solr indexes, query them, and receive results in the database session.

Both of these systems provide powerful, enterprise-quality document indexing and searching services. Greenplum Database text search is immediately available to you, with no need to install and maintain additional software. If it meets your applications' requirements, you should use it.

GPText, with Solr, has many capabilities that are not available with Greenplum Database text search. In particular, GPText is better for advanced text analysis applications. Following are some of the advantages and capabilities available to you when you use GPText for text search applications.

- The Apache Solr cluster can be scaled separately from the database. Solr nodes can be deployed on the Greenplum Database hosts or on separate hosts on the network.
- Indexing and search workloads can be moved out of Greenplum Database to Solr to maintain database query performance.
- GPText creates Solr indexes that are split into shards, one per Greenplum Database segment, so the advantages of the Greenplum Database MPP architecture are extended to text search workloads.
- Indexing and searching documents with Solr is very fast and can be scaled by adding more Solr nodes to the cluster.
- Document content can be stored in Greenplum Database tables, in the Solr index, or both.
- Through GPText, Solr can index documents stored as text in Greenplum Database tables, as well as documents in external stores accessible using HTTP, FTP, S3, or HDFS URLs.
- Solr automatically recognizes most rich document formats and indexes document content and metadata separately.
- Solr indexes are highly customizable. You can customize the text analysis chain down to the field level.
- In addition to the large number of languages, tokenizers, and filters available from the Apache project, GPText provides a social media tokenizer, an international text tokenizer, and a universal query parser that understands several common text search syntaxes.
- The GPText API supports advanced text analysis tools, such as facetting, named entity recognition (NER), and parts of speech (POS) recognition.

See the GPText Documentation web site for more information about GPText.

Searching Text in Database Tables

This topic shows how to use text search operators to search database tables and how to create indexes to speed up text searches.

The examples in the previous section illustrated full text matching using simple constant strings. This section shows how to search table data, optionally using indexes.

This section contains the following subtopics:

- Searching a Table
- Creating Indexes

Searching a Table

It is possible to do a full text search without an index. A simple query to print the title of each row that contains the word friend in its body field is:

```sql
SELECT title
FROM pgweb
WHERE to_tsvector('english', body) @@ to_tsquery('english', 'friend');
```
This will also find related words such as friends and friendly, since all these are reduced to the same normalized lexeme.

The query above specifies that the english configuration is to be used to parse and normalize the strings. Alternatively we could omit the configuration parameters:

```sql
SELECT title
FROM pgweb
WHERE to_tsvector(body) @@ to_tsquery('friend');
```

This query will use the configuration set by `default_text_search_config`.

A more complex example is to select the ten most recent documents that contain create and table in the title or body:

```sql
SELECT title
FROM pgweb
WHERE to_tsvector(title || ' ' || body) @@ to_tsquery('create & table')
ORDER BY last_mod_date DESC
LIMIT 10;
```

For clarity we omitted the `coalesce` function calls which would be needed to find rows that contain NULL in one of the two fields.

Although these queries will work without an index, most applications will find this approach too slow, except perhaps for occasional ad-hoc searches. Practical use of text searching usually requires creating an index.

**Creating Indexes**

We can create a GIN index (GiST and GIN Indexes for Text Search) to speed up text searches:

```sql
CREATE INDEX pgweb_idx ON pgweb USING gin(to_tsvector('english', body));
```

Notice that the two-argument version of `to_tsvector` is used. Only text search functions that specify a configuration name can be used in expression indexes. This is because the index contents must be unaffected by `default_text_search_config`. If they were affected, the index contents might be inconsistent because different entries could contain `tsvector`s that were created with different text search configurations, and there would be no way to guess which was which. It would be impossible to dump and restore such an index correctly.

Because the two-argument version of `to_tsvector` was used in the index above, only a query reference that uses the two-argument version of `to_tsvector` with the same configuration name will use that index. That is, `WHERE to_tsvector('english', body) @@ 'a & b'` can use the index, but `WHERE to_tsvector(body) @@ 'a & b'` cannot. This ensures that an index will be used only with the same configuration used to create the index entries.

It is possible to set up more complex expression indexes wherein the configuration name is specified by another column, e.g.:

```sql
CREATE INDEX pgweb_idx ON pgweb USING gin(to_tsvector(config_name, body));
```

where `config_name` is a column in the `pgweb` table. This allows mixed configurations in the same index while recording which configuration was used for each index entry. This would be useful, for example, if the document collection contained documents in different languages. Again, queries that are meant to use the index must be phrased to match, e.g., `WHERE to_tsvector(config_name, body) @@ 'a & b'`.

Indexes can even concatenate columns:

```sql
CREATE INDEX pgweb_idx ON pgweb USING gin(to_tsvector('english', title || ' ' || body));
```
Another approach is to create a separate tsvector column to hold the output of to_tsvector. This example is a concatenation of title and body, using coalesce to ensure that one field will still be indexed when the other is NULL:

```
ALTER TABLE pgweb ADD COLUMN textsearchable_index_col tsvector;
UPDATE pgweb SET textsearchable_index_col =
    to_tsvector('english', coalesce(title,'') || ' ' || coalesce(body,''));
```

Then we create a GIN index to speed up the search:

```
CREATE INDEX textsearch_idx ON pgweb USING gin(textsearchable_index_col);
```

Now we are ready to perform a fast full text search:

```
SELECT title FROM pgweb WHERE textsearchable_index_col @@ to_tsquery('create & table')
ORDER BY last_mod_date DESC LIMIT 10;
```

One advantage of the separate-column approach over an expression index is that it is not necessary to explicitly specify the text search configuration in queries in order to make use of the index. As shown in the example above, the query can depend on default_text_search_config. Another advantage is that searches will be faster, since it will not be necessary to redo the to_tsvector calls to verify index matches. (This is more important when using a GiST index than a GIN index; see GiST and GIN Indexes for Text Search.) The expression-index approach is simpler to set up, however, and it requires less disk space since the tsvector representation is not stored explicitly.

### Controlling Text Search

This topic shows how to create search and query vectors, how to rank search results, and how to highlight search terms in the results of text search queries.

To implement full text searching there must be a function to create a tsvector from a document and a tsquery from a user query. Also, we need to return results in a useful order, so we need a function that compares documents with respect to their relevance to the query. It's also important to be able to display the results nicely. Greenplum Database provides support for all of these functions.

This topic contains the following subtopics:

- Parsing Documents
- Parsing Queries
- Ranking Search Results
- Highlighting Results

### Parsing Documents

Greenplum Database provides the function to_tsvector for converting a document to the tsvector data type.

```
to_tsvector([config regconfig, ] document text) returns tsvector
```

to_tsvector parses a textual document into tokens, reduces the tokens to lexemes, and returns a tsvector which lists the lexemes together with their positions in the document. The document is processed according to the specified or default text search configuration. Here is a simple example:

```
SELECT to_tsvector('english', 'a fat cat sat on a mat - it ate a fat rats');
```

```
to_tsvector
--------------------------
'ate':9 'cat':3 'fat':2,11 'mat':7 'rat':12 'sat':4
```
In the example above we see that the resulting tsvector does not contain the words a, on, or it, the word rats became rat, and the punctuation sign – was ignored.

The to_tsvector function internally calls a parser which breaks the document text into tokens and assigns a type to each token. For each token, a list of dictionaries (Text Search Dictionaries) is consulted, where the list can vary depending on the token type. The first dictionary that recognizes the token emits one or more normalized lexemes to represent the token. For example, rats became rat because one of the dictionaries recognized that the word rats is a plural form of rat. Some words are recognized as stop words, which causes them to be ignored since they occur too frequently to be useful in searching. In our example these are a, on, and it. If no dictionary in the list recognizes the token then it is also ignored. In this example that happened to the punctuation sign – because there are in fact no dictionaries assigned for its token type (Space symbols), meaning space tokens will never be indexed. The choices of parser, dictionaries and which types of tokens to index are determined by the selected text search configuration (Text Search Configuration Example). It is possible to have many different configurations in the same database, and predefined configurations are available for various languages. In our example we used the default configuration english for the English language.

The function setweight can be used to label the entries of a tsvector with a given weight, where a weight is one of the letters A, B, C, or D. This is typically used to mark entries coming from different parts of a document, such as title versus body. Later, this information can be used for ranking of search results.

Because to_tsvector(NULL) will return NULL, it is recommended to use coalesce whenever a field might be null. Here is the recommended method for creating a tsvector from a structured document:

```sql
UPDATE tt SET ti = setweight(to_tsvector(coalesce(title,'')), 'A')
    || setweight(to_tsvector(coalesce(keyword,'')), 'B')
    || setweight(to_tsvector(coalesce(abstract,'')), 'C')
    || setweight(to_tsvector(coalesce(body,'')), 'D');
```

Here we have used setweight to label the source of each lexeme in the finished tsvector, and then merged the labeled tsvector values using the tsvector concatenation operator ||. (Additional Text Search Features gives details about these operations.)

Parsing Queries

Greenplum Database provides the functions to_tsquery and plainto_tsquery for converting a query to the tsquery data type. to_tsquery offers access to more features than plainto_tsquery, but is less forgiving about its input.

```sql
to_tsquery([config regconfig, ] querytext text) returns tsquery
```

to_tsquery creates a tsquery value from querytext, which must consist of single tokens separated by the Boolean operators & (AND), | (OR), and ! (NOT). These operators can be grouped using parentheses. In other words, the input to to_tsquery must already follow the general rules for tsquery input, as described in Text Search Data Types. The difference is that while basic tsquery input takes the tokens at face value, to_tsquery normalizes each token to a lexeme using the specified or default configuration, and discards any tokens that are stop words according to the configuration. For example:

```sql
SELECT to_tsquery('english', 'The & Fat & Rats');
  to_tsquery
----------
 'fat' & 'rat'
```

As in basic tsquery input, weight(s) can be attached to each lexeme to restrict it to match only tsvector lexemes of those weight(s). For example:

```sql
SELECT to_tsquery('english', 'Fat | Rats:AB');
  to_tsquery
-----
```
Also, * can be attached to a lexeme to specify prefix matching:

```
SELECT to_tsquery('supern:*A & star:A*B');
---------------
'supern':*A & 'star':*AB
```

Such a lexeme will match any word in a `tsvector` that begins with the given string.

`to_tsquery` can also accept single-quoted phrases. This is primarily useful when the configuration includes a thesaurus dictionary that may trigger on such phrases. In the example below, a thesaurus contains the rule `supernovae stars : sn`:

```
SELECT to_tsquery('''supernovae stars'' & !crab');
---------------
'sn' & '!crab'
```

Without quotes, `to_tsquery` will generate a syntax error for tokens that are not separated by an AND or OR operator.

```
plainto_tsquery([ config regconfig, ] querytext ext) returns tsquery
```

`plainto_tsquery` transforms unformatted text `querytext` to `tsquery`. The text is parsed and normalized much as for `to_tsvector`, then the & (AND) Boolean operator is inserted between surviving words.

Example:

```
SELECT plainto_tsquery('english', 'The Fat Rats');
plainto_tsquery
---------------
'fat' & 'rat'
```

Note that `plainto_tsquery` cannot recognize Boolean operators, weight labels, or prefix-match labels in its input:

```
SELECT plainto_tsquery('english', 'The Fat & Rats:C');
plainto_tsquery
---------------
'fat' & 'rat' & 'c'
```

Here, all the input punctuation was discarded as being space symbols.

**Ranking Search Results**

Ranking attempts to measure how relevant documents are to a particular query, so that when there are many matches the most relevant ones can be shown first. Greenplum Database provides two predefined ranking functions, which take into account lexical, proximity, and structural information; that is, they consider how often the query terms appear in the document, how close together the terms are in the document, and how important is the part of the document where they occur. However, the concept of relevancy is vague and very application-specific. Different applications might require additional information for ranking, e.g., document modification time. The built-in ranking functions are only examples. You can write your own ranking functions and/or combine their results with additional factors to fit your specific needs.

The two ranking functions currently available are:
ts_rank([ weights float4[], ] vector tsvector, query tsquery [, normalization integer ]) returns float4

Ranks vectors based on the frequency of their matching lexemes.

ts_rank_cd([ weights float4[], ] vector tsvector, query tsquery [, normalization integer ]) returns float4

This function computes the cover density ranking for the given document vector and query, as described in Clarke, Cormack, and Tudhope's "Relevance Ranking for One to Three Term Queries" in the journal "Information Processing and Management", 1999. Cover density is similar to ts_rank ranking except that the proximity of matching lexemes to each other is taken into consideration.

This function requires lexeme positional information to perform its calculation. Therefore, it ignores any "stripped" lexemes in the tsvector. If there are no unstripped lexemes in the input, the result will be zero. (See Manipulating Documents for more information about the strip function and positional information in tsvector.)

For both these functions, the optional weights argument offers the ability to weigh word instances more or less heavily depending on how they are labeled. The weight arrays specify how heavily to weigh each category of word, in the order:

{D-weight, C-weight, B-weight, A-weight}

If no weights are provided, then these defaults are used:

{0.1, 0.2, 0.4, 1.0}

Typically weights are used to mark words from special areas of the document, like the title or an initial abstract, so they can be treated with more or less importance than words in the document body.

Since a longer document has a greater chance of containing a query term it is reasonable to take into account document size, e.g., a hundred-word document with five instances of a search word is probably more relevant than a thousand-word document with five instances. Both ranking functions take an integer normalization option that specifies whether and how a document’s length should impact its rank. The integer option controls several behaviors, so it is a bit mask: you can specify one or more behaviors using | (for example, 2|4).

• 0 (the default) ignores the document length
• 1 divides the rank by 1 + the logarithm of the document length
• 2 divides the rank by the document length
• 4 divides the rank by the mean harmonic distance between extents (this is implemented only by ts_rank_cd)
• 8 divides the rank by the number of unique words in document
• 16 divides the rank by 1 + the logarithm of the number of unique words in document
• 32 divides the rank by itself + 1

If more than one flag bit is specified, the transformations are applied in the order listed.

It is important to note that the ranking functions do not use any global information, so it is impossible to produce a fair normalization to 1% or 100% as sometimes desired. Normalization option 32 (rank/(rank+1)) can be applied to scale all ranks into the range zero to one, but of course this is just a cosmetic change; it will not affect the ordering of the search results.
Here is an example that selects only the ten highest-ranked matches:

```sql
SELECT title, ts_rank_cd(textsearch, query) AS rank
FROM apod, to_tsquery('neutrino|(dark & matter)') query
WHERE query @@ textsearch
ORDER BY rank DESC
LIMIT 10;
```

<table>
<thead>
<tr>
<th>title</th>
<th>rank</th>
</tr>
</thead>
<tbody>
<tr>
<td>Neutrinos in the Sun</td>
<td>3.1</td>
</tr>
<tr>
<td>The Sudbury Neutrino Detector</td>
<td>2.4</td>
</tr>
<tr>
<td>A MACHO View of Galactic Dark Matter</td>
<td>2.01317</td>
</tr>
<tr>
<td>Hot Gas and Dark Matter</td>
<td>1.91171</td>
</tr>
<tr>
<td>The Virgo Cluster: Hot Plasma and Dark Matter</td>
<td>1.90953</td>
</tr>
<tr>
<td>Rafting for Solar Neutrinos</td>
<td>1.9</td>
</tr>
<tr>
<td>NGC 4650A: Strange Galaxy and Dark Matter</td>
<td>1.85774</td>
</tr>
<tr>
<td>Hot Gas and Dark Matter</td>
<td>1.6123</td>
</tr>
<tr>
<td>Ice Fishing for Cosmic Neutrinos</td>
<td>1.6</td>
</tr>
<tr>
<td>Weak Lensing Distorts the Universe</td>
<td>0.818218</td>
</tr>
</tbody>
</table>

This is the same example using normalized ranking:

```sql
SELECT title, ts_rank_cd(textsearch, query, 32 /* rank/(rank+1) */ ) AS rank
FROM apod, to_tsquery('neutrino|(dark & matter)') query
WHERE  query @@ textsearch
ORDER BY rank DESC
LIMIT 10;
```

<table>
<thead>
<tr>
<th>title</th>
<th>rank</th>
</tr>
</thead>
<tbody>
<tr>
<td>Neutrinos in the Sun</td>
<td>0.756097569485493</td>
</tr>
<tr>
<td>The Sudbury Neutrino Detector</td>
<td>0.705882361190954</td>
</tr>
<tr>
<td>A MACHO View of Galactic Dark Matter</td>
<td>0.668123210574724</td>
</tr>
<tr>
<td>Hot Gas and Dark Matter</td>
<td>0.6565958650282</td>
</tr>
<tr>
<td>The Virgo Cluster: Hot Plasma and Dark Matter</td>
<td>0.656301290640973</td>
</tr>
<tr>
<td>Rafting for Solar Neutrinos</td>
<td>0.655172410958162</td>
</tr>
<tr>
<td>NGC 4650A: Strange Galaxy and Dark Matter</td>
<td>0.65007298361481</td>
</tr>
<tr>
<td>Hot Gas and Dark Matter</td>
<td>0.617195790024749</td>
</tr>
<tr>
<td>Ice Fishing for Cosmic Neutrinos</td>
<td>0.615384618911517</td>
</tr>
<tr>
<td>Weak Lensing Distorts the Universe</td>
<td>0.450010798361481</td>
</tr>
</tbody>
</table>

Ranking can be expensive since it requires consulting the tsvector of each matching document, which can be I/O bound and therefore slow. Unfortunately, it is almost impossible to avoid since practical queries often result in large numbers of matches.

**Highlighting Results**

To present search results it is ideal to show a part of each document and how it is related to the query. Usually, search engines show fragments of the document with marked search terms. Greenplum Database provides a function `ts_headline` that implements this functionality.

```sql
ts_headline([config regconfig, ] document text, query tsquery [, options text ]) returns text
```

`ts_headline` accepts a document along with a query, and returns an excerpt from the document in which terms from the query are highlighted. The configuration to be used to parse the document can be specified by `config`; if `config` is omitted, the `default_text_search_config` configuration is used.

If an `options` string is specified it must consist of a comma-separated list of one or more `option=value` pairs. The available options are:
- **StartSel, StopSel**: the strings with which to delimit query words appearing in the document, to distinguish them from other excerpted words. You must double-quote these strings if they contain spaces or commas.
- **MaxWords, MinWords**: these numbers determine the longest and shortest headlines to output.
- **ShortWord**: words of this length or less will be dropped at the start and end of a headline. The default value of three eliminates common English articles.
- **HighlightAll**: Boolean flag; if **true** the whole document will be used as the headline, ignoring the preceding three parameters.
- **MaxFragments**: maximum number of text excerpts or fragments to display. The default value of zero selects a non-fragment-oriented headline generation method. A value greater than zero selects fragment-based headline generation. This method finds text fragments with as many query words as possible and stretches those fragments around the query words. As a result query words are close to the middle of each fragment and have words on each side. Each fragment will be of at most **MaxWords** and words of length **ShortWord** or less are dropped at the start and end of each fragment. If not all query words are found in the document, then a single fragment of the first **MinWords** in the document will be displayed.
- **FragmentDelimiter**: When more than one fragment is displayed, the fragments will be separated by this string.

Any unspecified options receive these defaults:

```
StartSel=<b>, StopSel=</b>,
MaxWords=35, MinWords=15, ShortWord=3, HighlightAll=FALSE,
MaxFragments=0, FragmentDelimiter=" ... "
```

For example:

```sql
SELECT ts_headline('english',
   'The most common type of search
is to find all documents containing given query terms
and return them in order of their similarity to the
query.',
   to_tsquery('query & similarity'));
```

```
ts_headline------------------------------------------------------------
containing given <b>query</b> terms
and return them in order of their <b>similarity</b> to the
<b>query</b>.
```

```sql
SELECT ts_headline('english',
   'The most common type of search
is to find all documents containing given query terms
and return them in order of their similarity to the
query.',
   to_tsquery('query & similarity'),
   'StartSel = <, StopSel = >');
```

```
ts_headline-------------------------------------------------------
containing given <query> terms
and return them in order of their <similarity> to the
<query>.
```

**ts_headline** uses the original document, not a **tsvector** summary, so it can be slow and should be used with care. A typical mistake is to call **ts_headline** for every matching document when only ten documents are to be shown. SQL subqueries can help; here is an example:

```sql
SELECT id, ts_headline(body, q), rank
FROM (SELECT id, body, q, ts_rank_cd(ti, q) AS rank
      FROM apod, to_tsquery('stars') q
      WHERE ti @@ q
```

```sql
WHERE ti @@ q
```
ORDER BY rank DESC
LIMIT 10) AS foo;

Additional Text Search Features
Greenplum Database has additional functions and operators you can use to manipulate search and query vectors, and to rewrite search queries.

This section contains the following subtopics:
- Manipulating Documents
- Manipulating Queries
- Rewriting Queries
- Gathering Document Statistics

Manipulating Documents
Parsing Documents showed how raw textual documents can be converted into \textit{tsvector} values. Greenplum Database also provides functions and operators that can be used to manipulate documents that are already in \textit{tsvector} form.

\begin{verbatim}
\texttt{tsvector \|\| tsvector}
\end{verbatim}

The \texttt{tsvector} concatenation operator returns a vector which combines the lexemes and positional information of the two vectors given as arguments. Positions and weight labels are retained during the concatenation. Positions appearing in the right-hand vector are offset by the largest position mentioned in the left-hand vector, so that the result is nearly equivalent to the result of performing \texttt{to\_tsvector} on the concatenation of the two original document strings. (The equivalence is not exact, because any stop-words removed from the end of the left-hand argument will not affect the result, whereas they would have affected the positions of the lexemes in the right-hand argument if textual concatenation were used.)

One advantage of using concatenation in the vector form, rather than concatenating text before applying \texttt{to\_tsvector}, is that you can use different configurations to parse different sections of the document. Also, because the \texttt{setweight} function marks all lexemes of the given vector the same way, it is necessary to parse the text and do \texttt{setweight} before concatenating if you want to label different parts of the document with different weights.

\begin{verbatim}
\texttt{setweight(vector tsvector, weight "char") returns tsvector}
\end{verbatim}

\texttt{setweight} returns a copy of the input vector in which every position has been labeled with the given \texttt{weight}, either A, B, C, or D. (D is the default for new vectors and as such is not displayed on output.) These labels are retained when vectors are concatenated, allowing words from different parts of a document to be weighted differently by ranking functions.
Note that weight labels apply to positions, not lexemes. If the input vector has been stripped of positions then setweight does nothing.

\[
\text{length(vector tsvector) returns integer}
\]

Returns the number of lexemes stored in the vector.

\[
\text{strip(vector tsvector) returns tsvector}
\]

Returns a vector which lists the same lexemes as the given vector, but which lacks any position or weight information. While the returned vector is much less useful than an unstripped vector for relevance ranking, it will usually be much smaller.

### Manipulating Queries

*Parsing Queries* showed how raw textual queries can be converted into tsquery values. Greenplum Database also provides functions and operators that can be used to manipulate queries that are already in tsquery form.

\[
\text{tsquery && tsquery}
\]

Returns the AND-combination of the two given queries.

\[
\text{tsquery || tsquery}
\]

Returns the OR-combination of the two given queries.

\[
!! \text{tsquery}
\]

Returns the negation (NOT) of the given query.

\[
\text{numnode(query tsquery) returns integer}
\]

Returns the number of nodes (lexemes plus operators) in a tsquery. This function is useful to determine if the query is meaningful (returns > 0), or contains only stop words (returns 0). Examples:

```
SELECT numnode(plainto_tsquery('the any'));
NOTICE: query contains only stopword(s) or doesn't contain lexeme(s), ignored
numnode
---------
0
```

```
SELECT numnode('foo & bar'::tsquery);
numnode
---------
3
```

\[
\text{querytree(query tsquery) returns text}
\]

Returns the portion of a tsquery that can be used for searching an index. This function is useful for detecting unindexable queries, for example those containing only stop words or only negated terms. For example:

```
SELECT querytree(to_tsquery('! defined'));
querytree
---------
```
Rewriting Queries

The `ts_rewrite` family of functions search a given `tsquery` for occurrences of a target subquery, and replace each occurrence with a substitute subquery. In essence this operation is a `tsquery`-specific version of substring replacement. A target and substitute combination can be thought of as a query rewrite rule. A collection of such rewrite rules can be a powerful search aid. For example, you can expand the search using synonyms (e.g., new york, big apple, nyc, gotham) or narrow the search to direct the user to some hot topic. There is some overlap in functionality between this feature and thesaurus dictionaries (`Thesaurus Dictionary`). However, you can modify a set of rewrite rules on-the-fly without reindexing, whereas updating a thesaurus requires reindexing to be effective.

```
ts_rewrite(query tsquery, target tsquery, substitute tsquery) returns tsquery
```

This form of `ts_rewrite` simply applies a single rewrite rule: target is replaced by substitute wherever it appears in query. For example:

```
SELECT ts_rewrite('a & b'::tsquery, 'a'::tsquery, 'c'::tsquery);
```

```
ts_rewrite
------------
'b' & 'c'
```

```
CREATE TABLE aliases (id int, t tsquery primary key, s tsquery);
INSERT INTO aliases VALUES('a', 'c');
SELECT ts_rewrite(to_tsquery('supernovae & crab'), 'SELECT t, s FROM aliases');
```

```
CREATE TABLE aliases (id int, t tsquery primary key, s tsquery);
INSERT INTO aliases VALUES('a', 'c');
SELECT ts_rewrite('a & b'::tsquery, 'SELECT t, s FROM aliases');
```

```
t rewrite
------------
'b' & 'c'
```

Note that when multiple rewrite rules are applied in this way, the order of application can be important; so in practice you will want the source query to ORDER BY some ordering key.

Let's consider a real-life astronomical example. We'll expand query supernovae using table-driven rewriting rules:

```
CREATE TABLE aliases (id int, t tsquery primary key, s tsquery);
INSERT INTO aliases VALUES(1, to_tsquery('supernovae'), to_tsquery('supernovae|sn'));
SELECT ts_rewrite(to_tsquery('supernovae & crab'), 'SELECT t, s FROM aliases');
```

```
CREATE TABLE aliases (id int, t tsquery primary key, s tsquery);
INSERT INTO aliases VALUES(1, to_tsquery('supernovae'), to_tsquery('supernovae|sn'));
SELECT ts_rewrite('a & b'::tsquery, 'SELECT t, s FROM aliases');
```

```
t rewrite
------------
'crab' & ( 'supernova' | 'sn' )
```
We can change the rewriting rules just by updating the table:

```sql
UPDATE aliases
SET s = to_tsquery('supernovae|sn & !nebulae')
WHERE t = to_tsquery('supernovae');

SELECT ts_rewrite(to_tsquery('supernovae & crab'), 'SELECT t, s FROM aliases');
```

ts_rewrite

```
'crab' & ( 'supernova' | 'sn' & 'nebula' )
```

Rewriting can be slow when there are many rewriting rules, since it checks every rule for a possible match. To filter out obvious non-candidate rules we can use the containment operators for the tsquery type. In the example below, we select only those rules which might match the original query:

```sql
SELECT ts_rewrite('a & b'::tsquery,
    'SELECT t,s FROM aliases WHERE ''a & b''::tsquery @> t');
```

ts_rewrite

```
'b' & 'c'
```

### Gathering Document Statistics

The function ts_stat is useful for checking your configuration and for finding stop-word candidates.

```sql
ts_stat(sqlquery text, [ weights text, ]
    OUT word text, OUT ndoc integer,
    OUT nentry integer) returns setof record
```

*sqlquery* is a text value containing an SQL query which must return a single tsvector column. *ts_stat* executes the query and returns statistics about each distinct lexeme (word) contained in the tsvector data. The columns returned are

- **word** text — the value of a lexeme
- **ndoc** integer — number of documents (tsvector s) the word occurred in
- **nentry** integer — total number of occurrences of the word

If weights is supplied, only occurrences having one of those weights are counted.

For example, to find the ten most frequent words in a document collection:

```sql
SELECT * FROM ts_stat('SELECT vector FROM apod')
ORDER BY nentry DESC, ndoc DESC, word
LIMIT 10;
```

The same, but counting only word occurrences with weight A or B:

```sql
SELECT * FROM ts_stat('SELECT vector FROM apod', 'ab')
ORDER BY nentry DESC, ndoc DESC, word
LIMIT 10;
```

### Text Search Parsers

This topic describes the types of tokens the Greenplum Database text search parser produces from raw text.

Text search parsers are responsible for splitting raw document text into *tokens* and identifying each token's type, where the set of possible types is defined by the parser itself. Note that a parser does not modify the text at all — it simply identifies plausible word boundaries. Because of this limited scope,
there is less need for application-specific custom parsers than there is for custom dictionaries. At present
Greenplum Database provides just one built-in parser, which has been found to be useful for a wide range
of applications.

The built-in parser is named `pg_catalog.default`. It recognizes 23 token types, shown in the following
table.

**Table 55: Default Parser’s Token Types**

<table>
<thead>
<tr>
<th>Alias</th>
<th>Description</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>asciiword</td>
<td>Word, all ASCII letters</td>
<td>elephant</td>
</tr>
<tr>
<td>word</td>
<td>Word, all letters</td>
<td>mañana</td>
</tr>
<tr>
<td>numword</td>

<td>Hyphenated word, all letters</td>
<td>lógico-matemática</td>
</tr>
<tr>
<td>numhword</td>
<td>Hyphenated word, letters and digits</td>
<td>postgresql-beta1</td>
</tr>
<tr>
<td>hword_asciipart</td>
<td>Hyphenated word part, all ASCII</td>
<td>postgresql in the context postgresql-beta1</td>
</tr>
<tr>
<td>hword_part</td>
<td>Hyphenated word part, all letters</td>
<td>lógico or matemática in the context lógico-matemática</td>
</tr>
<tr>
<td>hword_numpart</td>
<td>Hyphenated word part, letters and digits</td>
<td>beta1 in the context postgresql-beta1</td>
</tr>
<tr>
<td>email</td>
<td>Email address</td>
<td><a href="mailto:foo@example.com">foo@example.com</a></td>
</tr>
<tr>
<td>protocol</td>
<td>Protocol head</td>
<td>http://</td>
</tr>
<tr>
<td>url</td>
<td>URL</td>
<td>example.com/stuff/index.html</td>
</tr>
<tr>
<td>host</td>
<td>Host</td>
<td>example.com</td>
</tr>
<tr>
<td>url_path</td>
<td>URL path</td>
<td>/stuff/index.html, in the context of a URL</td>
</tr>
<tr>
<td>file</td>
<td>File or path name</td>
<td>/usr/local/foo.txt, if not within a URL</td>
</tr>
<tr>
<td>sfloat</td>
<td>Scientific notation</td>
<td>-1.234e56</td>
</tr>
<tr>
<td>float</td>
<td>Decimal notation</td>
<td>-1.234</td>
</tr>
<tr>
<td>int</td>
<td>Signed integer</td>
<td>-1234</td>
</tr>
<tr>
<td>uint</td>
<td>Unsigned integer</td>
<td>1234</td>
</tr>
<tr>
<td>version</td>
<td>Version number</td>
<td>8.3.0</td>
</tr>
<tr>
<td>tag</td>
<td>XML tag</td>
<td>&lt;a href=&quot;dictionaries.html&quot;&gt;</td>
</tr>
<tr>
<td>entity</td>
<td>XML entity</td>
<td>&amp;</td>
</tr>
<tr>
<td>blank</td>
<td>Space symbols</td>
<td>(any whitespace or punctuation not otherwise recognized)</td>
</tr>
</tbody>
</table>

**Note:**
The parser's notion of a "letter" is determined by the database's locale setting, specifically `lc_ctype`. Words containing only the basic ASCII letters are reported as a separate token type, since it is sometimes useful to distinguish them. In most European languages, token types `word` and `asciword` should be treated alike.

`email` does not support all valid email characters as defined by RFC 5322. Specifically, the only non-alphanumeric characters supported for email user names are period, dash, and underscore.

It is possible for the parser to produce overlapping tokens from the same piece of text. As an example, a hyphenated word will be reported both as the entire word and as each component:

```sql
SELECT alias, description, token FROM ts_debug('foo-bar-beta1');
```

<table>
<thead>
<tr>
<th>alias</th>
<th>description</th>
<th>token</th>
</tr>
</thead>
<tbody>
<tr>
<td>numhword</td>
<td>Hyphenated word, letters and digits</td>
<td>foo-bar-beta1</td>
</tr>
<tr>
<td>hword_asciipart</td>
<td>Hyphenated word part, all ASCII</td>
<td>foo</td>
</tr>
<tr>
<td>blank</td>
<td>Space symbols</td>
<td></td>
</tr>
<tr>
<td>hword_asciipart</td>
<td>Hyphenated word part, all ASCII</td>
<td>bar</td>
</tr>
<tr>
<td>blank</td>
<td>Space symbols</td>
<td></td>
</tr>
<tr>
<td>hword_numpart</td>
<td>Hyphenated word part, letters and digits</td>
<td>beta1</td>
</tr>
</tbody>
</table>

This behavior is desirable since it allows searches to work for both the whole compound word and for components. Here is another instructive example:

```sql
SELECT alias, description, token FROM ts_debug('http://example.com/stuff/index.html');
```

<table>
<thead>
<tr>
<th>alias</th>
<th>description</th>
<th>token</th>
</tr>
</thead>
<tbody>
<tr>
<td>protocol</td>
<td>Protocol head</td>
<td>http://</td>
</tr>
<tr>
<td>url</td>
<td>URL</td>
<td>example.com/stuff/index.html</td>
</tr>
<tr>
<td>host</td>
<td>Host</td>
<td>example.com</td>
</tr>
<tr>
<td>url_path</td>
<td>URL path</td>
<td>/stuff/index.html</td>
</tr>
</tbody>
</table>

**Text Search Dictionaries**

Tokens produced by the Greenplum Database full text search parser are passed through a chain of dictionaries to produce a normalized term or "lexeme". Different kinds of dictionaries are available to filter and transform tokens in different ways and for different languages.

This section contains the following subtopics:

- About Text Search Dictionaries
- Stop Words
- Simple Dictionary
- Synonym Dictionary
- Thesaurus Dictionary
- Ispell Dictionary
- SnowBall Dictionary

**About Text Search Dictionaries**

Dictionaries are used to eliminate words that should not be considered in a search (stop words), and to normalize words so that different derived forms of the same word will match. A successfully normalized word is called a lexeme. Aside from improving search quality, normalization and removal of stop words reduces the size of the tsvector representation of a document, thereby improving performance.

Normalization does not always have linguistic meaning and usually depends on application semantics. Some examples of normalization:
• Linguistic - Ispell dictionaries try to reduce input words to a normalized form; stemmer dictionaries remove word endings
• URL locations can be canonicalized to make equivalent URLs match:
  * http://www.pgsql.ru/db/mw/index.html
  * http://www.pgsql.ru/db/mw/
  * http://www.pgsql.ru/db/../../db/mw/index.html
• Color names can be replaced by their hexadecimal values, e.g., red, green, blue, magenta -> FF0000, 00FF00, 0000FF, FF00FF
• If indexing numbers, we can remove some fractional digits to reduce the range of possible numbers, so for example 3.14159265359, 3.1415926, 3.14 will be the same after normalization if only two digits are kept after the decimal point.

A dictionary is a program that accepts a token as input and returns:
• an array of lexemes if the input token is known to the dictionary (notice that one token can produce more than one lexeme)
• a single lexeme with the TSL_FILTER flag set, to replace the original token with a new token to be passed to subsequent dictionaries (a dictionary that does this is called a filtering dictionary)
• an empty array if the dictionary knows the token, but it is a stop word
• NULL if the dictionary does not recognize the input token

Greenplum Database provides predefined dictionaries for many languages. There are also several predefined templates that can be used to create new dictionaries with custom parameters. Each predefined dictionary template is described below. If no existing template is suitable, it is possible to create new ones; see the contrib/ area of the Greenplum Database distribution for examples.

A text search configuration binds a parser together with a set of dictionaries to process the parser's output tokens. For each token type that the parser can return, a separate list of dictionaries is specified by the configuration. When a token of that type is found by the parser, each dictionary in the list is consulted in turn, until some dictionary recognizes it as a known word. If it is identified as a stop word, or if no dictionary recognizes the token, it will be discarded and not indexed or searched for. Normally, the first dictionary that returns a non-NULL output determines the result, and any remaining dictionaries are not consulted; but a filtering dictionary can replace the given word with a modified word, which is then passed to subsequent dictionaries.

The general rule for configuring a list of dictionaries is to place first the most narrow, most specific dictionary, then the more general dictionaries, finishing with a very general dictionary, like a Snowball stemmer or simple, which recognizes everything. For example, for an astronomy-specific search (astro_en configuration) one could bind token type asciiword (ASCII word) to a synonym dictionary of astronomical terms, a general English dictionary and a Snowball English stemmer:

```
ALTER TEXT SEARCH CONFIGURATION astro_en
    ADD MAPPING FOR asciiword WITH astrosyn, english_ispell, english_stem;
```

A filtering dictionary can be placed anywhere in the list, except at the end where it'd be useless. Filtering dictionaries are useful to partially normalize words to simplify the task of later dictionaries. For example, a filtering dictionary could be used to remove accents from accented letters, as is done by the unaccent module.

**Stop Words**

Stop words are words that are very common, appear in almost every document, and have no discrimination value. Therefore, they can be ignored in the context of full text searching. For example, every English text contains words like a and the, so it is useless to store them in an index. However, stop words do affect the positions in tsvector, which in turn affect ranking:

```
SELECT to_tsvector('english','in the list of stop words');
to_tsvector
```
The missing positions 1, 2, 4 are because of stop words. Ranks calculated for documents with and without stop words are quite different:

```
SELECT ts_rank_cd (to_tsvector('english','in the list of stop words'),
                 to_tsquery('list & stop'));
    ts_rank_cd
-------------
       0.05
```

```
SELECT ts_rank_cd (to_tsvector('english','list stop words'),
                 to_tsquery('list & stop'));
    ts_rank_cd
-------------
       0.1
```

It is up to the specific dictionary how it treats stop words. For example, `ispell` dictionaries first normalize words and then look at the list of stop words, while `Snowball` stemmers first check the list of stop words. The reason for the different behavior is an attempt to decrease noise.

### Simple Dictionary

The simple dictionary template operates by converting the input token to lower case and checking it against a file of stop words. If it is found in the file then an empty array is returned, causing the token to be discarded. If not, the lower-cased form of the word is returned as the normalized lexeme. Alternatively, the dictionary can be configured to report non-stop-words as unrecognized, allowing them to be passed on to the next dictionary in the list.

Here is an example of a dictionary definition using the simple template:

```
CREATE TEXT SEARCH DICTIONARY public.simple_dict (  
    TEMPLATE = pg_catalog.simple,
    STOPWORDS = english
);
```

Here, `english` is the base name of a file of stop words. The file's full name will be `${SHAREDIR}/tsearch_data/english.stop`, where `${SHAREDIR}` means the Greenplum Database installation's shared-data directory, often `/usr/local/greenplum-db--<version>/share/postgresql` (use `pg_config --sharedir` to determine it if you're not sure). The file format is simply a list of words, one per line. Blank lines and trailing spaces are ignored, and upper case is folded to lower case, but no other processing is done on the file contents.

Now we can test our dictionary:

```
SELECT ts_lexize('public.simple_dict','YeS');
   ts_lexize
----------
    {yes}
```

```
SELECT ts_lexize('public.simple_dict','The');
   ts_lexize
----------
    {}
```

We can also choose to return `NULL`, instead of the lower-cased word, if it is not found in the stop words file. This behavior is selected by setting the dictionary's `Accept` parameter to `false`. Continuing the example:

```
ALTER TEXT SEARCH DICTIONARY public.simple_dict ( Accept = false );
```
With the default setting of `Accept = true`, it is only useful to place a simple dictionary at the end of a list of dictionaries, since it will never pass on any token to a following dictionary. Conversely, `Accept = false` is only useful when there is at least one following dictionary.

**Caution:** Most types of dictionaries rely on configuration files, such as files of stop words. These files must be stored in UTF-8 encoding. They will be translated to the actual database encoding, if that is different, when they are read into the server.

**Caution:** Normally, a database session will read a dictionary configuration file only once, when it is first used within the session. If you modify a configuration file and want to force existing sessions to pick up the new contents, issue an `ALTER TEXT SEARCH DICTIONARY` command on the dictionary. This can be a “dummy” update that doesn't actually change any parameter values.

### Synonym Dictionary

This dictionary template is used to create dictionaries that replace a word with a synonym. Phrases are not supported—use the thesaurus template (Thesaurus Dictionary) for that. A synonym dictionary can be used to overcome linguistic problems, for example, to prevent an English stemmer dictionary from reducing the word “Paris” to “pari”. It is enough to have a `Paris pari` line in the synonym dictionary and put it before the `english_stem` dictionary. For example:

```sql
CREATE TEXT SEARCH DICTIONARY my_synonym
    TEMPLATE = synonym,
    SYNONYMS = my_synonyms;
ALTER TEXT SEARCH CONFIGURATION english
    ALTER MAPPING FOR asciiword
        WITH my_synonym, english_stem;
```

The only parameter required by the synonym template is `SYNONYMS`, which is the base name of its configuration file — `my_synonyms` in the above example. The file's full name will be `$SHAREDIR/tsearch_data/my_synonyms.syn` (where `$SHAREDIR` means the Greenplum Database installation's shared-data directory). The file format is just one line per word to be substituted, with the word followed by its synonym, separated by white space. Blank lines and trailing spaces are ignored.
The synonym template also has an optional parameter `CaseSensitive`, which defaults to `false`. When `CaseSensitive` is `false`, words in the synonym file are folded to lower case, as are input tokens. When it is `true`, words and tokens are not folded to lower case, but are compared as-is.

An asterisk (\('*\)) can be placed at the end of a synonym in the configuration file. This indicates that the synonym is a prefix. The asterisk is ignored when the entry is used in `to_tsvector()`, but when it is used in `to_tsquery()`, the result will be a query item with the prefix match marker (see Parsing Queries). For example, suppose we have these entries in `$SHAREDIR/tsearch_data/synonym_sample.syn`:

```plaintext
postgres pgsql postgresql pgsql postgre pgsql
google googl
indices index*
```

Then we will get these results:

```sql
mydb=# CREATE TEXT SEARCH DICTIONARY syn (template=synonym, synonyms='synonym_sample');
mydb=# SELECT ts_lexize('syn','indices');
ts_lexize
-------
{index}
(1 row)

mydb=# CREATE TEXT SEARCH CONFIGURATION tst (copy=simple);
mydb=# ALTER TEXT SEARCH CONFIGURATION tst ALTER MAPPING FOR asciiword WITH syn;
mydb=# SELECT to_tsvector('tst','indices');
to_tsvector
--------
'index':1
(1 row)

mydb=# SELECT to_tsquery('tst','indices');
to_tsquery
--------
'index':*
(1 row)

mydb=# SELECT 'indexes are very useful'::tsvector;
tsvector
-----------------------------
'are' 'indexes' 'useful' 'very'
(1 row)

mydb=# SELECT 'indexes are very useful'::tsvector @@
       to_tsquery('tst','indices');
?column?
--------
t
(1 row)
```

### Thesaurus Dictionary

A thesaurus dictionary (sometimes abbreviated as TZ) is a collection of words that includes information about the relationships of words and phrases, i.e., broader terms (BT), narrower terms (NT), preferred terms, non-preferred terms, related terms, etc.

Basically a thesaurus dictionary replaces all non-preferred terms by one preferred term and, optionally, preserves the original terms for indexing as well. Greenplum Database's current implementation of the
The thesaurus dictionary is an extension of the synonym dictionary with added phrase support. A thesaurus dictionary requires a configuration file of the following format:

```plaintext
# this is a comment
sample word(s) : indexed word(s)
more sample word(s) : more indexed word(s)
...
```

where the colon (:) symbol acts as a delimiter between a phrase and its replacement.

A thesaurus dictionary uses a subdictionary (which is specified in the dictionary's configuration) to normalize the input text before checking for phrase matches. It is only possible to select one subdictionary. An error is reported if the subdictionary fails to recognize a word. In that case, you should remove the use of the word or teach the subdictionary about it. You can place an asterisk (*) at the beginning of an indexed word to skip applying the subdictionary to it, but all sample words must be known to the subdictionary.

The thesaurus dictionary chooses the longest match if there are multiple phrases matching the input, and ties are broken by using the last definition.

Specific stop words recognized by the subdictionary cannot be specified; instead use ? to mark the location where any stop word can appear. For example, assuming that a and the are stop words according to the subdictionary:

```plaintext
? one ? two : swsw
```

matches a one the two and the one a two; both would be replaced by swsw.

Since a thesaurus dictionary has the capability to recognize phrases it must remember its state and interact with the parser. A thesaurus dictionary uses these assignments to check if it should handle the next word or stop accumulation. The thesaurus dictionary must be configured carefully. For example, if the thesaurus dictionary is assigned to handle only the asciiword token, then a thesaurus dictionary definition like one 7 will not work since token type uint is not assigned to the thesaurus dictionary.

**Caution:** Thesauruses are used during indexing so any change in the thesaurus dictionary's parameters requires reindexing. For most other dictionary types, small changes such as adding or removing stop words does not force reindexing.

**Thesaurus Configuration**

To define a new thesaurus dictionary, use the thesaurus template. For example:

```sql
CREATE TEXT SEARCH DICTIONARY thesaurus_simple (  
    TEMPLATE = thesaurus,  
    DictFile = mythesaurus,  
    Dictionary = pg_catalog.english_stem  
);
```

Here:

- `thesaurus_simple` is the new dictionary's name
- `mythesaurus` is the base name of the thesaurus configuration file. (Its full name will be `$SHAREDIR/tsearch_data/mythesaurus.ths`, where `$SHAREDIR` means the installation shared-data directory.)
- `pg_catalog.english_stem` is the subdictionary (here, a Snowball English stemmer) to use for thesaurus normalization. Notice that the subdictionary will have its own configuration (for example, stop words), which is not shown here.

Now it is possible to bind the thesaurus dictionary `thesaurus_simple` to the desired token types in a configuration, for example:

```sql
ALTER TEXT SEARCH CONFIGURATION russian
```
ALTER MAPPING FOR asciiword, asciihword, hword_asciipart
    WITH thesaurus_simple;

Thesaurus Example
Consider a simple astronomical thesaurus thesaurus_astro, which contains some astronomical word combinations:
supernovae stars : sn
    crab nebulae : crab

Below we create a dictionary and bind some token types to an astronomical thesaurus and English stemmer:

CREATE TEXT SEARCH DICTIONARY thesaurus_astro (
    TEMPLATE = thesaurus,
    DictFile = thesaurus_astro,
    Dictionary = english_stem
);

ALTER TEXT SEARCH CONFIGURATION russian
    ALTER MAPPING FOR asciiword, asciihword, hword_asciipart
    WITH thesaurus_astro, english_stem;

Now we can see how it works. ts_lexize is not very useful for testing a thesaurus, because it treats its input as a single token. Instead we can use plainto_tsquery and to_tsvector, which will break their input strings into multiple tokens:

SELECT plainto_tsquery('supernova star');
    plainto_tsquery
    ------------------
    'sn'

SELECT to_tsvector('supernova star');
    to_tsvector
    ------------
    'sn':1

In principle, one can use to_tsquery if you quote the argument:

SELECT to_tsquery('"supernova star"');
    to_tsquery
    ------------------
    'sn'

Notice that supernova star matches supernovae stars in thesaurus_astro because we specified the english_stem stemmer in the thesaurus definition. The stemmer removed the e and s.

To index the original phrase as well as the substitute, just include it in the right-hand part of the definition:

supernovae stars : sn supernovae stars

SELECT plainto_tsquery('supernova star');
    plainto_tsquery
    ------------------
    'sn' & 'supernova' & 'star'

Ispell Dictionary
The Ispell dictionary template supports morphological dictionaries, which can normalize many different linguistic forms of a word into the same lexeme. For example, an English Ispell dictionary can match all
The standard Greenplum Database distribution does not include any Ispell configuration files. Dictionaries for a large number of languages are available from Ispell. Also, some more modern dictionary file formats are supported — MySpell (OO < 2.0.1) and Hunspell (OO >= 2.0.2). A large list of dictionaries is available on the OpenOffice Wiki.

To create an Ispell dictionary, use the built-in ispell template and specify several parameters:

```
CREATE TEXT SEARCH DICTIONARY english_ispell (  
    TEMPLATE = ispell,
    DictFile = english,
    AffFile = english,
    StopWords = english
);
```

Here, DictFile, AffFile, and StopWords specify the base names of the dictionary, affixes, and stop-words files. The stop-words file has the same format explained above for the simple dictionary type. The format of the other files is not specified here but is available from the above-mentioned web sites.

Ispell dictionaries usually recognize a limited set of words, so they should be followed by another broader dictionary; for example, a Snowball dictionary, which recognizes everything.

Ispell dictionaries support splitting compound words; a useful feature. Notice that the affix file should specify a special flag using the compoundwords controlled statement that marks dictionary words that can participate in compound formation:

```
compoundwords  controlled z
```

Here are some examples for the Norwegian language:

```
SELECT ts_lexize('norwegian_ispell', 'overbuljongterningpakkmesterassistent');
{over,buljong,terning,pakk,mester,assistent}
SELECT ts_lexize('norwegian_ispell', 'sjokoladefabrikk');
{sjokoladefabrikk,sjokolade,fabrikk}
```

**Note:**
MySpell does not support compound words. Hunspell has sophisticated support for compound words. At present, Greenplum Database implements only the basic compound word operations of Hunspell.

**SnowBall Dictionary**

The Snowball dictionary template is based on a project by Martin Porter, inventor of the popular Porter’s stemming algorithm for the English language. Snowball now provides stemming algorithms for many languages (see the Snowball site for more information). Each algorithm understands how to reduce common variant forms of words to a base, or stem, spelling within its language. A Snowball dictionary requires a language parameter to identify which stemmer to use, and optionally can specify a stopword file name that gives a list of words to eliminate. (Greenplum Database’s standard stopword lists are also provided by the Snowball project.) For example, there is a built-in definition equivalent to

```
CREATE TEXT SEARCH DICTIONARY english_stem (  
    TEMPLATE = snowball,
    Language = english,
    StopWords = english
);
```

The stopword file format is the same as already explained.
A Snowball dictionary recognizes everything, whether or not it is able to simplify the word, so it should be placed at the end of the dictionary list. It is useless to have it before any other dictionary because a token will never pass through it to the next dictionary.

**Text Search Configuration Example**

This topic shows how to create a customized text search configuration to process document and query text.

A text search configuration specifies all options necessary to transform a document into a `tsvector`: the parser to use to break text into tokens, and the dictionaries to use to transform each token into a lexeme. Every call of `to_tsvector` or `to_tsquery` needs a text search configuration to perform its processing. The configuration parameter `default_text_search_config` specifies the name of the default configuration, which is the one used by text search functions if an explicit configuration parameter is omitted. It can be set in `postgresql.conf` using the `gpconfig` command-line utility, or set for an individual session using the `SET` command.

Several predefined text search configurations are available, and you can create custom configurations easily. To facilitate management of text search objects, a set of SQL commands is available, and there are several `psql` commands that display information about text search objects (*psql* Support).

As an example we will create a configuration `pg`, starting by duplicating the built-in `english` configuration:

```sql
CREATE TEXT SEARCH CONFIGURATION public.pg ( COPY = pg_catalog.english );
```

We will use a PostgreSQL-specific synonym list and store it in `$SHAREDIR/tsearch_data/pg_dict.syn`. The file contents look like:

```
postgres    pg
pgsql       pg
postgresql  pg
```

We define the synonym dictionary like this:

```sql
CREATE TEXT SEARCH DICTIONARY pg_dict (  
    TEMPLATE = synonym,  
    SYNONYMS = pg_dict
);
```

Next we register the `Ispell` dictionary `english_ispell`, which has its own configuration files:

```sql
CREATE TEXT SEARCH DICTIONARY english_ispell (  
    TEMPLATE = ispell,  
    DictFile = english,  
    AffFile = english,  
    StopWords = english
);
```

Now we can set up the mappings for words in configuration `pg`:

```sql
ALTER TEXT SEARCH CONFIGURATION pg  
    ALTER MAPPING FOR asciiword, asciihword, hword_asciipart,  
                      word, hword, hword_part  
    WITH pg_dict, english_ispell, english_stem;
```

We choose not to index or search some token types that the built-in configuration does handle:

```sql
ALTER TEXT SEARCH CONFIGURATION pg  
    DROP MAPPING FOR email, url, url_path, sfloat, float;
```
Now we can test our configuration:

```sql
SELECT * FROM ts_debug('public.pg', 'PostgreSQL, the highly scalable, SQL compliant, open source object-relational database management system, is now undergoing beta testing of the next version of our software.');
```

The next step is to set the session to use the new configuration, which was created in the public schema:

```sql
=> \dF
  List of text search configurations
  Schema | Name | Description
  -------+------+-----------------------------
  public | pg   |
  SET default_text_search_config = 'public.pg';
  SET SHOW default_text_search_config;
  default_text_search_config
  -----------------------------
  public.pg
```

### Testing and Debugging Text Search

This topic introduces the Greenplum Database functions you can use to test and debug a search configuration or the individual parser and dictionaries specified in a configuration.

The behavior of a custom text search configuration can easily become confusing. The functions described in this section are useful for testing text search objects. You can test a complete configuration, or test parsers and dictionaries separately.

This section contains the following subtopics:

- **Configuration Testing**
- **Parser Testing**
- **Dictionary Testing**

### Configuration Testing

The function `ts_debug` allows easy testing of a text search configuration.

```sql
ts_debug([config regconfig, ] document text, 
  OUT alias text, 
  OUT description text, 
  OUT token text, 
  OUT dictionaries regdictionary[], 
  OUT dictionary regdictionary, 
  OUT lexemes text[])
returns setof record
```

The `ts_debug` function displays information about every token of `document` as produced by the parser and processed by the configured dictionaries. It uses the configuration specified by `config`, or `default_text_search_config` if that argument is omitted.

`ts_debug` returns one row for each token identified in the text by the parser. The columns returned are:

- **alias text** — short name of the token type
- **description text** — description of the token type
- **token text** — text of the token
- **dictionaries regdictionary[]** — the dictionaries selected by the configuration for this token type
- **dictionary regdictionary** — the dictionary that recognized the token, or NULL if none did
- **lexemes text[]** — the lexeme(s) produced by the dictionary that recognized the token, or NULL if none did; an empty array ([]) means it was recognized as a stop word

Here is a simple example:

```sql
SELECT * FROM ts_debug('english','a fat cat sat on a mat - it ate a fat rats');
```

<table>
<thead>
<tr>
<th>alias</th>
<th>description</th>
<th>token</th>
<th>dictionaries</th>
<th>dictionary</th>
<th>lexemes</th>
</tr>
</thead>
<tbody>
<tr>
<td>asciiword</td>
<td>Word, all ASCII</td>
<td>a</td>
<td>{english_stem}</td>
<td>english_stem</td>
<td>{}</td>
</tr>
<tr>
<td>blank</td>
<td>Space symbols</td>
<td></td>
<td>()</td>
<td></td>
<td></td>
</tr>
<tr>
<td>asciiword</td>
<td>Word, all ASCII</td>
<td>fat</td>
<td>{english_stem}</td>
<td>english_stem</td>
<td>{fat}</td>
</tr>
<tr>
<td>blank</td>
<td>Space symbols</td>
<td></td>
<td>()</td>
<td></td>
<td></td>
</tr>
<tr>
<td>asciiword</td>
<td>Word, all ASCII</td>
<td>cat</td>
<td>{english_stem}</td>
<td>english_stem</td>
<td>{cat}</td>
</tr>
<tr>
<td>blank</td>
<td>Space symbols</td>
<td></td>
<td>()</td>
<td></td>
<td></td>
</tr>
<tr>
<td>asciiword</td>
<td>Word, all ASCII</td>
<td>sat</td>
<td>{english_stem}</td>
<td>english_stem</td>
<td>{sat}</td>
</tr>
<tr>
<td>blank</td>
<td>Space symbols</td>
<td></td>
<td>()</td>
<td></td>
<td></td>
</tr>
<tr>
<td>asciiword</td>
<td>Word, all ASCII</td>
<td>on</td>
<td>{english_stem}</td>
<td>english_stem</td>
<td>{}</td>
</tr>
<tr>
<td>blank</td>
<td>Space symbols</td>
<td></td>
<td>()</td>
<td></td>
<td></td>
</tr>
<tr>
<td>asciiword</td>
<td>Word, all ASCII</td>
<td>a</td>
<td>{english_stem}</td>
<td>english_stem</td>
<td>{}</td>
</tr>
<tr>
<td>blank</td>
<td>Space symbols</td>
<td></td>
<td>()</td>
<td></td>
<td></td>
</tr>
<tr>
<td>asciiword</td>
<td>Word, all ASCII</td>
<td>mat</td>
<td>{english_stem}</td>
<td>english_stem</td>
<td>{mat}</td>
</tr>
<tr>
<td>blank</td>
<td>Space symbols</td>
<td></td>
<td>()</td>
<td></td>
<td></td>
</tr>
<tr>
<td>asciiword</td>
<td>Word, all ASCII</td>
<td>it</td>
<td>{english_stem}</td>
<td>english_stem</td>
<td>{}</td>
</tr>
<tr>
<td>blank</td>
<td>Space symbols</td>
<td></td>
<td>()</td>
<td></td>
<td></td>
</tr>
<tr>
<td>asciiword</td>
<td>Word, all ASCII</td>
<td>ate</td>
<td>{english_stem}</td>
<td>english_stem</td>
<td>{ate}</td>
</tr>
<tr>
<td>blank</td>
<td>Space symbols</td>
<td></td>
<td>()</td>
<td></td>
<td></td>
</tr>
<tr>
<td>asciiword</td>
<td>Word, all ASCII</td>
<td>a</td>
<td>{english_stem}</td>
<td>english_stem</td>
<td>{}</td>
</tr>
<tr>
<td>blank</td>
<td>Space symbols</td>
<td></td>
<td>()</td>
<td></td>
<td></td>
</tr>
<tr>
<td>asciiword</td>
<td>Word, all ASCII</td>
<td>fat</td>
<td>{english_stem}</td>
<td>english_stem</td>
<td>{fat}</td>
</tr>
<tr>
<td>blank</td>
<td>Space symbols</td>
<td></td>
<td>()</td>
<td></td>
<td></td>
</tr>
<tr>
<td>asciiword</td>
<td>Word, all ASCII</td>
<td>rats</td>
<td>{english_stem}</td>
<td>english_stem</td>
<td>{rat}</td>
</tr>
</tbody>
</table>

For a more extensive demonstration, we first create a `public.english` configuration and Ispell dictionary for the English language:

```sql
CREATE TEXT SEARCH CONFIGURATION public.english ( COPY = pg_catalog.english );

CREATE TEXT SEARCH DICTIONARY english_ispell ( TEMPLATE = ispell,
  DictFile = english,
  AffFile = english,
  StopWords = english
);

ALTER TEXT SEARCH CONFIGURATION public.english
  ALTER MAPPING FOR asciiword WITH english_ispell, english_stem;

SELECT * FROM ts_debug('public.english','The Brightest supernovae');
```

<table>
<thead>
<tr>
<th>alias</th>
<th>description</th>
<th>token</th>
<th>dictionaries</th>
<th>dictionary</th>
<th>lexemes</th>
</tr>
</thead>
<tbody>
<tr>
<td>asciiword</td>
<td>Word, all ASCII</td>
<td>a</td>
<td>{english_stem}</td>
<td>english_stem</td>
<td>{}</td>
</tr>
<tr>
<td>blank</td>
<td>Space symbols</td>
<td></td>
<td>()</td>
<td></td>
<td></td>
</tr>
<tr>
<td>asciiword</td>
<td>Word, all ASCII</td>
<td>the</td>
<td>{english_stem}</td>
<td>english_stem</td>
<td>{the}</td>
</tr>
<tr>
<td>blank</td>
<td>Space symbols</td>
<td></td>
<td>()</td>
<td></td>
<td></td>
</tr>
<tr>
<td>asciiword</td>
<td>Word, all ASCII</td>
<td>bright</td>
<td>{english_stem}</td>
<td>english_stem</td>
<td>{bright}</td>
</tr>
<tr>
<td>blank</td>
<td>Space symbols</td>
<td></td>
<td>()</td>
<td></td>
<td></td>
</tr>
<tr>
<td>asciiword</td>
<td>Word, all ASCII</td>
<td>es</td>
<td>{english_stem}</td>
<td>english_stem</td>
<td>{es}</td>
</tr>
<tr>
<td>blank</td>
<td>Space symbols</td>
<td></td>
<td>()</td>
<td></td>
<td></td>
</tr>
<tr>
<td>asciiword</td>
<td>Word, all ASCII</td>
<td>supernova</td>
<td>{english_stem}</td>
<td>english_stem</td>
<td>{supernova}</td>
</tr>
<tr>
<td>blank</td>
<td>Space symbols</td>
<td></td>
<td>()</td>
<td></td>
<td></td>
</tr>
<tr>
<td>asciiword</td>
<td>Word, all ASCII</td>
<td>e</td>
<td>{english_stem}</td>
<td>english_stem</td>
<td>{e}</td>
</tr>
<tr>
<td>blank</td>
<td>Space symbols</td>
<td></td>
<td>()</td>
<td></td>
<td></td>
</tr>
<tr>
<td>asciiword</td>
<td>Word, all ASCII</td>
<td>s</td>
<td>{english_stem}</td>
<td>english_stem</td>
<td>{s}</td>
</tr>
<tr>
<td>blank</td>
<td>Space symbols</td>
<td></td>
<td>()</td>
<td></td>
<td></td>
</tr>
<tr>
<td>asciiword</td>
<td>Word, all ASCII</td>
<td>e</td>
<td>{english_stem}</td>
<td>english_stem</td>
<td>{e}</td>
</tr>
<tr>
<td>blank</td>
<td>Space symbols</td>
<td></td>
<td>()</td>
<td></td>
<td></td>
</tr>
<tr>
<td>asciiword</td>
<td>Word, all ASCII</td>
<td>novae</td>
<td>{english_stem}</td>
<td>english_stem</td>
<td>{novae}</td>
</tr>
<tr>
<td>blank</td>
<td>Space symbols</td>
<td></td>
<td>()</td>
<td></td>
<td></td>
</tr>
<tr>
<td>asciiword</td>
<td>Word, all ASCII</td>
<td></td>
<td>{english_stem}</td>
<td>english_stem</td>
<td>{}</td>
</tr>
<tr>
<td>blank</td>
<td>Space symbols</td>
<td></td>
<td>()</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
In this example, the word *Brightest* was recognized by the parser as an ASCII word (alias \texttt{asciiword}). For this token type the dictionary list is \texttt{english_ispell} and \texttt{english_stem}. The word was recognized by \texttt{english_ispell}, which reduced it to the noun \texttt{bright}. The word \texttt{supernovaes} is unknown to the \texttt{english_ispell} dictionary so it was passed to the next dictionary, and, fortunately, was recognized (in fact, \texttt{english_stem} is a Snowball dictionary which recognizes everything; that is why it was placed at the end of the dictionary list).

The word *The* was recognized by the \texttt{english_ispell} dictionary as a stop word (\textit{Stop Words}) and will not be indexed. The spaces are discarded too, since the configuration provides no dictionaries at all for them.

You can reduce the width of the output by explicitly specifying which columns you want to see:

```sql
SELECT alias, token, dictionary, lexemes FROM ts_debug('public.english','The Brightest supernovaes');
```

<table>
<thead>
<tr>
<th>alias</th>
<th>token</th>
<th>dictionary</th>
<th>lexemes</th>
</tr>
</thead>
<tbody>
<tr>
<td>asciiword</td>
<td>The</td>
<td>english_ispell</td>
<td>{}</td>
</tr>
<tr>
<td>blank</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>asciiword</td>
<td>Brightest</td>
<td>english_ispell</td>
<td>{bright}</td>
</tr>
<tr>
<td>blank</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>asciiword</td>
<td>supernovaes</td>
<td>english_stem</td>
<td>{supernova}</td>
</tr>
</tbody>
</table>

### Parser Testing

The following functions allow direct testing of a text search parser.

```sql
ts_parse(parser_name text, document text, 
          OUT tokid integer, OUT token text) returns setof record

ts_parse(parser_oid oid, document text, 
          OUT tokid integer, OUT token text) returns setof record
```

\texttt{ts_parse} parses the given document and returns a series of records, one for each token produced by parsing. Each record includes a \texttt{tokid} showing the assigned token type and a \texttt{token}, which is the text of the token. For example:

```sql
SELECT * FROM ts_parse('default', '123 - a number');
```

<table>
<thead>
<tr>
<th>tokid</th>
<th>token</th>
</tr>
</thead>
<tbody>
<tr>
<td>22</td>
<td>123</td>
</tr>
<tr>
<td>12</td>
<td>-</td>
</tr>
<tr>
<td>1</td>
<td>a</td>
</tr>
<tr>
<td>12</td>
<td>number</td>
</tr>
</tbody>
</table>

```sql
ts_token_type(parser_name text, OUT tokid integer, 
              OUT alias text, OUT description text) returns setof record

ts_token_type(parser_oid oid, OUT tokid integer, 
              OUT alias text, OUT description text) returns setof record
```
ts_token_type returns a table which describes each type of token the specified parser can recognize. For each token type, the table gives the integer tokid that the parser uses to label a token of that type, the alias that names the token type in configuration commands, and a short description. For example:

```sql
SELECT * FROM ts_token_type('default');
```

<table>
<thead>
<tr>
<th>tokid</th>
<th>alias</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>asciiword</td>
<td>Word, all ASCII</td>
</tr>
<tr>
<td>2</td>
<td>word</td>
<td>Word, all letters</td>
</tr>
<tr>
<td>3</td>
<td>numword</td>
<td>Word, letters and digits</td>
</tr>
<tr>
<td>4</td>
<td>email</td>
<td>Email address</td>
</tr>
<tr>
<td>5</td>
<td>url</td>
<td>URL</td>
</tr>
<tr>
<td>6</td>
<td>host</td>
<td>Host</td>
</tr>
<tr>
<td>7</td>
<td>sfloat</td>
<td>Scientific notation</td>
</tr>
<tr>
<td>8</td>
<td>version</td>
<td>Version number</td>
</tr>
<tr>
<td>9</td>
<td>hword_numpart</td>
<td>Hyphenated word part, letters and digits</td>
</tr>
<tr>
<td>10</td>
<td>hword_part</td>
<td>Hyphenated word part, all letters</td>
</tr>
<tr>
<td>11</td>
<td>hword_asciipart</td>
<td>Hyphenated word part, all ASCII</td>
</tr>
<tr>
<td>12</td>
<td>blank</td>
<td>Space symbols</td>
</tr>
<tr>
<td>13</td>
<td>tag</td>
<td>XML tag</td>
</tr>
<tr>
<td>14</td>
<td>protocol</td>
<td>Protocol head</td>
</tr>
<tr>
<td>15</td>
<td>numhword</td>
<td>Hyphenated word, letters and digits</td>
</tr>
<tr>
<td>16</td>
<td>asciihword</td>
<td>Hyphenated word, all ASCII</td>
</tr>
<tr>
<td>17</td>
<td>hword</td>
<td>Hyphenated word, all letters</td>
</tr>
<tr>
<td>18</td>
<td>url_path</td>
<td>URL path</td>
</tr>
<tr>
<td>19</td>
<td>file</td>
<td>File or path name</td>
</tr>
<tr>
<td>20</td>
<td>float</td>
<td>Decimal notation</td>
</tr>
<tr>
<td>21</td>
<td>int</td>
<td>Signed integer</td>
</tr>
<tr>
<td>22</td>
<td>uint</td>
<td>Unsigned integer</td>
</tr>
<tr>
<td>23</td>
<td>entity</td>
<td>XML entity</td>
</tr>
</tbody>
</table>

**Dictionary Testing**

The ts_lexize function facilitates dictionary testing.

ts_lexize(dictreg dictionary, token text) returns text[]

ts_lexize returns an array of lexemes if the input token is known to the dictionary, or an empty array if the token is known to the dictionary but it is a stop word, or NULL if it is an unknown word.

Examples:

```sql
SELECT ts_lexize('english_stem', 'stars');
```

```
{star}
```

```sql
SELECT ts_lexize('english_stem', 'a');
```

```
{}
```

**Note:** The ts_lexize function expects a single token, not text. Here is a case where this can be confusing:

```sql
SELECT ts_lexize('thesaurus_astro', 'supernovae stars') is null;
```

```
?column?
```

```
t
```
GiST and GIN Indexes for Text Search

This topic describes and compares the Greenplum Database index types that are used for full text searching.

There are two kinds of indexes that can be used to speed up full text searches. Indexes are not mandatory for full text searching, but in cases where a column is searched on a regular basis, an index is usually desirable.

CREATE INDEX name ON table USING gist(column);

Creates a GiST (Generalized Search Tree)-based index. The column can be of tsvector or tsquery type.

CREATE INDEX name ON table USING gin(column);

Creates a GIN (Generalized Inverted Index)-based index. The column must be of tsvector type.

There are substantial performance differences between the two index types, so it is important to understand their characteristics.

A GiST index is lossy, meaning that the index may produce false matches, and it is necessary to check the actual table row to eliminate such false matches. (Greenplum Database does this automatically when needed.) GiST indexes are lossy because each document is represented in the index by a fixed-length signature. The signature is generated by hashing each word into a single bit in an n-bit string, with all these bits OR-ed together to produce an n-bit document signature. When two words hash to the same bit position there will be a false match. If all words in the query have matches (real or false) then the table row must be retrieved to see if the match is correct.

Lossiness causes performance degradation due to unnecessary fetches of table records that turn out to be false matches. Since random access to table records is slow, this limits the usefulness of GiST indexes. The likelihood of false matches depends on several factors, in particular the number of unique words, so using dictionaries to reduce this number is recommended.

GIN indexes are not lossy for standard queries, but their performance depends logarithmically on the number of unique words. (However, GIN indexes store only the words (lexemes) of tsvector values, and not their weight labels. Thus a table row recheck is needed when using a query that involves weights.)

In choosing which index type to use, GiST or GIN, consider these performance differences:

• GIN index lookups are about three times faster than GiST
• GIN indexes take about three times longer to build than GiST
• GIN indexes are moderately slower to update than GiST indexes, but about 10 times slower if fast-update support was disabled (see GIN Fast Update Technique in the PostgreSQL documentation for details)
• GIN indexes are two-to-three times larger than GiST indexes

As a rule of thumb, GIN indexes are best for static data because lookups are faster. For dynamic data, GiST indexes are faster to update. Specifically, GiST indexes are very good for dynamic data and fast if the number of unique words (lexemes) is under 100,000, while GIN indexes will handle 100,000+ lexemes better but are slower to update.
Note that GIN index build time can often be improved by increasing `maintenance_work_mem`, while GiST index build time is not sensitive to that parameter.

Partitioning of big collections and the proper use of GiST and GIN indexes allows the implementation of very fast searches with online update. Partitioning can be done at the database level using table inheritance, or by distributing documents over servers and collecting search results using `dblink`. The latter is possible because ranking functions use only local information.

**psql Support**

The psql command-line utility provides a meta-command to display information about Greenplum Database full text search configurations.

Information about text search configuration objects can be obtained in psql using a set of commands:

```
\df{d,p,t}{+} [PATTERN]
```

An optional `+` produces more details.

The optional parameter `PATTERN` can be the name of a text search object, optionally schema-qualified. If `PATTERN` is omitted then information about all visible objects will be displayed. `PATTERN` can be a regular expression and can provide separate patterns for the schema and object names. The following examples illustrate this:

```
=> \df *fulltext*
List of text search configurations
  Schema |  Name         | Description
--------+---------------+-------------
  public | fulltext cfg  |

=> \df *.fulltext*
List of text search configurations
  Schema |  Name         |
--------+---------------
  fulltext | fulltext cfg  |
  public  | fulltext cfg  |
```

The available commands are:

```
\df{+} [PATTERN]
```

List text search configurations (add `+` for more detail).

```
=> \df russian
List of text search configurations
  Schema |  Name         | Description
--------+---------------+-------------
  pg_catalog | russian | configuration for russian language

=> \df+ russian
Text search configuration
"pg_catalog.russian"
Parser: "pg_catalog.default"
  Token   | Dictionaries
----------+--------------
  asciihword | english_stem
  asciiword  | english_stem
  email     | simple
```
<table>
<thead>
<tr>
<th>Schema</th>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pg_catalog</td>
<td>danish_stem</td>
<td>snowball stemmer for danish language</td>
</tr>

+-----------------------------------------------------------
pg_catalog | ispell    | ispell dictionary
pg_catalog | simple    | simple dictionary: just lower case and check for stopword
pg_catalog | snowball  | snowball stemmer
pg_catalog | synonym   | synonym dictionary: replace word by its synonym
pg_catalog | thesaurus | thesaurus dictionary: phrase by phrase substitution
```

**Limitations**

This topic lists limitations and maximums for Greenplum Database full text search objects.

The current limitations of Greenplum Database’s text search features are:

- The `tsvector` and `tsquery` types are not supported in the distribution key for a Greenplum Database table
- The length of each lexeme must be less than 2K bytes
- The length of a `tsvector` (lexemes + positions) must be less than 1 megabyte
- The number of lexemes must be less than $2^{64}$
- Position values in `tsvector` must be greater than 0 and no more than 16,383
- No more than 256 positions per lexeme
- The number of nodes (lexemes + operators) in a `tsquery` must be less than 32,768

For comparison, the PostgreSQL 8.1 documentation contained 10,441 unique words, a total of 335,420 words, and the most frequent word “postgresql” was mentioned 6,127 times in 655 documents.

Another example — the PostgreSQL mailing list archives contained 910,989 unique words with 57,491,343 lexemes in 461,020 messages.
Using Greenplum MapReduce

MapReduce is a programming model developed by Google for processing and generating large data sets on an array of commodity servers. Greenplum MapReduce allows programmers who are familiar with the MapReduce model to write map and reduce functions and submit them to the Greenplum Database parallel engine for processing.

You configure a Greenplum MapReduce job via a YAML-formatted configuration file, then pass the file to the Greenplum MapReduce program, `gpmapreduce`, for execution by the Greenplum Database parallel engine. The Greenplum Database system distributes the input data, executes the program across a set of machines, handles machine failures, and manages the required inter-machine communication.

Refer to `gpmapreduce` for details about running the Greenplum MapReduce program.

About the Greenplum MapReduce Configuration File

This section explains some basics of the Greenplum MapReduce configuration file format to help you get started creating your own Greenplum MapReduce configuration files. Greenplum uses the YAML 1.1 document format and then implements its own schema for defining the various steps of a MapReduce job.

All Greenplum MapReduce configuration files must first declare the version of the YAML specification they are using. After that, three dashes (---) denote the start of a document, and three dots (....) indicate the end of a document without starting a new one. (A document in this context is equivalent to a MapReduce job.) Comment lines are prefixed with a pound symbol (#). You can declare multiple Greenplum MapReduce documents/jobs in the same file:

```
---
# Begin Document 1
# ...
---
# Begin Document 2
# ...
```

Within a Greenplum MapReduce document, there are three basic types of data structures or nodes: scalars, sequences and mappings.

A scalar is a basic string of text indented by a space. If you have a scalar input that spans multiple lines, a preceding pipe ( | ) denotes a literal style, where all line breaks are significant. Alternatively, a preceding angle bracket ( > ) folds a single line break to a space for subsequent lines that have the same indentation level. If a string contains characters that have reserved meaning, the string must be quoted or the special character must be escaped with a backslash ( \ ).

```
# Read each new line literally
sosomekey: | this value contains two lines
            and each line is read literally
# Treat each new line as a space
anotherkey: >
             this value contains two lines
             but is treated as one continuous line
# This quoted string contains a special character
ThirdKey: "This is a string: not a mapping"
```

A sequence is a list with each entry in the list on its own line denoted by a dash and a space ( - ). Alternatively, you can specify an inline sequence as a comma-separated list within square brackets. A sequence provides a set of data and gives it an order. When you load a list into the Greenplum MapReduce program, the order is kept.

```
# list sequence
```
A *mapping* is used to pair up data values with identifiers called *keys*. Mappings use a colon and space (:) for each key: value pair, or can also be specified inline as a comma-separated list within curly braces. The *key* is used as an index for retrieving data from a mapping.

```plaintext
# a mapping of items
title: War and Peace
author: Leo Tolstoy
date: 1865

# same mapping written inline
{title: War and Peace, author: Leo Tolstoy, date: 1865}
```

Keys are used to associate meta information with each node and specify the expected node type (*scalar, sequence or mapping*).

The Greenplum MapReduce program processes the nodes of a document in order and uses indentation (spaces) to determine the document hierarchy and the relationships of the nodes to one another. The use of white space is significant. White space should not be used simply for formatting purposes, and tabs should not be used at all.

Refer to `gpmapreduce.yaml` for detailed information about the Greenplum MapReduce configuration file format and the keys and values supported.

### Example Greenplum MapReduce Job

In this example, you create a MapReduce job that processes text documents and reports on the number of occurrences of certain keywords in each document. The documents and keywords are stored in separate Greenplum Database tables that you create as part of the exercise.

This example MapReduce job utilizes the untrusted `plpythonu` language; as such, you must run the job as a user with Greenplum Database administrative privileges.

1. Log in to the Greenplum Database master host as the `gpadmin` administrative user and set up your environment. For example:

   ```bash
   $ ssh gpadmin@<gpmaster>
   gpadmin@gpmaster$ . /usr/local/greenplum-db/greenplum_path.sh
   ```

2. Create a new database for the MapReduce example: For example:

   ```bash
   gpadmin@gpmaster$ createdb mapredex_db
   ```

3. Start the `psql` subsystem, connecting to the new database:

   ```bash
   gpadmin@gpmaster$ psql -d mapredex_db
   ```

4. Register the PL/Python language in the database. For example:

   ```plpython
   mapredex_db=> CREATE EXTENSION plpythonu;
   ```

5. Create the `documents` table and add some data to the table. For example:

   ```sql
   CREATE TABLE documents (doc_id int, url text, data text);
   INSERT INTO documents VALUES (1, 'http:/url/1', 'this is one document in the corpus');
   ```
6. Create the `keywords` table and add some data to the table. For example:

```sql
CREATE TABLE keywords (keyword_id int, keyword text);
INSERT INTO keywords VALUES (1, 'the');
INSERT INTO keywords VALUES (2, 'document');
INSERT INTO keywords VALUES (3, 'me');
INSERT INTO keywords VALUES (4, 'being');
INSERT INTO keywords VALUES (5, 'now');
INSERT INTO keywords VALUES (6, 'corpus');
INSERT INTO keywords VALUES (7, 'is');
INSERT INTO keywords VALUES (8, 'third');
```

7. Construct the MapReduce YAML configuration file. For example, open a file named `mymrjob.yaml` in the editor of your choice and copy/paste the following large text block:

```yaml
# This example MapReduce job processes documents and looks for keywords in
# them.
# It takes two database tables as input:
# - documents (doc_id integer, url text, data text)
# - keywords (keyword_id integer, keyword text)
# The documents data is searched for occurrences of keywords and returns
# results of
# url, data and keyword (a keyword can be multiple words, such as "high
# performance # computing")
%YAML 1.1
---
VERSION: 1.0.0.2

# Connect to Greenplum Database using this database and role
DATABASE: mapredex_db
USER: gpadmin

# Begin definition section
DEFINE:

# Declare the input, which selects all columns and rows from the
# 'documents' and 'keywords' tables.
- INPUT:
  NAME: doc
  TABLE: documents
- INPUT:
  NAME: kw
  TABLE: keywords

# Define the map functions to extract terms from documents and keyword
# This example simply splits on white space, but it would be possible
# to make use of a python library like nltk (the natural language
toolkit)
# to perform more complex tokenization and word stemming.
- MAP:
  NAME: doc_map
  LANGUAGE: python
  FUNCTION: |
    i = 0           # the index of a word within the document
terms = {} # a hash of terms and their indexes within the document
    # Lower-case and split the text string on space
```
for term in data.lower().split():
    i = i + 1 # increment i (the index)
    # Check for the term in the terms list:
    # if stem word already exists, append the i value to the array
    # corresponding to the term. This counts multiple occurrences of
    # the word.
    # If stem word does not exist, add it to the dictionary with
    # position i.
    # For example:
    # data: "a computer is a machine that manipulates data"
    # "a" [1, 4]
    # "computer" [2]
    # "machine" [3]
    # ...
    if term in terms:

  RETURNS:
  - count integer
  MODE: MULTI
  FUNCTION: |

  if not state:
    yield 0
    kw_split = state.split(':')

  # This function does the following:
  # 1) Splits 'kw_split' on ':'
  #    for example, 1,5,7:2,8 creates '1,5,7' and '2,8'
# 2) For each group of positions in 'kw_split', splits the set on ','
# to create ['1','5','7'] from Set 0: 1,5,7 and
# eventually ['2', '8'] from Set 1: 2,8
# 3) Checks for empty strings
# 4) Adjusts the split sets by subtracting the position of the
#    set in the 'kw_split' array
# ['1','5','7'] - 0 from each element = ['1','5','7']
# ['2', '8'] - 1 from each element = ['1', '7']
# 5) Resulting arrays after subtracting the offset in step 4 are
#    intersected and their overlapping values kept:
# ['1','5','7'].intersect['1', '7'] = [1,7]
# 6) Determines the length of the intersection, which is the
#    number of
# times that an entire keyword (with all its pieces) matches in
# the
# document data.
previous = None
for i in range(0,len(kw_split)):

# Define the 'term_match' task which is then executed as part
# of the 'final_output' query. It takes the INPUT 'term_join' defined
# earlier and uses the REDUCE function 'term_reducer' defined earlier
- TASK:
  NAME: term_match
  SOURCE: term_join
  REDUCE: term_reducer
- INPUT:
  NAME: final_output
  QUERY: |
    SELECT doc.*, kw.*, tm.count
    FROM documents doc, keywords kw, term_match tm
    WHERE doc.doc_id = tm.doc_id
    AND kw.keyword_id = tm.keyword_id
    AND tm.count > 0

# Execute this MapReduce job and send output to STDOUT
EXECUTE:
- RUN:
  SOURCE: final_output
  TARGET: STDOUT

8. Save the file and exit the editor.
9. Run the MapReduce job. For example:

    gpadmin@gpmaster$ gpmapreduce -f mymrfjob.yaml

The job displays the number of occurrences of each keyword in each document to stdout.
**Flow Diagram for MapReduce Example**

The following diagram shows the job flow of the MapReduce job defined in the example:

1. **TASK: doc_prep**
   - **INPUT:** doc
   - **TABLE:** documents
   - **EXAMPLE ROW:** `<doc_id=100, data="A mapreduce tutorial for keyword matching in Greenplum mapreduce">`
   - **MAP FUNCTION:** doc_map
     - **RETURNS:** doc_id int, term text, positions [text]
     - **EXAMPLE:**
       - `<doc_id=100, term="A", positions="1">`
       - `<doc_id=100, term="mapreduce", positions="2,9">`

2. **TASK: kw_prep**
   - **INPUT:** kw
   - **TABLE:** keywords
   - **EXAMPLE ROW:** `<keyword_id=1, keyword="mapreduce tutorial">`
   - **MAP FUNCTION:** kw_map
     - **RETURNS:** keyword_id int, nterms int, term text, positions [text]
     - **EXAMPLE:**
       - `<keyword_id=1, term="mapreduce", positions="1">`
       - `<keyword_id=1, term="tutorial", positions="2">`

3. **TASK: term_match**
   - **INPUT:** term_join
   - **QUERY:**
     ```sql
     SELECT doc.doc_id, kw.keyword_id, kw.term, kw.terms, doc.positions as doc_positions, kw.positions as kw_positions
     FROM doc_prep doc
     INNER JOIN kw_prep kw ON doc.doc_term = kw.term
     ``
   - **EXAMPLE:**
     - `<doc_id=100, keyword_id=1, term="mapreduce", nterms=2, doc_positions="2,9", kw_positions="1">`
     - `<doc_id=100, keyword_id=1, term="tutorial", nterms=2, doc_positions="3", kw_positions="2">`

4. **REDUCE FUNCTION:** term_reducer
   - **KEYS:** [doc_id, keyword_id]
   - **TRANSITION FUNCTION:** term_transition
     - **RETURNS:** state text
     - **EXAMPLE:** `<state="2,9:3">`
   - **EXAMPLE:**
     - `<doc_id=100, keyword_id=1, count=1>`

5. **FINALIZE FUNCTION:** term_finalizer
   - **RETURNS:** count integer
   - **EXAMPLE:** `<count=1>`

6. **EXECUTE**
   - **INPUT:** final_output
   - **QUERY:**
     ```sql
     SELECT doc.*, kw.*, tm.count
     FROM documents doc, keywords kw, term_match tm
     WHERE doc.doc_id = tm.doc_id AND kw.keyword_id = tm.keyword_id AND tm.count > 0
     ```
   - **EXAMPLE:**
     `<doc_id=100, data="A mapreduce tutorial for keyword matching in Greenplum mapreduce", keyword_id=1, keyword="mapreduce tutorial", count=1>`

7. **STDOUT**
**Query Performance**

Greenplum Database dynamically eliminates irrelevant partitions in a table and optimally allocates memory for different operators in a query. These enhancements scan less data for a query, accelerate query processing, and support more concurrency.

- **Dynamic Partition Elimination**
  
  In Greenplum Database, values available only when a query runs are used to dynamically prune partitions, which improves query processing speed. Enable or disable dynamic partition elimination by setting the server configuration parameter `gp_dynamic_partition_pruning` to `ON` or `OFF`; it is `ON` by default.

- **Memory Optimizations**

  Greenplum Database allocates memory optimally for different operators in a query and frees and re-allocates memory during the stages of processing a query.

  **Note:** Greenplum Database uses GPORCA, the Greenplum next generation query optimizer, by default. GPORCA extends the planning and optimization capabilities of the Postgres optimizer. For information about the features and limitations of GPORCA, see *Overview of GPORCA*.

**Managing Spill Files Generated by Queries**

Greenplum Database creates spill files, also known as workfiles, on disk if it does not have sufficient memory to execute an SQL query in memory. The maximum number of spill files for a given query is governed by the `gp_workfile_limit_files_per_query` server configuration parameter setting. The default value of 100,000 spill files is sufficient for the majority of queries.

If a query creates more than the configured number of spill files, Greenplum Database returns this error:

```
ERROR: number of workfiles per query limit exceeded
```

Greenplum Database may generate a large number of spill files when:

- Data skew is present in the queried data. To check for data skew, see *Checking for Data Distribution Skew*.
- The amount of memory allocated for the query is too low. You control the maximum amount of memory that can be used by a query with the Greenplum Database server configuration parameters `max_statement_mem` and `statement_mem`, or through resource group or resource queue configuration.

You might be able to run the query successfully by changing the query, changing the data distribution, or changing the system memory configuration. The `gp_toolkit gp_workfile_*` views display spill file usage information. You can use this information to troubleshoot and tune queries. The `gp_workfile_*` views are described in *Checking Query Disk Spill Space Usage*.

Additional documentation resources:

- *Memory Consumption Parameters* identifies the memory-related spill file server configuration parameters.
- *Using Resource Groups* describes memory and spill considerations when resource group-based resource management is active.
- *Using Resource Queues* describes memory and spill considerations when resource queue-based resource management is active.

**Query Profiling**

Examine the query plans of poorly performing queries to identify possible performance tuning opportunities.
Greenplum Database devises a query plan for each query. Choosing the right query plan to match the query and data structure is necessary for good performance. A query plan defines how Greenplum Database will run the query in the parallel execution environment.

The query optimizer uses data statistics maintained by the database to choose a query plan with the lowest possible cost. Cost is measured in disk I/O, shown as units of disk page fetches. The goal is to minimize the total execution cost for the plan.

View the plan for a given query with the EXPLAIN command. EXPLAIN shows the query optimizer's estimated cost for the query plan. For example:

```sql
EXPLAIN SELECT * FROM names WHERE id=22;
```

EXPLAIN ANALYZE runs the statement in addition to displaying its plan. This is useful for determining how close the optimizer's estimates are to reality. For example:

```sql
EXPLAIN ANALYZE SELECT * FROM names WHERE id=22;
```

**Note:** In Greenplum Database, the default GPORCA optimizer co-exists with the Postgres Planner. The EXPLAIN output generated by GPORCA is different than the output generated by the Postgres Planner.

By default, Greenplum Database uses GPORCA to generate an execution plan for a query when possible.

When the EXPLAIN ANALYZE command uses GPORCA, the EXPLAIN plan shows only the number of partitions that are being eliminated. The scanned partitions are not shown. To show name of the scanned partitions in the segment logs set the server configuration parameter `gp_log_dynamic_partition_pruning` to on. This example SET command enables the parameter.

```sql
SET gp_log_dynamic_partition_pruning = on;
```

For information about GPORCA, see Querying Data.

### Reading EXPLAIN Output

A query plan is a tree of nodes. Each node in the plan represents a single operation, such as a table scan, join, aggregation, or sort.

Read plans from the bottom to the top: each node feeds rows into the node directly above it. The bottom nodes of a plan are usually table scan operations: sequential, index, or bitmap index scans. If the query requires joins, aggregations, sorts, or other operations on the rows, there are additional nodes above the scan nodes to perform these operations. The topmost plan nodes are usually Greenplum Database motion nodes: redistribute, explicit redistribute, broadcast, or gather motions. These operations move rows between segment instances during query processing.

The output of EXPLAIN has one line for each node in the plan tree and shows the basic node type and the following execution cost estimates for that plan node:

- **cost** —Measured in units of disk page fetches. 1.0 equals one sequential disk page read. The first estimate is the start-up cost of getting the first row and the second is the total cost of getting all rows. The total cost assumes all rows will be retrieved, which is not always true; for example, if the query uses LIMIT, not all rows are retrieved.

  **Note:** The cost values generated by the Pivotal Query Optimizer and the Postgres Planner are not directly comparable. The two optimizers use different cost models, as well as different algorithms, to determine the cost of an execution plan. Nothing can or should be inferred by comparing cost values between the two optimizers.
In addition, the cost generated for any given optimizer is valid only for comparing plan alternatives for a given single query and set of statistics. Different queries can generate plans with different costs, even when keeping the optimizer a constant.

To summarize, the cost is essentially an internal number used by a given optimizer, and nothing should be inferred by examining only the cost value displayed in the EXPLAIN plans.

- **rows** — The total number of rows output by this plan node. This number is usually less than the number of rows processed or scanned by the plan node, reflecting the estimated selectivity of any WHERE clause conditions. Ideally, the estimate for the topmost node approximates the number of rows that the query actually returns, updates, or deletes.
- **width** — The total bytes of all the rows that this plan node outputs.

Note the following:

- The cost of a node includes the cost of its child nodes. The topmost plan node has the estimated total execution cost for the plan. This is the number the optimizer intends to minimize.
- The cost reflects only the aspects of plan execution that the query optimizer takes into consideration. For example, the cost does not reflect time spent transmitting result rows to the client.

**EXPLAIN Example**

The following example describes how to read an EXPLAIN query plan for a query:

```sql
EXPLAIN SELECT * FROM names WHERE name = 'Joelle';
```

```
QUERY PLAN
------------------------------------------------------------
Gather Motion 2:1 (slice1) (cost=0.00..20.88 rows=1 width=13)
  ->  Seq Scan on 'names' (cost=0.00..20.88 rows=1 width=13)
      Filter: name::text ~~ 'Joelle'::text
```

Read the plan from the bottom to the top. To start, the query optimizer sequentially scans the names table. Notice the WHERE clause is applied as a filter condition. This means the scan operation checks the condition for each row it scans and outputs only the rows that satisfy the condition.

The results of the scan operation are passed to a gather motion operation. In Greenplum Database, a gather motion is when segments send rows to the master. In this example, we have two segment instances that send to one master instance. This operation is working on slice1 of the parallel query execution plan. A query plan is divided into slices so the segments can work on portions of the query plan in parallel.

The estimated startup cost for this plan is 00.00 (no cost) and a total cost of 20.88 disk page fetches. The optimizer estimates this query will return one row.

**Reading EXPLAIN ANALYZE Output**

EXPLAIN ANALYZE plans and runs the statement. The EXPLAIN ANALYZE plan shows the actual execution cost along with the optimizer's estimates. This allows you to see if the optimizer's estimates are close to reality. EXPLAIN ANALYZE also shows the following:

- The total runtime (in milliseconds) in which the query executed.
- The memory used by each slice of the query plan, as well as the memory reserved for the whole query statement.
- The number of workers (segments) involved in a plan node operation. Only segments that return rows are counted.
- The maximum number of rows returned by the segment that produced the most rows for the operation. If multiple segments produce an equal number of rows, EXPLAIN ANALYZE shows the segment with the longest <time> to end.
- The segment id of the segment that produced the most rows for an operation.
• For relevant operations, the amount of memory (work_mem) used by the operation. If the work_mem was insufficient to perform the operation in memory, the plan shows the amount of data spilled to disk for the lowest-performing segment. For example:

```
Work_mem used: 64K bytes avg, 64K bytes max (seg0).
Work_mem wanted: 90K bytes avg, 90K bytes max (seg0) to lessen workfile I/O affecting 2 workers.
```

• The time (in milliseconds) in which the segment that produced the most rows retrieved the first row, and the time taken for that segment to retrieve all rows. The result may omit <time> to first row if it is the same as the <time> to end.

**EXPLAIN ANALYZE Examples**

This example describes how to read an EXPLAIN ANALYZE query plan using the same query. The bold parts of the plan show actual timing and rows returned for each plan node, as well as memory and time statistics for the whole query.

```
EXPLAIN ANALYZE SELECT * FROM names WHERE name = 'Joelle';
```

```
QUERY PLAN
------------------------------------------------------------
Gather Motion 2:1 (slice1; segments: 2) (cost=0.00..20.88 rows=1 width=13)
  Rows out: 1 rows at destination with 0.305 ms to first row, 0.537 ms to end, start offset by 0.289 ms.
  -> Seq Scan on names (cost=0.00..20.88 rows=1 width=13)
     Rows out: Avg 1 rows x 2 workers. Max 1 rows (seg0) with 0.255 ms to first row, 0.486 ms to end, start offset by 0.968 ms.
     Filter: name = 'Joelle'::text
Slice statistics:
  (slice0) Executor memory: 135K bytes.
  (slice1) Executor memory: 151K bytes avg x 2 workers, 151K bytes max (seg0).

Statement statistics:
  Memory used: 128000K bytes
  Total runtime: 22.548 ms
```

Read the plan from the bottom to the top. The total elapsed time to run this query was **22.548 milliseconds**.

The **sequential scan** operation had only one segment (seg0) that returned rows, and it returned just 1 row. It took 0.255 milliseconds to find the first row and 0.486 to scan all rows. This result is close to the optimizer's estimate: the query optimizer estimated it would return one row for this query. The **gather motion** (segments sending data to the master) received 1 row. The total elapsed time for this operation was 0.537 milliseconds.

**Determining the Query Optimizer**

You can view EXPLAIN output to determine if GPORCA is enabled for the query plan and whether GPORCA or the Postgres Planner generated the explain plan. The information appears at the end of the EXPLAIN output. The **Settings** line displays the setting of the server configuration parameter OPTIMIZER. The **Optimizer status** line displays whether GPORCA or the Postgres Planner generated the explain plan.

For these two example query plans, GPORCA is enabled, the server configuration parameter OPTIMIZER is on. For the first plan, GPORCA generated the EXPLAIN plan. For the second plan, Greenplum Database fell back to the Postgres Planner to generate the query plan.
Examine Query Plans to Solve Problems

If a query performs poorly, examine its query plan and ask the following questions:

- **Do operations in the plan take an exceptionally long time?** Look for an operation that consumes a large majority of query processing time. For example, if an index scan takes longer than expected, the index might be out-of-date and need to be reindexed. Or, adjust `enable_<operator>` parameters to see if you can force the Postgres Planner to choose a different plan by disabling a particular query plan operator for that query.

- **Are the optimizer's estimates close to reality?** Run `EXPLAIN ANALYZE` and see if the number of rows the optimizer estimates is close to the number of rows the query operation actually returns. If there is a large discrepancy, collect more statistics on the relevant columns.

See the Greenplum Database Reference Guide for more information on the `EXPLAIN` and `ANALYZE` commands.

- **Are selective predicates applied early in the plan?** Apply the most selective filters early in the plan so fewer rows move up the plan tree. If the query plan does not correctly estimate query predicate selectivity, collect more statistics on the relevant columns. See the `ANALYZE` command in the Greenplum Database Reference Guide for more information on collecting statistics. You can also try reordering the `WHERE` clause of your SQL statement.
• **Does the optimizer choose the best join order?** When you have a query that joins multiple tables, make sure that the optimizer chooses the most selective join order. Joins that eliminate the largest number of rows should be done earlier in the plan so fewer rows move up the plan tree.

If the plan is not choosing the optimal join order, set `JOIN_COLLAPSE_LIMIT=1` and use explicit `JOIN` syntax in your SQL statement to force the Postgres Planner to the specified join order. You can also collect more statistics on the relevant join columns.

See the `ANALYZE` command in the *Greenplum Database Reference Guide* for more information collecting statistics.

• **Does the optimizer selectively scan partitioned tables?** If you use table partitioning, is the optimizer selectively scanning only the child tables required to satisfy the query predicates? Scans of the parent tables should return 0 rows since the parent tables do not contain any data. See *Verifying Your Partition Strategy* for an example of a query plan that shows a selective partition scan.

• **Does the optimizer choose hash aggregate and hash join operations where applicable?** Hash operations are typically much faster than other types of joins or aggregations. Row comparison and sorting is done in memory rather than reading/writing from disk. To enable the query optimizer to choose hash operations, there must be sufficient memory available to hold the estimated number of rows. Try increasing work memory to improve performance for a query. If possible, run an `EXPLAIN ANALYZE` for the query to show which plan operations spilled to disk, how much work memory they used, and how much memory was required to avoid spilling to disk. For example:

```sql
Work_mem used: 23430K bytes avg, 23430K bytes max (seg0). Work_mem wanted: 33649K bytes avg, 33649K bytes max (seg0) to lessen workfile I/O affecting 2 workers.
```

The "bytes wanted" message from `EXPLAIN ANALYZE` is based on the amount of data written to work files and is not exact. The minimum `work_mem` needed can differ from the suggested value.
Working with External Data

Both external and foreign tables provide access to data stored in data sources outside of Greenplum Database as if the data were stored in regular database tables. You can read data from and write data to external and foreign tables.

An external table is a Greenplum Database table backed with data that resides outside of the database. You create a readable external table to read data from the external data source and create a writable external table to write data to the external source. You can use external tables in SQL commands just as you would a regular database table. For example, you can SELECT (readable external table), INSERT (writable external table), and join external tables with other Greenplum tables. External tables are most often used to load and unload database data. Refer to Defining External Tables for more information about using external tables to access external data.

Accessing External Data with PXF describes using PXF and external tables to access external data sources.

A foreign table is a different kind of Greenplum Database table backed with data that resides outside of the database. You can both read from and write to the same foreign table. You can similarly use foreign tables in SQL commands as described above for external tables. Refer to Accessing External Data with Foreign Tables for more information about accessing external data using foreign tables.

Web-based external tables provide access to data served by an HTTP server or an operating system process. See Creating and Using External Web Tables for more about web-based tables.

Accessing External Data with PXF

Data managed by your organization may already reside in external sources such as Hadoop, object stores, and other SQL databases. The Greenplum Platform Extension Framework (PXF) provides access to this external data via built-in connectors that map an external data source to a Greenplum Database table definition.

PXF is installed with Hadoop and Object Storage connectors. These connectors enable you to read external data stored in text, Avro, JSON, RCFile, Parquet, SequenceFile, and ORC formats. You can use the JDBC connector to access an external SQL database.

Note: In previous versions of Greenplum Database, you may have used the gphdfs external table protocol to access data stored in Hadoop. Greenplum Database version 6.0.0 removes the gphdfs protocol. Use PXF and the pxf external table protocol to access Hadoop in Greenplum Database version 6.x.

The Greenplum Platform Extension Framework includes a protocol C library and a Java service. After you configure and initialize PXF, you start a single PXF JVM process on each Greenplum Database segment host. This long-running process concurrently serves multiple query requests.

For detailed information about the architecture of and using PXF, refer to the Greenplum Platform Extension Framework (PXF) documentation.

Defining External Tables

External tables enable accessing external data as if it were a regular database table. They are often used to move data into and out of a Greenplum database.

To create an external table definition, you specify the format of your input files and the location of your external data sources. For information about input file formats, see Formatting Data Files.

Use one of the following protocols to access external table data sources. You cannot mix protocols in CREATE EXTERNAL TABLE statements:
• file:// accesses external data files on segment hosts that the Greenplum Database superuser (gpadmin) can access. See file:// Protocol.
• gpfdist:// points to a directory on the file host and serves external data files to all Greenplum Database segments in parallel. See gpfdist:// Protocol.
• gpfdists:// is the secure version of gpfdist. See gpfdists:// Protocol.
• The pxf:// protocol accesses object store systems (Azure, Google Cloud Storage, Minio, S3), external Hadoop systems (HDFS, Hive, HBase), and SQL databases using the Greenplum Platform Extension Framework (PXF). See pxf:// Protocol.
• s3:// accesses files in an Amazon S3 bucket. See s3:// Protocol.

The pxf:// and s3:// protocols are custom data access protocols, where the file://, gpfdist://, and gpfdists:// protocols are implemented internally in Greenplum Database. The custom and internal protocols differ in these ways:

• pxf:// and s3:// are custom protocols that must be registered using the CREATE EXTENSION command (pxf) or the CREATE PROTOCOL command (s3). Registering the PXF extension in a database creates the pxf protocol. (See Accessing External Data with PXF.) To use the s3 protocol, you must configure the database and register the s3 protocol. (See Configuring and Using S3 External Tables.) Internal protocols are always present and cannot be unregistered.
• When a custom protocol is registered, a row is added to the pg_extprotocol catalog table to specify the handler functions that implement the protocol. The protocol's shared libraries must have been installed on all Greenplum Database hosts. The internal protocols are not represented in the pg_extprotocol table and have no additional libraries to install.
• To grant users permissions on custom protocols, you use GRANT [SELECT | INSERT | ALL] ON PROTOCOL. To allow (or deny) users permissions on the internal protocols, you use CREATE ROLE or ALTER ROLE to add the CREATEEXTTABLE (or NOCREATEEXTTABLE) attribute to each user's role.

External tables access external files from within the database as if they are regular database tables. External tables defined with the gpfdist/gpfdists, pxf, and s3 protocols utilize Greenplum parallelism by using the resources of all Greenplum Database segments to load or unload data. The pxf protocol leverages the parallel architecture of the Hadoop Distributed File System to access files on that system. The s3 protocol utilizes the Amazon Web Services (AWS) capabilities.

You can query external table data directly and in parallel using SQL commands such as SELECT, JOIN, or SORT EXTERNAL TABLE DATA, and you can create views for external tables.

The steps for using external tables are:

1. Define the external table.
   To use the pxf or s3 protocol, you must also configure Greenplum Database and enable the protocol. See pxf:// Protocol or s3:// Protocol.
2. Do one of the following:
   • Start the Greenplum Database file server(s) when using the gpfdist or gpfdists protocols.
   • Verify the configuration for the PXF service and start the service.
   • Verify the Greenplum Database configuration for the s3 protocol.
3. Place the data files in the correct locations.
4. Query the external table with SQL commands.

Greenplum Database provides readable and writable external tables:

• Readable external tables for data loading. Readable external tables support:
  • Basic extraction, transformation, and loading (ETL) tasks common in data warehousing
  • Reading external table data in parallel from multiple Greenplum database segment instances, to optimize large load operations
  • Filter pushdown. If a query contains a WHERE clause, it may be passed to the external data source. Refer to the gp_external_enable_filter_pushdown server configuration parameter discussion for
more information. Note that this feature is currently supported only with the `pxf` protocol (see `pxf://` Protocol).

Readable external tables allow only `SELECT` operations.

- Writable external tables for data unloading. Writable external tables support:
  - Selecting data from database tables to insert into the writable external table
  - Sending data to an application as a stream of data. For example, unload data from Greenplum Database and send it to an application that connects to another database or ETL tool to load the data elsewhere
  - Receiving output from Greenplum parallel MapReduce calculations.

Writable external tables allow only `INSERT` operations.

External tables can be file-based or web-based. External tables using the `file://` protocol are read-only tables.

- Regular (file-based) external tables access static flat files. Regular external tables are rescannable: the data is static while the query runs.
- Web (web-based) external tables access dynamic data sources, either on a web server with the `http://` protocol or by executing OS commands or scripts. External web tables are not rescannable: the data can change while the query runs.

Greenplum Database backup and restore operations back up and restore only external and external web table definitions, not the data source data.

file:// Protocol

The `file://` protocol is used in a URI that specifies the location of an operating system file. The URI includes the host name, port, and path to the file. Each file must reside on a segment host in a location accessible by the Greenplum Database superuser (`gpadmin`). The host name used in the URI must match a segment host name registered in the `gp_segment_configuration` system catalog table.

The `LOCATION` clause can have multiple URIs, as shown in this example:

```sql
CREATE EXTERNAL TABLE ext_expenses (name text, date date, amount float4, category text, descl text) LOCATION ('file://host1:5432/data/expense/*.csv', 'file://host2:5432/data/expense/*.csv', 'file://host3:5432/data/expense/*.csv') FORMAT 'CSV' (HEADER);
```

The number of URIs you specify in the `LOCATION` clause is the number of segment instances that will work in parallel to access the external table. For each URI, Greenplum assigns a primary segment on the specified host to the file. For maximum parallelism when loading data, divide the data into as many equally sized files as you have primary segments. This ensures that all segments participate in the load. The number of external files per segment host cannot exceed the number of primary segment instances on that host. For example, if your array has four primary segment instances per segment host, you can place four external files on each segment host. Tables based on the `file://` protocol can only be readable tables.

The system view `pg_max_external_files` shows how many external table files are permitted per external table. This view lists the available file slots per segment host when using the `file://` protocol. The view is only applicable for the `file://` protocol. For example:

```sql
SELECT * FROM pg_max_external_files;
```
**gpfdist:// Protocol**

The gpfdist:// protocol is used in a URI to reference a running gpfdist instance.

The gpfdist utility serves external data files from a directory on a file host to all Greenplum Database segments in parallel.

gpfdist is located in the $GPHOME/bin directory on your Greenplum Database master host and on each segment host.

Run gpfdist on the host where the external data files reside. For readable external tables, gpfdist uncompresses gzip (.gz) and bzip2 (.bz2) files automatically. For writable external tables, data is compressed using gzip if the target file has a .gz extension. You can use the wildcard character (*) or other C-style pattern matching to denote multiple files to read. The files specified are assumed to be relative to the directory that you specified when you started the gpfdist instance.

**Note:** Compression is not supported for readable and writeable external tables when the gpfdist utility runs on Windows platforms.

All primary segments access the external file(s) in parallel, subject to the number of segments set in the gp_external_max_segments server configuration parameter. Use multiple gpfdist data sources in a CREATE EXTERNAL TABLE statement to scale the external table’s scan performance.

gpfdist supports data transformations. You can write a transformation process to convert external data from or to a format that is not directly supported with Greenplum Database external tables.

For more information about configuring gpfdist, see *Using the Greenplum Parallel File Server (gpfdist)*. See the gpfdist reference documentation for more information about using gpfdist with external tables.

**gpfdists:// Protocol**

The gpfdists:// protocol is a secure version of the gpfdist:// protocol.

To use it, you run the gpfdist utility with the --ssl option. When specified in a URI, the gpfdists:// protocol enables encrypted communication and secure identification of the file server and the Greenplum Database to protect against attacks such as eavesdropping and man-in-the-middle attacks.

gpfdists implements SSL security in a client/server scheme with the following attributes and limitations:

- Client certificates are required.
- Multilingual certificates are not supported.
- A Certificate Revocation List (CRL) is not supported.
- The TLSv1 protocol is used with the TLS_RSA_WITH_AES_128_CBC_SHA encryption algorithm.
- SSL parameters cannot be changed.
- SSL renegotiation is supported.
- The SSL ignore host mismatch parameter is set to false.
- Private keys containing a passphrase are not supported for the gpfdist file server (server.key) and for the Greenplum Database (client.key).
- Issuing certificates that are appropriate for the operating system in use is the user’s responsibility. Generally, converting certificates as shown in https://www.sslshopper.com/ssl-converter.html is supported.

**Note:** A server started with the gpfdist --ssl option can only communicate with the gpfdists protocol. A server that was started with gpfdist without the --ssl option can only communicate with the gpfdist protocol.

- The client certificate file, client.crt
- The client private key file, client.key

Use one of the following methods to invoke the gpfdists protocol.
- Run `gpfdist` with the `--ssl` option and then use the `gpfdists` protocol in the LOCATION clause of a CREATE EXTERNAL TABLE statement.
- Use a `gpload` YAML control file with the SSL option set to true. Running `gpload` starts the `gpfdist` server with the `--ssl` option, then uses the `gpfdists` protocol.

Using `gpfdists` requires that the following client certificates reside in the `$PGDATA/gpfdists` directory on each segment:
- The client certificate file, `client.crt`
- The client private key file, `client.key`
- The trusted certificate authorities, `root.crt`

For an example of loading data into an external table security, see Example 3—Multiple `gpfdists` instances.

The server configuration parameter `verify_gpfdists_cert` controls whether SSL certificate authentication is enabled when Greenplum Database communicates with the `gpfdist` utility to either read data from or write data to an external data source. You can set the parameter value to `false` to disable authentication when testing the communication between the Greenplum Database external table and the `gpfdist` utility that is serving the external data. If the value is `false`, these SSL exceptions are ignored:
- The self-signed SSL certificate that is used by `gpfdist` is not trusted by Greenplum Database.
- The host name contained in the SSL certificate does not match the host name that is running `gpfdist`.

Warning: Disabling SSL certificate authentication exposes a security risk by not validating the `gpfdists` SSL certificate.

**pxf:// Protocol**

You can use the Greenplum Platform Extension Framework (PXF) `pxf://` protocol to access data residing in object store systems (Azure, Google Cloud Storage, Minio, S3), external Hadoop systems (HDFS, Hive, HBase), and SQL databases.

The PXF `pxf` protocol is packaged as a Greenplum Database extension. The `pxf` protocol supports reading from external data stores. You can also write text, binary, and parquet-format data with the `pxf` protocol.

When you use the `pxf` protocol to query an external data store, you specify the directory, file, or table that you want to access. PXF requests the data from the data store and delivers the relevant portions in parallel to each Greenplum Database segment instance serving the query.

You must explicitly initialize and start PXF before you can use the `pxf` protocol to read or write external data. You must also enable PXF in each database in which you want to allow users to create external tables to access external data, and grant permissions on the `pxf` protocol to those Greenplum Database users.

For detailed information about configuring and using PXF and the `pxf` protocol, refer to Accessing External Data with PXF.

**s3:// Protocol**

The `s3` protocol is used in a URL that specifies the location of an Amazon S3 bucket and a prefix to use for reading or writing files in the bucket.

Amazon Simple Storage Service (Amazon S3) provides secure, durable, highly-scalable object storage. For information about Amazon S3, see Amazon S3.

You can define read-only external tables that use existing data files in the S3 bucket for table data, or writable external tables that store the data from INSERT operations to files in the S3 bucket. Greenplum Database uses the S3 URL and prefix specified in the protocol URL either to select one or more files for a read-only table, or to define the location and filename format to use when uploading S3 files for INSERT operations to writable tables.
The s3 protocol also supports Dell EMC Elastic Cloud Storage (ECS), an Amazon S3 compatible service.

Note: The pxf protocol can access data in S3 and other object store systems such as Azure, Google Cloud Storage, and Minio. The pxf protocol can also access data in external Hadoop systems (HDFS, Hive, HBase), and SQL databases. See pxf:// Protocol.

This topic contains the sections:

- s3 Protocol Configuration File
- s3 Protocol Limitations
- Using the gpcheckcloud Utility

Configuring and Using S3 External Tables

Follow these basic steps to configure the S3 protocol and use S3 external tables, using the available links for more information. See also s3 Protocol Limitations to better understand the capabilities and limitations of S3 external tables:

1. Configure each database to support the s3 protocol:
   a. In each database that will access an S3 bucket with the s3 protocol, create the read and write functions for the s3 protocol library:

```
CREATE OR REPLACE FUNCTION write_to_s3() RETURNS integer AS
    '$libdir/gps3ext.so', 's3_export' LANGUAGE C STABLE;
```

```
CREATE OR REPLACE FUNCTION read_from_s3() RETURNS integer AS
    '$libdir/gps3ext.so', 's3_import' LANGUAGE C STABLE;
```

b. In each database that will access an S3 bucket, declare the s3 protocol and specify the read and write functions you created in the previous step:

```
CREATE PROTOCOL s3 (writefunc = write_to_s3, readfunc = read_from_s3);
```

Note: The protocol name s3 must be the same as the protocol of the URL specified for the external table you create to access an S3 resource.

The corresponding function is called by every Greenplum Database segment instance. All segment hosts must have access to the S3 bucket.

2. On each Greenplum Database segment, create and install the s3 protocol configuration file:
   a. Create a template s3 protocol configuration file using the gpcheckcloud utility:

```
gpcheckcloud -t > ./mytest_s3.config
```
   b. Edit the template file to specify the accessid and secret required to connect to the S3 location. See s3 Protocol Configuration File for information about other s3 protocol configuration parameters.
   c. Copy the file to the same location and filename for all Greenplum Database segments on all hosts. The default file location is gpseg_data_dir/gpseg_prefixN/s3/s3.conf. gpseg_data_dir is the path to the Greenplum Database segment data directory, gpseg_prefix is the segment prefix, and N is the segment ID. The segment data directory, prefix, and ID are set when you initialize a Greenplum Database system.
If you copy the file to a different location or filename, then you must specify the location with the config parameter in the s3 protocol URL. See About the s3 Protocol config Parameter.

d. Use the gpcheckcloud utility to validate connectivity to the S3 bucket:

```
gpcheckcloud -c "s3://<s3-endpoint>/<s3-bucket> config=./mytest_s3.config"
```

Specify the correct path to the configuration file for your system, as well as the S3 endpoint name and bucket that you want to check. gpcheckcloud attempts to connect to the S3 endpoint and lists any files in the S3 bucket, if available. A successful connection ends with the message:

Your configuration works well.

You can optionally use gpcheckcloud to validate uploading to and downloading from the S3 bucket, as described in Using the gpcheckcloud Utility.

3. After completing the previous steps to create and configure the s3 protocol, you can specify an s3 protocol URL in the CREATE EXTERNAL TABLE command to define S3 external tables. For read-only S3 tables, the URL defines the location and prefix used to select existing data files that comprise the S3 table. For example:

```
CREATE READABLE EXTERNAL TABLE S3TBL (date text, time text, amt int)
LOCATION('s3://s3-us-west-2.amazonaws.com/s3test.example.com/dataset1/normal/config=/home/gpadmin/aws_s3/s3.conf')
FORMAT 'csv';
```

For writable S3 tables, the protocol URL defines the S3 location in which Greenplum database stores data files for the table, as well as a prefix to use when creating files for table INSERT operations. For example:

```
CREATE WRITABLE EXTERNAL TABLE S3WRIT (LIKE S3TBL)
LOCATION('s3://s3-us-west-2.amazonaws.com/s3test.example.com/dataset1/normal/config=/home/gpadmin/aws_s3/s3.conf')
FORMAT 'csv';
```

See About the S3 Protocol URL for more information.

**About the S3 Protocol URL**

For the s3 protocol, you specify a location for files and an optional configuration file location in the LOCATION clause of the CREATE EXTERNAL TABLE command. This is the syntax:

```
's3://S3_endpoint[:port]/bucket_name/[S3_prefix] [region=S3_region]
[config=config_file_location]'
```

The s3 protocol requires that you specify the S3 endpoint and S3 bucket name. Each Greenplum Database segment instance must have access to the S3 location. The optional S3 prefix value is used to select files for read-only S3 tables, or as a filename prefix to use when uploading files for S3 writable tables.

**Note:** The Greenplum Database s3 protocol URL must include the S3 endpoint hostname.

To specify an ECS endpoint (an Amazon S3 compatible service) in the LOCATION clause, you must set the s3 configuration file parameter version to 2. The version parameter controls whether the region parameter is used in the LOCATION clause. You can also specify an Amazon S3 location when the version parameter is 2. For information about version parameter, see s3 Protocol Configuration File.
**Note:** Although the *S3_prefix* is an optional part of the syntax, you should always include an S3 prefix for both writable and read-only S3 tables to separate datasets as part of the *CREATE EXTERNAL TABLE* syntax.

For writable S3 tables, the *s3* protocol URL specifies the endpoint and bucket name where Greenplum Database uploads data files for the table. The S3 bucket permissions must be *Upload/Delete* for the S3 user ID that uploads the files. The S3 file prefix is used for each new file uploaded to the S3 location as a result of inserting data to the table. See *About S3 Data Files*.

For read-only S3 tables, the S3 file prefix is optional. If you specify an *S3_prefix*, then the *s3* protocol selects all files that start with the specified prefix as data files for the external table. The *s3* protocol does not use the slash character (/) as a delimiter, so a slash character following a prefix is treated as part of the prefix itself.

For example, consider the following 5 files that each have the *S3_endpoint* named *s3-us-west-2.amazonaws.com* and the *bucket_name* named *test1*:

- s3://s3-us-west-2.amazonaws.com/test1/abc
- s3://s3-us-west-2.amazonaws.com/test1/abc/
- s3://s3-us-west-2.amazonaws.com/test1/abc/xx
- s3://s3-us-west-2.amazonaws.com/test1/abcdef
- s3://s3-us-west-2.amazonaws.com/test1/abcdefff

- If the S3 URL is provided as `s3://s3-us-west-2.amazonaws.com/test1/abc`, then the `abc` prefix selects all 5 files.
- If the S3 URL is provided as `s3://s3-us-west-2.amazonaws.com/test1/abc/`, then the `abc/` prefix selects the files `s3://s3-us-west-2.amazonaws.com/test1/abc/` and `s3://s3-us-west-2.amazonaws.com/test1/abc/xx`.
- If the S3 URL is provided as `s3://s3-us-west-2.amazonaws.com/test1/abcd`, then the `abcd` prefix selects the files `s3://s3-us-west-2.amazonaws.com/test1/abcdef` and `s3://s3-us-west-2.amazonaws.com/test1/abcdefff`.

Wildcard characters are not supported in an *S3_prefix*; however, the S3 prefix functions as if a wildcard character immediately followed the prefix itself.

All of the files selected by the S3 URL (*S3_endpoint/bucket_name/S3_prefix*) are used as the source for the external table, so they must have the same format. Each file must also contain complete data rows. A data row cannot be split between files. The S3 file permissions must be *Open/Download* and *View* for the S3 user ID that is accessing the files.

For information about the Amazon S3 endpoints see [http://docs.aws.amazon.com/general/latest/gr/rande.html#s3_region](http://docs.aws.amazon.com/general/latest/gr/rande.html#s3_region). For information about S3 buckets and folders, see the Amazon S3 documentation [https://aws.amazon.com/documentation/s3/](https://aws.amazon.com/documentation/s3/). For information about the S3 file prefix, see the Amazon S3 documentation [Listing Keys Hierarchically Using a Prefix and Delimiter](https://aws.amazon.com/documentation/s3/).

The `config` parameter specifies the location of the required *s3* protocol configuration file that contains AWS connection credentials and communication parameters. See *About the s3 Protocol config Parameter*.

### About S3 Data Files

For each *INSERT* operation to a writable S3 table, each Greenplum Database segment uploads a single file to the configured S3 bucket using the filename format `<prefix><segment_id><random>.<extension>[.gz]` where:

- `<prefix>` is the prefix specified in the S3 URL.
- `<segment_id>` is the Greenplum Database segment ID.
- `<random>` is a random number that is used to ensure that the filename is unique.
- `<extension>` describes the file type (.txt or .csv, depending on the value you provide in the *FORMAT* clause of *CREATE WRITABLE EXTERNAL TABLE*). Files created by the `gpcheckcloud` utility always use the extension .data.
• .gz is appended to the filename if compression is enabled for S3 writable tables (the default).
For writable S3 tables, you can configure the buffer size and the number of threads that segments use for uploading files. See s3 Protocol Configuration File.
For read-only S3 tables, all of the files specified by the S3 file location
(S3_endpoint/bucket_name/S3_prefix) are used as the source for the external table and must have the same format. Each file must also contain complete data rows. If the files contain an optional header row, the column names in the header row cannot contain a newline character (\n) or a carriage return (\r). Also, the column delimiter cannot be a newline character (\n) or a carriage return character (\r).
The s3 protocol recognizes the gzip format and uncompress the files. Only the gzip compression format is supported.
The S3 file permissions must be Open/Download and View for the S3 user ID that is accessing the files. Writable S3 tables require the S3 user ID to have Upload/Delete permissions.
For read-only S3 tables, each segment can download one file at a time from S3 location using several threads. To take advantage of the parallel processing performed by the Greenplum Database segments, the files in the S3 location should be similar in size and the number of files should allow for multiple segments to download the data from the S3 location. For example, if the Greenplum Database system consists of 16 segments and there was sufficient network bandwidth, creating 16 files in the S3 location allows each segment to download a file from the S3 location. In contrast, if the location contained only 1 or 2 files, only 1 or 2 segments download data.

s3 Protocol AWS Server-Side Encryption Support
Greenplum Database supports server-side encryption using Amazon S3-managed keys (SSE-S3) for AWS S3 files you access with readable and writable external tables created using the s3 protocol. SSE-S3 encrypts your object data as it writes to disk, and transparently decrypts the data for you when you access it.

Note: The s3 protocol supports SSE-S3 only for Amazon Web Services S3 files. SS3-SE is not supported when accessing files in S3 compatible services.

Your S3 accessid and secret permissions govern your access to all S3 bucket objects, whether the data is encrypted or not. However, you must configure your client to use S3-managed keys for accessing encrypted data.

Refer to Protecting Data Using Server-Side Encryption in the AWS documentation for additional information about AWS Server-Side Encryption.

Configuring S3 Server-Side Encryption
s3 protocol server-side encryption is disabled by default. To take advantage of server-side encryption on AWS S3 objects you write using the Greenplum Database s3 protocol, you must set the server_side_encryption configuration parameter in your s3 configuration file to the value sse-s3:

```
server_side_encryption = sse-s3
```

When the configuration file you provide to a CREATE WRITABLE EXTERNAL TABLE call using the s3 protocol includes the server_side_encryption = sse-s3 setting, Greenplum Database applies encryption headers for you on all INSERT operations on that external table. S3 then encrypts on write the object(s) identified by the URI you provided in the LOCATION clause.
S3 transparently decrypts data during read operations of encrypted files accessed via readable external tables you create using the s3 protocol. No additional configuration is required.

For further encryption configuration granularity, you may consider creating Amazon Web Services S3 Bucket Policy(s), identifying the objects you want to encrypt and the write actions on those objects as described in the Protecting Data Using Server-Side Encryption with Amazon S3-Managed Encryption Keys (SSE-S3) AWS documentation.
s3 Protocol Proxy Support

You can specify a URL that is the proxy that S3 uses to connect to a data source. S3 supports these protocols: HTTP and HTTPS. You can specify a proxy with the s3 protocol configuration parameter proxy or an environment variable. If the configuration parameter is set, the environment variables are ignored.

To specify proxy with an environment variable, you set the environment variable based on the protocol: http_proxy or https_proxy. You can specify a different URL for each protocol by setting the appropriate environment variable. S3 supports these environment variables.

- all_proxy specifies the proxy URL that is used if an environment variable for a specific protocol is not set.
- no_proxy specifies a comma-separated list of hosts names that do not use the proxy specified by an environment variable.

The environment variables must be set must and must be accessible to Greenplum Database on all Greenplum Database hosts.

For information about the configuration parameter proxy, see s3 Protocol Configuration File.

About the s3 Protocol config Parameter

The optional config parameter specifies the location of the required s3 protocol configuration file. The file contains Amazon Web Services (AWS) connection credentials and communication parameters. For information about the file, see s3 Protocol Configuration File.

The configuration file is required on all Greenplum Database segment hosts. This is default location is a location in the data directory of each Greenplum Database segment instance.

```
gpseg_data_dir/gpseg_prefixN/s3/s3.conf
```

The gpseg_data_dir is the path to the Greenplum Database segment data directory, the gpseg_prefix is the segment prefix, and N is the segment ID. The segment data directory, prefix, and ID are set when you initialize a Greenplum Database system.

If you have multiple segment instances on segment hosts, you can simplify the configuration by creating a single location on each segment host. Then you specify the absolute path to the location with the config parameter in the s3 protocol LOCATION clause. This example specifies a location in the gpadmin home directory.

```
LOCATION ('s3://s3-us-west-2.amazonaws.com/test/my_data config=/home/gpadmin/s3.conf')
```

All segment instances on the hosts use the file /home/gpadmin/s3.conf.

s3 Protocol Configuration File

When using the s3 protocol, an s3 protocol configuration file is required on all Greenplum Database segments. The default location is:

```
gpseg_data_dir/gpseg-prefixN/s3/s3.conf
```

The gpseg_data_dir is the path to the Greenplum Database segment data directory, the gpseg-prefix is the segment prefix, and N is the segment ID. The segment data directory, prefix, and ID are set when you initialize a Greenplum Database system.

If you have multiple segment instances on segment hosts, you can simplify the configuration by creating a single location on each segment host. Then you can specify the absolute path to the location with the config parameter in the s3 protocol LOCATION clause. However, note that both read-only and writable S3 external tables use the same parameter values for their connections. If you want to configure protocol parameters differently for read-only and writable S3 tables, then you must use two different s3 protocol
configuration files and specify the correct file in the `CREATE EXTERNAL TABLE` statement when you create each table.

This example specifies a single file location in the `s3` directory of the `gpadmin` home directory:

```sql
config=/home/gpadmin/s3/s3.conf
```

All segment instances on the hosts use the file `/home/gpadmin/s3/s3.conf`. The `s3` protocol configuration file is a text file that consists of a `[default]` section and parameters. This is an example configuration file:

```
[default]
secret = "secret"
accessid = "user access id"
threadnum = 3
chunksize = 67108864
```

You can use the Greenplum Database `gpcheckcloud` utility to test the S3 configuration file. See Using the `gpcheckcloud` Utility.

**s3 Configuration File Parameters**

**accessid**
Required. AWS S3 ID to access the S3 bucket.

**secret**
Required. AWS S3 passcode for the S3 ID to access the S3 bucket.

**autocompress**
For writable S3 external tables, this parameter specifies whether to compress files (using gzip) before uploading to S3. Files are compressed by default if you do not specify this parameter.

**chunksize**
The buffer size that each segment thread uses for reading from or writing to the S3 server. The default is 64 MB. The minimum is 8MB and the maximum is 128MB.

When inserting data to a writable S3 table, each Greenplum Database segment writes the data into its buffer (using multiple threads up to the `threadnum` value) until it is full, after which it writes the buffer to a file in the S3 bucket. This process is then repeated as necessary on each segment until the insert operation completes.

Because Amazon S3 allows a maximum of 10,000 parts for multipart uploads, the minimum `chunksize` value of 8MB supports a maximum insert size of 80GB per Greenplum database segment. The maximum `chunksize` value of 128MB supports a maximum insert size 1.28TB per segment. For writable S3 tables, you must ensure that the `chunksize` setting can support the anticipated table size of your table. See Multipart Upload Overview in the S3 documentation for more information about uploads to S3.

**encryption**
Use connections that are secured with Secure Sockets Layer (SSL). Default value is `true`. The values `true`, `t`, `on`, `yes`, and `y` (case insensitive) are treated as `true`. Any other value is treated as `false`.

If the port is not specified in the URL in the `LOCATION` clause of the `CREATE EXTERNAL TABLE` command, the configuration file `encryption` parameter affects the port used by the `s3` protocol (port 80 for HTTP or port 443 for HTTPS). If the port is specified, that port is used regardless of the encryption setting.

`gpcheckcloud_newline`
When downloading files from an S3 location, the \texttt{gpcheckcloud} utility appends a new line character to last line of a file if the last line of a file does not have an EOL (end of line) character. The default character is \texttt{\n} (newline). The value can be \texttt{\n}, \texttt{\r} (carriage return), or \texttt{\n\r} (newline/carriage return).

Adding an EOL character prevents the last line of one file from being concatenated with the first line of next file.

\texttt{\textbf{low\_speed\_limit}}

The upload/download speed lower limit, in bytes per second. The default speed is 10240 (10K). If the upload or download speed is slower than the limit for longer than the time specified by \texttt{low\_speed\_time}, then the connection is aborted and retried. After 3 retries, the s3 protocol returns an error. A value of 0 specifies no lower limit.

\texttt{\textbf{low\_speed\_time}}

When the connection speed is less than \texttt{low\_speed\_limit}, this parameter specified the amount of time, in seconds, to wait before aborting an upload to or a download from the S3 bucket. The default is 60 seconds. A value of 0 specifies no time limit.

\texttt{\textbf{proxy}}

Specify a URL that is the proxy that S3 uses to connect to a data source. S3 supports these protocols: HTTP and HTTPS. This is the format for the parameter.

\begin{verbatim}
proxy = protocol://[user:password@]proxyhost[:port]
\end{verbatim}

If this parameter is not set or is an empty string (\texttt{proxy = ""}), S3 uses the proxy specified by the environment variable \texttt{http\_proxy} or \texttt{https\_proxy} (and the environment variables \texttt{all\_proxy} and \texttt{no\_proxy}). The environment variable that S3 uses depends on the protocol. For information about the environment variables, see \texttt{s3 Protocol Proxy Support} in the \textit{Greenplum Database Administrator Guide}.

There can be at most one \texttt{proxy} parameter in the configuration file. The URL specified by the parameter is the proxy for all supported protocols.

\texttt{\textbf{server\_side\_encryption}}

The S3 server-side encryption method that has been configured for the bucket. Greenplum Database supports only server-side encryption with Amazon S3-managed keys, identified by the configuration parameter value \texttt{sse-s3}. Server-side encryption is disabled (\texttt{none}) by default.

\texttt{\textbf{threadnum}}

The maximum number of concurrent threads a segment can create when uploading data to or downloading data from the S3 bucket. The default is 4. The minimum is 1 and the maximum is 8.

\texttt{\textbf{verifycert}}

Controls how the s3 protocol handles authentication when establishing encrypted communication between a client and an S3 data source over HTTPS. The value is either \texttt{true} or \texttt{false}. The default value is \texttt{true}.

- \texttt{verifycert=false} - Ignores authentication errors and allows encrypted communication over HTTPS.
- \texttt{verifycert=true} - Requires valid authentication (a proper certificate) for encrypted communication over HTTPS.

Setting the value to \texttt{false} can be useful in testing and development environments to allow communication without changing certificates.

\textbf{Warning:} Setting the value to \texttt{false} exposes a security risk by ignoring invalid credentials when establishing communication between a client and a S3 data store.
version

Specifies the version of the information specified in the LOCATION clause of the CREATE EXTERNAL TABLE command. The value is either 1 or 2. The default value is 1.

If the value is 1, the LOCATION clause supports an Amazon S3 URL, and does not contain the region parameter. If the value is 2, the LOCATION clause supports S3 compatible services and must include the region parameter. The region parameter specifies the S3 data source region. For this S3 URL s3://s3-us-west-2.amazonaws.com/s3test.example.com/dataset1/normal/, the AWS S3 region is us-west-2.

If version is 1 or is not specified, this is an example of the LOCATION clause of the CREATE EXTERNAL TABLE command that specifies an Amazon S3 endpoint.

```
LOCATION ('s3://s3-us-west-2.amazonaws.com/s3test.example.com/dataset1/normal/ config=/home/gpadmin/aws_s3/s3.conf')
```

If version is 2, this is an example LOCATION clause with the region parameter for an AWS S3 compatible service.

```
LOCATION ('s3://test.company.com/s3test.company/test1/normal/ region=local-test config=/home/gpadmin/aws_s3/s3.conf')
```

If version is 2, the LOCATION clause can also specify an Amazon S3 endpoint. This example specifies an Amazon S3 endpoint that uses the region parameter.

```
LOCATION ('s3://s3-us-west-2.amazonaws.com/s3test.example.com/dataset1/normal/ region=us-west-2 config=/home/gpadmin/aws_s3/s3.conf')
```

**Note:** Greenplum Database can require up to threadnum * chunksize memory on each segment host when uploading or downloading S3 files. Consider this s3 protocol memory requirement when you configure overall Greenplum Database memory.

### s3 Protocol Limitations

These are s3 protocol limitations:

- Only the S3 path-style URL is supported.

```
S3_endpoint/bucketname/[S3_prefix]
```

- Only the S3 endpoint is supported. The protocol does not support virtual hosting of S3 buckets (binding a domain name to an S3 bucket).
- AWS signature version 4 signing process is supported.
- Only a single URL and optional configuration file is supported in the LOCATION clause of the CREATE EXTERNAL TABLE command.
- If the NEWLINE parameter is not specified in the CREATE EXTERNAL TABLE command, the newline character must be identical in all data files for specific prefix. If the newline character is different in some data files with the same prefix, read operations on the files might fail.
- For writable S3 external tables, only the INSERT operation is supported. UPDATE, DELETE, and TRUNCATE operations are not supported.
- Because Amazon S3 allows a maximum of 10,000 parts for multipart uploads, the maximum chunksize value of 128MB supports a maximum insert size of 1.28TB per Greenplum database segment for writable s3 tables. You must ensure that the chunksize setting can support the anticipated table size of your table. See Multipart Upload Overview in the S3 documentation for more information about uploads to S3.
• To take advantage of the parallel processing performed by the Greenplum Database segment instances, the files in the S3 location for read-only S3 tables should be similar in size and the number of files should allow for multiple segments to download the data from the S3 location. For example, if the Greenplum Database system consists of 16 segments and there was sufficient network bandwidth, creating 16 files in the S3 location allows each segment to download a file from the S3 location. In contrast, if the location contained only 1 or 2 files, only 1 or 2 segments download data.

Using the gpcheckcloud Utility

The Greenplum Database utility gpcheckcloud helps users create an s3 protocol configuration file and test a configuration file. You can specify options to test the ability to access an S3 bucket with a configuration file, and optionally upload data to or download data from files in the bucket.

If you run the utility without any options, it sends a template configuration file to STDOUT. You can capture the output and create an s3 configuration file to connect to Amazon S3.

The utility is installed in the Greenplum Database $GPHOME/bin directory.

Syntax

```
gpcheckcloud { -c | -d } "s3://S3_endpoint/bucketname/[S3_prefix]
[config=path_to_config_file]"
gpcheckcloud -u <file_to_upload> "s3://S3_endpoint/bucketname/[S3_prefix]
[config=path_to_config_file]"
gpcheckcloud -t
```

Options

- `-c`  
  Connect to the specified S3 location with the configuration specified in the s3 protocol URL and return information about the files in the S3 location.  
  If the connection fails, the utility displays information about failures such as invalid credentials, prefix, or server address (DNS error), or server not available.

- `-d`  
  Download data from the specified S3 location with the configuration specified in the s3 protocol URL and send the output to STDOUT.  
  If files are gzip compressed, the uncompressed data is sent to STDOUT.

- `-u`  
  Upload a file to the S3 bucket specified in the s3 protocol URL using the specified configuration file if available. Use this option to test compression and chunksize and autocompress settings for your configuration.

- `-t`  
  Sends a template configuration file to STDOUT. You can capture the output and create an s3 configuration file to connect to Amazon S3.

- `-h`  
  Display gpcheckcloud help.

Examples

This example runs the utility without options to create a template s3 configuration file mytest_s3.config in the current directory.

```
gpcheckcloud -t > ./mytest_s3.config
```
This example attempts to upload a local file, `test-data.csv` to an S3 bucket location using the `s3` configuration file `s3.mytestconf`:

```
gpcheckcloud -u ./test-data.csv "s3://s3-us-west-2.amazonaws.com/test1/abc config=s3.mytestconf"
```

A successful upload results in one or more files placed in the S3 bucket using the filename format `abc<segment_id><random>.data[.gz]`. See About S3 Data Files.

This example attempts to connect to an S3 bucket location with the `s3` configuration file `s3.mytestconf`:

```
gpcheckcloud -c "s3://s3-us-west-2.amazonaws.com/test1/abc config=s3.mytestconf"
```

Download all files from the S3 bucket location and send the output to `STDOUT`.

```
gpcheckcloud -d "s3://s3-us-west-2.amazonaws.com/test1/abc config=s3.mytestconf"
```

### Using a Custom Protocol

A custom protocol allows you to connect Greenplum Database to a data source that cannot be accessed with the `file://`, `gpfdist://`, or `pxf://` protocols.

Creating a custom protocol requires that you implement a set of C functions with specified interfaces, declare the functions in Greenplum Database, and then use the `CREATE TRUSTED PROTOCOL` command to enable the protocol in the database.

See Example Custom Data Access Protocol for an example.

### Handling Errors in External Table Data

By default, if external table data contains an error, the command fails and no data loads into the target database table.

Define the external table with single row error handling to enable loading correctly formatted rows and to isolate data errors in external table data. See Handling Load Errors.

The `gpfdist` file server uses the HTTP protocol. External table queries that use LIMIT end the connection after retrieving the rows, causing an HTTP socket error. If you use LIMIT in queries of external tables that use the `gpfdist://` or `http://` protocols, ignore these errors – data is returned to the database as expected.

### Creating and Using External Web Tables

External web tables allow Greenplum Database to treat dynamic data sources like regular database tables. Because web table data can change as a query runs, the data is not rescannable.

`CREATE EXTERNAL WEB TABLE` creates a web table definition. You can define command-based or URL-based external web tables. The definition forms are distinct: you cannot mix command-based and URL-based definitions.

#### Command-based External Web Tables

The output of a shell command or script defines command-based web table data. Specify the command in the `EXECUTE` clause of `CREATE EXTERNAL WEB TABLE`. The data is current as of the time the command runs. The `EXECUTE` clause runs the shell command or script on the specified master, and/or segment host or hosts. The command or script must reside on the hosts corresponding to the host(s) defined in the `EXECUTE` clause.
By default, the command is run on segment hosts when active segments have output rows to process. For example, if each segment host runs four primary segment instances that have output rows to process, the command runs four times per segment host. You can optionally limit the number of segment instances that execute the web table command. All segments included in the web table definition in the ON clause run the command in parallel.

The command that you specify in the external table definition executes from the database and cannot access environment variables from .bashrc or .profile. Set environment variables in the EXECUTE clause. For example:

```sql
=# CREATE EXTERNAL WEB TABLE output (output text)  
   EXECUTE 'PATH=/home/gpadmin/programs; export PATH; myprogram.sh'  
   FORMAT 'TEXT';
```

Scripts must be executable by the gpadmin user and reside in the same location on the master or segment hosts.

The following command defines a web table that runs a script. The script runs on each segment host where a segment has output rows to process.

```sql
=# CREATE EXTERNAL WEB TABLE log_output  
   (linenum int, message text)  
   EXECUTE '/var/load_scripts/get_log_data.sh' ON HOST  
   FORMAT 'TEXT' (DELIMITER '|');
```

**URL-based External Web Tables**

A URL-based web table accesses data from a web server using the HTTP protocol. Web table data is dynamic; the data is not rescannable.

Specify the LOCATION of files on a web server using http://. The web data file(s) must reside on a web server that Greenplum segment hosts can access. The number of URLs specified corresponds to the number of segment instances that work in parallel to access the web table. For example, if you specify two external files to a Greenplum Database system with eight primary segments, two of the eight segments access the web table in parallel at query runtime.

The following sample command defines a web table that gets data from several URLs.

```sql
=# CREATE EXTERNAL WEB TABLE ext_expenses (name text,  
    date date, amount float4, category text, description text)  
   LOCATION ('http://intranet.company.com/expenses/sales/file.csv',  
              'http://intranet.company.com/expenses/exec/file.csv',  
              'http://intranet.company.com/expenses/finance/file.csv',  
              'http://intranet.company.com/expenses/ops/file.csv',  
              'http://intranet.company.com/expenses/marketing/file.csv',  
              'http://intranet.company.com/expenses/eng/file.csv')  
   )  
   FORMAT 'CSV' ( HEADER );
```

**Examples for Creating External Tables**

These examples show how to define external data with different protocols. Each CREATE EXTERNAL TABLE command can contain only one protocol.

**Note:** When using IPv6, always enclose the numeric IP addresses in square brackets.
Start `gpfdist` before you create external tables with the `gpfdist` protocol. The following code starts the `gpfdist` file server program in the background on port 8081 serving files from directory `/var/data/staging`. The logs are saved in `/home/gpadmin/log`.

```bash
gpfdist -p 8081 -d /var/data/staging -l /home/gpadmin/log &
```

**Example 1—Single gpfdist instance on single-NIC machine**

Creates a readable external table, `ext_expenses`, using the `gpfdist` protocol. The files are formatted with a pipe (`|`) as the column delimiter.

```sql
=# CREATE EXTERNAL TABLE ext_expenses ( name text,
   date date, amount float4, category text, desc1 text )
   LOCATION ('gpfdist://etlhost-1:8081/*')
   FORMAT 'TEXT' (DELIMITER '|');
```

**Example 2—Multiple gpfdist instances**

Creates a readable external table, `ext_expenses`, using the `gpfdist` protocol from all files with the `.txt` extension. The column delimiter is a pipe (`|`) and NULL (`"`) is a space.

```sql
=# CREATE EXTERNAL TABLE ext_expenses ( name text,
   date date, amount float4, category text, desc1 text )
   LOCATION ('gpfdist://etlhost-1:8081/*.txt',
   'gpfdist://etlhost-2:8082/*.txt')
   FORMAT 'TEXT' ( DELIMITER '|' NULL ' ');
```

**Example 3—Multiple gpfdists instances**

Creates a readable external table, `ext_expenses`, from all files with the `.txt` extension using the `gpfdists` protocol. The column delimiter is a pipe (`|`) and NULL (`"`) is a space. For information about the location of security certificates, see `gpfdists:// Protocol`.

1. Run `gpfdist` with the `--ssl` option.
2. Run the following command.

```sql
=# CREATE EXTERNAL TABLE ext_expenses ( name text,
   date date, amount float4, category text, desc1 text )
   LOCATION ('gpfdists://etlhost-1:8081/*.txt',
   'gpfdists://etlhost-2:8082/*.txt')
   FORMAT 'TEXT' ( DELIMITER '|' NULL ' ');
```

**Example 4—Single gpfdist instance with error logging**

Uses the `gpfdist` protocol to create a readable external table, `ext_expenses`, from all files with the `.txt` extension. The column delimiter is a pipe (`|`) and NULL (`"`) is a space.

Access to the external table is single row error isolation mode. Input data formatting errors are captured internally in Greenplum Database with a description of the error. See `Viewing Bad Rows in the Error Log` for information about investigating error rows. You can view the errors, fix the issues, and then reload the rejected data. If the error count on a segment is greater than five (the `SEGMENT REJECT LIMIT` value), the entire external table operation fails and no rows are processed.

```sql
=# CREATE EXTERNAL TABLE ext_expenses ( name text,
   date date, amount float4, category text, desc1 text )
   LOCATION ('gpfdist://etlhost-1:8081/*.txt',
   'gpfdist://etlhost-2:8082/*.txt')
   FORMAT 'TEXT' ( DELIMITER '|' NULL ' ');
```
To create the readable ext_expenses table from CSV-formatted text files:

```sql
=# CREATE EXTERNAL TABLE ext_expenses ( name text, date date, amount float4, category text, desc1 text )
   LOCATION ('gpfdist://etlhost-1:8081/*.txt',
             'gpfdist://etlhost-2:8082/*.txt')
   FORMAT 'CSV' ( DELIMITER ',',
                  LOG ERRORS SEGMENT REJECT LIMIT 5;)
```

**Example 5—TEXT Format on a Hadoop Distributed File Server**

Creates a readable external table, ext_expenses, using the `pxf` protocol. The column delimiter is a pipe (`|`).

```sql
=# CREATE EXTERNAL TABLE ext_expenses ( name text, date date, amount float4, category text, desc1 text )
   LOCATION ('pxf://dir/data/filename.txt?PROFILE=hdfs:text')
   FORMAT 'TEXT' (DELIMITER '|');
```

Refer to [Accessing External Data with PXF](#) for information about using the Greenplum Platform Extension Framework (PXF) to access data on a Hadoop Distributed File System.

**Example 6—Multiple files in CSV format with header rows**

Creates a readable external table, ext_expenses, using the `file` protocol. The files are CSV format and have a header row.

```sql
=# CREATE EXTERNAL TABLE ext_expenses ( name text, date date, amount float4, category text, desc1 text )
   LOCATION ('file://filehost/data/international/*.csv',
             'file://filehost/data/regional/*.csv')
   FORMAT 'CSV' (HEADER);
```

**Example 7—Readable External Web Table with Script**

Creates a readable external web table that executes a script once per segment host:

```sql
=# CREATE EXTERNAL WEB TABLE log_output (linenum int, message text)
    EXECUTE '/var/load_scripts/get_log_data.sh' ON HOST
    FORMAT 'TEXT' (DELIMITER '|');
```

**Example 8—Writable External Table with gpfdist**

Creates a writable external table, sales_out, that uses gpfdist to write output data to the file sales.out. The column delimiter is a pipe (`|`) and NULL (`"`) is a space. The file will be created in the directory specified when you started the gpfdist file server.

```sql
=# CREATE WRITABLE EXTERNAL TABLE sales_out (LIKE sales)
    LOCATION ('gpfdist://etl1:8081/sales.out')
    FORMAT 'TEXT' ( DELIMITER '|' NULL ' ')
    DISTRIBUTED BY (txn_id);
```
Example 9—Writable External Web Table with Script

Creates a writable external web table, `campaign_out`, that pipes output data received by the segments to an executable script, `to_adreport_etl.sh`:

```sql
=# CREATE WRITABLE EXTERNAL WEB TABLE campaign_out
   (LIKE campaign)
   EXECUTE '/var/unload_scripts/to_adreport_etl.sh'
   FORMAT 'TEXT' (DELIMITER '|');
```

Example 10—Readable and Writable External Tables with XML Transformations

Greenplum Database can read and write XML data to and from external tables with gpfdist. For information about setting up an XML transform, see Transforming External Data with gpfdist and gpload.

Accessing External Data with Foreign Tables

Greenplum Database implements portions of the SQL/MED specification, allowing you to access data that resides outside of Greenplum using regular SQL queries. Such data is referred to as foreign or external data.

You can access foreign data with help from a foreign-data wrapper. A foreign-data wrapper is a library that communicates with a remote data source. This library hides the source-specific connection and data access details.

**Note:** Most PostgreSQL foreign-data wrappers should work with Greenplum Database. However, PostgreSQL foreign-data wrappers connect only through the Greenplum Database master and do not access the Greenplum Database segment instances directly.

If none of the existing foreign-data wrappers suit your needs, you can write your own as described in Writing a Foreign Data Wrapper.

To access foreign data, you create a foreign server object, which defines how to connect to a particular remote data source according to the set of options used by its supporting foreign-data wrapper. Then you create one or more foreign tables, which define the structure of the remote data. A foreign table can be used in queries just like a normal table, but a foreign table has no storage in the Greenplum Database server. Whenever a foreign table is accessed, Greenplum Database asks the foreign-data wrapper to fetch data from, or update data in (if supported by the wrapper), the remote source.

**Note:** The Pivotal Query Optimizer, GPORCA, does not support foreign tables. A query on a foreign table always falls back to the Postgres Planner.

Accessing remote data may require authenticating to the remote data source. This information can be provided by a user mapping, which can provide additional data such as a user name and password based on the current Greenplum Database role.

For additional information, refer to CREATE FOREIGN DATA WRAPPER, CREATE SERVER, CREATE USER MAPPING, and CREATE FOREIGN TABLE.

Writing a Foreign Data Wrapper

This chapter outlines how to write a new foreign-data wrapper.

All operations on a foreign table are handled through its foreign-data wrapper (FDW), a library that consists of a set of functions that the core Greenplum Database server calls. The foreign-data wrapper is responsible for fetching data from the remote data store and returning it to the Greenplum Database executor. If updating foreign-data is supported, the wrapper must handle that, too.

The foreign-data wrappers included in the Greenplum Database open source github repository are good references when trying to write your own. You may want to examine the file_fdw and postgres_fdw...
modules in the contrib/ directory. The CREATE FOREIGN DATA WRAPPER reference page also provides some useful details.

**Note:** The SQL standard specifies an interface for writing foreign-data wrappers. Greenplum Database does not implement that API, however, because the effort to accommodate it into Greenplum would be large, and the standard API hasn't yet gained wide adoption.

This topic includes the following sections:

- Requirements
- Known Issues and Limitations
- Header Files
- Foreign Data Wrapper Functions
- Foreign Data Wrapper Callback Functions
- Foreign Data Wrapper Helper Functions
- Greenplum Database Considerations
- Building a Foreign Data Wrapper Extension with PGXS
- Deployment Considerations

**Requirements**

When you develop with the Greenplum Database foreign-data wrapper API:

- You must develop your code on a system with the same hardware and software architecture as that of your Greenplum Database hosts.
- Your code must be written in a compiled language such as C, using the version-1 interface. For details on C language calling conventions and dynamic loading, refer to C Language Functions in the PostgreSQL documentation.
- Symbol names in your object files must not conflict with each other nor with symbols defined in the Greenplum Database server. You must rename your functions or variables if you get error messages to this effect.
- Review the foreign table introduction described in Accessing External Data with Foreign Tables.

**Known Issues and Limitations**

The Greenplum Database 6 foreign-data wrapper implementation has the following known issues and limitations:

- The Greenplum Database 6 distribution does not install any foreign data wrappers.
- Greenplum Database uses the mpp_execute option value for foreign table scans only. Greenplum does not honor the mpp_execute setting when you write to, or update, a foreign table; all write operations are initiated through the master.

**Header Files**

The Greenplum Database header files that you may use when you develop a foreign-data wrapper are located in the greenplum-db/src/include/ directory (when developing against the Greenplum Database open source github repository), or installed in the $GPHOME/include/postgresql/server/ directory (when developing against a Greenplum installation):

- foreign/fdwapi.h - FDW API structures and callback function signatures
- foreign/foreign.h - foreign-data wrapper helper structs and functions
- catalog/pg_foreign_table.h - foreign table definition
- catalog/pg_foreign_server.h - foreign server definition

Your FDW code may also be dependent on header files and libraries required to access the remote data store.
**Foreign Data Wrapper Functions**

The developer of a foreign-data wrapper must implement an SQL-invokable *handler* function, and optionally an SQL-invokable *validator* function. Both functions must be written in a compiled language such as C, using the version-1 interface.

The *handler* function simply returns a struct of function pointers to callback functions that will be called by the Greenplum Database planner, executor, and various maintenance commands. The *handler* function must be registered with Greenplum Database as taking no arguments and returning the special pseudo-type `fdw_handler`. For example:

```sql
CREATE FUNCTION NEW_fdw_handler()
  RETURNS fdw_handler
  AS 'MODULE_PATHNAME'
  LANGUAGE C STRICT;
```

Most of the effort in writing a foreign-data wrapper is in implementing the callback functions. The FDW API callback functions, plain C functions that are not visible or callable at the SQL level, are described in Foreign Data Wrapper Callback Functions.

The *validator* function is responsible for validating options provided in `CREATE` and `ALTER` commands for its foreign-data wrapper, as well as foreign servers, user mappings, and foreign tables using the wrapper. The *validator* function must be registered as taking two arguments, a text array containing the options to be validated, and an OID representing the type of object with which the options are associated. For example:

```sql
CREATE FUNCTION NEW_fdw_validator( text[], oid )
  RETURNS void
  AS 'MODULE_PATHNAME'
  LANGUAGE C STRICT;
```

The OID argument reflects the type of the system catalog that the object would be stored in, one of `ForeignDataWrapperRelationId`, `ForeignServerRelationId`, `UserMappingRelationId`, or `ForeignTableRelationId`. If no *validator* function is supplied by a foreign data wrapper, Greenplum Database does not check option validity at object creation time or object alteration time.

**Foreign Data Wrapper Callback Functions**

The foreign-data wrapper API defines callback functions that Greenplum Database invokes when scanning and updating foreign tables. The API also includes callbacks for performing explain and analyze operations on a foreign table.

The *handler* function of a foreign-data wrapper returns a `palloc'd FdwRoutine` struct containing pointers to callback functions described below. The `FdwRoutine` struct is located in the `foreign/fdwapi.h` header file, and is defined as follows:

```c
typedef struct FdwRoutine
{
    NodeTag  type;
    /* Functions for scanning foreign tables */
} */
```

More function pointers are likely to be added in the future. Therefore, it's recommended that the handler initialize the struct with `makeNode(FdwRoutine)` so that all fields are set to `NULL`. This will ensure that no fields are accidentally left undefined.

```c
typedef struct FdwRoutine
{
    NodeTag  type;
    /* Functions for scanning foreign tables */
} */
```
GetForeignRelSize_function GetForeignRelSize;
GetForeignPaths_function GetForeignPaths;
GetForeignPlan_function GetForeignPlan;
BeginForeignScan_function BeginForeignScan;
IterateForeignScan_function IterateForeignScan;
ReScanForeignScan_function ReScanForeignScan;
EndForeignScan_function EndForeignScan;

/*
 * Remaining functions are optional. Set the pointer to NULL for any that
 * are not provided.
 */

/* Functions for updating foreign tables */
AddForeignUpdateTargets_function AddForeignUpdateTargets;
PlanForeignModify_function PlanForeignModify;
BeginForeignModify_function BeginForeignModify;
ExecForeignInsert_function ExecForeignInsert;
ExecForeignUpdate_function ExecForeignUpdate;
ExecForeignDelete_function ExecForeignDelete;
EndForeignModify_function EndForeignModify;
IsForeignRelUpdatable_function IsForeignRelUpdatable;

/* Support functions for EXPLAIN */
ExplainForeignScan_function ExplainForeignScan;
ExplainForeignModify_function ExplainForeignModify;

/* Support functions for ANALYZE */
AnalyzeForeignTable_function AnalyzeForeignTable;
}

You must implement the scan-related functions in your foreign-data wrapper; implementing the other
callback functions is optional.
Scan-related callback functions include:

<table>
<thead>
<tr>
<th>Callback Signature</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void GetForeignRelSize</td>
<td>Obtain relation size estimates for a foreign table. Called at the beginning of planning for a query on a foreign table.</td>
</tr>
<tr>
<td>(PlannerInfo *root, RelOptInfo *baserel, Oid foreigntableid)</td>
<td></td>
</tr>
<tr>
<td>void GetForeignPaths</td>
<td>Create possible access paths for a scan on a foreign table. Called during query planning.</td>
</tr>
<tr>
<td>(PlannerInfo *root, RelOptInfo *baserel, Oid foreigntableid)</td>
<td>Note: A Greenplum Database-compatible FDW must call create_foreignscan_path() in its GetForeignPaths() callback function.</td>
</tr>
<tr>
<td>ForeignScan * GetForeignPlan</td>
<td>Create a ForeignScan plan node from the selected foreign access path. Called at the end of query planning.</td>
</tr>
<tr>
<td>(PlannerInfo *root, RelOptInfo *baserel, Oid foreigntableid, ForeignPath *best_path, List *tlist, List *scan_clauses)</td>
<td></td>
</tr>
<tr>
<td>void BeginForeignScan</td>
<td>Begin executing a foreign scan. Called during executor startup.</td>
</tr>
<tr>
<td>(ForeignScanState *node, int eflags)</td>
<td></td>
</tr>
<tr>
<td>TupleTableSlot * IterateForeignScan</td>
<td>Fetch one row from the foreign source, returning it in a tuple table slot; return NULL if no more rows are available.</td>
</tr>
<tr>
<td>(ForeignScanState *node)</td>
<td></td>
</tr>
<tr>
<td>void ReScanForeignScan</td>
<td>Restart the scan from the beginning.</td>
</tr>
<tr>
<td>(ForeignScanState *node)</td>
<td></td>
</tr>
<tr>
<td>void</td>
<td>End the scan and release resources.</td>
</tr>
</tbody>
</table>
**Callback Signature** | **Description**
--- | ---
EndForeignScan
(ForeignScanState
*node) |  

Refer to *Foreign Data Wrapper Callback Routines* in the PostgreSQL documentation for detailed information about the inputs and outputs of the FDW callback functions.

**Foreign Data Wrapper Helper Functions**

The FDW API exports several helper functions from the Greenplum Database core server so that authors of foreign-data wrappers have easy access to attributes of FDW-related objects, such as options provided when the user creates or alters the foreign-data wrapper, server, or foreign table. To use these helper functions, you must include `foreign.h` header file in your source file:

```
#include "foreign/foreign.h"
```
The FDW API includes the helper functions listed in the table below. Refer to *Foreign Data Wrapper Helper Functions* in the PostgreSQL documentation for more information about these functions.

<table>
<thead>
<tr>
<th>Helper Signature</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>ForeignDataWrapper * GetForeignDataWrapper(Oid fdwid);</code></td>
<td>Returns the <code>ForeignDataWrapper</code> object for the foreign-data wrapper with the given OID.</td>
</tr>
<tr>
<td><code>ForeignDataWrapper * GetForeignDataWrapperByName(const char *name, bool missing_ok);</code></td>
<td>Returns the <code>ForeignDataWrapper</code> object for the foreign-data wrapper with the given name.</td>
</tr>
<tr>
<td><code>ForeignServer * GetForeignServer(Oid serverid);</code></td>
<td>Returns the <code>ForeignServer</code> object for the foreign server with the given OID.</td>
</tr>
<tr>
<td><code>ForeignServer * GetForeignServerByName(const char *name, bool missing_ok);</code></td>
<td>Returns the <code>ForeignServer</code> object for the foreign server with the given name.</td>
</tr>
<tr>
<td><code>UserMapping * GetUserMapping(Oid userid, Oid serverid);</code></td>
<td>Returns the <code>UserMapping</code> object for the user mapping of the given role on the given server.</td>
</tr>
<tr>
<td><code>ForeignTable * GetForeignTable(Oid relid);</code></td>
<td>Returns the <code>ForeignTable</code> object for the foreign table with the given OID.</td>
</tr>
<tr>
<td><code>List * GetForeignColumnOptions(Oid relid, AttrNumber attnum);</code></td>
<td>Returns the per-column FDW options for the column with the given foreign table OID and attribute number.</td>
</tr>
</tbody>
</table>

**Greenplum Database Considerations**

A Greenplum Database user can specify the `mpp_execute` option when they create or alter a foreign table, foreign server, or foreign data wrapper. A Greenplum Database-compatible foreign-data wrapper examines the `mpp_execute` option value on a scan and uses it to determine where to request data - from the master (the default), any (master or any one segment), or all segments.

**Note:** Write/update operations using a foreign data wrapper are always executed on the Greenplum Database master, regardless of the `mpp_execute` setting.

The following scan code snippet probes the `mpp_execute` value associated with a foreign table:

```c
ForeignTable *table = GetForeignTable(foreign_table_id);
if (table->exec_location == FTEXECLOCATION_ALL_SEGMENTS)
{
    ...}
```
else if (table->exec_location == FTEXECLOCATION_ANY) {
    ...
} else if (table->exec_location == FTEXECLOCATION_MASTER) {
    ...
}

If the foreign table was not created with an `mpp_execute` option setting, the `mpp_execute` setting of the foreign server, and then the foreign data wrapper, is probed and used. If none of the foreign-data-related objects has an `mpp_execute` setting, the default setting is `master`.

If a foreign-data wrapper supports `mpp_execute 'all'`, it will implement a policy that matches Greenplum segments to data. So as not to duplicate data retrieved from the remote, the FDW on each segment must be able to establish which portion of the data is their responsibility. An FDW may use the segment identifier and the number of segments to help make this determination. The following code snippet demonstrates how a foreign-data wrapper may retrieve the segment number and total number of segments:

```c
int segmentNumber = GpIdentity.segindex;
int totalNumberOfSegments = getgpsegmentCount();
```

### Building a Foreign Data Wrapper Extension with PGXS

You compile the foreign-data wrapper functions that you write with the FDW API into one or more shared libraries that the Greenplum Database server loads on demand.

You can use the PostgreSQL build extension infrastructure (PGXS) to build the source code for your foreign-data wrapper against a Greenplum Database installation. This framework automates common build rules for simple modules. If you have a more complicated use case, you will need to write your own build system.

To use the PGXS infrastructure to generate a shared library for your FDW, create a simple `Makefile` that sets PGXS-specific variables.

**Note:** Refer to *Extension Building Infrastructure* in the PostgreSQL documentation for information about the `Makefile` variables supported by PGXS.

For example, the following `Makefile` generates a shared library in the current working directory named `base_fdw.so` from two C source files, `base_fdw_1.c` and `base_fdw_2.c`:

```makefile
MODULE_big = base_fdw
OBJS = base_fdw_1.o base_fdw_2.o
PG_CONFIG = pg_config
PGXS := $(shell $(PG_CONFIG) --pgxs)
PG_CPPFLAGS = -I$(shell $(PG_CONFIG) --includedir)
SHELlib_LINK = -L$(shell $(PG_CONFIG) --libdir)
include $(PGXS)
```

A description of the directives used in this `Makefile` follows:

- `MODULE_big` - identifies the base name of the shared library generated by the `Makefile`
- `PG_CPPFLAGS` - adds the Greenplum Database installation `include/` directory to the compiler header file search path
- `SHELlib_LINK` adds the Greenplum Database installation library directory (`$GPHOME/lib/`) to the linker search path
- The `PG_CONFIG` and `PGXS` variable settings and the `include` statement are required and typically reside in the last three lines of the `Makefile`.  

To package the foreign-data wrapper as a Greenplum Database extension, you create script (newfdw--version.sql) and control (newfdw.control) files that register the FDW handler and validator functions, create the foreign data wrapper, and identify the characteristics of the FDW shared library file.

**Note:** *Packaging Related Objects into an Extension* in the PostgreSQL documentation describes how to package an extension.

Example foreign-data wrapper extension script file named `base_fdw--1.0.sql`:

```sql
CREATE FUNCTION base_fdw_handler()
    RETURNS fdw_handler
    AS 'MODULE_PATHNAME'
    LANGUAGE C STRICT;

CREATE FUNCTION base_fdw_validator(text[], oid)
    RETURNS void
    AS 'MODULE_PATHNAME'
    LANGUAGE C STRICT;

CREATE FOREIGN DATA WRAPPER base_fdw
    HANDLER base_fdw_handler
    VALIDATOR base_fdw_validator;
```

Example FDW control file named `base_fdw.control`:

```ini
# base_fdw FDW extension
comment = 'base foreign-data wrapper implementation; does not do much'
default_version = '1.0'
module_pathname = '$libdir/base_fdw'
relocatable = true
```

When you add the following directives to the Makefile, you identify the FDW extension control file basename (EXTENSION) and SQL script (DATA):

```makefile
EXTENSION = base_fdw
DATA = base_fdw--1.0.sql
```

Running `make install` with these directives in the Makefile copies the shared library and FDW SQL and control files into the specified or default locations in your Greenplum Database installation ($GPHOME).

**Deployment Considerations**

You must package the FDW shared library and extension files in a form suitable for deployment in a Greenplum Database cluster. When you construct and deploy the package, take into consideration the following:

- The FDW shared library must be installed to the same file system location on the master host and on every segment host in the Greenplum Database cluster. You specify this location in the .control file. This location is typically the $GPHOME/lib/postgresql/ directory.
- The FDW .sql and .control files must be installed to the $GPHOME/share/postgresql/extension/ directory on the master host and on every segment host in the Greenplum Database cluster.
- The gpadmin user must have permission to traverse the complete file system path to the FDW shared library file and extension files.
Using the Greenplum Parallel File Server (gpfdist)

The gpfdist protocol is used in a CREATE EXTERNAL TABLE SQL command to access external data served by the Greenplum Database gpfdist file server utility. When external data is served by gpfdist, all segments in the Greenplum Database system can read or write external table data in parallel.

This topic describes the setup and management tasks for using gpfdist with external tables.

- About gpfdist and External Tables
- About gpfdist Setup and Performance
- Controlling Segment Parallelism
- Installing gpfdist
- Starting and Stopping gpfdist
- Troubleshooting gpfdist

About gpfdist and External Tables

The gpfdist file server utility is located in the $GPHOME/bin directory on your Greenplum Database master host and on each segment host. When you start a gpfdist instance you specify a listen port and the path to a directory containing files to read or where files are to be written. For example, this command runs gpfdist in the background, listening on port 8801, and serving files in the /home/gpadmin/external_files directory:

```
$ gpfdist -p 8801 -d /home/gpadmin/external_files &
```

The CREATE EXTERNAL TABLE command LOCATION clause connects an external table definition to one or more gpfdist instances. If the external table is readable, the gpfdist server reads data records from files from in specified directory, packs them into a block, and sends the block in a response to a Greenplum Database segment's request. The segments unpack rows they receive and distribute them according to the external table's distribution policy. If the external table is a writable table, segments send blocks of rows in a request to gpfdist and gpfdist writes them to the external file.

External data files can contain rows in CSV format or any delimited text format supported by the FORMAT clause of the CREATE EXTERNAL TABLE command. In addition, gpfdist can be configured with a YAML-formatted file to transform external data files between a supported text format and another format, for example XML or JSON. See <ref> for an example that shows how to use gpfdist to read external XML files into a Greenplum Database readable external table.

For readable external tables, gpfdist uncompresses gzip (.gz) and bzip2 (.bz2) files automatically. You can use the wildcard character (*) or other C-style pattern matching to denote multiple files to read. External files are assumed to be relative to the directory specified when you started the gpfdist instance.

About gpfdist Setup and Performance

You can run gpfdist instances on multiple hosts and you can run multiple gpfdist instances on each host. This allows you to deploy gpfdist servers strategically so that you can attain fast data load and unload rates by utilizing all of the available network bandwidth and Greenplum Database's parallelism.

- Allow network traffic to use all ETL host network interfaces simultaneously. Run one instance of gpfdist for each interface on the ETL host, then declare the host name of each NIC in the LOCATION clause of your external table definition (see Examples for Creating External Tables).
Figure 25: External Table Using Single gpfdist Instance with Multiple NICs

- Divide external table data equally among multiple gpfdist instances on the ETL host. For example, on an ETL system with two NICs, run two gpfdist instances (one on each NIC) to optimize data load performance and divide the external table data files evenly between the two gpfdist servers.

Figure 26: External Tables Using Multiple gpfdist Instances with Multiple NICs
**Note:** Use pipes (|) to separate formatted text when you submit files to `gpfdist`. Greenplum Database encloses comma-separated text strings in single or double quotes. `gpfdist` has to remove the quotes to parse the strings. Using pipes to separate formatted text avoids the extra step and improves performance.

### Controlling Segment Parallelism

The `gp_external_max_segs` server configuration parameter controls the number of segment instances that can access a single `gpfdist` instance simultaneously. 64 is the default. You can set the number of segments such that some segments process external data files and some perform other database processing. Set this parameter in the `postgresql.conf` file of your master instance.

### Installing gpfdist

`gpfdist` is installed in `$GPHOME/bin` of your Greenplum Database master host installation. Run `gpfdist` on a machine other than the Greenplum Database master or standby master, such as on a machine devoted to ETL processing. Running `gpfdist` on the master or standby master can have a performance impact on query execution. To install `gpfdist` on your ETL server, get it from the *Greenplum Load Tools* package and follow its installation instructions.

### Starting and Stopping gpfdist

You can start `gpfdist` in your current directory location or in any directory that you specify. The default port is 8080.

From your current directory, type:

```
gpfdist &
```

From a different directory, specify the directory from which to serve files, and optionally, the HTTP port to run on.

To start `gpfdist` in the background and log output messages and errors to a log file:

```
$ gpfdist -d /var/load_files -p 8081 -l /home/gpadmin/log &
```

For multiple `gpfdist` instances on the same ETL host (see *Figure 25: External Table Using Single gpfdist Instance with Multiple NICs*), use a different base directory and port for each instance. For example:

```
$ gpfdist -d /var/load_files1 -p 8081 -l /home/gpadmin/log1 &
$ gpfdist -d /var/load_files2 -p 8082 -l /home/gpadmin/log2 &
```

To stop `gpfdist` when it is running in the background:

First find its process id:

```
$ ps -ef | grep gpfdist
```

Then kill the process, for example (where 3456 is the process ID in this example):

```
$ kill 3456
```
Troubleshooting gpfdist

The segments access gpfdist at runtime. Ensure that the Greenplum segment hosts have network access to gpfdist. gpfdist is a web server: test connectivity by running the following command from each host in the Greenplum array (segments and master):

$ wget http://gpfdist_hostname:port/filename

The CREATE EXTERNAL TABLE definition must have the correct host name, port, and file names for gpfdist. Specify file names and paths relative to the directory from which gpfdist serves files (the directory path specified when gpfdist started). See Examples for Creating External Tables.

If you start gpfdist on your system and IPv6 networking is disabled, gpfdist displays this warning message when testing for an IPv6 port.

[WRN gpfdist.c:2050] Creating the socket failed

If the corresponding IPv4 port is available, gpfdist uses that port and the warning for IPv6 port can be ignored. To see information about the ports that gpfdist tests, use the -V option.

For information about IPv6 and IPv4 networking, see your operating system documentation.

When reading or writing data with the gpfdist or gfdists protocol, the gpfdist utility rejects HTTP requests that do not include X-GP-PROTO in the request header. If X-GP-PROTO is not detected in the header request gpfdist returns a 400 error in the status line of the HTTP response header: 400 invalid request (no gp-proto).

Greenplum Database includes X-GP-PROTO in the HTTP request header to indicate that the request is from Greenplum Database.

If the gpfdist utility hangs with no read or write activity occurring, you can generate a core dump the next time a hang occurs to help debug the issue. Set the environment variable GPFDIST_WATCHDOG_TIMER to the number of seconds of no activity to wait before gpfdist is forced to exit. When the environment variable is set and gpfdist hangs, the utility aborts after the specified number of seconds, creates a core dump, and sends abort information to the log file.

This example sets the environment variable on a Linux system so that gpfdist exits after 300 seconds (5 minutes) of no activity.

export GPFDIST_WATCHDOG_TIMER=300
Loading and Unloading Data

The topics in this section describe methods for loading and writing data into and out of a Greenplum Database, and how to format data files.

Greenplum Database supports high-performance parallel data loading and unloading, and for smaller amounts of data, single file, non-parallel data import and export.

Greenplum Database can read from and write to several types of external data sources, including text files, Hadoop file systems, Amazon S3, and web servers.

- The `COPY` SQL command transfers data between an external text file on the master host, or multiple text files on segment hosts, and a Greenplum Database table.
- Readable external tables allow you to query data outside of the database directly and in parallel using SQL commands such as `SELECT, JOIN, or SORT EXTERNAL TABLE DATA`, and you can create views for external tables. External tables are often used to load external data into a regular database table using a command such as `CREATE TABLE table AS SELECT * FROM ext_table`.
- External web tables provide access to dynamic data. They can be backed with data from URLs accessed using the HTTP protocol or by the output of an OS script running on one or more segments.
- The `gpfdist` utility is the Greenplum Database parallel file distribution program. It is an HTTP server that is used with external tables to allow Greenplum Database segments to load external data in parallel, from multiple file systems. You can run multiple instances of `gpfdist` on different hosts and network interfaces and access them in parallel.
- The `gpload` utility automates the steps of a load task using `gpfdist` and a YAML-formatted control file.
- You can create readable and writable external tables with the Greenplum Platform Extension Framework (PXF), and use these tables to load data into, or offload data from, Greenplum Database. For information about using PXF, refer to Accessing External Data with PXF.
- The Greenplum-Kafka Integration provides high-speed, parallel data transfer from Kafka to Greenplum Database. For information about using these tools, refer to the documentation at Pivotal Greenplum-Kafka Integration.
- The Greenplum-Spark Connector provides high speed, parallel data transfer between Pivotal Greenplum Database and Apache Spark. For information about using the Greenplum-Spark Connector, refer to the documentation at https://greenplum-spark.docs.pivotal.io/.
- The Greenplum-Informatica Connector provides high speed data transfer from an Informatica PowerCenter cluster to a Pivotal Greenplum Database cluster for batch and streaming ETL operations. For information about using the Greenplum-Informatica Connector, refer to the documentation at https://greenplum-informatica.docs.pivotal.io/.

The method you choose to load data depends on the characteristics of the source data—its location, size, format, and any transformations required.

In the simplest case, the `COPY` SQL command loads data into a table from a text file that is accessible to the Greenplum Database master instance. This requires no setup and provides good performance for smaller amounts of data. With the `COPY` command, the data copied into or out of the database passes between a single file on the master host and the database. This limits the total size of the dataset to the capacity of the file system where the external file resides and limits the data transfer to a single file write stream.

More efficient data loading options for large datasets take advantage of the Greenplum Database MPP architecture, using the Greenplum Database segments to load data in parallel. These methods allow data to load simultaneously from multiple file systems, through multiple NICs, on multiple hosts, achieving very high data transfer rates. External tables allow you to access external files from within the database as if they are regular database tables. When used with `gpfdist`, the Greenplum Database parallel file distribution program, external tables provide full parallelism by using the resources of all Greenplum Database segments to load or unload data.
Greenplum Database leverages the parallel architecture of the Hadoop Distributed File System to access files on that system.

### Loading Data Using an External Table

Use SQL commands such as `INSERT` and `SELECT` to query a readable external table, the same way that you query a regular database table. For example, to load travel expense data from an external table, `ext_expenses`, into a database table, `expenses_travel`:

```
=# INSERT INTO expenses_travel
    SELECT * from ext_expenses where category='travel';
```

To load all data into a new database table:

```
=# CREATE TABLE expenses AS SELECT * from ext_expenses;
```

### Loading and Writing Non-HDFS Custom Data

Greenplum Database supports `TEXT` and `CSV` formats for importing and exporting data through external tables. You can load and save data in other formats by defining a custom format or custom protocol or by setting up a transformation with the `gpfdist` parallel file server.

#### Using a Custom Format

You specify a custom data format in the `FORMAT` clause of `CREATE EXTERNAL TABLE`.

```
FORMAT 'CUSTOM' (formatter=format_function, key1=val1,...keyn=valn)
```

Where the `CUSTOM` keyword indicates that the data has a custom format and `formatter` specifies the function to use to format the data, followed by comma-separated parameters to the formatter function.

Greenplum Database provides functions for formatting fixed-width data, but you must author the formatter functions for variable-width data. The steps are as follows.

1. Author and compile input and output functions as a shared library.
2. Specify the shared library function with `CREATE FUNCTION` in Greenplum Database.
3. Use the `formatter` parameter of `CREATE EXTERNAL TABLE`'s `FORMAT` clause to call the function.

#### Importing and Exporting Fixed Width Data

Specify custom formats for fixed-width data with the Greenplum Database functions `fixedwith_in` and `fixedwidth_out`. These functions already exist in the file `$GPHOME/share/postgresql/cdb_external_extensions.sql`. The following example declares a custom format, then calls the `fixedwidth_in` function to format the data.

```
CREATE READABLE EXTERNAL TABLE students (
    name varchar(20), address varchar(30), age int)
LOCATION ('file://<host>/file/path/')
FORMAT 'CUSTOM' (formatter=fixedwidth_in,
                   name='20', address='30', age='4');
```

The following options specify how to import fixed width data.

- Read all the data.

  To load all the fields on a line of fixed with data, you must load them in their physical order. You must specify the field length, but cannot specify a starting and ending position. The fields names in the fixed width arguments must match the order in the field list at the beginning of the `CREATE TABLE` command.
• Set options for blank and null characters.

  Trailing blanks are trimmed by default. To keep trailing blanks, use the preserve_blanks=on option. You can reset the trailing blanks option to the default with the preserve_blanks=off option.

  Use the null='null_string_value' option to specify a value for null characters.

• If you specify preserve_blanks=on, you must also define a value for null characters.

• If you specify preserve_blanks=off, null is not defined, and the field contains only blanks, Greenplum writes a null to the table. If null is defined, Greenplum writes an empty string to the table.

Use the line_delim='line_ending' parameter to specify the line ending character. The following examples cover most cases. The \E specifies an escape string constant.

```
line_delim=E'\n'
line_delim=E'\r'
line_delim=E'\r\n'
line_delim='abc'
```

**Examples: Read Fixed-Width Data**

The following examples show how to read fixed-width data.

**Example 1 – Loading a table with all fields defined**

```sql
CREATE READABLE EXTERNAL TABLE students (  
  name varchar(20), address varchar(30), age int)  
LOCATION ('file://<host>/file/path/')  
FORMAT 'CUSTOM' (formatter=fixedwidth_in,  
  name=20, address=30, age=4);
```

**Example 2 – Loading a table with PRESERVED_BLANKS on**

```sql
CREATE READABLE EXTERNAL TABLE students (  
  name varchar(20), address varchar(30), age int)  
LOCATION ('gpfdist://<host>:<portNum>/file/path/')  
FORMAT 'CUSTOM' (formatter=fixedwidth_in,  
  name=20, address=30, age=4,  
  preserve_blanks='on',null='NULL');
```

**Example 3 – Loading data with no line delimiter**

```sql
CREATE READABLE EXTERNAL TABLE students (  
  name varchar(20), address varchar(30), age int)  
LOCATION ('file://<host>/file/path/')  
FORMAT 'CUSTOM' (formatter=fixedwidth_in,  
  name='20', address='30', age='4', line_delim='?@')
```

**Example 4 – Create a writable external table with a \n line delimiter**

```sql
CREATE WRITABLE EXTERNAL TABLE students_out (  
  name varchar(20), address varchar(30), age int)  
LOCATION ('gpfdist://<host>:<portNum>/file/path/students_out.txt')  
FORMAT 'CUSTOM' (formatter=fixedwidth_out,  
  name=20, address=30, age=4, line_delim=E'\r\n');
```
Using a Custom Protocol

Greenplum Database provides protocols such as gpfdist, http, and file for accessing data over a network, or you can author a custom protocol. You can use the standard data formats, TEXT and CSV, or a custom data format with custom protocols.

You can create a custom protocol whenever the available built-in protocols do not suffice for a particular need. For example, you could connect Greenplum Database in parallel to another system directly, and stream data from one to the other without the need to materialize the data on disk or use an intermediate process such as gpfdist. You must be a superuser to create and register a custom protocol.

1. Author the send, receive, and (optionally) validator functions in C, with a predefined API. These functions are compiled and registered with the Greenplum Database. For an example custom protocol, see Example Custom Data Access Protocol.

2. After writing and compiling the read and write functions into a shared object (.so), declare a database function that points to the .so file and function names.

The following examples use the compiled import and export code.

```sql
CREATE FUNCTION myread() RETURNS integer
as '$libdir/gpextprotocol.so', 'myprot_import'
LANGUAGE C STABLE;
CREATE FUNCTION mywrite() RETURNS integer
as '$libdir/gpextprotocol.so', 'myprot_export'
LANGUAGE C STABLE;
```

The format of the optional validator function is:

```sql
CREATE OR REPLACE FUNCTION myvalidate() RETURNS void
AS '$libdir/gpextprotocol.so', 'myprot_validate'
LANGUAGE C STABLE;
```

3. Create a protocol that accesses these functions. Validatorfunc is optional.

```sql
CREATE TRUSTED PROTOCOL myprot(
    writefunc='mywrite',
    readfunc='myread',
    validatorfunc='myvalidate');
```

4. Grant access to any other users, as necessary.

```sql
GRANT ALL ON PROTOCOL myprot TO otheruser;
```

5. Use the protocol in readable or writable external tables.

```sql
CREATE WRITABLE EXTERNAL TABLE ext_sales(LIKE sales)
LOCATION ('myprot://<meta>/<meta>/...')
FORMAT 'TEXT';
CREATE READABLE EXTERNAL TABLE ext_sales(LIKE sales)
LOCATION('myprot://<meta>/<meta>/...')
FORMAT 'TEXT';
```

Declare custom protocols with the SQL command CREATE TRUSTED PROTOCOL, then use the GRANT command to grant access to your users. For example:

- Allow a user to create a readable external table with a trusted protocol

```sql
GRANT SELECT ON PROTOCOL <protocol name> TO <user name>;
```
• Allow a user to create a writable external table with a trusted protocol

   GRANT INSERT ON PROTOCOL <protocol name> TO <user name>;

• Allow a user to create readable and writable external tables with a trusted protocol

   GRANT ALL ON PROTOCOL <protocol name> TO <user name>;

Handling Load Errors

Readable external tables are most commonly used to select data to load into regular database tables. You use the `CREATE TABLE AS SELECT` or `INSERT INTO` commands to query the external table data. By default, if the data contains an error, the entire command fails and the data is not loaded into the target database table.

The `SEGMENT REJECT LIMIT` clause allows you to isolate format errors in external table data and to continue loading correctly formatted rows. Use `SEGMENT REJECT LIMIT` to set an error threshold, specifying the reject limit count as number of `ROWS` (the default) or as a `PERCENT` of total rows (1-100).

The entire external table operation is aborted, and no rows are processed, if the number of error rows reaches the `SEGMENT REJECT LIMIT`. The limit of error rows is per-segment, not per entire operation. The operation processes all good rows, and it discards and optionally logs formatting errors for erroneous rows, if the number of error rows does not reach the `SEGMENT REJECT LIMIT`.

The `LOG ERRORS` clause allows you to keep error rows for further examination. For information about the `LOG ERRORS` clause, see the `CREATE EXTERNAL TABLE` command in the *Greenplum Database Reference Guide*.

When you set `SEGMENT REJECT LIMIT`, Greenplum scans the external data in single row error isolation mode. Single row error isolation mode applies to external data rows with format errors such as extra or missing attributes, attributes of a wrong data type, or invalid client encoding sequences. Greenplum does not check constraint errors, but you can filter constraint errors by limiting the `SELECT` from an external table at runtime. For example, to eliminate duplicate key errors:

```sql
=# INSERT INTO table_with_pkeys
   SELECT DISTINCT * FROM external_table;
```

**Note:** When loading data with the `COPY` command or an external table, the value of the server configuration parameter `gp_initial_bad_row_limit` limits the initial number of rows that are processed that are not formatted properly. The default is to stop processing if the first 1000 rows contain formatting errors. See the *Greenplum Database Reference Guide* for information about the parameter.

Define an External Table with Single Row Error Isolation

The following example logs errors internally in Greenplum Database and sets an error threshold of 10 errors.

```sql
=# CREATE EXTERNAL TABLE ext_expenses ( name text, date date, amount float4, category text, desc1 text )
   LOCATION ('gpfdist://etlhost-1:8081/*', 'gpfdist://etlhost-2:8082/*')
   FORMAT 'TEXT' (DELIMITER '|')
   LOG ERRORS SEGMENT REJECT LIMIT 10
   ROWS;
```
Use the built-in SQL function `gp_read_error_log('external_table')` to read the error log data. This example command displays the log errors for `ext_expenses`:

```sql
SELECT gp_read_error_log('ext_expenses');
```

For information about the format of the error log, see [Viewing Bad Rows in the Error Log](#).

The built-in SQL function `gp_truncate_error_log('external_table')` deletes the error data. This example deletes the error log data created from the previous external table example:

```sql
SELECT gp_truncate_error_log('ext_expenses');
```

**Capture Row Formatting Errors and Declare a Reject Limit**

The following SQL fragment captures formatting errors internally in Greenplum Database and declares a reject limit of 10 rows.

```sql
LOG ERRORS SEGMENT REJECT LIMIT 10 ROWS
```

Use the built-in SQL function `gp_read_error_log()` to read the error log data. For information about viewing log errors, see [Viewing Bad Rows in the Error Log](#).

**Viewing Bad Rows in the Error Log**

If you use single row error isolation (see [Define an External Table with Single Row Error Isolation](#) or [Running COPY in Single Row Error Isolation Mode](#)), any rows with formatting errors are logged internally by Greenplum Database.

Greenplum Database captures the following error information in a table format:

**Table 56: Error Log Format**

<table>
<thead>
<tr>
<th>column</th>
<th>type</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>
<td>cmdtime</td>
<td>timestamptz</td>
<td>Timestamp when the error occurred.</td>
</tr>
<tr>
<td>relname</td>
<td>text</td>
<td>The name of the external table or the target table of a COPY command.</td>
</tr>
<tr>
<td>filename</td>
<td>text</td>
<td>The name of the load file that contains the error.</td>
</tr>
<tr>
<td>linenum</td>
<td>int</td>
<td>If COPY was used, the line number in the load file where the error occurred. For external tables using file:// protocol or gpfdist:// protocol and CSV format, the file name and line number is logged.</td>
</tr>
<tr>
<td>bytenum</td>
<td>int</td>
<td>For external tables with the gpfdist:// protocol and data in TEXT format: the byte offset in the load file where the error occurred. gpfdist parses TEXT files in blocks, so logging a line number is not possible. CSV files are parsed a line at a time so line number tracking is possible for CSV files.</td>
</tr>
<tr>
<td>errmsg</td>
<td>text</td>
<td>The error message text.</td>
</tr>
<tr>
<td>rawdata</td>
<td>text</td>
<td>The raw data of the rejected row.</td>
</tr>
</tbody>
</table>
You can use the Greenplum Database built-in SQL function `gp_read_error_log()` to display formatting errors that are logged internally. For example, this command displays the error log information for the table `ext_expenses`:

```
SELECT gp_read_error_log('ext_expenses');
```

For information about managing formatting errors that are logged internally, see the command `COPY` or `CREATE EXTERNAL TABLE` in the *Greenplum Database Reference Guide*.

### Moving Data between Tables

You can use `CREATE TABLE AS` or `INSERT...SELECT` to load external and external web table data into another (non-external) database table, and the data will be loaded in parallel according to the external or external web table definition.

If an external table file or external web table data source has an error, one of the following will happen, depending on the isolation mode used:

- **Tables without error isolation mode**: any operation that reads from that table fails. Loading from external and external web tables without error isolation mode is an all or nothing operation.
- **Tables with error isolation mode**: the entire file will be loaded, except for the problematic rows (subject to the configured `REJECT_LIMIT`)

### Loading Data with gpload

The Greenplum `gpload` utility loads data using readable external tables and the Greenplum parallel file server (`gpfdist` or `gpfdists`). It handles parallel file-based external table setup and allows users to configure their data format, external table definition, and `gpfdist` or `gpfdists` setup in a single configuration file.

**Note:** `gpfdist` and `gpload` are compatible only with the Greenplum Database major version in which they are shipped. For example, a `gpfdist` utility that is installed with Greenplum Database 4.x cannot be used with Greenplum Database 5.x or 6.x.

**Note:** `MERGE` and `UPDATE` operations are not supported if the target table column name is a reserved keyword, has capital letters, or includes any character that requires quotes (" ") to identify the column.

### To use gpload

1. Ensure that your environment is set up to run `gpload`. Some dependent files from your Greenplum Database installation are required, such as `gpfdist` and Python, as well as network access to the Greenplum segment hosts.

   See the *Greenplum Database Reference Guide* for details.

2. Create your load control file. This is a YAML-formatted file that specifies the Greenplum Database connection information, `gpfdist` configuration information, external table options, and data format.

   See the *Greenplum Database Reference Guide* for details.
For example:

```plaintext
---
VERSION: 1.0.0.1
DATABASE: ops
USER: gpadmin
HOST: mdw-1
PORT: 5432
GPLOAD:
   INPUT:
   - SOURCE:
     LOCAL_HOSTNAME:
     - etl1-1
     - etl1-2
     - etl1-3
     - etl1-4
   PORT: 8081
   FILE:
     - /var/load/data/*
   COLUMNS:
     - name: text
     - amount: float4
     - category: text
     - descr: text
     - date: date
   FORMAT: text
   DELIMITER: '|'
   ERROR_LIMIT: 25
   LOG_ERRORS: true
OUTPUT:
   - TABLE: payables.expenses
   - MODE: INSERT
PRELOAD:
   - REUSE_TABLES: true
SQL:
   - BEFORE: "INSERT INTO audit VALUES('start', current_timestamp)"
   - AFTER: "INSERT INTO audit VALUES('end', current_timestamp)"
```

3. Run `gpload`, passing in the load control file. For example:

```
gpload -f my_load.yml
```

### Accessing External Data with PXF

Data managed by your organization may already reside in external sources such as Hadoop, object stores, and other SQL databases. The Greenplum Platform Extension Framework (PXF) provides access to this external data via built-in connectors that map an external data source to a Greenplum Database table definition.

PXF is installed with Hadoop and Object Storage connectors. These connectors enable you to read external data stored in text, Avro, JSON, RCFile, Parquet, SequenceFile, and ORC formats. You can use the JDBC connector to access an external SQL database.

**Note:** In previous versions of Greenplum Database, you may have used the `gphdfs` external table protocol to access data stored in Hadoop. Greenplum Database version 6.0.0 removes the `gphdfs` protocol. Use PXF and the `pxf` external table protocol to access Hadoop in Greenplum Database version 6.x.

The Greenplum Platform Extension Framework includes a protocol C library and a Java service. After you configure and initialize PXF, you start a single PXF JVM process on each Greenplum Database segment host. This long-running process concurrently serves multiple query requests.
For detailed information about the architecture of and using PXF, refer to the *Greenplum Platform Extension Framework (PXF)* documentation.

**Transforming External Data with gpfdist and gpload**

The gpfdist parallel file server allows you to set up transformations that enable Greenplum Database external tables to read and write files in formats that are not supported with the `CREATE EXTERNAL TABLE` command's `FORMAT` clause. An *input* transformation reads a file in the foreign data format and outputs rows to gpfdist in the CSV or other text format specified in the external table's `FORMAT` clause. An *output* transformation receives rows from gpfdist in text format and converts them to the foreign data format.

**Note:** gpfdist and gpload are compatible only with the Greenplum Database major version in which they are shipped. For example, a gpfdist utility that is installed with Greenplum Database 4.x cannot be used with Greenplum Database 5.x or 6.x.

This topic describes the tasks to set up data transformations that work with gpfdist to read or write external data files with formats that Greenplum Database does not support.

- About gpfdist Transformations
- Determine the Transformation Schema
- Write a Transformation
- Write the gpfdist Configuration File
- Transfer the Data
- Configuration File Format
- XML Transformation Examples

**About gpfdist Transformations**

To set up a transformation for a data format, you provide an executable command that gpfdist can call with the name of the file containing data. For example, you could write a shell script that runs an XSLT transformation on an XML file to output rows with columns delimited with a vertical bar (|) character and rows delimited with linefeeds.

Transformations are configured in a YAML-formatted configuration file passed to gpfdist on the command line.

If you want to load the external data into a table in the Greenplum database, you can use the gpload utility to automate the tasks to create an external table, run gpfdist, and load the transformed data into the database table.

Accessing data in external XML files from within the database is a common example requiring transformation. The following diagram shows gpfdist performing a transformation on XML files on an ETL server.
**Determine the Transformation Schema**

To prepare for the transformation project:

1. Determine the goal of the project, such as indexing data, analyzing data, combining data, and so on.
2. Examine the source files and note the file structure and element names.
3. Choose the elements to import and decide if any other limits are appropriate.

For example, the following XML file, *prices.xml*, is a simple XML file that contains price records. Each price record contains two fields: an item number and a price.

```xml
<?xml version="1.0" encoding="ISO-8859-1" ?>
<prices>
  <pricerecord>
    <itemnumber>708421</itemnumber>
    <price>19.99</price>
  </pricerecord>
  <pricerecord>
    <itemnumber>708466</itemnumber>
    <price>59.25</price>
  </pricerecord>
  <pricerecord>
    <itemnumber>711121</itemnumber>
    <price>24.99</price>
  </pricerecord>
</prices>
```
The goal of this transformation is to import all the data into a Greenplum Database readable external table with an integer `itemnumber` column and a decimal `price` column.

**Write a Transformation**

The transformation specifies what to extract from the data. You can use any authoring environment and language appropriate for your project. For XML transformations choose from technologies such as XSLT, Joost (STX), Java, Python, or Perl, based on the goals and scope of the project.

In the price example, the next step is to transform the XML data into a two-column delimited text format.

```
708421|19.99
708466|59.25
711121|24.99
```

The following STX transform, called `input_transform.stx`, performs the data transformation.

```xml
<?xml version="1.0"?>
<stx:transform version="1.0"
    xmlns:stx="http://stx.sourceforge.net/2002/ns"
    pass-through="none">
    <!-- declare variables -->
    <stx:variable name="itemnumber"/>
    <stx:variable name="price"/>
    <!-- match and output prices as columns delimited by | -->
    <stx:template match="/prices/pricerecord">
        <stx:process-children/>
        <stx:value-of select="$itemnumber"/>
        <stx:text>|</stx:text>
        <stx:value-of select="$price"/>
    </stx:template>
    <stx:template match="itemnumber">
        <stx:assign name="itemnumber" select="."/>
    </stx:template>
    <stx:template match="price">
        <stx:assign name="price" select="."/>
    </stx:template>
</stx:transform>
```

This STX transform declares two temporary variables, `itemnumber` and `price`, and the following rules.

1. When an element that satisfies the XPath expression `/prices/pricerecord` is found, examine the child elements and generate output that contains the value of the `itemnumber` variable, a `|` character, the value of the `price` variable, and a newline.
2. When an `<itemnumber>` element is found, store the content of that element in the variable `itemnumber`.
3. When a `<price>` element is found, store the content of that element in the variable `price`.

**Write the gpfdist Configuration File**

The `gpfdist` configuration is specified as a YAML 1.1 document. It contains rules that `gpfdist` uses to select a transformation to apply when loading or extracting data.

This example `gpfdist` configuration contains the following items that are required for the `prices.xml` transformation scenario:

- the `config.yaml` file defining `TRANSFORMATIONS`
- the `input_transform.sh` wrapper script, referenced in the `config.yaml` file
- the `input_transform.stx` Joost transformation, called from `input_transform.sh`
Aside from the ordinary YAML rules, such as starting the document with three dashes (---), a gpfdist configuration must conform to the following restrictions:

1. A VERSION setting must be present with the value 1.0.0.1.
2. A TRANSFORMATIONS setting must be present and contain one or more mappings.
3. Each mapping in the TRANSFORMATION must contain:
   - a TYPE with the value 'input' or 'output'
   - a COMMAND indicating how the transformation is run.
4. Each mapping in the TRANSFORMATION can contain optional CONTENT, SAFE, and STDERR settings.

The following gpfdist configuration, called config.yaml, applies to the prices example. The initial indentation on each line is significant and reflects the hierarchical nature of the specification. The transformation name prices_input in the following example will be referenced later when creating the table in SQL.

```
---
VERSION: 1.0.0.1
TRANSFORMATIONS:
  prices_input:
    TYPE:     input
    COMMAND:  /bin/bash input_transform.sh %filename%
```

The COMMAND setting uses a wrapper script called input_transform.sh with a %filename% placeholder. When gpfdist runs the prices_input transform, it invokes input_transform.sh with /bin/bash and replaces the %filename% placeholder with the path to the input file to transform. The wrapper script called input_transform.sh contains the logic to invoke the STX transformation and return the output.

If Joost is used, the Joost STX engine must be installed.

```
#!/bin/bash
# input_transform.sh - sample input transformation,
# demonstrating use of Java and Joost STX to convert XML into
# text to load into Greenplum Database.
# java arguments:
#   -jar joost.jar                     joost STX engine
#   -nodecl                           don't generate a <?xml?> declaration
#   $1                                filename to process
#   input_transform.stx              the STX transformation
#
# the AWK step eliminates a blank line joost emits at the end
java \
   -jar joost.jar \
   -nodecl \
   $1 \
   input_transform.stx \
| awk 'NF>0
```

The input_transform.sh file uses the Joost STX engine with the AWK interpreter. The following diagram shows the process flow as gpfdist runs the transformation.
Transfer the Data

Create the target database tables with SQL statements based on the appropriate schema.

There are no special requirements for Greenplum Database tables that hold loaded data. In the prices example, the following command creates the `prices` table, where the data is to be loaded.

```sql
CREATE TABLE prices (
    itemnumber integer,
    price       decimal
) DISTRIBUTED BY (itemnumber);
```

Next, use one of the following approaches to transform the data with `gpfdist`.

- `gpload` supports only input transformations, but in many cases is easier to implement.
- `gpfdist` with `INSERT INTO SELECT FROM` supports both input and output transformations, but exposes details that `gpload` automates for you.

**Transforming with gpload**

The Greenplum Database `gpload` utility orchestrates a data load operation using the `gpfdist` parallel file server and a YAML-formatted configuration file. `gpload` automates these tasks:

- Creates a readable external table in the database.
- Starts `gpfdist` instances with the configuration file that contains the transformation.
- Runs `INSERT INTO table_name SELECT FROM external_table` to load the data.
- Removes the external table definition.

Transforming data with `gpload` requires that the settings `TRANSFORM` and `TRANSFORM_CONFIG` appear in the `INPUT` section of the `gpload` control file.

For more information about the syntax and placement of these settings in the `gpload` control file, see the Greenplum Database Reference Guide.

- `TRANSFORM_CONFIG` specifies the name of the `gpfdist` configuration file.
- The `TRANSFORM` setting indicates the name of the transformation that is described in the file named in `TRANSFORM_CONFIG`.

---

VERSION: 1.0.0.1
DATABASE: ops
The transformation name must appear in two places: in the TRANSFORM setting of the gpfdist configuration file and in the TRANSFORMATIONS section of the file named in the TRANSFORM_CONFIG section.

In the gpload control file, the optional parameter MAX_LINE_LENGTH specifies the maximum length of a line in the XML transformation data that is passed to gpload.

The following diagram shows the relationships between the gpload control file, the gpfdist configuration file, and the XML data file.

---

Transforming with gpfdist and INSERT INTO SELECT FROM

With this load method, you perform each of the tasks that gpload automates. You start gpfdist, create an external table, load the data, and clean up by dropping the table and stopping gpfdist.

Specify the transformation in the CREATE EXTERNAL TABLE definition's LOCATION clause. For example, the transform is shown in bold in the following command. (Run gpfdist first, using the command gpfdist -c config.yaml).

```
CREATE READABLE EXTERNAL TABLE prices_readable (LIKE prices)
    LOCATION ('gpfdist://hostname:8080/prices.xml#transform=prices_input')
    FORMAT 'TEXT' (DELIMITER '|')
    LOG ERRORS SEGMENT REJECT LIMIT 10;
```

In the command above, change hostname to your hostname. prices_input comes from the gpfdist configuration file.
The following query then loads the data into the `prices` table.

```sql
INSERT INTO prices SELECT * FROM prices_readable;
```

**Configuration File Format**

The `gpfdist` configuration file uses the YAML 1.1 document format and implements a schema for defining the transformation parameters. The configuration file must be a valid YAML document.

The `gpfdist` program processes the document in order and uses indentation (spaces) to determine the document hierarchy and relationships of the sections to one another. The use of white space is significant. Do not use white space for formatting and do not use tabs.

The following is the basic structure of a configuration file.

```yaml
---
VERSION:   1.0.0.1
TRANSFORMATIONS:
  transformation_name1:
    TYPE:      input | output
    COMMAND:   command
    CONTENT:   data | paths
    SAFE:      posix-regex
    STDERR:    server | console
  transformation_name2:
    TYPE:      input | output
    COMMAND:   command
...
```

**VERSION**

Required. The version of the `gpfdist` configuration file schema. The current version is 1.0.0.1.

**TRANSFORMATIONS**

Required. Begins the transformation specification section. A configuration file must have at least one transformation. When `gpfdist` receives a transformation request, it looks in this section for an entry with the matching transformation name.

**TYPE**

Required. Specifies the direction of transformation. Values are `input` or `output`.

- `input`: `gpfdist` treats the standard output of the transformation process as a stream of records to load into Greenplum Database.
- `output`: `gpfdist` treats the standard input of the transformation process as a stream of records from Greenplum Database to transform and write to the appropriate output.

**COMMAND**

Required. Specifies the command `gpfdist` will execute to perform the transformation.

For input transformations, `gpfdist` invokes the command specified in the `CONTENT` setting. The command is expected to open the underlying file(s) as appropriate and produce one line of `TEXT` for each row to load into Greenplum Database. The input transform determines whether the entire content should be converted to one row or to multiple rows.

For output transformations, `gpfdist` invokes this command as specified in the `CONTENT` setting. The output command is expected to open and write to the underlying file(s) as appropriate. The output transformation determines the final placement of the converted output.

**CONTENT**
Optional. The values are data and paths. The default value is data.

- When CONTENT specifies data, the text %filename% in the COMMAND section is replaced by the path to the file to read or write.
- When CONTENT specifies paths, the text %filename% in the COMMAND section is replaced by the path to the temporary file that contains the list of files to read or write.

The following is an example of a COMMAND section showing the text %filename% that is replaced.

```
COMMAND: /bin/bash input_transform.sh %filename%
```

SAFE

Optional. A POSIX regular expression that the paths must match to be passed to the transformation. Specify SAFE when there is a concern about injection or improper interpretation of paths passed to the command. The default is no restriction on paths.

STDERR

Optional. The values are server and console.

This setting specifies how to handle standard error output from the transformation. The default, server, specifies that gpfdist will capture the standard error output from the transformation in a temporary file and send the first 8k of that file to Greenplum Database as an error message. The error message will appear as an SQL error. Console specifies that gpfdist does not redirect or transmit the standard error output from the transformation.

XML Transformation Examples

The following examples demonstrate the complete process for different types of XML data and STX transformations. Files and detailed instructions associated with these examples are in the GitHub repo github.com://greenplum-db/gpdb in the gpMgmt/demo/gpfdist_transform directory. Read the README file in the Before You Begin section before you run the examples. The README file explains how to download the example data file used in the examples.

Command-based External Web Tables

The output of a shell command or script defines command-based web table data. Specify the command in the EXECUTE clause of CREATE EXTERNAL WEB TABLE. The data is current as of the time the command runs. The EXECUTE clause runs the shell command or script on the specified master, and/or segment host or hosts. The command or script must reside on the hosts corresponding to the host(s) defined in the EXECUTE clause.

By default, the command is run on segment hosts when active segments have output rows to process. For example, if each segment host runs four primary segment instances that have output rows to process, the command runs four times per segment host. You can optionally limit the number of segment instances that execute the web table command. All segments included in the web table definition in the ON clause run the command in parallel.

The command that you specify in the external table definition executes from the database and cannot access environment variables from .bashrc or .profile. Set environment variables in the EXECUTE clause. For example:

```
=# CREATE EXTERNAL WEB TABLE output (output text)
   EXECUTE 'PATH=/home/gpadmin/programs; export PATH; myprogram.sh'
   FORMAT 'TEXT';
```

Scripts must be executable by the gpadmin user and reside in the same location on the master or segment hosts.
The following command defines a web table that runs a script. The script runs on each segment host where a segment has output rows to process.

```sql
=# CREATE EXTERNAL WEB TABLE log_output
   (linenum int, message text)
EXECUTE '/var/load_scripts/get_log_data.sh' ON HOST
FORMAT 'TEXT' (DELIMITER '||');
```

**IRS MeF XML Files (In demo Directory)**

This example demonstrates loading a sample IRS Modernized eFile tax return using a Joost STX transformation. The data is in the form of a complex XML file.

The U.S. Internal Revenue Service (IRS) made a significant commitment to XML and specifies its use in its Modernized e-File (MeF) system. In MeF, each tax return is an XML document with a deep hierarchical structure that closely reflects the particular form of the underlying tax code.

XML, XML Schema and stylesheets play a role in their data representation and business workflow. The actual XML data is extracted from a ZIP file attached to a MIME "transmission file" message. For more information about MeF, see [Modernized e-File (Overview)](http://www.irs.gov) on the IRS web site.

The sample XML document, `RET990EZ_2006.xml`, is about 350KB in size with two elements:

- ReturnHeader
- ReturnData

The `<ReturnHeader>` element contains general details about the tax return such as the taxpayer's name, the tax year of the return, and the preparer. The `<ReturnData>` element contains multiple sections with specific details about the tax return and associated schedules.

The following is an abridged sample of the XML file.

```xml
<?xml version="1.0" encoding="UTF-8"?>
<Return returnVersion="2006v2.0"
   xmlns="https://www.irs.gov/efile"
xmlns:efile="https://www.irs.gov/efile"
 xsi:schemaLocation="https://www.irs.gov/efile"
xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance">
<ReturnHeader binaryAttachmentCount="1">
   <ReturnId>AAAAAAAAAAAAAAAAAAAA</ReturnId>
   <Timestamp>1999-05-30T12:01:01+05:01</Timestamp>
   <ReturnType>990EZ</ReturnType>
   <TaxPeriodBeginDate>2005-01-01</TaxPeriodBeginDate>
   <TaxPeriodEndDate>2005-12-31</TaxPeriodEndDate>
   <Filer>
      <EIN>011248772</EIN>
      ... more data ...
   </Filer>
   <Preparer>
      <Name>Percy Polar</Name>
      ... more data ...
   </Preparer>
   <TaxYear>2005</TaxYear>
</ReturnHeader>
... more data ...
```

The goal is to import all the data into a Greenplum database. First, convert the XML document into text with newlines "escaped", with two columns: ReturnId and a single column on the end for the entire MeF tax return. For example:

```
AAAAAAAAAAAAAAAAAAAAA|<Return returnVersion="2006v2.0"...```
Load the data into Greenplum Database.

**WITSML™ Files (In demo Directory)**

This example demonstrates loading sample data describing an oil rig using a Joost STX transformation. The data is in the form of a complex XML file downloaded from energistics.org.

The Wellsite Information Transfer Standard Markup Language (WITSML™) is an oil industry initiative to provide open, non-proprietary, standard interfaces for technology and software to share information among oil companies, service companies, drilling contractors, application vendors, and regulatory agencies. For more information about WITSML™, see [http://www.energistics.org/](http://www.energistics.org/).

The oil rig information consists of a top level `<rigs>` element with multiple child elements such as `<documentInfo>`, `<rig>`, and so on. The following excerpt from the file shows the type of information in the `<rig>` tag.

```xml
<?xml version="1.0" encoding="UTF-8"?>
<rigs xmlns="http://www.energistics.org/schemas/131"
      xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
      xsi:schemaLocation="http://www.energistics.org/schemas/131 ../obj_rig.xsd"
      version="1.3.1.1">
  <documentInfo>
    ... misc data ...
  </documentInfo>
  <rig uidWell="W-12" uidWellbore="B-01" uid="xr31">
    <nameWell>6507/7-A-42</nameWell>
    <nameWellbore>A-42</nameWellbore>
    <owner>Deep Drill #5</owner>
    <typeRig>floater</typeRig>
    <manufacturer>Fitsui Engineering</manufacturer>
    <yearEntService>1980</yearEntService>
    <classRig>ABS Class A1 M CSDU AMS ACCU</classRig>
    <approvals>DNV</approvals>
    ... more data ...
  </rig>
</rigs>
```

The goal is to import the information for this rig into Greenplum Database.

The sample document, `rig.xml`, is about 11KB in size. The input does not contain tabs so the relevant information can be converted into records delimited with a pipe (|).

```
W-12|6507/7-A-42|xr31|Deep Drill #5|Deep Drilling Co.|John Doe|
    John.Doe@example.com|
```

With the columns:

- `well_uid` text, -- e.g. `W-12`
- `well_name` text, -- e.g. `6507/7-A-42`
- `rig_uid` text, -- e.g. `xr31`
- `rig_name` text, -- e.g. `Deep Drill #5`
- `rig_owner` text, -- e.g. `Deep Drilling Co.`
- `rig_contact` text, -- e.g. `John Doe`
- `rig_email` text, -- e.g. `John.Doe@example.com`
- `doc xml`

Then, load the data into Greenplum Database.
**Loading Data with COPY**

COPY FROM copies data from a file or standard input into a table and appends the data to the table contents. COPY is non-parallel: data is loaded in a single process using the Greenplum master instance. Using COPY is only recommended for very small data files.

The COPY source file must be accessible to the postgres process on the master host. Specify the COPY source file name relative to the data directory on the master host, or specify an absolute path.

Greenplum copies data from stdin or stdout using the connection between the client and the master server.

### Loading From a File

The COPY command asks the postgres backend to open the specified file, read it and append it to the table. In order to be able to read the file, the backend needs to have read permissions on the file, and the file name must be specified using an absolute path on the master host, or a relative path to the master data directory.

```
COPY table_name FROM /path/to/filename;
```

### Loading From STDIN

To avoid the problem of copying the data file to the master host before loading the data, COPY FROM STDIN uses the Standard Input channel and feeds data directly into the postgres backend. After the COPY FROM STDIN command started, the backend will accept lines of data until a single line only contains a backslash-period (\.).

```
COPY table_name FROM STDIN;
```

### Loading Data Using \copy in psql

Do not confuse the psql \copy command with the COPY SQL command. The \copy invokes a regular COPY FROM STDIN and sends the data from the psql client to the backend. Therefore any file must reside on the host where the psql client runs, and must be accessible to the user which runs the client.

To avoid the problem of copying the data file to the master host before loading the data, COPY FROM STDIN uses the Standard Input channel and feeds data directly into the postgres backend. After the COPY FROM STDIN command started, the backend will accept lines of data until a single line only contains a backslash-period (\.). psql is wrapping all of this into the handy \copy command.

```
\copy table_name FROM filename;
```

### Input Format

COPY FROM accepts a FORMAT parameter, which specifies the format of the input data. The possible values are TEXT, CSV (Comma Separated Values), and BINARY.

```
COPY table_name FROM /path/to/filename WITH (FORMAT csv);
```

The FORMAT csv will read comma-separated values. The FORMAT text by default uses tabulators to separate the values, the DELIMITER option specifies a different character as value delimiter.

```
COPY table_name FROM /path/to/filename WITH (FORMAT text, DELIMITER ' | ');
```
By default, the default client encoding is used, this can be changed with the `ENCODING` option. This is useful if data is coming from another operating system.

```
COPY table_name FROM /path/to/filename WITH (ENCODING 'latin1');
```

**Running COPY in Single Row Error Isolation Mode**

By default, `COPY` stops an operation at the first error: if the data contains an error, the operation fails and no data loads. If you run `COPY FROM` in *single row error isolation mode*, Greenplum skips rows that contain format errors and loads properly formatted rows. Single row error isolation mode applies only to rows in the input file that contain format errors. If the data contains a constraint error such as violation of a `NOT NULL`, `CHECK`, or `UNIQUE` constraint, the operation fails and no data loads.

Specifying `SEGMENT REJECT LIMIT` runs the `COPY` operation in single row error isolation mode. Specify the acceptable number of error rows on each segment, after which the entire `COPY FROM` operation fails and no rows load. The error row count is for each Greenplum Database segment, not for the entire load operation.

If the `COPY` operation does not reach the error limit, Greenplum loads all correctly-formatted rows and discards the error rows. Use the `LOG ERRORS` clause to capture data formatting errors internally in Greenplum Database. For example:

```
=> COPY country FROM '/data/gpdb/country_data'
   WITH DELIMITER '|' LOG ERRORS
   SEGMENT REJECT LIMIT 10 ROWS;
```

See *Viewing Bad Rows in the Error Log* for information about investigating error rows.

**Optimizing Data Load and Query Performance**

Use the following tips to help optimize your data load and subsequent query performance.

- Drop indexes before loading data into existing tables.
  
  Creating an index on pre-existing data is faster than updating it incrementally as each row is loaded. You can temporarily increase the `maintenance_work_mem` server configuration parameter to help speed up `CREATE INDEX` commands, though load performance is affected. Drop and recreate indexes only when there are no active users on the system.

- Create indexes last when loading data into new tables. Create the table, load the data, and create any required indexes.

- Run `ANALYZE` after loading data. If you significantly altered the data in a table, run `ANALYZE` or `VACUUM ANALYZE` to update table statistics for the query optimizer. Current statistics ensure that the optimizer makes the best decisions during query planning and avoids poor performance due to inaccurate or nonexistent statistics.

- Run `VACUUM` after load errors. If the load operation does not run in single row error isolation mode, the operation stops at the first error. The target table contains the rows loaded before the error occurred. You cannot access these rows, but they occupy disk space. Use the `VACUUM` command to recover the wasted space.

**Unloading Data from Greenplum Database**

A writable external table allows you to select rows from other database tables and output the rows to files, named pipes, to applications, or as output targets for Greenplum parallel MapReduce calculations. You can define file-based and web-based writable external tables.
This topic describes how to unload data from Greenplum Database using parallel unload (writable external tables) and non-parallel unload (COPY).

## Defining a File-Based Writable External Table

Writable external tables that output data to files can use the Greenplum parallel file server program, `gpfdist`, or the Greenplum Platform Extension Framework (PXF), Greenplum’s interface to Hadoop.

Use the `CREATE WRITABLE EXTERNAL TABLE` command to define the external table and specify the location and format of the output files. See [Using the Greenplum Parallel File Server (gpfdist)] for instructions on setting up `gpfdist` for use with an external table and [Accessing External Data with PXF] for instructions on setting up PXF for use with an external table.

- With a writable external table using the `gpfdist` protocol, the Greenplum segments send their data to `gpfdist`, which writes the data to the named file. `gpfdist` must run on a host that the Greenplum segments can access over the network. `gpfdist` points to a file location on the output host and writes data received from the Greenplum segments to the file. To divide the output data among multiple files, list multiple `gpfdist` URIs in your writable external table definition.

- A writable external web table sends data to an application as a stream of data. For example, unload data from Greenplum Database and send it to an application that connects to another database or ETL tool to load the data elsewhere. Writable external web tables use the `EXECUTE` clause to specify a shell command, script, or application to run on the segment hosts and accept an input stream of data. See [Defining a Command-Based Writable External Web Table] for more information about using `EXECUTE` commands in a writable external table definition.

You can optionally declare a distribution policy for your writable external tables. By default, writable external tables use a random distribution policy. If the source table you are exporting data from has a hash distribution policy, defining the same distribution key column(s) for the writable external table improves unload performance by eliminating the requirement to move rows over the interconnect. If you unload data from a particular table, you can use the `LIKE` clause to copy the column definitions and distribution policy from the source table.

### Example 1—Greenplum file server (gpfdist)

```sql
=# CREATE WRITABLE EXTERNAL TABLE unload_expenses
   ( LIKE expenses )
   LOCATION ('gpfdist://etlhost-1:8081/expenses1.out',
             'gpfdist://etlhost-2:8081/expenses2.out')
   FORMAT 'TEXT' (DELIMITER ',')
   DISTRIBUTED BY (exp_id);
```

### Example 2—Hadoop file server (pxf)

```sql
=# CREATE WRITABLE EXTERNAL TABLE unload_expenses
   ( LIKE expenses )
   LOCATION ('pxf://dir/path?PROFILE=hdfs:text')
   FORMAT 'TEXT' (DELIMITER ',')
   DISTRIBUTED BY (exp_id);
```

You specify an HDFS directory for a writable external table that you create with the `pxf` protocol.

## Defining a Command-Based Writable External Web Table

You can define writable external web tables to send output rows to an application or script. The application must accept an input stream, reside in the same location on all of the Greenplum segment hosts, and be executable by the `gpadmin` user. All segments in the Greenplum system run the application or script, whether or not a segment has output rows to process.
Use `CREATE WRITABLE EXTERNAL WEB TABLE` to define the external table and specify the application or script to run on the segment hosts. Commands execute from within the database and cannot access environment variables (such as `$PATH`). Set environment variables in the `EXECUTE` clause of your writable external table definition. For example:

```
=# CREATE WRITABLE EXTERNAL WEB TABLE output (output text)
   EXECUTE 'export PATH=$PATH:/home/gpadmin/programs;
   myprogram.sh'
   FORMAT 'TEXT'
   DISTRIBUTED RANDOMLY;
```

The following Greenplum Database variables are available for use in OS commands executed by a web or writable external table. Set these variables as environment variables in the shell that executes the command(s). They can be used to identify a set of requests made by an external table statement across the Greenplum Database array of hosts and segment instances.

**Table 57: External Table EXECUTE Variables**

<table>
<thead>
<tr>
<th>Variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>$GP_CID</td>
<td>Command count of the transaction executing the external table statement.</td>
</tr>
<tr>
<td>$GP_DATABASE</td>
<td>The database in which the external table definition resides.</td>
</tr>
<tr>
<td>$GP_DATE</td>
<td>The date on which the external table command ran.</td>
</tr>
<tr>
<td>$GP_MASTER_HOST</td>
<td>The host name of the Greenplum master host from which the external table statement was dispatched.</td>
</tr>
<tr>
<td>$GP_MASTER_PORT</td>
<td>The port number of the Greenplum master instance from which the external table statement was dispatched.</td>
</tr>
<tr>
<td>$GP_QUERY_STRING</td>
<td>The SQL command (DML or SQL query) executed by Greenplum Database.</td>
</tr>
<tr>
<td>$GP_SEG_DATADIR</td>
<td>The location of the data directory of the segment instance executing the external table command.</td>
</tr>
<tr>
<td>$GP_SEG_PG_CONF</td>
<td>The location of the <code>postgresql.conf</code> file of the segment instance executing the external table command.</td>
</tr>
<tr>
<td>$GP_SEG_PORT</td>
<td>The port number of the segment instance executing the external table command.</td>
</tr>
<tr>
<td>$GP_SEGMENT_COUNT</td>
<td>The total number of primary segment instances in the Greenplum Database system.</td>
</tr>
<tr>
<td>$GP_SEGMENT_ID</td>
<td>The ID number of the segment instance executing the external table command (same as <code>dbid</code> in <code>gp_segment_configuration</code>).</td>
</tr>
<tr>
<td>$GP_SESSION_ID</td>
<td>The database session identifier number associated with the external table statement.</td>
</tr>
<tr>
<td>$GP_SN</td>
<td>Serial number of the external table scan node in the query plan of the external table statement.</td>
</tr>
<tr>
<td>$GP_TIME</td>
<td>The time the external table command was executed.</td>
</tr>
<tr>
<td>$GP_USER</td>
<td>The database user executing the external table statement.</td>
</tr>
<tr>
<td>$GP_XID</td>
<td>The transaction ID of the external table statement.</td>
</tr>
</tbody>
</table>
**Disabling EXECUTE for Web or Writable External Tables**

There is a security risk associated with allowing external tables to execute OS commands or scripts. To disable the use of `EXECUTE` in web and writable external table definitions, set the `gp_external_enable_exec` server configuration parameter to off in your master `postgresql.conf` file:

```
gp_external_enable_exec = off
```

**Unloading Data Using a Writable External Table**

Writable external tables allow only `INSERT` operations. You must grant `INSERT` permission on a table to enable access to users who are not the table owner or a superuser. For example:

```
GRANT INSERT ON writable_ext_table TO admin;
```

To unload data using a writable external table, select the data from the source table(s) and insert it into the writable external table. The resulting rows are output to the writable external table. For example:

```
INSERT INTO writable_ext_table SELECT * FROM regular_table;
```

**Unloading Data Using COPY**

`COPY TO` copies data from a table to a file (or standard input) on the Greenplum master host using a single process on the Greenplum master instance. Use `COPY` to output a table's entire contents, or filter the output using a `SELECT` statement. For example:

```
COPY (SELECT * FROM country WHERE country_name LIKE 'A%')
TO '/home/gpadmin/a_list_countries.out';
```

**Formatting Data Files**

When you use the Greenplum tools for loading and unloading data, you must specify how your data is formatted. `COPY`, `CREATE EXTERNAL TABLE`, and `gpload` have clauses that allow you to specify how your data is formatted. Data can be delimited text (`TEXT`) or comma separated values (`CSV`) format. External data must be formatted correctly to be read by Greenplum Database. This topic explains the format of data files expected by Greenplum Database.

**Formatting Rows**

Greenplum Database expects rows of data to be separated by the `LF` character (Line feed, 0x0A), `CR` (Carriage return, 0x0D), or `CR` followed by `LF` (0x0D 0x0A). `LF` is the standard newline representation on UNIX or UNIX-like operating systems. Operating systems such as Windows or Mac OS X use `CR` or `CR+LF`. All of these representations of a newline are supported by Greenplum Database as a row delimiter. For more information, see `Importing and Exporting Fixed Width Data`.

**Formatting Columns**

The default column or field delimiter is the horizontal `TAB` character (0x09) for text files and the comma character (0x2C) for CSV files. You can declare a single character delimiter using the `DELIMITER` clause of `COPY`, `CREATE EXTERNAL TABLE` or `gpload` when you define your data format. The delimiter
character must appear between any two data value fields. Do not place a delimiter at the beginning or end of a row. For example, if the pipe character ( | ) is your delimiter:

```
data value 1|data value 2|data value 3
```

The following command shows the use of the pipe character as a column delimiter:

```
=# CREATE EXTERNAL TABLE ext_table (name text, date date)
    LOCATION ('gpfdist://<hostname>/filename.txt')
    FORMAT 'TEXT' (DELIMITER ' | ');
```

**Representing NULL Values**

NULL represents an unknown piece of data in a column or field. Within your data files you can designate a string to represent null values. The default string is \N (backslash-N) in TEXT mode, or an empty value with no quotations in CSV mode. You can also declare a different string using the NULL clause of COPY, CREATE EXTERNAL TABLE or gpload when defining your data format. For example, you can use an empty string if you do not want to distinguish nulls from empty strings. When using the Greenplum Database loading tools, any data item that matches the designated null string is considered a null value.

**Escaping**

There are two reserved characters that have special meaning to Greenplum Database:

- The designated delimiter character separates columns or fields in the data file.
- The newline character designates a new row in the data file.

If your data contains either of these characters, you must escape the character so that Greenplum treats it as data and not as a field separator or new row. By default, the escape character is a \ (backslash) for text-formatted files and a double quote (") for csv-formatted files.

**Escaping in Text Formatted Files**

By default, the escape character is a \ (backslash) for text-formatted files. You can declare a different escape character in the ESCAPE clause of COPY, CREATE EXTERNAL TABLE or gpload. If your escape character appears in your data, use it to escape itself.

For example, suppose you have a table with three columns and you want to load the following three fields:

- `backslash = \`
- `vertical bar = |`
- `exclamation point = !`

Your designated delimiter character is | (pipe character), and your designated escape character is \ (backslash). The formatted row in your data file looks like this:

```
backslash = \ \ | vertical bar = \ | exclamation point = !
```

Notice how the backslash character that is part of the data is escaped with another backslash character, and the pipe character that is part of the data is escaped with a backslash character.

You can use the escape character to escape octal and hexadecimal sequences. The escaped value is converted to the equivalent character when loaded into Greenplum Database. For example, to load the ampersand character (&), use the escape character to escape its equivalent hexadecimal (\0x26) or octal (\046) representation.
You can disable escaping in TEXT-formatted files using the `ESCAPE` clause of `COPY`, `CREATE EXTERNAL TABLE` or `gpload` as follows:

```
ESCAPE 'OFF'
```

This is useful for input data that contains many backslash characters, such as web log data.

**Escaping in CSV Formatted Files**

By default, the escape character is a " (double quote) for CSV-formatted files. If you want to use a different escape character, use the `ESCAPE` clause of `COPY`, `CREATE EXTERNAL TABLE` or `gpload` to declare a different escape character. In cases where your selected escape character is present in your data, you can use it to escape itself.

For example, suppose you have a table with three columns and you want to load the following three fields:

- Free trip to A,B
- 5.89
- Special rate "$1.79"

Your designated delimiter character is `,` (comma), and your designated escape character is " (double quote). The formatted row in your data file looks like this:

```
"Free trip to A,B","5.89","Special rate "$1.79"
```

The data value with a comma character that is part of the data is enclosed in double quotes. The double quotes that are part of the data are escaped with a double quote even though the field value is enclosed in double quotes.

Embedding the entire field inside a set of double quotes guarantees preservation of leading and trailing whitespace characters:

```
"Free trip to A,B","5.89","Special rate "$1.79"
```

**Note:** In CSV mode, all characters are significant. A quoted value surrounded by white space, or any characters other than `DELIMITER`, includes those characters. This can cause errors if you import data from a system that pads CSV lines with white space to some fixed width. In this case, preprocess the CSV file to remove the trailing white space before importing the data into Greenplum Database.

**Character Encoding**

Character encoding systems consist of a code that pairs each character from a character set with something else, such as a sequence of numbers or octets, to facilitate data transmission and storage. Greenplum Database supports a variety of character sets, including single-byte character sets such as the ISO 8859 series and multiple-byte character sets such as EUC (Extended UNIX Code), UTF-8, and Mule internal code. The server-side character set is defined during database initialization, UTF-8 is the default and can be changed. Clients can use all supported character sets transparently, but a few are not supported for use within the server as a server-side encoding. When loading or inserting data into Greenplum Database, Greenplum transparently converts the data from the specified client encoding into the server encoding. When sending data back to the client, Greenplum converts the data from the server character encoding into the specified client encoding.

Data files must be in a character encoding recognized by Greenplum Database. See the Greenplum Database Reference Guide for the supported character sets. Data files that contain invalid or unsupported encoding sequences encounter errors when loading into Greenplum Database.
**Note:** On data files generated on a Microsoft Windows operating system, run the dos2unix system command to remove any Windows-only characters before loading into Greenplum Database.

**Note:** If you change the ENCODING value in an existing gpload control file, you must manually drop any external tables that were creating using the previous ENCODING configuration. gpload does not drop and recreate external tables to use the new ENCODING if REUSE_TABLES is set to true.

### Changing the Client-Side Character Encoding

The client-side character encoding can be changed for a session by setting the server configuration parameter `client_encoding`

```sql
SET client_encoding TO 'latin1';
```

Change the client-side character encoding back to the default value:

```sql
RESET client_encoding;
```

Show the current client-side character encoding setting:

```sql
SHOW client_encoding;
```

### Example Custom Data Access Protocol

The following is the API for the Greenplum Database custom data access protocol. The example protocol implementation `gpxextprocal.c` is written in C and shows how the API can be used. For information about accessing a custom data access protocol, see *Using a Custom Protocol*.

```c
/* ---- Read/Write function API ------*/
CALLED_AS_EXTPROTOCOL(fcinfo)
EXTPROTOCOL_GET_URL(fcinfo)(fcinfo)
EXTPROTOCOL_GET_DATABUF(fcinfo)
EXTPROTOCOL_GET_DATALEN(fcinfo)
EXTPROTOCOL_GET_SCANQUALS(fcinfo)
EXTPROTOCOL_GET_USER_CTX(fcinfo)
EXTPROTOCOL_IS_LAST_CALL(fcinfo)
EXTPROTOCOL_SET_LAST_CALL(fcinfo)
EXTPROTOCOL_SET_USER_CTX(fcinfo, p)

/* ------ Validator function API ------*/
CALLED_AS_EXTPROTOCOL_VALIDATOR(fcinfo)
EXTPROTOCOL_VALIDATOR_GET_URL_LIST(fcinfo)
EXTPROTOCOL_VALIDATOR_GET_NUM_URLS(fcinfo)
EXTPROTOCOL_VALIDATOR_GET_NTH_URL(fcinfo, n)
EXTPROTOCOL_VALIDATOR_GET_DIRECTION(fcinfo)
```

### Notes

The protocol corresponds to the example described in *Using a Custom Protocol*. The source code file name and shared object are `gpextprotocol.c` and `gpextprotocol.so`.

The protocol has the following properties:

- The name defined for the protocol is `myprot`.
- The protocol has the following simple form: the protocol name and a path, separated by `://`.
  ```sql
  myprot://path
  ```
- Three functions are implemented:
• myprot_import() a read function
• myprot_export() a write function
• myprot_validate_urls() a validation function

These functions are referenced in the `CREATE PROTOCOL` statement when the protocol is created and declared in the database.

The example implementation `gpextproto.c` uses `fopen()` and `fread()` to simulate a simple protocol that reads local files. In practice, however, the protocol would implement functionality such as a remote connection to some process over the network.

### Installing the External Table Protocol

To use the example external table protocol, you use the C compiler `cc` to compile and link the source code to create a shared object that can be dynamically loaded by Greenplum Database. The commands to compile and link the source code on a Linux system are similar to this:

```
cc -fpic -c gpextproto.c cc -shared -o gpextproto.so gpextproto.o
```

The option `-fpic` specifies creating position-independent code (PIC) and the `-c` option compiles the source code without linking and creates an object file. The object file needs to be created as position-independent code (PIC) so that it can be loaded at any arbitrary location in memory by Greenplum Database.

The flag `-shared` specifies creating a shared object (shared library) and the `-o` option specifies the shared object file name `gpextproto.so`. Refer to the GCC manual for more information on the `cc` options.

The header files that are declared as include files in `gpextproto.c` are located in subdirectories of `$GPHOME/include/postgresql/`.

For more information on compiling and linking dynamically-loaded functions and examples of compiling C source code to create a shared library on other operating systems, see the PostgreSQL documentation at [https://www.postgresql.org/docs/9.4/xfunc-c.html#DFUNC](https://www.postgresql.org/docs/9.4/xfunc-c.html#DFUNC).

The manual pages for the C compiler `cc` and the link editor `ld` for your operating system also contain information on compiling and linking source code on your system.

The compiled code (shared object file) for the custom protocol must be placed in the same location on every host in your Greenplum Database array (master and all segments). This location must also be in the `LD_LIBRARY_PATH` so that the server can locate the files. It is recommended to locate shared libraries either relative to `$libdir` (which is located at `$GPHOME/lib`) or through the dynamic library path (set by the `dynamic_library_path` server configuration parameter) on all master segment instances in the Greenplum Database array. You can use the Greenplum Database utilities `gpssh` and `gpscp` to update segments.

`gpextproto.c`

```c
/* Our chosen URI format. We can change it however needed */
typedef struct DemoUri
{
    char     *protocol;
```
char *path;

} DemoUri;

static DemoUri *ParseDemoUri(const char *uri_str);
static void FreeDemoUri(DemoUri *uri);

/* Do the module magic dance */
PG_MODULE_MAGIC;

Managing Performance

The topics in this section cover Greenplum Database performance management, including how to monitor performance and how to configure workloads to prioritize resource utilization.

This section contains the following topics:

- Defining Database Performance
- Common Causes of Performance Issues
- Greenplum Database Memory Overview
- Managing Resources
- Investigating a Performance Problem

Defining Database Performance

Managing system performance includes measuring performance, identifying the causes of performance problems, and applying the tools and techniques available to you to remedy the problems.

Greenplum measures database performance based on the rate at which the database management system (DBMS) supplies information to requesters.

Understanding the Performance Factors

Several key performance factors influence database performance. Understanding these factors helps identify performance opportunities and avoid problems:

- System Resources
- Workload
- Throughput
- Contention
- Optimization

System Resources

Database performance relies heavily on disk I/O and memory usage. To accurately set performance expectations, you need to know the baseline performance of the hardware on which your DBMS is deployed. Performance of hardware components such as CPUs, hard disks, disk controllers, RAM, and network interfaces will significantly affect how fast your database performs.

Workload

The workload equals the total demand from the DBMS, and it varies over time. The total workload is a combination of user queries, applications, batch jobs, transactions, and system commands directed through the DBMS at any given time. For example, it can increase when month-end reports are run or decrease on weekends when most users are out of the office. Workload strongly influences database performance. Knowing your workload and peak demand times helps you plan for the most efficient use of your system resources and enables processing the largest possible workload.

Throughput

A system’s throughput defines its overall capability to process data. DBMS throughput is measured in queries per second, transactions per second, or average response times. DBMS throughput is closely related to the processing capacity of the underlying systems (disk I/O, CPU speed, memory bandwidth, and so on), so it is important to know the throughput capacity of your hardware when setting DBMS throughput goals.
**Contestion**

Contestion is the condition in which two or more components of the workload attempt to use the system in a conflicting way — for example, multiple queries that try to update the same piece of data at the same time or multiple large workloads that compete for system resources. As contention increases, throughput decreases.

**Optimization**

DBMS optimizations can affect the overall system performance. SQL formulation, database configuration parameters, table design, data distribution, and so on enable the database query optimizer to create the most efficient access plans.

**Determining Acceptable Performance**

When approaching a performance tuning initiative, you should know your system's expected level of performance and define measurable performance requirements so you can accurately evaluate your system's performance. Consider the following when setting performance goals:

- **Baseline Hardware Performance**
- **Performance Benchmarks**

**Baseline Hardware Performance**

Most database performance problems are caused not by the database, but by the underlying systems on which the database runs. I/O bottlenecks, memory problems, and network issues can notably degrade database performance. Knowing the baseline capabilities of your hardware and operating system (OS) will help you identify and troubleshoot hardware-related problems before you explore database-level or query-level tuning initiatives.

See the *Greenplum Database Reference Guide* for information about running the `gpcheckperf` utility to validate hardware and network performance.

**Performance Benchmarks**

To maintain good performance or fix performance issues, you should know the capabilities of your DBMS on a defined workload. A benchmark is a predefined workload that produces a known result set. Periodically run the same benchmark tests to help identify system-related performance degradation over time. Use benchmarks to compare workloads and identify queries or applications that need optimization.

Many third-party organizations, such as the Transaction Processing Performance Council (TPC), provide benchmark tools for the database industry. TPC provides TPC-H, a decision support system that examines large volumes of data, executes queries with a high degree of complexity, and gives answers to critical business questions. For more information about TPC-H, go to:

http://www.tpc.org/tpch

**Common Causes of Performance Issues**

This section explains the troubleshooting processes for common performance issues and potential solutions to these issues.

**Identifying Hardware and Segment Failures**

The performance of Greenplum Database depends on the hardware and IT infrastructure on which it runs. Greenplum Database is comprised of several servers (hosts) acting together as one cohesive system (array); as a first step in diagnosing performance problems, ensure that all Greenplum Database segments are online. Greenplum Database's performance will be as fast as the slowest host in the array. Problems
with CPU utilization, memory management, I/O processing, or network load affect performance. Common hardware-related issues are:

- **Disk Failure** – Although a single disk failure should not dramatically affect database performance if you are using RAID, disk resynchronization does consume resources on the host with failed disks. The `gpcheckperf` utility can help identify segment hosts that have disk I/O issues.

- **Host Failure** – When a host is offline, the segments on that host are nonoperational. This means other hosts in the array must perform twice their usual workload because they are running the primary segments and multiple mirrors. If mirrors are not enabled, service is interrupted. Service is temporarily interrupted to recover failed segments. The `gpstate` utility helps identify failed segments.

- **Network Failure** – Failure of a network interface card, a switch, or DNS server can bring down segments. If host names or IP addresses cannot be resolved within your Greenplum array, these manifest themselves as interconnect errors in Greenplum Database. The `gpcheckperf` utility helps identify segment hosts that have network issues.

- **Disk Capacity** – Disk capacity on your segment hosts should never exceed 70 percent full. Greenplum Database needs some free space for runtime processing. To reclaim disk space that deleted rows occupy, run `VACUUM` after loads or updates. The `gp_toolkit` administrative schema has many views for checking the size of distributed database objects.

See the *Greenplum Database Reference Guide* for information about checking database object sizes and disk space.

### Managing Workload

A database system has a limited CPU capacity, memory, and disk I/O resources. When multiple workloads compete for access to these resources, database performance suffers. Resource management maximizes system throughput while meeting varied business requirements. Greenplum Database provides resource queues and resource groups to help you manage these system resources.

Resource queues and resource groups limit resource usage and the total number of concurrent queries executing in the particular queue or group. By assigning database roles to the appropriate queue or group, administrators can control concurrent user queries and prevent system overload. For more information about resource queues and resource groups, including selecting the appropriate scheme for your Greenplum Database environment, see *Managing Resources*.

Greenplum Database administrators should run maintenance workloads such as data loads and `VACUUM ANALYZE` operations after business hours. Do not compete with database users for system resources; perform administrative tasks at low-usage times.

### Avoiding Contention

Contention arises when multiple users or workloads try to use the system in a conflicting way; for example, contention occurs when two transactions try to update a table simultaneously. A transaction that seeks a table-level or row-level lock will wait indefinitely for conflicting locks to be released. Applications should not hold transactions open for long periods of time, for example, while waiting for user input.

### Maintaining Database Statistics

Greenplum Database uses a cost-based query optimizer that relies on database statistics. Accurate statistics allow the query optimizer to better estimate the number of rows retrieved by a query to choose the most efficient query plan. Without database statistics, the query optimizer cannot estimate how many records will be returned. The optimizer does not assume it has sufficient memory to perform certain operations such as aggregations, so it takes the most conservative action and does these operations by reading and writing from disk. This is significantly slower than doing them in memory. `ANALYZE` collects statistics about the database that the query optimizer needs.

**Note:** When executing an SQL command with GPORCA, Greenplum Database issues a warning if the command performance could be improved by collecting statistics on a column or set of columns.
referenced by the command. The warning is issued on the command line and information is added to the Greenplum Database log file. For information about collecting statistics on table columns, see the `ANALYZE` command in the *Greenplum Database Reference Guide*

**Identifying Statistics Problems in Query Plans**

Before you interpret a query plan for a query using `EXPLAIN` or `EXPLAIN ANALYZE`, familiarize yourself with the data to help identify possible statistics problems. Check the plan for the following indicators of inaccurate statistics:

- **Are the optimizer's estimates close to reality?** Run `EXPLAIN ANALYZE` and see if the number of rows the optimizer estimated is close to the number of rows the query operation returned.
- **Are selective predicates applied early in the plan?** The most selective filters should be applied early in the plan so fewer rows move up the plan tree.
- **Is the optimizer choosing the best join order?** When you have a query that joins multiple tables, make sure the optimizer chooses the most selective join order. Joins that eliminate the largest number of rows should be done earlier in the plan so fewer rows move up the plan tree.

See *Query Profiling* for more information about reading query plans.

**Tuning Statistics Collection**

The following configuration parameters control the amount of data sampled for statistics collection:

- **default_statistics_target**

These parameters control statistics sampling at the system level. It is better to sample only increased statistics for columns used most frequently in query predicates. You can adjust statistics for a particular column using the command:

```
ALTER TABLE...SET STATISTICS
```

For example:

```
ALTER TABLE sales ALTER COLUMN region SET STATISTICS 50;
```

This is equivalent to changing `default_statistics_target` for a particular column. Subsequent `ANALYZE` operations will then gather more statistics data for that column and produce better query plans as a result.

**Optimizing Data Distribution**

When you create a table in Greenplum Database, you must declare a distribution key that allows for even data distribution across all segments in the system. Because the segments work on a query in parallel, Greenplum Database will always be as fast as the slowest segment. If the data is unbalanced, the segments that have more data will return their results slower and therefore slow down the entire system.

**Optimizing Your Database Design**

Many performance issues can be improved by database design. Examine your database design and consider the following:

- Does the schema reflect the way the data is accessed?
- Can larger tables be broken down into partitions?
- Are you using the smallest data type possible to store column values?
- Are columns used to join tables of the same datatype?
- Are your indexes being used?
**Greenplum Database Maximum Limits**

To help optimize database design, review the maximum limits that Greenplum Database supports:

**Table 58: Maximum Limits of Greenplum Database**

<table>
<thead>
<tr>
<th>Dimension</th>
<th>Limit</th>
</tr>
</thead>
<tbody>
<tr>
<td>Database Size</td>
<td>Unlimited</td>
</tr>
<tr>
<td>Table Size</td>
<td>Unlimited, 128 TB per partition per segment</td>
</tr>
<tr>
<td>Row Size</td>
<td>1.6 TB (1600 columns * 1 GB)</td>
</tr>
<tr>
<td>Field Size</td>
<td>1 GB</td>
</tr>
<tr>
<td>Rows per Table</td>
<td>281479476710656 (2^48)</td>
</tr>
<tr>
<td>Columns per Table/View</td>
<td>1600</td>
</tr>
<tr>
<td>Indexes per Table</td>
<td>Unlimited</td>
</tr>
<tr>
<td>Columns per Index</td>
<td>32</td>
</tr>
<tr>
<td>Table-level Constraints per Table</td>
<td>Unlimited</td>
</tr>
<tr>
<td>Table Name Length</td>
<td>63 Bytes (Limited by name data type)</td>
</tr>
</tbody>
</table>

Dimensions listed as unlimited are not intrinsically limited by Greenplum Database. However, they are limited in practice to available disk space and memory/swap space. Performance may suffer when these values are unusually large.

**Note:**

There is a maximum limit on the number of objects (tables, indexes, and views, but not rows) that may exist at one time. This limit is 4294967296 (2^32).

**Greenplum Database Memory Overview**

Memory is a key resource for a Greenplum Database system and, when used efficiently, can ensure high performance and throughput. This topic describes how segment host memory is allocated between segments and the options available to administrators to configure memory.

A Greenplum Database segment host runs multiple PostgreSQL instances, all sharing the host's memory. The segments have an identical configuration and they consume similar amounts of memory, CPU, and disk IO simultaneously, while working on queries in parallel.

For best query throughput, the memory configuration should be managed carefully. There are memory configuration options at every level in Greenplum Database, from operating system parameters, to managing resources with resource queues and resource groups, to setting the amount of memory allocated to an individual query.

**Segment Host Memory**

On a Greenplum Database segment host, the available host memory is shared among all the processes executing on the computer, including the operating system, Greenplum Database segment instances, and other application processes. Administrators must determine what Greenplum Database and non-Greenplum Database processes share the hosts' memory and configure the system to use the memory efficiently. It is equally important to monitor memory usage regularly to detect any changes in the way host memory is consumed by Greenplum Database or other processes.
The following figure illustrates how memory is consumed on a Greenplum Database segment host when resource queue-based resource management is active.

![Greenplum Database Segment Host Memory](image)

**Figure 28: Greenplum Database Segment Host Memory**

Beginning at the bottom of the illustration, the line labeled A represents the total host memory. The line directly above line A shows that the total host memory comprises both physical RAM and swap space.

The line labelled B shows that the total memory available must be shared by Greenplum Database and all other processes on the host. Non-Greenplum Database processes include the operating system and any other applications, for example system monitoring agents. Some applications may use a significant portion of memory and, as a result, you may have to adjust the number of segments per Greenplum Database host or the amount of memory per segment.

The segments (C) each get an equal share of the Greenplum Database Memory (B).

Within a segment, the currently active resource management scheme, Resource Queues or Resource Groups, governs how memory is allocated to execute a SQL statement. These constructs allow you to translate business requirements into execution policies in your Greenplum Database system and to guard against queries that could degrade performance. For an overview of resource groups and resource queues, refer to Managing Resources.

**Options for Configuring Segment Host Memory**

Host memory is the total memory shared by all applications on the segment host. You can configure the amount of host memory using any of the following methods:

- Add more RAM to the nodes to increase the physical memory.
- Allocate swap space to increase the size of virtual memory.
- Set the kernel parameters `vm.overcommit_memory` and `vm.overcommit_ratio` to configure how the operating system handles large memory allocation requests.

The physical RAM and OS configuration are usually managed by the platform team and system administrators. See the Greenplum Database Installation Guide for the recommended kernel parameters and for how to set the `/etc/sysctl.conf` file parameters.

The amount of memory to reserve for the operating system and other processes is workload dependent. The minimum recommendation for operating system memory is 32GB, but if there is much concurrency in Greenplum Database, increasing to 64GB of reserved memory may be required. The largest user of
operating system memory is SLAB, which increases as Greenplum Database concurrency and the number of sockets used increases.

The `vm.overcommit_memory` kernel parameter should always be set to 2, the only safe value for Greenplum Database.

The `vm.overcommit_ratio` kernel parameter sets the percentage of RAM that is used for application processes, the remainder reserved for the operating system. The default for Red Hat is 50 (50%). Setting this parameter too high may result in insufficient memory reserved for the operating system, which can cause segment host failure or database failure. Leaving the setting at the default of 50 is generally safe, but conservative. Setting the value too low reduces the amount of concurrency and the complexity of queries you can run at the same time by reducing the amount of memory available to Greenplum Database. When increasing `vm.overcommit_ratio`, it is important to remember to always reserve some memory for operating system activities.

**Configuring vm.overcommit_ratio when Resource Group-Based Resource Management is Active**

When resource group-based resource management is active, tune the operating system `vm.overcommit_ratio` as necessary. If your memory utilization is too low, increase the value; if your memory or swap usage is too high, decrease the setting.

**Configuring vm.overcommit_ratio when Resource Queue-Based Resource Management is Active**

To calculate a safe value for `vm.overcommit_ratio` when resource queue-based resource management is active, first determine the total memory available to Greenplum Database processes, `gp_vmem_rq`, with this formula:

\[
gp_vmem_rq = ((SWAP + RAM) - (7.5GB + 0.05 \times RAM)) / 1.7
\]

where `SWAP` is the swap space on the host in GB, and `RAM` is the number of GB of RAM installed on the host. When resource queue-based resource management is active, use `gp_vmem_rq` to calculate the `vm.overcommit_ratio` value with this formula:

\[
vm.overcommit_ratio = (RAM - 0.026 \times gp_vmem_rq) / RAM
\]

**Configuring Greenplum Database Memory**

Greenplum Database Memory is the amount of memory available to all Greenplum Database segment instances.

When you set up the Greenplum Database cluster, you determine the number of primary segments to run per host and the amount of memory to allocate for each segment. Depending on the CPU cores, amount of physical RAM, and workload characteristics, the number of segments is usually a value between 4 and 8. With segment mirroring enabled, it is important to allocate memory for the maximum number of primary segments executing on a host during a failure. For example, if you use the default grouping mirror configuration, a segment host failure doubles the number of acting primaries on the host that has the failed host's mirrors. Mirror configurations that spread each host's mirrors over multiple other hosts can lower the maximum, allowing more memory to be allocated for each segment. For example, if you use a block mirroring configuration with 4 hosts per block and 8 primary segments per host, a single host failure would cause other hosts in the block to have a maximum of 11 active primaries, compared to 16 for the default grouping mirror configuration.

**Configuring Segment Memory when Resource Group-Based Resource Management is Active**

When resource group-based resource management is active, the amount of memory allocated to each segment on a segment host is the memory available to Greenplum Database multiplied by the `gp_resource_group_memory_limit` server configuration parameter and divided by the number of active primary segments on the host. Use the following formula to calculate segment memory when using resource groups for resource management.
rg_perseg_mem = (\((\text{RAM} \times (\frac{\text{vm.overcommit\_ratio}}{100}) + \text{SWAP}) \times \frac{\text{gp\_resource\_group\_memory\_limit}}{\text{num\_active\_primary\_segments}}\)

Resource groups expose additional configuration parameters that enable you to further control and refine the amount of memory allocated for queries.

**Configuring Segment Memory when Resource Queue-Based Resource Management is Active**

When resource queue-based resource management is active, the \( \text{gp\_vmem\_protect\_limit} \) server configuration parameter value identifies the amount of memory to allocate to each segment. This value is estimated by calculating the memory available for all Greenplum Database processes and dividing by the maximum number of primary segments during a failure. If \( \text{gp\_vmem\_protect\_limit} \) is set too high, queries can fail. Use the following formula to calculate a safe value for \( \text{gp\_vmem\_protect\_limit} \); provide the \( \text{gp\_vmem\_rq} \) value that you calculated earlier.

\[
\text{gp\_vmem\_protect\_limit} = \frac{\text{gp\_vmem\_rq}}{\text{max\_acting\_primary\_segments}}
\]

where \( \text{max\_acting\_primary\_segments} \) is the maximum number of primary segments that could be running on a host when mirror segments are activated due to a host or segment failure.

\( \text{gp\_vmem\_protect\_limit} \) does not affect segment memory when using resource groups for Greenplum Database resource management.

Resource queues expose additional configuration parameters that enable you to further control and refine the amount of memory allocated for queries.

**Example Memory Configuration Calculations**

This section provides example memory calculations for resource queues and resource groups for a Greenplum Database system with the following specifications:

- Total RAM = 256GB
- Swap = 64GB
- 8 primary segments and 8 mirror segments per host, in blocks of 4 hosts
- Maximum number of primaries per host during failure is 11

**Resource Group Example**

When resource group-based resource management is active in Greenplum Database, the usable memory available on a host is a function of the amount of RAM and swap space configured for the system, as well as the \( \text{vm.overcommit\_ratio} \) system parameter setting:

\[
\text{total\_node\_usable\_memory} = \text{RAM} \times (\frac{\text{vm.overcommit\_ratio}}{100}) + \text{Swap} = 256GB \times (50/100) + 64GB = 192GB
\]

Assuming the default \( \text{gp\_resource\_group\_memory\_limit} \) value (.7), the memory allocated to a Greenplum Database host with the example configuration is:

\[
\text{total\_gp\_memory} = \text{total\_node\_usable\_memory} \times \text{gp\_resource\_group\_memory\_limit} = 192GB \times 0.7 = 134.4GB
\]

The memory available to a Greenplum Database segment on a segment host is a function of the memory reserved for Greenplum on the host and the number of active primary segments on the host. On cluster startup:
The \texttt{gp\_seg\_memory} calculation for the example system when resource queue-based resource management is active in Greenplum Database follows:

\[
gp\_seg\_memory = \frac{\text{total\_gp\_memory}}{\text{number\_of\_active\_primary\_segments}} = \frac{134.4\text{GB}}{8} = 16.8\text{GB}
\]

Note that when 3 mirror segments switch to primary segments, the per-segment memory is still 16.8GB. Total memory usage on the segment host may approach:

\[
\text{total\_gp\_memory\_with\_primaries} = 16.8\text{GB} \times 11 = 184.8\text{GB}
\]

**Resource Queue Example**

The \texttt{vm\_overcommit\_ratio} calculation for the example system when resource queue-based resource management is active in Greenplum Database follows:

\[
gp\_vmem\_rq = \frac{(\text{SWAP} + \text{RAM}) - (7.5\text{GB} + 0.05 \times \text{RAM})}{1.7} = \frac{((64 + 256) - (7.5 + 0.05 \times 256))}{1.7} = 176
\]

\[
\text{vm\_overcommit\_ratio} = \frac{\text{RAM} - (0.026 \times \text{gp\_vmem\_rq})}{\text{RAM}} = \frac{256 - (0.026 \times 176)}{256} = .982
\]

You would set \texttt{vm\_overcommit\_ratio} of the example system to 98.

The \texttt{gp\_vmem\_protect\_limit} calculation when resource queue-based resource management is active in Greenplum Database:

\[
gp\_vmem\_protect\_limit = \frac{\text{gp\_vmem\_rq}}{\text{maximum\_acting\_primary\_segments}} = \frac{176}{11} = 16\text{GB} = 16384\text{MB}
\]

You would set the \texttt{gp\_vmem\_protect\_limit} server configuration parameter on the example system to 16384.

**Managing Resources**

Greenplum Database provides features to help you prioritize and allocate resources to queries according to business requirements and to prevent queries from starting when resources are unavailable.

You can use resource management features to limit the number of concurrent queries, the amount of memory used to execute a query, and the relative amount of CPU devoted to processing a query.

Greenplum Database provides two schemes to manage resources - Resource Queues and Resource Groups.

\textbf{Important: } Significant Greenplum Database performance degradation has been observed when enabling resource group-based workload management on RedHat 6.x and CentOS 6.x. This issue is caused by a Linux cgroup kernel bug. This kernel bug has been fixed in CentOS 7.x and Red Hat 7.x systems.

If you use RedHat 6 and the performance with resource groups is acceptable for your use case, upgrade your kernel to version 2.6.32-696 or higher to benefit from other fixes to the cgroups implementation.

Either the resource queue or the resource group management scheme can be active in Greenplum Database; both schemes cannot be active at the same time.

Resource queues are enabled by default when you install your Greenplum Database cluster. While you can create and assign resource groups when resource queues are active, you must explicitly enable resource groups to start using that management scheme.
The following table summarizes some of the differences between Resource Queues and Resource Groups.

<table>
<thead>
<tr>
<th>Metric</th>
<th>Resource Queues</th>
<th>Resource Groups</th>
</tr>
</thead>
<tbody>
<tr>
<td>Concurrency</td>
<td>Managed at the query level</td>
<td>Managed at the transaction level</td>
</tr>
<tr>
<td>CPU</td>
<td>Specify query priority</td>
<td>Specify percentage of CPU resources; uses Linux Control Groups</td>
</tr>
<tr>

</tbody>
</table>

**Using Resource Groups**

You use resource groups to set and enforce CPU, memory, and concurrent transaction limits in Greenplum Database. After you define a resource group, you can then assign the group to one or more Greenplum Database roles, or to an external component such as PL/Container, in order to control the resources used by those roles or components.

When you assign a resource group to a role (a role-based resource group), the resource limits that you define for the group apply to all of the roles to which you assign the group. For example, the memory limit for a resource group identifies the maximum memory usage for all running transactions submitted by Greenplum Database users in all roles to which you assign the group.

Similarly, when you assign a resource group to an external component, the group limits apply to all running instances of the component. For example, if you create a resource group for a PL/Container external component, the memory limit that you define for the group specifies the maximum memory usage for all running instances of each PL/Container runtime to which you assign the group.

This topic includes the following subtopics:

- *Understanding Role and Component Resource Groups*
- *Resource Group Attributes and Limits*
Understanding Role and Component Resource Groups

Greenplum Database supports two types of resource groups: groups that manage resources for roles, and groups that manage resources for external components such as PL/Container.

The most common application for resource groups is to manage the number of active queries that different roles may execute concurrently in your Greenplum Database cluster. You can also manage the amount of CPU and memory resources that Greenplum allocates to each query.

Resource groups for roles use Linux control groups (cgroups) for CPU resource management. Greenplum Database tracks virtual memory internally for these resource groups using a memory auditor referred to as vmtracker.

When the user executes a query, Greenplum Database evaluates the query against a set of limits defined for the resource group. Greenplum Database executes the query immediately if the group's resource limits have not yet been reached and the query does not cause the group to exceed the concurrent transaction limit. If these conditions are not met, Greenplum Database queues the query. For example, if the maximum number of concurrent transactions for the resource group has already been reached, a subsequent query is queued and must wait until other queries complete before it runs. Greenplum Database may also execute a pending query when the resource group’s concurrency and memory limits are altered to large enough values.

Within a resource group for roles, transactions are evaluated on a first in, first out basis. Greenplum Database periodically assesses the active workload of the system, reallocating resources and starting/queuing jobs as necessary.

You can also use resource groups to manage the CPU and memory resources of external components such as PL/Container. Resource groups for external components use Linux cgroups to manage both the total CPU and total memory resources for the component.

Note: Containerized deployments of Greenplum Database, such as Greenplum for Kubernetes, might create a hierarchical set of nested cgroups to manage host system resources. The nesting of cgroups affects the Greenplum Database resource group limits for CPU percentage, CPU cores, and memory (except for Greenplum Database external components). The Greenplum Database resource group system resource limit is based on the quota for the parent group.

For example, Greenplum Database is running in a cgroup demo, and the Greenplum Database cgroup is nested in the cgroup demo. If the cgroup demo is configured with a CPU limit of 60% of system CPU resources and the Greenplum Database resource group CPU limit is set 90%, the Greenplum Database limit of host system CPU resources is 54% (0.6 x 0.9).

Nested cgroups do not affect memory limits for Greenplum Database external components such as PL/Container. Memory limits for external components can only be managed if the cgroup that is used to manage Greenplum Database resources is not nested, the cgroup is configured as a top-level cgroup.

For information about configuring cgroups for use by resource groups, see Using Resource Groups.
Resource Group Attributes and Limits

When you create a resource group, you:

- Specify the type of resource group by identifying how memory for the group is audited.
- Provide a set of limits that determine the amount of CPU and memory resources available to the group.

Resource group attributes and limits:

<table>
<thead>
<tr>
<th>Limit Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>MEMORY_AUDITOR</td>
<td>The memory auditor in use for the resource group. vmtracker (the default) is required if you want to assign the resource group to roles. Specify cgroup to assign the resource group to an external component.</td>
</tr>
<tr>
<td>CONCURRENGENCY</td>
<td>The maximum number of concurrent transactions, including active and idle transactions, that are permitted in the resource group.</td>
</tr>
<tr>
<td>CPU_RATE_LIMIT</td>
<td>The percentage of CPU resources available to this resource group.</td>
</tr>
<tr>
<td>CPUSET</td>
<td>The CPU cores to reserve for this resource group.</td>
</tr>
<tr>
<td>MEMORY_LIMIT</td>
<td>The percentage of reserved memory resources available to this resource group.</td>
</tr>
<tr>
<td>MEMORY_SHARED_QUOTA</td>
<td>The percentage of reserved memory to share across transactions submitted in this resource group.</td>
</tr>
<tr>
<td>MEMORY_SPILL_RATIO</td>
<td>The memory usage threshold for memory-intensive transactions. When a transaction reaches this threshold, it spills to disk.</td>
</tr>
</tbody>
</table>

Note: Resource limits are not enforced on SET, RESET, and SHOW commands.

Memory Auditor

The MEMORY_AUDITOR attribute specifies the type of resource group by identifying the memory auditor for the group. A resource group that specifies the vmtracker MEMORY_AUDITOR identifies a resource group for roles. A resource group specifying the cgroup MEMORY_AUDITOR identifies a resource group for external components.

The default MEMORY_AUDITOR is vmtracker.

The MEMORY_AUDITOR that you specify for a resource group determines if and how Greenplum Database uses the limit attributes to manage CPU and memory resources:

<table>
<thead>
<tr>
<th>Limit Type</th>
<th>Resource Group for Roles</th>
<th>Resource Group for External Components</th>
</tr>
</thead>
<tbody>
<tr>
<td>CONCURRENGENCY</td>
<td>Yes</td>
<td>No; must be zero (0)</td>
</tr>
<tr>
<td>CPU_RATE_LIMIT</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>CPUSET</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>MEMORY_LIMIT</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>MEMORY_SHARED_QUOTA</td>
<td>Yes</td>
<td>Component-specific</td>
</tr>
</tbody>
</table>
### Transaction Concurrency Limit

The `CONCURRENCY` limit controls the maximum number of concurrent transactions permitted for a resource group for roles.

**Note:** The `CONCURRENCY` limit is not applicable to resource groups for external components and must be set to zero (0) for such groups.

Each resource group for roles is logically divided into a fixed number of slots equal to the `CONCURRENCY` limit. Greenplum Database allocates these slots an equal, fixed percentage of memory resources.

The default `CONCURRENCY` limit value for a resource group for roles is 20.

Greenplum Database queues any transactions submitted after the resource group reaches its `CONCURRENCY` limit. When a running transaction completes, Greenplum Database un-queues and executes the earliest queued transaction if sufficient memory resources exist.

You can set the server configuration parameter `gp_resource_group_bypass` to bypass a resource group concurrency limit.

### CPU Limits

You configure the share of CPU resources to reserve for a resource group on a segment host by assigning specific CPU core(s) to the group, or by identifying the percentage of segment CPU resources to allocate to the group. Greenplum Database uses the `CPUSET` and `CPU_RATE_LIMIT` resource group limits to identify the CPU resource allocation mode. You must specify only one of these limits when you configure a resource group.

You may employ both modes of CPU resource allocation simultaneously in your Greenplum Database cluster. You may also change the CPU resource allocation mode for a resource group at runtime.

The `gp_resource_group_cpu_limit` server configuration parameter identifies the maximum percentage of system CPU resources to allocate to resource groups on each Greenplum Database segment host. This limit governs the maximum CPU usage of all resource groups on a segment host regardless of the CPU allocation mode configured for the group. The remaining unreserved CPU resources are used for the OS kernel and the Greenplum Database auxiliary daemon processes. The default `gp_resource_group_cpu_limit` value is .9 (90%).

**Note:** The default `gp_resource_group_cpu_limit` value may not leave sufficient CPU resources if you are running other workloads on your Greenplum Database cluster nodes, so be sure to adjust this server configuration parameter accordingly.

**Warning:** Avoid setting `gp_resource_group_cpu_limit` to a value higher than .9. Doing so may result in high workload queries taking near all CPU resources, potentially starving Greenplum Database auxiliary processes.

### Assigning CPU Resources by Core

You identify the CPU cores that you want to reserve for a resource group with the `CPUSET` property. The CPU cores that you specify must be available in the system and cannot overlap with any CPU cores that you reserved for other resource groups. (Although Greenplum Database uses the cores that you assign to a resource group exclusively for that group, note that those CPU cores may also be used by non-Greenplum processes in the system.)

Specify a comma-separated list of single core numbers or number intervals when you configure `CPUSET`. You must enclose the core numbers/intervals in single quotes, for example, ‘1,3-4’.

<table>
<thead>
<tr>
<th>Limit Type</th>
<th>Resource Group for Roles</th>
<th>Resource Group for External Components</th>
</tr>
</thead>
<tbody>
<tr>
<td>MEMORY_SPILL_RATIO</td>
<td>Yes</td>
<td>Component-specific</td>
</tr>
</tbody>
</table>
When you assign CPU cores to `CPUSET` groups, consider the following:

- A resource group that you create with `CPUSET` uses the specified cores exclusively. If there are no running queries in the group, the reserved cores are idle and cannot be used by queries in other resource groups. Consider minimizing the number of `CPUSET` groups to avoid wasting system CPU resources.
- Consider keeping CPU core 0 unassigned. CPU core 0 is used as a fallback mechanism in the following cases:
  - `admin_group` and `default_group` require at least one CPU core. When all CPU cores are reserved, Greenplum Database assigns CPU core 0 to these default groups. In this situation, the resource group to which you assigned CPU core 0 shares the core with `admin_group` and `default_group`.
  - If you restart your Greenplum Database cluster with one node replacement and the node does not have enough cores to service all `CPUSET` resource groups, the groups are automatically assigned CPU core 0 to avoid system start failure.
- Use the lowest possible core numbers when you assign cores to resource groups. If you replace a Greenplum Database node and the new node has fewer CPU cores than the original, or if you back up the database and want to restore it on a cluster with nodes with fewer CPU cores, the operation may fail. For example, if your Greenplum Database cluster has 16 cores, assigning cores 1-7 is optimal. If you create a resource group and assign CPU core 9 to this group, database restore to an 8 core node will fail.

Resource groups that you configure with `CPUSET` have a higher priority on CPU resources. The maximum CPU resource usage percentage for all resource groups configured with `CPUSET` on a segment host is the number of CPU cores reserved divided by the number of all CPU cores, multiplied by 100.

When you configure `CPUSET` for a resource group, Greenplum Database disables `CPU_RATE_LIMIT` for the group and sets the value to -1.

**Note:** You must configure `CPUSET` for a resource group after you have enabled resource group-based resource management for your Greenplum Database cluster.

### Assigning CPU Resources by Percentage

The Greenplum Database node CPU percentage is divided equally among each segment on the Greenplum node. Each resource group that you configure with a `CPU_RATE_LIMIT` reserves the specified percentage of the segment CPU for resource management.

The minimum `CPU_RATE_LIMIT` percentage you can specify for a resource group is 1, the maximum is 100.

The sum of `CPU_RATE_LIMIT` specified for all resource groups that you define in your Greenplum Database cluster must not exceed 100.

The maximum CPU resource usage for all resource groups configured with a `CPU_RATE_LIMIT` on a segment host is the minimum of:

- The number of non-reserved CPU cores divided by the number of all CPU cores, multiplied by 100, and
- The `gp_resource_group_cpu_limit` value.

CPU resource assignment for resource groups configured with a `CPU_RATE_LIMIT` is elastic in that Greenplum Database may allocate the CPU resources of an idle resource group to a busier one(s). In such situations, CPU resources are re-allocated to the previously idle resource group when that resource group next becomes active. If multiple resource groups are busy, they are allocated the CPU resources of any idle resource groups based on the ratio of their `CPU_RATE_LIMITs`. For example, a resource group created with a `CPU_RATE_LIMIT` of 40 will be allocated twice as much extra CPU resource as a resource group that you create with a `CPU_RATE_LIMIT` of 20.

When you configure `CPU_RATE_LIMIT` for a resource group, Greenplum Database disables `CPUSET` for the group and sets the value to -1.
**Memory Limits**

When resource groups are enabled, memory usage is managed at the Greenplum Database node, segment, and resource group levels. You can also manage memory at the transaction level with a resource group for roles.

The `gp_resource_group_memory_limit` server configuration parameter identifies the maximum percentage of system memory resources to allocate to resource groups on each Greenplum Database segment host. The default `gp_resource_group_memory_limit` value is 0.7 (70%).

The memory resource available on a Greenplum Database node is further divided equally among each segment on the node. When resource group-based resource management is active, the amount of memory allocated to each segment on a segment host is the memory available to Greenplum Database multiplied by the `gp_resource_group_memory_limit` server configuration parameter and divided by the number of active primary segments on the host:

```
rg_perseg_mem = ((RAM * (vm.overcommit_ratio / 100) + SWAP) *
gp_resource_group_memory_limit) / num_active_primary_segments
```

Each resource group may reserve a percentage of the segment memory for resource management. You identify this percentage via the `MEMORY_LIMIT` value that you specify when you create the resource group. The minimum `MEMORY_LIMIT` percentage you can specify for a resource group is 0, the maximum is 100. When `MEMORY_LIMIT` is 0, Greenplum Database reserves no memory for the resource group, but uses resource group global shared memory to fulfill all memory requests in the group. Refer to *Global Shared Memory* for more information about resource group global shared memory.

The sum of `MEMORY_LIMIT`s specified for all resource groups that you define in your Greenplum Database cluster must not exceed 100.

**Additional Memory Limits for Role-based Resource Groups**

If resource group memory is reserved for roles (non-zero `MEMORY_LIMIT`), the memory is further divided into fixed and shared components. The `MEMORY_SHARED_QUOTA` value that you specify when you create the resource group identifies the percentage of reserved resource group memory that may be shared among the currently running transactions. This memory is allotted on a first-come, first-served basis. A running transaction may use none, some, or all of the `MEMORY_SHARED_QUOTA`.

The minimum `MEMORY_SHARED_QUOTA` that you can specify is 0, the maximum is 100. The default `MEMORY_SHARED_QUOTA` is 80.

As mentioned previously, `CONCURRENCY` identifies the maximum number of concurrently running transactions permitted in a resource group for roles. If fixed memory is reserved by a resource group (non-zero `MEMORY_LIMIT`), it is divided into `CONCURRENCY` number of transaction slots. Each slot is allocated a fixed, equal amount of the resource group memory. Greenplum Database guarantees this fixed memory to each transaction.
Figure 29: Resource Group Memory Allotments

When a query’s memory usage exceeds the fixed per-transaction memory usage amount, Greenplum Database allocates available resource group shared memory to the query. The maximum amount of resource group memory available to a specific transaction slot is the sum of the transaction’s fixed memory and the full resource group shared memory allotment.

Global Shared Memory

The sum of the MEMORY_LIMITs configured for all resource groups (including the default admin_group and default_group groups) identifies the percentage of reserved resource group memory. If this sum is less than 100, Greenplum Database allocates any unreserved memory to a resource group global shared memory pool.

Resource group global shared memory is available only to resource groups that you configure with the vmtracker memory auditor.

When available, Greenplum Database allocates global shared memory to a transaction after first allocating slot and resource group shared memory (if applicable). Greenplum Database allocates resource group global shared memory to transactions on a first-come first-served basis.
**Note:** Greenplum Database tracks, but does not actively monitor, transaction memory usage in resource groups. If the memory usage for a resource group exceeds its fixed memory allotment, a transaction in the resource group fails when all of these conditions are met:

- No available resource group shared memory exists.
- No available global shared memory exists.
- The transaction requests additional memory.

Greenplum Database uses resource group memory more efficiently when you leave some memory (for example, 10-20%) unallocated for the global shared memory pool. The availability of global shared memory also helps to mitigate the failure of memory-consuming or unpredicted queries.

**Query Operator Memory**

Most query operators are non-memory-intensive; that is, during processing, Greenplum Database can hold their data in allocated memory. When memory-intensive query operators such as join and sort process more data than can be held in memory, data is spilled to disk.

The `gp_resgroup_memory_policy` server configuration parameter governs the memory allocation and distribution algorithm for all query operators. Greenplum Database supports eager-free (the default) and auto memory policies for resource groups. When you specify the auto policy, Greenplum Database uses resource group memory limits to distribute memory across query operators, allocating a fixed size of memory to non-memory-intensive operators and the rest to memory-intensive operators. When the eager_free policy is in place, Greenplum Database distributes memory among operators more optimally by re-allocating memory released by operators that have completed their processing to operators in a later query stage.

The `MEMORY_SPILL_RATIO` identifies the memory usage threshold for memory-intensive operators in a transaction. When this threshold is reached, a transaction spills to disk. Greenplum Database uses the `MEMORY_SPILL_RATIO` to determine the initial memory to allocate to a transaction.

You can specify an integer percentage value from 0 to 100 inclusive for `MEMORY_SPILL_RATIO`. The default `MEMORY_SPILL_RATIO` is 0.

When `MEMORY_SPILL_RATIO` is 0, Greenplum Database uses the `statement_mem` server configuration parameter value to control initial query operator memory.

**Note:** When you set `MEMORY_LIMIT` to 0, `MEMORY_SPILL_RATIO` must also be set to 0.

You can selectively set the `MEMORY_SPILL_RATIO` on a per-query basis at the session level with the `memory_spill_ratio` server configuration parameter.

**memory_spill_ratio and Low Memory Queries**

A low `statement_mem` setting (for example, in the 10MB range) has been shown to increase the performance of queries with low memory requirements. Use the `memory_spill_ratio` and `statement_mem` server configuration parameters to override the setting on a per-query basis. For example:

```
SET memory_spill_ratio=0;
SET statement_mem='10 MB';
```

**About Using Reserved Resource Group Memory vs. Using Resource Group Global Shared Memory**

When you do not reserve memory for a resource group (`MEMORY_LIMIT` and `MEMORY_SPILL_RATIO` are set to 0):

- It increases the size of the resource group global shared memory pool.
- The resource group functions similarly to a resource queue, using the `statement_mem` server configuration parameter value to control initial query operator memory.
• Any query submitted in the resource group competes for resource group global shared memory on a first-come, first-served basis with queries running in other groups.
• There is no guarantee that Greenplum Database will be able to allocate memory for a query running in the resource group. The risk of a query in the group encountering an out of memory (OOM) condition increases when there are many concurrent queries consuming memory from the resource group global shared memory pool at the same time.

To reduce the risk of OOM for a query running in an important resource group, consider reserving some fixed memory for the group. While reserving fixed memory for a group reduces the size of the resource group global shared memory pool, this may be a fair tradeoff to reduce the risk of encountering an OOM condition in a query running in a critical resource group.

Other Memory Considerations

Resource groups for roles track all Greenplum Database memory allocated via the palloc() function. Memory that you allocate using the Linux malloc() function is not managed by these resource groups. To ensure that resource groups for roles are accurately tracking memory usage, avoid using malloc() to allocate large amounts of memory in custom Greenplum Database user-defined functions.

Using Greenplum Command Center to Manage Resource Groups

Using Pivotal Greenplum Command Center, an administrator can create and manage resource groups, change roles' resource groups, and create workload management rules.

Workload management assignment rules assign transactions to different resource groups based on user-defined criteria. If no assignment rule is matched, Greenplum Database assigns the transaction to the role's default resource group.

Refer to the Greenplum Command Center documentation for more information about creating and managing resource groups and workload management rules.

Using Resource Groups

Important: Significant Greenplum Database performance degradation has been observed when enabling resource group-based workload management on RedHat 6.x and CentOS 6.x systems. This issue is caused by a Linux cgroup kernel bug. This kernel bug has been fixed in CentOS 7.x and Red Hat 7.x systems.

If you use RedHat 6 and the performance with resource groups is acceptable for your use case, upgrade your kernel to version 2.6.32-696 or higher to benefit from other fixes to the cgroups implementation.

Prerequisite

Greenplum Database resource groups use Linux Control Groups (cgroups) to manage CPU resources. Greenplum Database also uses cgroups to manage memory for resource groups for external components. With cgroups, Greenplum isolates the CPU and external component memory usage of your Greenplum processes from other processes on the node. This allows Greenplum to support CPU and external component memory usage restrictions on a per-resource-group basis.

For detailed information about cgroups, refer to the Control Groups documentation for your Linux distribution.

Complete the following tasks on each node in your Greenplum Database cluster to set up cgroups for use with resource groups:

1. If you are running the SuSE 11+ operating system on your Greenplum Database cluster nodes, you must enable swap accounting on each node and restart your Greenplum Database cluster. The swapaccount kernel boot parameter governs the swap accounting setting on SuSE 11+ systems. After setting this boot parameter, you must reboot your systems. For details, refer to the Cgroup Swap
Control discussion in the SuSE 11 release notes. You must be the superuser or have sudo access to configure kernel boot parameters and reboot systems.

2. Create the Greenplum Database cgroups configuration file /etc/cgconfig.d/gpdb.conf. You must be the superuser or have sudo access to configure kernel boot parameters and reboot systems:

```bash
sudo vi /etc/cgconfig.d/gpdb.conf
```

3. Add the following configuration information to /etc/cgconfig.d/gpdb.conf:

```plaintext
group gpdb {
    perm {
        task {
            uid = gpadmin;
            gid = gpadmin;
        }
        admin {
            uid = gpadmin;
            gid = gpadmin;
        }
    }
    cpu {
    }
    cpuacct {
    }
    cpuset {
    }
    memory {
    }
}
```

This content configures CPU, CPU accounting, CPU core set, and memory control groups managed by the gpadmin user. Greenplum Database uses the memory control group only for those resource groups created with the `cgroup MEMORY_AUDITOR`.

4. If not already installed and running, install the Control Groups operating system package and start the cgroups service on each Greenplum Database node. The commands that you run to perform these tasks will differ based on the operating system installed on the node. You must be the superuser or have sudo access to run these commands:

   - **Redhat/CentOS 7.x systems:**
     ```bash
     sudo yum install libcgroup-tools
     sudo cgconfigparser -l /etc/cgconfig.d/gpdb.conf
     ```
   
   - **Redhat/CentOS 6.x systems:**
     ```bash
     sudo yum install libcgroup
     sudo service cgconfig start
     ```
   
   - **SuSE 11+ systems:**
     ```bash
     sudo zypper install libcgroup-tools
     sudo cgconfigparser -l /etc/cgconfig.d/gpdb.conf
     ```

5. Identify the cgroup directory mount point for the node:

```bash
grep cgroup /proc/mounts
```

The first line of output identifies the cgroup mount point.
6. Verify that you set up the Greenplum Database cgroups configuration correctly by running the following commands. Replace `<cgroup_mount_point>` with the mount point that you identified in the previous step:

<table>
<thead>
<tr>
<th>Command</th>
</tr>
</thead>
<tbody>
<tr>
<td>ls -l <code>&lt;cgroup_mount_point&gt;/cpu/gpdb</code></td>
</tr>
<tr>
<td>ls -l <code>&lt;cgroup_mount_point&gt;/cpuacct/gpdb</code></td>
</tr>
<tr>
<td>ls -l <code>&lt;cgroup_mount_point&gt;/cpuset/gpdb</code></td>
</tr>
<tr>
<td>ls -l <code>&lt;cgroup_mount_point&gt;/memory/gpdb</code></td>
</tr>
</tbody>
</table>

If these directories exist and are owned by `gpadmin:gpadmin`, you have successfully configured cgroups for Greenplum Database CPU resource management.

7. To automatically recreate Greenplum Database required cgroup hierarchies and parameters when your system is restarted, configure your system to enable the Linux cgroup service daemon `cgconfig.service` (Redhat/CentOS 7.x and SuSE 11+) or `cgconfig` (Redhat/CentOS 6.x) at node start-up. For example, configure one of the following cgroup service commands in your preferred service auto-start tool:

- **Redhat/CentOS 7.x and SuSE11+ systems:**
  
  ```
  sudo systemctl enable cgconfig.service
  ```

  To start the service immediately (without having to reboot) enter:

  ```
  sudo systemctl start cgconfig.service
  ```

- **Redhat/CentOS 6.x systems:**
  
  ```
  sudo chkconfig cgconfig on
  ```

You may choose a different method to recreate the Greenplum Database resource group cgroup hierarchies.

**Procedure**

To use resource groups in your Greenplum Database cluster, you:

1. **Enable resource groups for your Greenplum Database cluster.**
2. **Create resource groups.**
3. **Assign the resource groups to one or more roles.**
4. **Use resource management system views to monitor and manage the resource groups.**

**Enabling Resource Groups**

When you install Greenplum Database, resource queues are enabled by default. To use resource groups instead of resource queues, you must set the `gp_resource_manager` server configuration parameter.

1. Set the `gp_resource_manager` server configuration parameter to the value "group":

   ```
   gpconfig -s gp_resource_manager
   gpconfig -c gp_resource_manager -v "group"
   ```

2. Restart Greenplum Database:

   ```
   gpstop
gpstart
   ```

Once enabled, any transaction submitted by a role is directed to the resource group assigned to the role, and is governed by that resource group's concurrency, memory, and CPU limits. Similarly, CPU and memory usage by an external component is governed by the CPU and memory limits configured for the resource group assigned to the component.
Greenplum Database creates two default resource groups for roles named `admin_group` and `default_group`. When you enable resources groups, any role that was not explicitly assigned a resource group is assigned the default group for the role’s capability. `SUPERUSER` roles are assigned the `admin_group`, non-admin roles are assigned the group named `default_group`.

The default resource groups `admin_group` and `default_group` are created with the following resource limits:

<table>
<thead>
<tr>
<th>Limit Type</th>
<th>admin_group</th>
<th>default_group</th>
</tr>
</thead>
<tbody>
<tr>
<td>CONCURRENCY</td>
<td>10</td>
<td>20</td>
</tr>
<tr>
<td>CPU_RATE_LIMIT</td>
<td>10</td>
<td>30</td>
</tr>
<tr>
<td>CPUSET</td>
<td>-1</td>
<td>-1</td>
</tr>
<tr>
<td>MEMORY_LIMIT</td>
<td>10</td>
<td>0</td>
</tr>
<tr>
<td>MEMORY_SHARED_QUOTA</td>
<td>80</td>
<td>80</td>
</tr>
<tr>
<td>MEMORY_SPILL_RATIO</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>MEMORY_AUDITOR</td>
<td>vmtracker</td>
<td>vmtracker</td>
</tr>
</tbody>
</table>

Keep in mind that the `CPU_RATE_LIMIT` and `MEMORY_LIMIT` values for the default resource groups `admin_group` and `default_group` contribute to the total percentages on a segment host. You may find that you need to adjust these limits for `admin_group` and/or `default_group` as you create and add new resource groups to your Greenplum Database deployment.

**Creating Resource Groups**

When you create a resource group for a role, you provide a name and a CPU resource allocation mode. You can optionally provide a concurrent transaction limit and memory limit, shared quota, and spill ratio values. Use the `CREATE RESOURCE GROUP` command to create a new resource group.

When you create a resource group for a role, you must provide a `CPU_RATE_LIMIT` or `CPUSET` limit value. These limits identify the percentage of Greenplum Database CPU resources to allocate to this resource group. You may specify a `MEMORY_LIMIT` to reserve a fixed amount of memory for the resource group. If you specify a `MEMORY_LIMIT` of 0, Greenplum Database uses global shared memory to fulfill all memory requirements for the resource group.

For example, to create a resource group named `rgroup1` with a CPU limit of 20, a memory limit of 25, and a memory spill ratio of 20:

```sql
=# CREATE RESOURCE GROUP rgroup1 WITH (CPU_RATE_LIMIT=20, MEMORY_LIMIT=25, MEMORY_SPILL_RATIO=20);
```

The CPU limit of 20 is shared by every role to which `rgroup1` is assigned. Similarly, the memory limit of 25 is shared by every role to which `rgroup1` is assigned. `rgroup1` utilizes the default `MEMORY_AUDITOR` `vmtracker` and the default `CONCURRENCY` setting of 20.

When you create a resource group for an external component, you must provide `CPU_RATE_LIMIT` or `CPUSET` and `MEMORY_LIMIT` limit values. You must also provide the `MEMORY_AUDITOR` and explicitly set `CONCURRENCY` to zero (0). For example, to create a resource group named `rgroup_extcomp` for which you reserve CPU core 1 and assign a memory limit of 15:

```sql
=# CREATE RESOURCE GROUP rgroup_extcomp WITH (MEMORY_AUDITOR=cgroup, CONCURRENCY=0, CPUSET='1', MEMORY_LIMIT=15);
```
The `ALTER RESOURCE GROUP` command updates the limits of a resource group. To change the limits of a resource group, specify the new values that you want for the group. For example:

```
=# ALTER RESOURCE GROUP rg_role_light SET CONCURRENCY 7;
=# ALTER RESOURCE GROUP exec SET MEMORY_SPILL_RATIO 25;
=# ALTER RESOURCE GROUP rgroup1 SET CPUSET '2,4';
```

**Note:** You cannot set or alter the `CONCURRENCY` value for the `admin_group` to zero (0).

The `DROP RESOURCE GROUP` command drops a resource group. To drop a resource group for a role, the group cannot be assigned to any role, nor can there be any transactions active or waiting in the resource group. Dropping a resource group for an external component in which there are running instances kills the running instances.

To drop a resource group:

```
=# DROP RESOURCE GROUP exec;
```

**Assigning a Resource Group to a Role**

When you create a resource group with the default `MEMORY_AUDITOR vmtracker`, the group is available for assignment to one or more roles (users). You assign a resource group to a database role using the RESOURCE GROUP clause of the `CREATE ROLE` or `ALTER ROLE` commands. If you do not specify a resource group for a role, the role is assigned the default group for the role's capability. SUPERUSER roles are assigned the `admin_group`, non-admin roles are assigned the group named `default_group`.

Use the `ALTER ROLE` or `CREATE ROLE` commands to assign a resource group to a role. For example:

```
=# ALTER ROLE bill RESOURCE GROUP rg_light;
=# CREATE ROLE mary RESOURCE GROUP exec;
```

You can assign a resource group to one or more roles. If you have defined a role hierarchy, assigning a resource group to a parent role does not propagate down to the members of that role group.

**Note:** You cannot assign a resource group that you create for an external component to a role.

If you wish to remove a resource group assignment from a role and assign the role the default group, change the role's group name assignment to `NONE`. For example:

```
=# ALTER ROLE mary RESOURCE GROUP NONE;
```

**Monitoring Resource Group Status**

Monitoring the status of your resource groups and queries may involve the following tasks:

- Viewing Resource Group Limits
- Viewing Resource Group Query Status and CPU/Memory Usage
- Viewing the Resource Group Assigned to a Role
- Viewing a Resource Group's Running and Pending Queries
- Cancelling a Running or Queued Transaction in a Resource Group

**Viewing Resource Group Limits**

The `gp_resgroup_config gp_toolkit` system view displays the current limits for a resource group. To view the limits of all resource groups:

```
=# SELECT * FROM gp_toolkit.gp_resgroup_config;
```
Viewing Resource Group Query Status and CPU/Memory Usage

The `gp_resgroup_status gp_toolkit` system view enables you to view the status and activity of a resource group. The view displays the number of running and queued transactions. It also displays the real-time CPU and memory usage of the resource group. To view this information:

```sql
=# SELECT * FROM gp_toolkit.gp_resgroup_status;
```

Viewing Resource Group CPU/Memory Usage Per Host

The `gp_resgroup_status_per_host gp_toolkit` system view enables you to view the real-time CPU and memory usage of a resource group on a per-host basis. To view this information:

```sql
=# SELECT * FROM gp_toolkit.gp_resgroup_status_per_host;
```

Viewing Resource Group CPU/Memory Usage Per Segment

The `gp_resgroup_status_per_segment gp_toolkit` system view enables you to view the real-time CPU and memory usage of a resource group on a per-segment, per-host basis. To view this information:

```sql
=# SELECT * FROM gp_toolkit.gp_resgroup_status_per_segment;
```

Viewing the Resource Group Assigned to a Role

To view the resource group-to-role assignments, perform the following query on the `pg_roles` and `pg_resgroup` system catalog tables:

```sql
=# SELECT rolname, rsgname FROM pg_roles, pg_resgroup
    WHERE pg_roles.rolresgroup=pg_resgroup.oid;
```

Viewing a Resource Group's Running and Pending Queries

To view a resource group's running queries, pending queries, and how long the pending queries have been queued, examine the `pg_stat_activity` system catalog table:

```sql
=# SELECT query, waiting, rsgname, rsgqueueduration
    FROM pg_stat_activity;
```

`pg_stat_activity` displays information about the user/role that initiated a query. A query that uses an external component such as PL/Container is composed of two parts: the query operator that runs in Greenplum Database and the UDF that runs in a PL/Container instance. Greenplum Database processes the query operators under the resource group assigned to the role that initiated the query. A UDF running in a PL/Container instance runs under the resource group assigned to the PL/Container runtime. The latter is not represented in the `pg_stat_activity` view; Greenplum Database does not have any insight into how external components such as PL/Container manage memory in running instances.

Cancelling a Running or Queued Transaction in a Resource Group

There may be cases when you want to cancel a running or queued transaction in a resource group. For example, you may want to remove a query that is waiting in the resource group queue but has not yet been executed. Or, you may want to stop a running query that is taking too long to execute, or one that is sitting idle in a transaction and taking up resource group transaction slots that are needed by other users.

To cancel a running or queued transaction, you must first determine the process id (pid) associated with the transaction. Once you have obtained the process id, you can invoke `pg_cancel_backend()` to end that process, as shown below.
For example, to view the process information associated with all statements currently active or waiting in all resource groups, run the following query. If the query returns no results, then there are no running or queued transactions in any resource group.

```sql
=# SELECT rolname, g.rsgname, pid, waiting, state, query, datname
    FROM pg_roles, gp_toolkit.gp_resgroup_status g, pg_stat_activity
    WHERE pg_roles.rolresgroup=g.groupid
    AND pg_stat_activity.usename=pg_roles.rolname;
```

Sample partial query output:

<table>
<thead>
<tr>
<th>rolname</th>
<th>rsgname</th>
<th>pid</th>
<th>waiting</th>
<th>state</th>
<th>query</th>
</tr>
</thead>
<tbody>
<tr>
<td>sammy</td>
<td>rg_light</td>
<td>31861</td>
<td>f</td>
<td>idle</td>
<td>SELECT * FROM mytesttbl;</td>
</tr>
<tr>
<td>billy</td>
<td>rg_light</td>
<td>31905</td>
<td>t</td>
<td>active</td>
<td>SELECT * FROM topten;</td>
</tr>
</tbody>
</table>

Use this output to identify the process id (pid) of the transaction you want to cancel, and then cancel the process. For example, to cancel the pending query identified in the sample output above:

```sql
=# SELECT pg_cancel_backend(31905);
```

You can provide an optional message in a second argument to `pg_cancel_backend()` to indicate to the user why the process was cancelled.

**Note:**
Do not use an operating system `KILL` command to cancel any Greenplum Database process.

### Resource Group Frequently Asked Questions

#### CPU

- **Why is CPU usage lower than the `CPU_RATE_LIMIT` configured for the resource group?**

  You may run into this situation when a low number of queries and slices are running in the resource group, and these processes are not utilizing all of the cores on the system.

- **Why is CPU usage for the resource group higher than the configured `CPU_RATE_LIMIT`?**

  This situation can occur in the following circumstances:

  - A resource group may utilize more CPU than its `CPU_RATE_LIMIT` when other resource groups are idle. In this situation, Greenplum Database allocates the CPU resource of an idle resource group to a busier one. This resource group feature is called CPU burst.
  
  - The operating system CPU scheduler may cause CPU usage to spike, then drop down. If you believe this might be occurring, calculate the average CPU usage within a given period of time (for example, 5 seconds) and use that average to determine if CPU usage is higher than the configured limit.

#### Memory

- **Why did my query return an "out of memory" error?**

  A transaction submitted in a resource group fails and exits when memory usage exceeds its fixed memory allotment, no available resource group shared memory exists, and the transaction requests more memory.

- **Why did my query return a "memory limit reached" error?**
Greenplum Database automatically adjusts transaction and group memory to the new settings when you use `ALTER RESOURCE GROUP` to change a resource group's memory and/or concurrency limits. An "out of memory" error may occur if you recently altered resource group attributes and there is no longer a sufficient amount of memory available for a currently running query.

- **Why does the actual memory usage of my resource group exceed the amount configured for the group?**

  The actual memory usage of a resource group may exceed the configured amount when one or more queries running in the group is allocated memory from the global shared memory pool. (If no global shared memory is available, queries fail and do not impact the memory resources of other resource groups.)

  When global shared memory is available, memory usage may also exceed the configured amount when a transaction spills to disk. Greenplum Database statements continue to request memory when they start to spill to disk because:

  - Spilling to disk requires extra memory to work.
  - Other operators may continue to request memory.

  Memory usage grows in spill situations; when global shared memory is available, the resource group may eventually use up to 200-300% of its configured group memory limit.

**Concurrency**

- **Why is the number of running transactions lower than the CONCURRENCY limit configured for the resource group?**

  Greenplum Database considers memory availability before running a transaction, and will queue the transaction if there is not enough memory available to serve it. If you use `ALTER RESOURCE GROUP` to increase the CONCURRENCY limit for a resource group but do not also adjust memory limits, currently running transactions may be consuming all allotted memory resources for the group. When in this state, Greenplum Database queues subsequent transactions in the resource group.

- **Why is the number of running transactions in the resource group higher than the configured CONCURRENCY limit?**

  The resource group may be running `SET` and `SHOW` commands, which bypass resource group transaction checks.

**Using Resource Queues**

Use Greenplum Database resource queues to prioritize and allocate resources to queries according to business requirements and to prevent queries from starting when resources are unavailable.

Resource queues are one tool to manage the degree of concurrency in a Greenplum Database system. Resource queues are database objects that you create with the `CREATE RESOURCE QUEUE` SQL statement. You can use them to manage the number of active queries that may execute concurrently, the amount of memory each type of query is allocated, and the relative priority of queries. Resource queues can also guard against queries that would consume too many resources and degrade overall system performance.

Each database role is associated with a single resource queue; multiple roles can share the same resource queue. Roles are assigned to resource queues using the `RESOURCE QUEUE` phrase of the `CREATE ROLE` or `ALTER ROLE` statements. If a resource queue is not specified, the role is associated with the default resource queue, `pg_default`.

When the user submits a query for execution, the query is evaluated against the resource queue's limits. If the query does not cause the queue to exceed its resource limits, then that query will run immediately. If the query causes the queue to exceed its limits (for example, if the maximum number of active statement slots are currently in use), then the query must wait until queue resources are free before it can run.

Queries are evaluated on a first in, first out basis. If query prioritization is enabled, the active workload on
the system is periodically assessed and processing resources are reallocated according to query priority (see How Priorities Work). Roles with the SUPERUSER attribute are exempt from resource queue limits. Superuser queries always run immediately regardless of limits imposed by their assigned resource queue.

Figure 30: Resource Queue Process

Resource queues define classes of queries with similar resource requirements. Administrators should create resource queues for the various types of workloads in their organization. For example, you could create resource queues for the following classes of queries, corresponding to different service level agreements:

- ETL queries
- Reporting queries
- Executive queries

A resource queue has the following characteristics:

**MEMORY_LIMIT**

The amount of memory used by all the queries in the queue (per segment). For example, setting MEMORY_LIMIT to 2GB on the ETL queue allows ETL queries to use up to 2GB of memory in each segment.

**ACTIVE_STATEMENTS**

The number of slots for a queue; the maximum concurrency level for a queue. When all slots are used, new queries must wait. Each query uses an equal amount of memory by default.

For example, the pg_default resource queue has ACTIVE_STATEMENTS = 20.

**PRIORITY**

The relative CPU usage for queries. This may be one of the following levels: LOW, MEDIUM, HIGH, MAX. The default level is MEDIUM. The query prioritization mechanism monitors the CPU usage of all the queries running in the system, and adjusts the CPU usage for each to conform to its priority level. For example, you could set MAX priority to the executive resource queue and MEDIUM to other queues to ensure that executive queries receive a greater share of CPU.

**MAX_COST**

Query plan cost limit.

The Greenplum Database optimizer assigns a numeric cost to each query. If the cost exceeds the MAX_COST value set for the resource queue, the query is rejected as too expensive.

**Note:** GPORCA and the Postgres Planner utilize different query costing models and may compute different costs for the same query. The Greenplum...
Database resource queue resource management scheme neither differentiates nor aligns costs between GPORCA and the Postgres Planner; it uses the literal cost value returned from the optimizer to throttle queries.

When resource queue-based resource management is active, use the `MEMORY_LIMIT` and `ACTIVE_STATEMENTS` limits for resource queues rather than configuring cost-based limits. Even when using GPORCA, Greenplum Database may fall back to using the Postgres Planner for certain queries, so using cost-based limits can lead to unexpected results.

The default configuration for a Greenplum Database system has a single default resource queue named `pg_default`. The `pg_default` resource queue has an `ACTIVE_STATEMENTS` setting of 20, no `MEMORY_LIMIT`, medium `PRIORITY`, and no set `MAX_COST`. This means that all queries are accepted and run immediately, at the same priority and with no memory limitations; however, only twenty queries may execute concurrently.

The number of concurrent queries a resource queue allows depends on whether the `MEMORY_LIMIT` parameter is set:

- If no `MEMORY_LIMIT` is set for a resource queue, the amount of memory allocated per query is the value of the `statement_mem` server configuration parameter. The maximum memory the resource queue can use is the product of `statement_mem` and `ACTIVE_STATEMENTS`.
- When a `MEMORY_LIMIT` is set on a resource queue, the number of queries that the queue can execute concurrently is limited by the queue's available memory.

A query admitted to the system is allocated an amount of memory and a query plan tree is generated for it. Each node of the tree is an operator, such as a sort or hash join. Each operator is a separate execution thread and is allocated a fraction of the overall statement memory, at minimum 100KB. If the plan has a large number of operators, the minimum memory required for operators can exceed the available memory and the query will be rejected with an insufficient memory error. Operators determine if they can complete their tasks in the memory allocated, or if they must spill data to disk, in work files. The mechanism that allocates and controls the amount of memory used by each operator is called memory quota.

Not all SQL statements submitted through a resource queue are evaluated against the queue limits. By default only `SELECT`, `SELECT INTO`, `CREATE TABLE AS SELECT`, and `DECLARE CURSOR` statements are evaluated. If the server configuration parameter `resource_select_only` is set to `off`, then `INSERT`, `UPDATE`, and `DELETE` statements will be evaluated as well.

Also, an SQL statement that is run during the execution of an `EXPLAIN ANALYZE` command is excluded from resource queues.

**Resource Queue Example**

The default resource queue, `pg_default`, allows a maximum of 20 active queries and allocates the same amount of memory to each. This is generally not adequate resource control for production systems. To ensure that the system meets performance expectations, you can define classes of queries and assign them to resource queues configured to execute them with the concurrency, memory, and CPU resources best suited for that class of query.

The following illustration shows an example resource queue configuration for a Greenplum Database system with `gp_vmem_protect_limit` set to 8GB:
This example has three classes of queries with different characteristics and service level agreements (SLAs). Three resource queues are configured for them. A portion of the segment memory is reserved as a safety margin.

<table>
<thead>
<tr>
<th>Resource Queue Name</th>
<th>Active Statements</th>
<th>Memory Limit</th>
<th>Memory per Query</th>
</tr>
</thead>
<tbody>
<tr>
<td>ETL</td>
<td>3</td>
<td>2GB</td>
<td>667MB</td>
</tr>
<tr>
<td>Reporting</td>
<td>7</td>
<td>3GB</td>
<td>429MB</td>
</tr>
<tr>
<td>Executive</td>
<td>1</td>
<td>1.4GB</td>
<td>1.4GB</td>
</tr>
</tbody>
</table>

The total memory allocated to the queues is 6.4GB, or 80% of the total segment memory defined by the `gp_vmem_protect_limit` server configuration parameter. Allowing a safety margin of 20% accommodates some operators and queries that are known to use more memory than they are allocated by the resource queue.

See the `CREATE RESOURCE QUEUE` and `CREATE/ALTER ROLE` statements in the Greenplum Database Reference Guide for help with command syntax and detailed reference information.

**How Memory Limits Work**

Setting `MEMORY_LIMIT` on a resource queue sets the maximum amount of memory that all active queries submitted through the queue can consume for a segment instance. The amount of memory allotted to a query is the queue memory limit divided by the active statement limit. (Use the memory limits in conjunction with statement-based queues rather than cost-based queues.) For example, if a queue has a memory limit of 2000MB and an active statement limit of 10, each query submitted through the queue is allotted 200MB of memory by default. The default memory allotment can be overridden on a per-query basis using the `statement_mem` server configuration parameter (up to the queue memory limit). Once a query has started executing, it holds its allotted memory in the queue until it completes, even if during execution it actually consumes less than its allotted amount of memory.

You can use the `statement_mem` server configuration parameter to override memory limits set by the current resource queue. At the session level, you can increase `statement_mem` up to the resource queue's `MEMORY_LIMIT`. This will allow an individual query to use all of the memory allocated for the entire queue without affecting other resource queues.

The value of `statement_mem` is capped using the `max_statement_mem` configuration parameter (a superuser parameter). For a query in a resource queue with `MEMORY_LIMIT` set, the maximum value for `statement_mem` is `min(MEMORY_LIMIT, max_statement_mem)`. When a query is admitted, the memory allocated to it is subtracted from `MEMORY_LIMIT`. If `MEMORY_LIMIT` is exhausted, new queries in the same resource queue must wait. This happens even if `ACTIVE_STATEMENTS` has not yet been reached. Note that this can happen only when `statement_mem` is used to override the memory allocated by the resource queue.

For example, consider a resource queue named `adhoc` with the following settings:

- `MEMORY_LIMIT` is 1.5GB
- `ACTIVE_STATEMENTS` is 3
By default each statement submitted to the queue is allocated 500MB of memory. Now consider the following series of events:

1. User ADHOC_1 submits query Q1, overriding STATEMENT_MEM to 800MB. The Q1 statement is admitted into the system.
2. User ADHOC_2 submits query Q2, using the default 500MB.
3. With Q1 and Q2 still running, user ADHOC_3 submits query Q3, using the default 500MB.

Queries Q1 and Q2 have used 1300MB of the queue's 1500MB. Therefore, Q3 must wait for Q1 or Q2 to complete before it can run.

If MEMORY_LIMIT is not set on a queue, queries are admitted until all of the ACTIVE_STATEMENTS slots are in use, and each query can set an arbitrarily high statement_mem. This could lead to a resource queue using unbounded amounts of memory.

For more information on configuring memory limits on a resource queue, and other memory utilization controls, see Creating Queues with Memory Limits.

statement_mem and Low Memory Queries

A low statement_mem setting (for example, in the 1-3MB range) has been shown to increase the performance of queries with low memory requirements. Use the statement_mem server configuration parameter to override the setting on a per-query basis. For example:

```sql
SET statement_mem='2MB';
```

How Priorities Work

The PRIORITY setting for a resource queue differs from the MEMORY_LIMIT and ACTIVE_STATEMENTS settings, which determine whether a query will be admitted to the queue and eventually executed. The PRIORITY setting applies to queries after they become active. Active queries share available CPU resources as determined by the priority settings for its resource queue. When a statement from a high-priority queue enters the group of actively running statements, it may claim a greater share of the available CPU, reducing the share allocated to already-running statements in queues with a lesser priority setting.

The comparative size or complexity of the queries does not affect the allotment of CPU. If a simple, low-cost query is running simultaneously with a large, complex query, and their priority settings are the same, they will be allocated the same share of available CPU resources. When a new query becomes active, the CPU shares will be recalculated, but queries of equal priority will still have equal amounts of CPU.

For example, an administrator creates three resource queues: adhoc for ongoing queries submitted by business analysts, reporting for scheduled reporting jobs, and executive for queries submitted by executive user roles. The administrator wants to ensure that scheduled reporting jobs are not heavily affected by unpredictable resource demands from ad-hoc analyst queries. Also, the administrator wants to make sure that queries submitted by executive roles are allotted a significant share of CPU. Accordingly, the resource queue priorities are set as shown:

- **adhoc** — Low priority
- **reporting** — High priority
- **executive** — Maximum priority

At runtime, the CPU share of active statements is determined by these priority settings. If queries 1 and 2 from the reporting queue are running simultaneously, they have equal shares of CPU. When an ad-hoc query becomes active, it claims a smaller share of CPU. The exact share used by the reporting queries is adjusted, but remains equal due to their equal priority setting:
Figure 32: CPU share readjusted according to priority

Note:

The percentages shown in these illustrations are approximate. CPU usage between high, low and maximum priority queues is not always calculated in precisely these proportions.

When an executive query enters the group of running statements, CPU usage is adjusted to account for its maximum priority setting. It may be a simple query compared to the analyst and reporting queries, but until it is completed, it will claim the largest share of CPU.
**Steps to Enable Resource Management**

Enabling and using resource management in Greenplum Database involves the following high-level tasks:

1. Configure resource management. See *Configuring Resource Management*.
2. Create the resource queues and set limits on them. See *Creating Resource Queues* and *Modifying Resource Queues*.
3. Assign a queue to one or more user roles. See *Assigning Roles (Users) to a Resource Queue*.
4. Use the resource management system views to monitor and manage the resource queues. See *Checking Resource Queue Status*.

**Configuring Resource Management**

Resource scheduling is enabled by default when you install Greenplum Database, and is required for all roles. The default resource queue, `pg_default`, has an active statement limit of 20, no memory limit, and a medium priority setting. Create resource queues for the various types of workloads.

**To configure resource management**

1. The following parameters are for the general configuration of resource queues:
   - `max_resource_queues` - Sets the maximum number of resource queues.
   - `max_resource_portals_per_transaction` - Sets the maximum number of simultaneously open cursors allowed per transaction. Note that an open cursor will hold an active query slot in a resource queue.
• **resource_select_only** - If set to **on**, then **SELECT, SELECT INTO, CREATE TABLE AS SELECT, and DECLARE CURSOR commands** are evaluated. If set to **off**, **INSERT, UPDATE, and DELETE commands** will be evaluated as well.

• **resource_cleanup_gangs_on_wait** - Cleans up idle segment worker processes before taking a slot in the resource queue.

• **stats_queue_level** - Enables statistics collection on resource queue usage, which can then be viewed by querying the **pg_stat_resqueues** system view.

2. The following parameters are related to memory utilization:

• **gp_resqueue_memory_policy** - Enables Greenplum Database memory management features.

  In Greenplum Database 4.2 and later, the distribution algorithm **eager_free** takes advantage of the fact that not all operators execute at the same time. The query plan is divided into stages and Greenplum Database eagerly frees memory allocated to a previous stage at the end of that stage's execution, then allocates the eagerly freed memory to the new stage.

  When set to **none**, memory management is the same as in Greenplum Database releases prior to 4.1. When set to **auto**, query memory usage is controlled by **statement_mem** and resource queue memory limits.

• **statement_mem** and **max_statement_mem** - Used to allocate memory to a particular query at runtime (override the default allocation assigned by the resource queue). **max_statement_mem** is set by database superusers to prevent regular database users from over-allocation.

• **gp_vmem_protect_limit** - Sets the upper boundary that all query processes can consume and should not exceed the amount of physical memory of a segment host. When a segment host reaches this limit during query execution, the queries that cause the limit to be exceeded will be cancelled.

• **gp_vmem_idle_resource_timeout** and **gp_vmem_protect_segworker_cache_limit** - Used to free memory on segment hosts held by idle database processes. Administrators may want to adjust these settings on systems with lots of concurrency.

• **shared_buffers** - Sets the amount of memory a Greenplum server instance uses for shared memory buffers. This setting must be at least 128 kilobytes and at least 16 kilobytes times **max_connections**. The value must not exceed the operating system shared memory maximum allocation request size, **shmmax** on Linux. See the **Greenplum Database Installation Guide** for recommended OS memory settings for your platform.

3. The following parameters are related to query prioritization. Note that the following parameters are all **local** parameters, meaning they must be set in the **postgresql.conf** files of the master and all segments:

• **gp_resqueue_priority** - The query prioritization feature is enabled by default.

• **gp_resqueue_priority_sweeper_interval** - Sets the interval at which CPU usage is recalculated for all active statements. The default value for this parameter should be sufficient for typical database operations.

• **gp_resqueue_priority_cpucores_per_segment** - Specifies the number of CPU cores allocated per segment instance. The default value is 4 for the master and segments.

  Each host checks its own **postgresql.conf** file for the value of this parameter. This parameter also affects the master node, where it should be set to a value reflecting the higher ratio of CPU cores. For example, on a cluster that has 10 CPU cores per host and 4 segments per host, you would specify these values for **gp_resqueue_priority_cpucores_per_segment**:

  10 for the master and standby master. Typically, only the master instance is on the master host.

  2.5 for segment instances on the segment hosts.

  If the parameter value is not set correctly, either the CPU might not be fully utilized, or query prioritization might not work as expected. For example, if the Greenplum Database cluster has fewer than one segment instance per CPU core on your segment hosts, make sure you adjust this value accordingly.
Actual CPU core utilization is based on the ability of Greenplum Database to parallelize a query and the resources required to execute the query.

Note: Any CPU core that is available to the operating system is included in the number of CPU cores. For example, virtual CPU cores are included in the number of CPU cores.

4. If you wish to view or change any of the resource management parameter values, you can use the gpconfig utility.

5. For example, to see the setting of a particular parameter:

   $ gpconfig --show gp_vmem_protect_limit

6. For example, to set one value on all segment instances and a different value on the master:

   $ gpconfig -c gp_resqueue_priority_cpcodes_per_segment -v 2 -m 8

7. Restart Greenplum Database to make the configuration changes effective:

   $ gpstop -r

Creating Resource Queues

Creating a resource queue involves giving it a name, setting an active query limit, and optionally a query priority on the resource queue. Use the CREATE RESOURCE QUEUE command to create new resource queues.

Creating Queues with an Active Query Limit

Resource queues with an ACTIVE_STATEMENTS setting limit the number of queries that can be executed by roles assigned to that queue. For example, to create a resource queue named adhoc with an active query limit of three:

   #$ CREATE RESOURCE QUEUE adhoc WITH (ACTIVE_STATEMENTS=3);

This means that for all roles assigned to the adhoc resource queue, only three active queries can be running on the system at any given time. If this queue has three queries running, and a fourth query is submitted by a role in that queue, that query must wait until a slot is free before it can run.

Creating Queues with Memory Limits

Resource queues with a MEMORY_LIMIT setting control the amount of memory for all the queries submitted through the queue. The total memory should not exceed the physical memory available per-segment. Set MEMORY_LIMIT to 90% of memory available on a per-segment basis. For example, if a host has 48 GB of physical memory and 6 segment instances, then the memory available per segment instance is 8 GB. You can calculate the recommended MEMORY_LIMIT for a single queue as 0.90*8=7.2 GB. If there are multiple queues created on the system, their total memory limits must also add up to 7.2 GB.

When used in conjunction with ACTIVE_STATEMENTS, the default amount of memory allotted per query is: MEMORY_LIMIT / ACTIVE_STATEMENTS. When used in conjunction with MAX_COST, the default amount of memory allotted per query is: MEMORY_LIMIT * (query_cost / MAX_COST). Use MEMORY_LIMIT in conjunction with ACTIVE_STATEMENTS rather than with MAX_COST.

For example, to create a resource queue with an active query limit of 10 and a total memory limit of 2000MB (each query will be allocated 200MB of segment host memory at execution time):

   #$ CREATE RESOURCE QUEUE myqueue WITH (ACTIVE_STATEMENTS=20,
   MEMORY_LIMIT='2000MB');
The default memory allotment can be overridden on a per-query basis using the `statement_mem` server configuration parameter, provided that `MEMORY_LIMIT` or `max_statement_mem` is not exceeded. For example, to allocate more memory to a particular query:

```sql
=> SET statement_mem='2GB';
=> SELECT * FROM my_big_table WHERE column='value' ORDER BY id;
=> RESET statement_mem;
```

As a general guideline, `MEMORY_LIMIT` for all of your resource queues should not exceed the amount of physical memory of a segment host. If workloads are staggered over multiple queues, it may be OK to oversubscribe memory allocations, keeping in mind that queries may be cancelled during execution if the segment host memory limit (`gp_vmem_protect_limit`) is exceeded.

**Setting Priority Levels**

To control a resource queue's consumption of available CPU resources, an administrator can assign an appropriate priority level. When high concurrency causes contention for CPU resources, queries and statements associated with a high-priority resource queue will claim a larger share of available CPU than lower priority queries and statements.

Priority settings are created or altered using the `WITH` parameter of the commands `CREATE RESOURCE QUEUE` and `ALTER RESOURCE QUEUE`. For example, to specify priority settings for the `adhoc` and `reporting` queues, an administrator would use the following commands:

```sql
=# ALTER RESOURCE QUEUE adhoc WITH (PRIORITY=LOW);
=# ALTER RESOURCE QUEUE reporting WITH (PRIORITY=HIGH);
```

To create the `executive` queue with maximum priority, an administrator would use the following command:

```sql
=# CREATE RESOURCE QUEUE executive WITH (ACTIVE_STATEMENTS=3, PRIORITY=MAX);
```

When the query prioritization feature is enabled, resource queues are given a `MEDIUM` priority by default if not explicitly assigned. For more information on how priority settings are evaluated at runtime, see [How Priorities Work](#).

**Important:** In order for resource queue priority levels to be enforced on the active query workload, you must enable the query prioritization feature by setting the associated server configuration parameters. See [Configuring Resource Management](#).

**Assigning Roles (Users) to a Resource Queue**

Once a resource queue is created, you must assign roles (users) to their appropriate resource queue. If roles are not explicitly assigned to a resource queue, they will go to the default resource queue, `pg_default`. The default resource queue has an active statement limit of 20, no cost limit, and a medium priority setting.

Use the `ALTER ROLE` or `CREATE ROLE` commands to assign a role to a resource queue. For example:

```sql
=# ALTER ROLE name RESOURCE QUEUE queue_name;
=# CREATE ROLE name WITH LOGIN RESOURCE QUEUE queue_name;
```

A role can only be assigned to one resource queue at any given time, so you can use the `ALTER ROLE` command to initially assign or change a role's resource queue.

Resource queues must be assigned on a user-by-user basis. If you have a role hierarchy (for example, a group-level role) then assigning a resource queue to the group does not propagate down to the users in that group.

Superusers are always exempt from resource queue limits. Superuser queries will always run regardless of the limits set on their assigned queue.
Removing a Role from a Resource Queue

All users must be assigned to a resource queue. If not explicitly assigned to a particular queue, users will go into the default resource queue, pg_default. If you wish to remove a role from a resource queue and put them in the default queue, change the role's queue assignment to none. For example:

```sql
=# ALTER ROLE role_name RESOURCE QUEUE none;
```

Modifying Resource Queues

After a resource queue has been created, you can change or reset the queue limits using the ALTER RESOURCE QUEUE command. You can remove a resource queue using the DROP RESOURCE QUEUE command. To change the roles (users) assigned to a resource queue, Assigning Roles (Users) to a Resource Queue.

Altering a Resource Queue

The ALTER RESOURCE QUEUE command changes the limits of a resource queue. To change the limits of a resource queue, specify the new values you want for the queue. For example:

```sql
=## ALTER RESOURCE QUEUE adhoc WITH (ACTIVE_STATEMENTS=5);
=## ALTER RESOURCE QUEUE exec WITH (PRIORITY=MAX);
```

To reset active statements or memory limit to no limit, enter a value of −1. To reset the maximum query cost to no limit, enter a value of −1.0. For example:

```sql
=## ALTER RESOURCE QUEUE adhoc WITH (MAX_COST=-1.0, MEMORY_LIMIT='2GB');
```

You can use the ALTER RESOURCE QUEUE command to change the priority of queries associated with a resource queue. For example, to set a queue to the minimum priority level:

```sql
ALTER RESOURCE QUEUE webuser WITH (PRIORITY=MIN);
```

Dropping a Resource Queue

The DROP RESOURCE QUEUE command drops a resource queue. To drop a resource queue, the queue cannot have any roles assigned to it, nor can it have any statements waiting in the queue. See Removing a Role from a Resource Queue and Clearing a Waiting Statement From a Resource Queue for instructions on emptying a resource queue. To drop a resource queue:

```sql
=## DROP RESOURCE QUEUE name;
```

Checking Resource Queue Status

Checking resource queue status involves the following tasks:

- Viewing Queued Statements and Resource Queue Status
- Viewing Resource Queue Statistics
- Viewing the Roles Assigned to a Resource Queue
- Viewing the Waiting Queries for a Resource Queue
- Clearing a Waiting Statement From a Resource Queue
- Viewing the Priority of Active Statements
- Resetting the Priority of an Active Statement
**Viewing Queued Statements and Resource Queue Status**

The `gp_toolkit.gp_resqueue_status` view allows administrators to see status and activity for a resource queue. It shows how many queries are waiting to run and how many queries are currently active in the system from a particular resource queue. To see the resource queues created in the system, their limit attributes, and their current status:

```
=# SELECT * FROM gp_toolkit.gp_resqueue_status;
```

**Viewing Resource Queue Statistics**

If you want to track statistics and performance of resource queues over time, you can enable statistics collecting for resource queues. This is done by setting the following server configuration parameter in your `postgresql.conf` file:

```
stats_queue_level = on
```

Once this is enabled, you can use the `pg_stat_resqueues` system view to see the statistics collected on resource queue usage. Note that enabling this feature does incur slight performance overhead, as each query submitted through a resource queue must be tracked. It may be useful to enable statistics collecting on resource queues for initial diagnostics and administrative planning, and then disable the feature for continued use.

See the Statistics Collector section in the PostgreSQL documentation for more information about collecting statistics in Greenplum Database.

**Viewing the Roles Assigned to a Resource Queue**

To see the roles assigned to a resource queue, perform the following query of the `pg_roles` and `gp_toolkit.gp_resqueue_status` system catalog tables:

```
=# SELECT rolname, rsqname FROM pg_roles, gp_toolkit.gp_resqueue_status
    WHERE pg_roles.rolresqueue=gp_toolkit.gp_resqueue_status.queueid;
```

You may want to create a view of this query to simplify future inquiries. For example:

```
=# CREATE VIEW role2queue AS
    SELECT rolname, rsqname FROM pg_roles, pg_resqueue
    WHERE pg_roles.rolresqueue=gp_toolkit.gp_resqueue_status.queueid;
```

Then you can just query the view:

```
=# SELECT * FROM role2queue;
```

**Viewing the Waiting Queries for a Resource Queue**

When a slot is in use for a resource queue, it is recorded in the `pg_locks` system catalog table. This is where you can see all of the currently active and waiting queries for all resource queues. To check that statements are being queued (even statements that are not waiting), you can also use the `gp_toolkit.gp_locks_on_resqueue` view. For example:

```
=# SELECT * FROM gp_toolkit.gp_locks_on_resqueue WHERE lorwaiting='true';
```

If this query returns no results, then that means there are currently no statements waiting in a resource queue.
Clearing a Waiting Statement From a Resource Queue

In some cases, you may want to clear a waiting statement from a resource queue. For example, you may want to remove a query that is waiting in the queue but has not been executed yet. You may also want to stop a query that has been started if it is taking too long to execute, or if it is sitting idle in a transaction and taking up resource queue slots that are needed by other users. To do this, you must first identify the statement you want to clear, determine its process id (pid), and then, use `pg_cancel_backend` with the process id to end that process, as shown below. An optional message to the process can be passed as the second parameter, to indicate to the user why the process was cancelled.

For example, to see process information about all statements currently active or waiting in all resource queues, run the following query:

```
=# SELECT rolname, rsqname, pg_locks.pid as pid, granted, state, query, datname
   FROM pg_roles, gp_toolkit.gp_resqueue_status, pg_locks,
       pg_stat_activity
   WHERE pg_roles.rolresqueue=pg_locks.objid
     AND pg_locks.objid=gp_toolkit.gp_resqueue_status.queueid
     AND pg_stat_activity.pid=pg_locks.pid
     AND pg_stat_activity.usename=pg_roles.rolname;
```

If this query returns no results, then that means there are currently no statements in a resource queue. A sample of a resource queue with two statements in it looks something like this:

```
rolname | rsqname | pid  | granted | state  | query                              |
--------+---------+-------+---------+--------+------------------------------------|
        |         |       |         |        | SELECT * FROM testtbl;             |
        |         |       |         |        | namesdb                            |
        |         |       |         |        | SELECT * FROM topten;              |
        |         |       |         |        | namesdb                            |
```

Use this output to identify the process id (pid) of the statement you want to clear from the resource queue. To clear the statement, you would then open a terminal window (as the `gpadmin` database superuser or as root) on the master host and cancel the corresponding process. For example:

```
=# pg_cancel_backend(31905)
```

**Important:** Do not use the operating system `KILL` command.

Viewing the Priority of Active Statements

The `gp_toolkit` administrative schema has a view called `gp_resq_priority_statement`, which lists all statements currently being executed and provides the priority, session ID, and other information.

This view is only available through the `gp_toolkit` administrative schema. See the Greenplum Database Reference Guide for more information.

Resetting the Priority of an Active Statement

Superusers can adjust the priority of a statement currently being executed using the built-in function `gp_adjust_priority(session_id, statement_count, priority)`. Using this function, superusers can raise or lower the priority of any query. For example:

```
=# SELECT gp_adjust_priority(752, 24905, 'HIGH')
```
To obtain the session ID and statement count parameters required by this function, superusers can use the `gp_toolkit` administrative schema view, `gp_resq_priority_statement`. From the view, use these values for the function parameters.

- The value of the `rqpsession` column for the `session_id` parameter
- The value of the `rqpcommand` column for the `statement_count` parameter
- The value of `rqppriority` column is the current priority. You can specify a string value of `MAX`, `HIGH`, `MEDIUM`, or `LOW` as the priority.

  **Note:** The `gp_adjust_priority()` function affects only the specified statement. Subsequent statements in the same resource queue are executed using the queue’s normally assigned priority.

### Investigating a Performance Problem

This section provides guidelines for identifying and troubleshooting performance problems in a Greenplum Database system.

This topic lists steps you can take to help identify the cause of a performance problem. If the problem affects a particular workload or query, you can focus on tuning that particular workload. If the performance problem is system-wide, then hardware problems, system failures, or resource contention may be the cause.

### Checking System State

Use the `gpstate` utility to identify failed segments. A Greenplum Database system will incur performance degradation when segment instances are down because other hosts must pick up the processing responsibilities of the down segments.

Failed segments can indicate a hardware failure, such as a failed disk drive or network card. Greenplum Database provides the hardware verification tool `gpcheckperf` to help identify the segment hosts with hardware issues.

### Checking Database Activity

- **Checking for Active Sessions (Workload)**
- **Checking for Locks (Contention)**
- **Checking Query Status and System Utilization**

#### Checking for Active Sessions (Workload)

The `pg_stat_activity` system catalog view shows one row per server process; it shows the database OID, database name, process ID, user OID, user name, current query, time at which the current query began execution, time at which the process was started, client address, and port number. To obtain the most information about the current system workload, query this view as the database superuser. For example:

```sql
SELECT * FROM pg_stat_activity;
```

Note that the information does not update instantaneously.

#### Checking for Locks (Contention)

The `pg_locks` system catalog view allows you to see information about outstanding locks. If a transaction is holding a lock on an object, any other queries must wait for that lock to be released before they can continue. This may appear to the user as if a query is hanging.

Examine `pg_locks` for ungranted locks to help identify contention between database client sessions. `pg_locks` provides a global view of all locks in the database system, not only those relevant to the current database. You can join its relation column against `pg_class.oid` to identify locked relations (such as tables), but this works correctly only for relations in the current database. You can join the `pid` column to
the `pg_stat_activity.pid` to see more information about the session holding or waiting to hold a lock. For example:

```sql
SELECT locktype, database, c.relname, l.relation, l.transactionid, l.pid, l.mode, l.granted,
       a.query
FROM pg_locks l, pg_class c, pg_stat_activity a
WHERE l.relation=c.oid AND l.pid=a.pid
ORDER BY c.relname;
```

If you use resource groups, queries that are waiting will also show in `pg_locks`. To see how many queries are waiting to run in a resource group, use the `gp_resgroup_status` system catalog view. For example:

```sql
SELECT * FROM gp_toolkit.gp_resgroup_status;
```

Similarly, if you use resource queues, queries that are waiting in a queue also show in `pg_locks`. To see how many queries are waiting to run from a resource queue, use the `gp_resqueue_status` system catalog view. For example:

```sql
SELECT * FROM gp_toolkit.gp_resqueue_status;
```

### Checking Query Status and System Utilization

You can use system monitoring utilities such as `ps`, `top`, `iostat`, `vmstat`, `netstat` and so on to monitor database activity on the hosts in your Greenplum Database array. These tools can help identify Greenplum Database processes (`postgres` processes) currently running on the system and the most resource intensive tasks with regards to CPU, memory, disk I/O, or network activity. Look at these system statistics to identify queries that degrade database performance by overloading the system and consuming excessive resources. Greenplum Database’s management tool `gpssh` allows you to run these system monitoring commands on several hosts simultaneously.

You can create and use the Greenplum Database `session_level_memory_consumption` view that provides information about the current memory utilization and idle time for sessions that are running queries on Greenplum Database. For information about the view, see [Viewing Session Memory Usage Information](#).

You can enable a dedicated database, `gpperfmon`, in which data collection agents running on each segment host save query and system utilization metrics. Refer to the `gpperfmon_install` management utility reference in the [Greenplum Database Management Utility Reference Guide](#) for help creating the `gpperfmon` database and managing the agents. See documentation for the tables and views in the `gpperfmon` database in the [Greenplum Database Reference Guide](#).

The optional Greenplum Command Center web-based user interface graphically displays query and system utilization metrics saved in the `gpperfmon` database. See the [Greenplum Command Center Documentation](#) web site for procedures to enable Greenplum Command Center.

### Troubleshooting Problem Queries

If a query performs poorly, look at its query plan to help identify problems. The `EXPLAIN` command shows the query plan for a given query. See [Query Profiling](#) for more information about reading query plans and identifying problems.

When an out of memory event occurs during query execution, the Greenplum Database memory accounting framework reports detailed memory consumption of every query running at the time of the event. The information is written to the Greenplum Database segment logs.

### Investigating Error Messages

Greenplum Database log messages are written to files in the `pg_log` directory within the master’s or segment’s data directory. Because the master log file contains the most information, you should always...
check it first. Log files roll over daily and use the naming convention: \texttt{gpdb-YYYY-MM-DD_hhmmss.csv}. To locate the log files on the master host:

\begin{verbatim}
$ cd $MASTER\_DATA\_DIRECTORY/pg\_log
\end{verbatim}

Log lines have the format of:

\begin{verbatim}
timestamp | user | database | statement\_id | con\#cmd#
<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>:-</td>
<td>:-</td>
<td>:-</td>
<td>:-</td>
<td>:-</td>
</tr>
</tbody>
</table>
LOG\_LEVEL: log\_message
\end{verbatim}

You may want to focus your search for \texttt{WARNING}, \texttt{ERROR}, \texttt{FATAL} or \texttt{PANIC} log level messages. You can use the Greenplum utility \texttt{gplogfilter} to search through Greenplum Database log files. For example, when you run the following command on the master host, it checks for problem log messages in the standard logging locations:

\begin{verbatim}
$ gplogfilter -t
\end{verbatim}

To search for related log entries in the segment log files, you can run \texttt{gplogfilter} on the segment hosts using \texttt{gpssh}. You can identify corresponding log entries by the \texttt{statement\_id} or \texttt{con\#} (session identifier). For example, to search for log messages in the segment log files containing the string \texttt{con6} and save output to a file:

\begin{verbatim}
gpssh -f seg\_hosts\_file -e 'source /usr/local/greenplum-db/greenplum_path.sh ; gplogfilter -f con6 /gpdata/*/pg\_log/gpdb*.csv' > seglog.out
\end{verbatim}

\textbf{Gathering Information for Pivotal Customer Support}

The Greenplum Magic Tool (GPMT) utility can run diagnostics and collect information from a Greenplum Database system. You can then send the information to Pivotal Customer Support to aid the diagnosis of Greenplum Database errors or system failures.

The GPMT utility is available from the Pivotal Knowledge Base on the GPMT page.
Chapter 8

Greenplum Database Security Configuration Guide

This guide describes how to secure a Greenplum Database system. The guide assumes knowledge of Linux/UNIX system administration and database management systems. Familiarity with structured query language (SQL) is helpful.

Because Greenplum Database is based on PostgreSQL 9.4, this guide assumes some familiarity with PostgreSQL. References to PostgreSQL documentation are provided throughout this guide for features that are similar to those in Greenplum Database.

This information is intended for system administrators responsible for administering a Greenplum Database system.
Securing the Database

Introduces Greenplum Database security topics.

The intent of security configuration is to configure the Greenplum Database server to eliminate as many security vulnerabilities as possible. This guide provides a baseline for minimum security requirements, and is supplemented by additional security documentation.

The essential security requirements fall into the following categories:

- **Authentication** covers the mechanisms that are supported and that can be used by the Greenplum database server to establish the identity of a client application.
- **Authorization** pertains to the privilege and permission models used by the database to authorize client access.
- **Auditing**, or log settings, covers the logging options available in Greenplum Database to track successful or failed user actions.
- **Data Encryption** addresses the encryption capabilities that are available for protecting data at rest and data in transit. This includes the security certifications that are relevant to the Greenplum Database.

Accessing a Kerberized Hadoop Cluster

You can use the Greenplum Platform Extension Framework (PXF) to read or write external tables referencing files in a Hadoop file system. If the Hadoop cluster is secured with Kerberos ("Kerberized"), you must configure Greenplum Database and PXF to allow users accessing external tables to authenticate with Kerberos. Refer to Configuring PXF for Secure HDFS for the procedure to perform this setup.

Platform Hardening

Platform hardening involves assessing and minimizing system vulnerability by following best practices and enforcing federal security standards. Hardening the product is based on the US Department of Defense (DoD) guidelines Security Template Implementation Guides (STIG). Hardening removes unnecessary packages, disables services that are not required, sets up restrictive file and directory permissions, removes unowned files and directories, performs authentication for single-user mode, and provides options for end users to configure the package to be compliant to the latest STIGs.
## Greenplum Database Ports and Protocols

Lists network ports and protocols used within the Greenplum cluster.

Greenplum Database clients connect with TCP to the Greenplum master instance at the client connection port, 5432 by default. The listen port can be reconfigured in the `postgresql.conf` configuration file. Client connections use the PostgreSQL `libpq` API. The `psql` command-line interface, several Greenplum utilities, and language-specific programming APIs all either use the `libpq` library directly or implement the `libpq` protocol internally.

Each segment instance also has a client connection port, used solely by the master instance to coordinate database operations with the segments. The `gpstate -p` command, executed on the Greenplum master, lists the port assignments for the Greenplum master and the primary segments and mirrors. For example:

```bash
[gpsadmin@mdw ~]$ gpstate -p

```
Additional Greenplum Database network connections are created for features such as standby replication, segment mirroring, statistics collection, and data exchange between segments. Some persistent connections are established when the database starts up and other transient connections are created during operations such as query execution. Transient connections for query execution processes, data movement, and statistics collection use available ports in the range 1025 to 65535 with both TCP and UDP protocols.

**Note:** To avoid port conflicts between Greenplum Database and other applications when initializing Greenplum Database, do not specify Greenplum Database ports in the range specified by the operating system parameter `net.ipv4.ip_local_port_range`. For example, if `net.ipv4.ip_local_port_range = 10000 65535`, you could set the Greenplum Database base port numbers to values outside of that range:

```
PORT_BASE = 6000
MIRROR_PORT_BASE = 7000
```

Some add-on products and services that work with Greenplum Database have additional networking requirements. The following table lists ports and protocols used within the Greenplum cluster, and includes services and applications that integrate with Greenplum Database.

**Table 59: Greenplum Database Ports and Protocols**

<table>
<thead>
<tr>
<th>Service</th>
<th>Protocol/Port</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Master SQL client connection</td>
<td>TCP 5432, libpq</td>
<td>SQL client connection port on the Greenplum master host. Supports clients using the PostgreSQL libpq API. Configurable.</td>
</tr>
<tr>
<td>Segment SQL client connection</td>
<td>varies, libpq</td>
<td>The SQL client connection port for a segment instance. Each primary and mirror segment on a host must have a unique port. Ports are assigned when the Greenplum system is initialized or expanded. The <code>gp_segment_configuration</code> system catalog records port numbers for each primary (p) or mirror (m) segment in the <code>port</code> column. Run <code>gpstate -p</code> to view the ports in use.</td>
</tr>
<tr>
<td>Segment mirroring port</td>
<td>varies, libpq</td>
<td>The port where a segment receives mirrored blocks from its primary. The port is assigned when the mirror is set up. The <code>gp_segment_configuration</code> system catalog records port numbers for each primary (p) or mirror (m) segment in the <code>port</code> column. Run <code>gpstate -p</code> to view the ports in use.</td>
</tr>
<tr>
<td>Greenplum Database Interconnect</td>
<td>UDP 1025-65535, dynamically allocated</td>
<td>The Interconnect transports database tuples between Greenplum segments during query execution.</td>
</tr>
<tr>
<td>Service</td>
<td>Protocol/Port</td>
<td>Description</td>
</tr>
<tr>
<td>---------</td>
<td>--------------</td>
<td>-------------</td>
</tr>
<tr>
<td>Standby master client listener</td>
<td>TCP 5432, libpq</td>
<td>SQL client connection port on the standby master host. Usually the same as the master client connection port. Configure with the gpinitstandby utility <code>-P</code> option.</td>
</tr>
<tr>
<td>Standby master replicator</td>
<td>TCP 1025-65535, gpssyncmaster</td>
<td>The gpssyncmaster process on the master host establishes a connection to the secondary master host to replicate the master’s log to the standby master.</td>
</tr>
<tr>
<td>Greenplum Database file load and transfer utilities: gpfdist, gpload.</td>
<td>TCP 8080, HTTP TCP 9000, HTTPS</td>
<td>The gpfdist file serving utility can run on Greenplum hosts or external hosts. Specify the connection port with the <code>-p</code> option when starting the server. The gpload utility runs one or more instances of gpfdist with ports or port ranges specified in a configuration file.</td>
</tr>
<tr>
<td>Gpperfmon agents</td>
<td>TCP 8888</td>
<td>Connection port for gpperfmon agents (gpmmmon and gpssmon) executing on Greenplum Database hosts. Configure by setting the gpperfmon_port configuration variable in <code>postgresql.conf</code> on master and segment hosts.</td>
</tr>
<tr>
<td>Backup completion notification</td>
<td>TCP 25, TCP 587, SMTP</td>
<td>The gpbackup backup utility can optionally send email to a list of email addresses at completion of a backup. The SMTP service must be enabled on the Greenplum master host.</td>
</tr>
<tr>
<td>Greenplum Database secure shell (SSH): gpssh, gpscp, gpssh-exkeys, gppkg</td>
<td>TCP 22, SSH</td>
<td>Many Greenplum utilities use scp and ssh to transfer files between hosts and manage the Greenplum system within the cluster.</td>
</tr>
<tr>
<td>Greenplum Platform Extension Framework (PXF)</td>
<td>TCP 5888</td>
<td>The PXF Java service runs on port number 5888 on each Greenplum Database segment host.</td>
</tr>

Configuring Client Authentication

Describes the available methods for authenticating Greenplum Database clients.

When a Greenplum Database system is first initialized, the system contains one predefined superuser role. This role will have the same name as the operating system user who initialized the Greenplum Database system. This role is referred to as gpadmin. By default, the system is configured to only allow local connections to the database from the gpadmin role. If you want to allow any other roles to connect, or if you want to allow connections from remote hosts, you have to configure Greenplum Database to allow such connections. This section explains how to configure client connections and authentication to Greenplum Database.

- Allowing Connections to Greenplum Database
- Editing the pg_hba.conf File
- Authentication Methods
- Limiting Concurrent Connections
- Encrypting Client/Server Connections

Allowing Connections to Greenplum Database

Client access and authentication is controlled by a configuration file named pg_hba.conf (the standard PostgreSQL host-based authentication file). For detailed information about this file, see The pg_hba.conf File in the PostgreSQL documentation.

In Greenplum Database, the pg_hba.conf file of the master instance controls client access and authentication to your Greenplum system. The segments also have pg_hba.conf files, but these are already correctly configured to only allow client connections from the master host. The segments never accept outside client connections, so there is no need to alter the pg_hba.conf file on segments.

The general format of the pg_hba.conf file is a set of records, one per line. Blank lines are ignored, as is any text after a # comment character. A record is made up of a number of fields which are separated by spaces and/or tabs. Fields can contain white space if the field value is quoted. Records cannot be continued across lines.

A record can have one of seven formats:

- `local` database user auth-method [auth-options]
- `host` database user address auth-method [auth-options]
- `hostssl` database user address auth-method [auth-options]
- `hostnossl` database user address auth-method [auth-options]
- `hostssl` database user IP-address IP-mask auth-method [auth-options]
- `hostnossl` database user IP-address IP-mask auth-method [auth-options]
- `host` database user IP-address IP-mask auth-method [auth-options]

The meaning of the pg_hba.conf fields is as follows:

**local**

Matches connection attempts using UNIX-domain sockets. Without a record of this type, UNIX-domain socket connections are disallowed.

**host**

Matches connection attempts made using TCP/IP. Remote TCP/IP connections will not be possible unless the server is started with an appropriate value for the listen_addresses server configuration parameter. Greenplum Database by default allows connections from all hosts (‘*’).

**hostssl**

Matches connection attempts made using TCP/IP, but only when the connection is made with SSL encryption. SSL must be enabled at server start time by setting the ssl configuration parameter to on. Requires SSL authentication be configured in postgresql.conf. See Configuring postgresql.conf for SSL Authentication.

**hostnossl**

Matches connection attempts made over TCP/IP that do not use SSL.

**database**

Specifies which database names this record matches. The value all specifies that it matches all databases. Multiple database names can be supplied by separating them with commas. A separate file containing database names can be specified by preceding the file name with @.

**user**

Specifies which database role names this record matches. The value all specifies that it matches all roles. If the specified role is a group and you want all members of that group to be included, precede the role name with a +. Multiple role names can be supplied by separating them with commas. A separate file containing role names can be specified by preceding the file name with @.

**address**

Specifies the client machine addresses that this record matches. This field can contain either a host name, an IP address range, or one of the special key words mentioned below.

An IP address range is specified using standard numeric notation for the range's starting address, then a slash (/) and a CIDR mask length. The mask length indicates the number of high-order bits of the client IP address that must match. Bits to the right of this should be zero in the given IP address. There must not be any white space between the IP address, the /, and the CIDR mask length.

Typical examples of an IPv4 address range specified this way are 172.20.143.89/32 for a single host, or 172.20.143.0/24 for a small network, or 10.6.0.0/16 for a larger one. An IPv6 address range might look like ::1/128 for a single host (in this case the IPv6 loopback address) or fe80::7a31:c1ff:0000:0000/96 for a small network. 0.0.0.0/0 represents all IPv4 addresses, and ::/0 represents all IPv6 addresses. To specify a single host, use a mask length of 32 for IPv4 or 128 for IPv6. In a network address, do not omit trailing zeroes.

An entry given in IPv4 format will match only IPv4 connections, and an entry given in IPv6 format will match only IPv6 connections, even if the represented address is in the IPv4-in-IPv6 range.

**Note:** Entries in IPv6 format will be rejected if the host system C library does not have support for IPv6 addresses.

You can also write all to match any IP address, samehost to match any of the server’s own IP addresses, or samenet to match any address in any subnet to which the server is directly connected.

If a host name is specified (an address that is not an IP address, IP range, or special key word is treated as a host name), that name is compared with the result of a reverse name resolution of the client IP address (for example, reverse DNS lookup, if DNS is used). Host name comparisons are case insensitive. If there is a match, then a forward name resolution (for example, forward DNS lookup) is performed on the host name to check whether any of the addresses it resolves to are equal to the client IP address. If both directions match, then the entry is considered to match.

The host name that is used in pg_hba.conf should be the one that address-to-name resolution of the client’s IP address returns, otherwise the line won’t be matched. Some
host name databases allow associating an IP address with multiple host names, but the operating system will only return one host name when asked to resolve an IP address.

A host name specification that starts with a dot (.) matches a suffix of the actual host name. So .example.com would match foo.example.com (but not just example.com).

When host names are specified in pg_hba.conf, you should ensure that name resolution is reasonably fast. It can be advantageous to set up a local name resolution cache such as nscd. Also, you can enable the server configuration parameter log_hostname to see the client host name instead of the IP address in the log.

**IP-address**

**IP-mask**

These two fields can be used as an alternative to the CIDR address notation. Instead of specifying the mask length, the actual mask is specified in a separate column. For example, 255.0.0.0 represents an IPv4 CIDR mask length of 8, and 255.255.255.255 represents a CIDR mask length of 32.

**auth-method**

Specifies the authentication method to use when a connection matches this record. See Authentication Methods for options.

**auth-options**

After the auth-method field, there can be field(s) of the form name=value that specify options for the authentication method. Details about which options are available for which authentication methods are described in Authentication Methods.

Files included by @ constructs are read as lists of names, which can be separated by either whitespace or commas. Comments are introduced by #, just as in pg_hba.conf, and nested @ constructs are allowed. Unless the file name following @ is an absolute path, it is taken to be relative to the directory containing the referencing file.

The pg_hba.conf records are examined sequentially for each connection attempt, so the order of the records is significant. Typically, earlier records will have tight connection match parameters and weaker authentication methods, while later records will have looser match parameters and stronger authentication methods. For example, you might wish to use trust authentication for local TCP/IP connections but require a password for remote TCP/IP connections. In this case a record specifying trust authentication for connections from 127.0.0.1 would appear before a record specifying password authentication for a wider range of allowed client IP addresses.

The pg_hba.conf file is read on start-up and when the main server process receives a SIGHUP signal. If you edit the file on an active system, you must reload the file using this command:

```
$ gpstop -u
```

**Caution:** For a more secure system, remove records for remote connections that use trust authentication from the pg_hba.conf file. Trust authentication grants any user who can connect to the server access to the database using any role they specify. You can safely replace trust authentication with ident authentication for local UNIX-socket connections. You can also use ident authentication for local and remote TCP clients, but the client host must be running an ident service and you must trust the integrity of that machine.

**Editing the pg_hba.conf File**

Initially, the pg_hba.conf file is set up with generous permissions for the gpadmin user and no database access for other Greenplum Database roles. You will need to edit the pg_hba.conf file to enable users’ access to databases and to secure the gpadmin user. Consider removing entries that have trust authentication, since they allow anyone with access to the server to connect with any role they choose. For local (UNIX socket) connections, use ident authentication, which requires the operating system user to match the role specified. For local and remote TCP connections, ident authentication requires the client’s
host to run an ident service. You could install an ident service on the master host and then use \texttt{idem}
text authentication for local TCP connections, for example 127.0.0.1/28. Using \texttt{idem}
text authentication for remote TCP connections is less secure because it requires you to trust the integrity of the ident service on the client's host.

\textbf{Note:} Greenplum Command Center provides an interface for editing the \texttt{pg_hba.conf} file. It verifies entries before you save them, keeps a version history of the file so that you can reload a previous version of the file, and reloads the file into Greenplum Database.

This example shows how to edit the \texttt{pg_hba.conf} file on the master host to allow remote client access to all databases from all roles using encrypted password authentication.

To edit \texttt{pg_hba.conf}:

1. Open the file $\text{MASTER\_DATA\_DIRECTORY}/pg_hba.conf in a text editor.
2. Add a line to the file for each type of connection you want to allow. Records are read sequentially, so the order of the records is significant. Typically, earlier records will have tight connection match parameters and weaker authentication methods, while later records will have looser match parameters and stronger authentication methods. For example:

```
# allow the gpadmin user local access to all databases
# using ident authentication
local   all   gpadmin   ident         sameuser
host all gpadmin 127.0.0.1/32 ident
host all gpadmin ::1/128 ident

# allow the 'dba' role access to any database from any
# host with IP address 192.168.x.x and use md5 encrypted
# passwords to authenticate the user
# Note that to use SHA-256 encryption, replace md5 with
# password in the line below
host    all   dba   192.168.0.0/32  md5
```

\section*{Authentication Methods}

- Basic Authentication
- GSSAPI Authentication
- LDAP Authentication
- SSL Client Authentication
- PAM Based Authentication
- Radius Authentication

\subsection*{Basic Authentication}

\textbf{Reject}

Reject the connections with the matching parameters. You should typically use this to restrict access from specific hosts or insecure connections.

\textbf{Ident}

Authenticate based on the client's operating system user name. This is secure for local socket connections. Using \texttt{idem} for TCP connections from remote hosts requires that the client's host is running an ident service. The \texttt{idem} authentication method should only be used with remote hosts on a trusted, closed network.

\textbf{md5}

Require the client to supply a double-MD5-hashed password for authentication.
Require the client to supply an unencrypted password for authentication. Since the password is sent in clear text over the network, this should not be used on untrusted networks.

The password-based authentication methods are `md5` and `password`. These methods operate similarly except for the way that the password is sent across the connection: MD5-hashed and clear-text respectively.

If you are at all concerned about password "sniffing" attacks then `md5` is preferred. Plain `password` should always be avoided if possible. If the connection is protected by SSL encryption then `password` can be used safely (although SSL certificate authentication might be a better choice if you are depending on using SSL).

Following are some sample `pg_hba.conf` basic authentication entries:

<table>
<thead>
<tr>
<th>Method</th>
<th>Database</th>
<th>User</th>
<th>Address</th>
<th>Authentication</th>
</tr>
</thead>
<tbody>

<td>ident</td>
</tr>
</tbody>
</table>

GSSAPI Authentication

GSSAPI is an industry-standard protocol for secure authentication defined in RFC 2743. Greenplum Database supports GSSAPI with Kerberos authentication according to RFC 1964. GSSAPI provides automatic authentication (single sign-on) for systems that support it. The authentication itself is secure, but the data sent over the database connection will be sent unencrypted unless SSL is used.

The `gss` authentication method is only available for TCP/IP connections.

When GSSAPI uses Kerberos, it uses a standard principal in the format `servicename/hostname@realm`. The Greenplum Database server will accept any principal that is included in the keytab file used by the server, but care needs to be taken to specify the correct principal details when making the connection from the client using the `krbsrvname` connection parameter. (See `Connection Parameter Key Words` in the PostgreSQL documentation.) In most environments, this parameter never needs to be changed. Some Kerberos implementations might require a different service name, such as Microsoft Active Directory, which requires the service name to be in upper case (POSTGRES).

`hostname` is the fully qualified host name of the server machine. The service principal's realm is the preferred realm of the server machine.

Client principals must have their Greenplum Database user name as their first component, for example `gpusername@realm`. Alternatively, you can use a user name mapping to map from the first component of the principal name to the database user name. By default, Greenplum Database does not check the realm of the client. If you have cross-realm authentication enabled and need to verify the realm, use the `krb_realm` parameter, or enable `include_realm` and use user name mapping to check the realm.

Make sure that your server keytab file is readable (and preferably only readable) by the `gpadmin` server account. The location of the key file is specified by the `krb_server_keyfile` configuration parameter. For security reasons, it is recommended to use a separate keytab just for the Greenplum Database server rather than opening up permissions on the system keytab file.

The keytab file is generated by the Kerberos software; see the Kerberos documentation for details. The following example is for MIT-compatible Kerberos 5 implementations:

```
kadmin% ank -randkey postgres/server.my.domain.org
kadmin% ktda -k krb5.keytab postgres/server.my.domain.org
```

When connecting to the database make sure you have a ticket for a principal matching the requested database user name. For example, for database user name `fred`, principal `fred@EXAMPLE.COM` would be able to connect. To also allow principal `fred/users.example.com@EXAMPLE.COM`, use a user name map, as described in `User Name Maps` in the PostgreSQL documentation.
The following configuration options are supported for GSSAPI:

**include_realm**
If set to 1, the realm name from the authenticated user principal is included in the system user name that is passed through user name mapping. This is the recommended configuration as, otherwise, it is impossible to differentiate users with the same username who are from different realms. The default for this parameter is 0 (meaning to not include the realm in the system user name) but may change to 1 in a future version of Greenplum Database. You can set it explicitly to avoid any issues when upgrading.

**map**
Allows for mapping between system and database user names. For a GSSAPI/Kerberos principal, such as `username@EXAMPLE.COM` (or, less commonly, `username/hostbased@EXAMPLE.COM`), the default user name used for mapping is `username` (or `username/hostbased`, respectively), unless `include_realm` has been set to 1 (as recommended, see above), in which case `username@EXAMPLE.COM` (or `username/hostbased@EXAMPLE.COM`) is what is seen as the system username when mapping.

**krb_realm**
Sets the realm to match user principal names against. If this parameter is set, only users of that realm will be accepted. If it is not set, users of any realm can connect, subject to whatever user name mapping is done.

### LDAP Authentication
You can authenticate against an LDAP directory.

- LDAPS and LDAP over TLS options encrypt the connection to the LDAP server.
- The connection from the client to the server is not encrypted unless SSL is enabled. Configure client connections to use SSL to encrypt connections from the client.
- To configure or customize LDAP settings, set the **LDAPCONF** environment variable with the path to the **ldap.conf** file and add this to the **greenplum_path.sh** script.

Following are the recommended steps for configuring your system for LDAP authentication:

1. Set up the LDAP server with the database users/roles to be authenticated via LDAP.
2. On the database:
   a. Verify that the database users to be authenticated via LDAP exist on the database. LDAP is only used for verifying username/password pairs, so the roles should exist in the database.
   b. Update the **pg_hba.conf** file in the **$MASTER_DATA_DIRECTORY** to use LDAP as the authentication method for the respective users. Note that the first entry to match the user/role in the **pg_hba.conf** file will be used as the authentication mechanism, so the position of the entry in the file is important.
   c. Reload the server for the **pg_hba.conf** configuration settings to take effect (**gpstop -u**).

Specify the following parameter **auth-options**.

**ldapserver**
Names or IP addresses of LDAP servers to connect to. Multiple servers may be specified, separated by spaces.

**ldapprefix**
String to prepend to the user name when forming the DN to bind as, when doing simple bind authentication.

**ldapsuffix**
String to append to the user name when forming the DN to bind as, when doing simple bind authentication.

**ldapport**
Port number on LDAP server to connect to. If no port is specified, the LDAP library’s default port setting will be used.

**ldaptls**
Set to 1 to make the connection between PostgreSQL and the LDAP server use TLS encryption. Note that this only encrypts the traffic to the LDAP server — the connection to the client will still be unencrypted unless SSL is used.

**ldapbasedn**
Root DN to begin the search for the user in, when doing search+bind authentication.

**ldapbinddn**
DN of user to bind to the directory with to perform the search when doing search+bind authentication.

**ldapbindpasswd**
Password for user to bind to the directory with to perform the search when doing search+bind authentication.

**ldapsearchattribute**
Attribute to match against the user name in the search when doing search+bind authentication.

Example:

```plaintext
ldapserver=ldap.greenplum.com prefix="cn=" suffix=", dc=greenplum, dc=com"
```

Following are sample `pg_hba.conf` file entries for LDAP authentication:

```plaintext
host all testuser 0.0.0.0/0 ldap ldap
ldapserver=ldapserver.greenplum.com ldapprefix="cn="
ldapsuffix="",ou=people,dc=greenplum,dc=com"
hostssl all ldaprole 0.0.0.0/0 ldap
ldapserver=ldapserver.greenplum.com ldaptls=1 ldapprefix="cn="
ldapsuffix="",ou=people,dc=greenplum,dc=com"
```

### SSL Client Authentication

SSL authentication compares the Common Name (cn) attribute of an SSL certificate provided by the connecting client during the SSL handshake to the requested database user name. The database user should exist in the database. A map file can be used for mapping between system and database user names.

### SSL Authentication Parameters

Authentication method:

- Cert

Authentication options:

- **Hostssl**
  Connection type must be hostssl.

- **map=mapping**
  mapping.

  This is specified in the `pg_ident.conf`, or in the file specified in the `ident_file server` setting.
Following are sample `pg_hba.conf` entries for SSL client authentication:

```
Hostssl testdb certuser 192.168.0.0/16 cert
Hostssl testdb all 192.168.0.0/16 cert map=gpuser
```

### OpenSSL Configuration

Greenplum Database reads the OpenSSL configuration file specified in `$GP_HOME/etc/openssl.cnf` by default. You can make changes to the default configuration for OpenSSL by modifying or updating this file and restarting the server.

### Creating a Self-Signed Certificate

A self-signed certificate can be used for testing, but a certificate signed by a certificate authority (CA) (either one of the global CAs or a local one) should be used in production so that clients can verify the server’s identity. If all the clients are local to the organization, using a local CA is recommended.

To create a self-signed certificate for the server:

1. Enter the following `openssl` command:
   
   ```
   openssl req -new -text -out server.req
   ```

2. Enter the requested information at the prompts.

   Make sure you enter the local host name for the Common Name. The challenge password can be left blank.

3. The program generates a key that is passphrase-protected; it does not accept a passphrase that is less than four characters long. To remove the passphrase (and you must if you want automatic start-up of the server), run the following command:

   ```
   openssl rsa -in privkey.pem -out server.key rm privkey.pem
   ```

4. Enter the old passphrase to unlock the existing key. Then run the following command:

   ```
   openssl req -x509 -in server.req -text -key server.key -out server.crt
   ```

   This turns the certificate into a self-signed certificate and copies the key and certificate to where the server will look for them.

5. Finally, run the following command:

   ```
   chmod og-rwx server.key
   ```

   For more details on how to create your server private key and certificate, refer to the OpenSSL documentation.

### Configuring `postgresql.conf` for SSL Authentication

The following Server settings need to be specified in the `postgresql.conf` configuration file:

- `ssl boolean`. Enables SSL connections.
- `ssl_renegotiation_limit integer`. Specifies the data limit before key renegotiation.
- `ssl_ciphers string`. Lists SSL ciphers that are allowed.

The following SSL server files can be found in the Master Data Directory:

- `server.crt`. Server certificate.
- `server.key`. Server private key.
- `root.crt`. Trusted certificate authorities.
• root.crt. Certificates revoked by certificate authorities.

## Configuring the SSL Client Connection

SSL options:

- **require**
  - Only use SSL connection. If a root CA file is present, verify the certificate in the same way as if verify-ca was specified.

- **verify-ca**
  - Only use an SSL connection. Verify that the server certificate is issued by a trusted CA.

- **verify-full**
  - Only use an SSL connection. Verify that the server certificate is issued by a trusted CA and that the server host name matches that in the certificate.

- **sslcert**
  - The file name of the client SSL certificate. The default is `~/.postgresql/postgresql.crt`.

- **sslkey**
  - The secret key used for the client certificate. The default is `~/.postgresql/postgresql.key`.

- **sslrootcert**
  - The name of a file containing SSL Certificate Authority certificate(s). The default is `~/.postgresql/root.crt`.

- **sslcrl**
  - The name of the SSL certificate revocation list. The default is `~/.postgresql/root.crl`.

The client connection parameters can be set using the following environment variables:

- `sslmode` – `PGSSLMODE`
- `sslkey` – `PGSSLKEY`
- `sslrootcert` – `PGSSLROOTCERT`
- `sslcert` – `PGSSLCERT`
- `sslcrl` – `PGSSLCRL`

## PAM Based Authentication

"PAM" (Pluggable Authentication Modules) is used to validate username/password pairs, similar to basic authentication. PAM authentication only works if the users already exist in the database.

### Parameters

- **pamservice**
  - The default PAM service is `postgresql`. Note that if PAM is set up to read `/etc/shadow`, authentication will fail because the PostgreSQL server is started by a non-root user.

Following are sample `pg_hba.conf` entries for PAM client authentication:

```
local    all gpuser am pamservice=postgresql
```
**Radius Authentication**

RADIUS (Remote Authentication Dial In User Service) authentication works by sending an Access Request message of type 'Authenticate Only' to a configured RADIUS server. It includes parameters for user name, password (encrypted), and the Network Access Server (NAS) Identifier. The request is encrypted using the shared secret specified in the `radiussecret` option. The RADIUS server responds with either `Access Accept` or `Access Reject`.

**Note:** RADIUS accounting is not supported.

RADIUS authentication only works if the users already exist in the database.

The RADIUS encryption vector requires SSL to be enabled in order to be cryptographically strong.

**RADIUS Authentication Options**

- **radiusserver**
  - The name of the RADIUS server.
- **radiussecret**
  - The RADIUS shared secret.
- **radiusport**
  - The port to connect to on the RADIUS server.
- **radiusidentifier**
  - NAS identifier in RADIUS requests.

Following are sample `pg_hba.conf` entries for RADIUS client authentication:

```bash
hostname  all all 0.0.0.0/0 radius radiusserver=servername
radiussecret=sharedsecret
```

**Limiting Concurrent Connections**

To limit the number of active concurrent sessions to your Greenplum Database system, you can configure the `max_connections` server configuration parameter. This is a local parameter, meaning that you must set it in the `postgresql.conf` file of the master, the standby master, and each segment instance (primary and mirror). The value of `max_connections` on segments must be 5-10 times the value on the master.

When you set `max_connections`, you must also set the dependent parameter `max_prepared_transactions`. This value must be at least as large as the value of `max_connections` on the master, and segment instances should be set to the same value as the master.

In `$MASTER_DATA_DIRECTORY/postgresql.conf` (including standby master):

```bash
max_connections=100
max_prepared_transactions=100
```

In `SEGMENT_DATA_DIRECTORY/postgresql.conf` for all segment instances:

```bash
max_connections=500
max_prepared_transactions=100
```

**Note:** Raising the values of these parameters may cause Greenplum Database to request more shared memory. To mitigate this effect, consider decreasing other memory-related parameters such as `gp_cached_segworkers_threshold`.

To change the number of allowed connections:
1. Stop your Greenplum Database system:

   $ gpstop

2. On the master host, edit $MASTER_DATA_DIRECTORY/postgresql.conf and change the following two parameters:

   • max_connections – the number of active user sessions you want to allow plus the number of superuser_reserved_connections.
   • max_prepared_transactions – must be greater than or equal to max_connections.

3. On each segment instance, edit $SEGMENT_DATA_DIRECTORY/postgresql.conf and change the following two parameters:

   • max_connections – must be 5-10 times the value on the master.
   • max_prepared_transactions – must be equal to the value on the master.

4. Restart your Greenplum Database system:

   $ gpstart

**Encrypting Client/Server Connections**

Greenplum Database has native support for SSL connections between the client and the master server. SSL connections prevent third parties from snooping on the packets, and also prevent man-in-the-middle attacks. SSL should be used whenever the client connection goes through an insecure link, and must be used whenever client certificate authentication is used.

   *Note:* For information about encrypting data between the gpfdist server and Greenplum Database segment hosts, see *Encrypting gpfdist Connections.*

To enable SSL requires that OpenSSL be installed on both the client and the master server systems. Greenplum can be started with SSL enabled by setting the server configuration parameter `ssl=on` in the master *postgresql.conf*. When starting in SSL mode, the server will look for the files `server.key` (server private key) and `server.crt` (server certificate) in the master data directory. These files must be set up correctly before an SSL-enabled Greenplum system can start.

   *Important:* Do not protect the private key with a passphrase. The server does not prompt for a passphrase for the private key, and the database startup fails with an error if one is required.

A self-signed certificate can be used for testing, but a certificate signed by a certificate authority (CA) should be used in production, so the client can verify the identity of the server. Either a global or local CA can be used. If all the clients are local to the organization, a local CA is recommended. See *Creating a Self-Signed Certificate* for steps to create a self-signed certificate.
Configuring Database Authorization

Describes how to restrict authorization access to database data at the user level by using roles and permissions.

Access Permissions and Roles

Greenplum Database manages database access permissions using roles. The concept of roles subsumes the concepts of users and groups. A role can be a database user, a group, or both. Roles can own database objects (for example, tables) and can assign privileges on those objects to other roles to control access to the objects. Roles can be members of other roles, thus a member role can inherit the object privileges of its parent role.

Every Greenplum Database system contains a set of database roles (users and groups). Those roles are separate from the users and groups managed by the operating system on which the server runs. However, for convenience you may want to maintain a relationship between operating system user names and Greenplum Database role names, since many of the client applications use the current operating system user name as the default.

In Greenplum Database, users log in and connect through the master instance, which verifies their role and access privileges. The master then issues out commands to the segment instances behind the scenes using the currently logged in role.

Roles are defined at the system level, so they are valid for all databases in the system.

To bootstrap the Greenplum Database system, a freshly initialized system always contains one predefined superuser role (also referred to as the system user). This role will have the same name as the operating system user that initialized the Greenplum Database system. Customarily, this role is named gpadmin. To create more roles you first must connect as this initial role.

Managing Object Privileges

When an object (table, view, sequence, database, function, language, schema, or tablespace) is created, it is assigned an owner. The owner is normally the role that executed the creation statement. For most kinds of objects, the initial state is that only the owner (or a superuser) can do anything with the object. To allow other roles to use it, privileges must be granted. Greenplum Database supports the following privileges for each object type:

<table>
<thead>
<tr>
<th>Object Type</th>
<th>Privileges</th>
</tr>
</thead>
<tbody>
<tr>
<td>Tables, Views, Sequences</td>
<td>SELECT, INSERT, UPDATE, DELETE, RULE, ALL</td>
</tr>
<tr>
<td>External Tables</td>
<td>SELECT, RULE, ALL</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Object Type</th>
<th>Privileges</th>
</tr>
</thead>
<tbody>
<tr>
<td>Databases</td>
<td>CONNECT</td>
</tr>
<tr>
<td></td>
<td>CREATE</td>
</tr>
<tr>
<td></td>
<td>TEMPORARY</td>
</tr>
<tr>
<td></td>
<td>ALL</td>
</tr>
<tr>
<td>Functions</td>
<td>EXECUTE</td>
</tr>
<tr>
<td>Procedural Languages</td>
<td>USAGE</td>
</tr>
<tr>
<td>Schemas</td>
<td>CREATE</td>
</tr>
<tr>
<td></td>
<td>USAGE</td>
</tr>
<tr>
<td></td>
<td>ALL</td>
</tr>
</tbody>
</table>

Privileges must be granted for each object individually. For example, granting ALL on a database does not grant full access to the objects within that database. It only grants all of the database-level privileges (CONNECT, CREATE, TEMPORARY) to the database itself.

Use the GRANT SQL command to give a specified role privileges on an object. For example:

```
=# GRANT INSERT ON mytable TO jsmith;
```

To revoke privileges, use the REVOKE command. For example:

```
=# REVOKE ALL PRIVILEGES ON mytable FROM jsmith;
```

You can also use the DROP OWNED and REASSIGN OWNED commands for managing objects owned by deprecated roles. (Note: only an object's owner or a superuser can drop an object or reassign ownership.) For example:

```
=# REASSIGN OWNED BY sally TO bob;
=# DROP OWNED BY visitor;
```

## Using SSH-256 Encryption

Greenplum Database access control corresponds roughly to the Orange Book 'C2' level of security, not the 'B1' level. Greenplum Database currently supports access privileges at the object level. Greenplum Database does not support row-level access or row-level, labeled security.

You can simulate row-level access by using views to restrict the rows that are selected. You can simulate row-level labels by adding an extra column to the table to store sensitivity information, and then using views to control row-level access based on this column. You can then grant roles access to the views rather than the base table. While these workarounds do not provide the same as "B1" level security, they may still be a viable alternative for many organizations.

To use SHA-256 encryption, you must set a parameter either at the system or the session level. This section outlines how to use a server parameter to implement SHA-256 encrypted password storage. Note that in order to use SHA-256 encryption for storage, the client authentication method must be set to password rather than the default, MD5. (See Configuring the SSL Client Connection for more details.) This means that the password is transmitted in clear text over the network, so we highly recommend that you set up SSL to encrypt the client server communication channel.

You can set your chosen encryption method system-wide or on a per-session basis. The available encryption methods are SHA-256 and MD5 (for backward compatibility).
Setting Encryption Method System-wide

To set the `password_hash_algorithm` server parameter on a complete Greenplum system (master and its segments):

1. Log in to your Greenplum Database instance as a superuser.
2. Execute `gpconfig` with the `password_hash_algorithm` set to SHA-256:
   
   ```
   $ gpconfig -c password_hash_algorithm -v 'SHA-256'
   ```
3. Verify the setting:
   
   ```
   $ gpconfig -s
   ```
   You will see:
   
   Master value: SHA-256
   Segment value: SHA-256

Setting Encryption Method for an Individual Session

To set the `password_hash_algorithm` server parameter for an individual session:

1. Log in to your Greenplum Database instance as a superuser.
2. Set the `password_hash_algorithm` to SHA-256:
   
   ```
   # set password_hash_algorithm = 'SHA-256'
   ```
3. Verify the setting:
   
   ```
   # show password_hash_algorithm;
   ```
   You will see:
   
   SHA-256

Following is an example of how the new setting works:

1. Log in as a super user and verify the password hash algorithm setting:
   
   ```
   # show password_hash_algorithm
   password_hash_algorithm
   ---------------------------
   SHA-256
   ```
2. Create a new role with password that has login privileges.
   
   ```
   create role testdb with password 'testdb12345#' LOGIN;
   ```
3. Change the client authentication method to allow for storage of SHA-256 encrypted passwords:
   
   Open the `pg_hba.conf` file on the master and add the following line:
   
   ```
   host all testdb 0.0.0.0/0 password
   ```
4. Restart the cluster.
5. Log in to the database as the user just created, testdb.

```bash
psql -U testdb
```

6. Enter the correct password at the prompt.

7. Verify that the password is stored as a SHA-256 hash.

   Password hashes are stored in `pg_authid.rolpassword`.

8. Log in as the super user.

9. Execute the following query:

```bash
# SELECT rolpassword FROM pg_authid WHERE rolname = 'testdb';
Rolpassword
----------
sha256<64 hexadecimal characters>
```

### Restricting Access by Time

Greenplum Database enables the administrator to restrict access to certain times by role. Use the `CREATE ROLE` or `ALTER ROLE` commands to specify time-based constraints.

Access can be restricted by day or by day and time. The constraints are removable without deleting and recreating the role.

Time-based constraints only apply to the role to which they are assigned. If a role is a member of another role that contains a time constraint, the time constraint is not inherited.

Time-based constraints are enforced only during login. The `SET ROLE` and `SET SESSION AUTHORIZATION` commands are not affected by any time-based constraints.

Superuser or `CREATEROLE` privileges are required to set time-based constraints for a role. No one can add time-based constraints to a superuser.

There are two ways to add time-based constraints. Use the keyword `DENY` in the `CREATE ROLE` or `ALTER ROLE` command followed by one of the following:

- A day, and optionally a time, when access is restricted. For example, no access on Wednesdays.
- An interval—that is, a beginning and ending day and optional time—when access is restricted. For example, no access from Wednesday 10 p.m. through Thursday at 8 a.m.

You can specify more than one restriction; for example, no access Wednesdays at any time and no access on Fridays between 3:00 p.m. and 5:00 p.m.

There are two ways to specify a day. Use the word `DAY` followed by either the English term for the weekday, in single quotation marks, or a number between 0 and 6, as shown in the table below.

<table>
<thead>
<tr>
<th>English Term</th>
<th>Number</th>
</tr>
</thead>
<tbody>
<tr>
<td>DAY 'Sunday'</td>
<td>DAY 0</td>
</tr>
<tr>
<td>DAY 'Monday'</td>
<td>DAY 1</td>
</tr>
<tr>
<td>DAY 'Tuesday'</td>
<td>DAY 2</td>
</tr>
<tr>
<td>DAY 'Wednesday'</td>
<td>DAY 3</td>
</tr>
<tr>
<td>DAY 'Thursday'</td>
<td>DAY 4</td>
</tr>
<tr>
<td>DAY 'Friday'</td>
<td>DAY 5</td>
</tr>
<tr>
<td>DAY 'Saturday'</td>
<td>DAY 6</td>
</tr>
</tbody>
</table>
A time of day is specified in either 12- or 24-hour format. The word `TIME` is followed by the specification in single quotation marks. Only hours and minutes are specified and are separated by a colon (:``). If using a 12-hour format, add `AM` or `PM` at the end. The following examples show various time specifications.

```
TIME '14:00'    # 24-hour time implied
TIME '02:00 PM' # 12-hour time specified by PM
TIME '02:00'    # 24-hour time implied. This is equivalent to TIME '02:00 AM'.
```

**Important:** Time-based authentication is enforced with the server time. Timezones are disregarded.

To specify an interval of time during which access is denied, use two day/time specifications with the words `BETWEEN` and `AND`, as shown. `DAY` is always required.

```
BETWEEN DAY 'Monday' AND DAY 'Tuesday'
BETWEEN DAY 'Monday' TIME '00:00' AND DAY 'Monday' TIME '01:00'
BETWEEN DAY 'Monday' TIME '12:00 AM' AND DAY 'Tuesday' TIME '02:00 AM'
BETWEEN DAY 'Monday' TIME '00:00' AND DAY 'Tuesday' TIME '02:00'
DAY 2 TIME '02:00'
```

The last three statements are equivalent.

**Note:** Intervals of days cannot wrap past Saturday.

The following syntax is not correct:

```
DENY BETWEEN DAY 'Saturday' AND DAY 'Sunday'
```

The correct specification uses two `DENY` clauses, as follows:

```
DENY DAY 'Saturday'
DENY DAY 'Sunday'
```

The following examples demonstrate creating a role with time-based constraints and modifying a role to add time-based constraints. Only the statements needed for time-based constraints are shown. For more details on creating and altering roles see the descriptions of `CREATE ROLE` and `ALTER ROLE` in in the *Greenplum Database Reference Guide*.

**Example 1 – Create a New Role with Time-based Constraints**

No access is allowed on weekends.

```
CREATE ROLE generaluser
DENY DAY 'Saturday'
DENY DAY 'Sunday'
...
```

**Example 2 – Alter a Role to Add Time-based Constraints**

No access is allowed every night between 2:00 a.m. and 4:00 a.m.

```
ALTER ROLE generaluser
DENY BETWEEN DAY 'Monday' TIME '02:00' AND DAY 'Monday' TIME '04:00'
```
DENY BETWEEN DAY 'Tuesday' TIME '02:00' AND DAY 'Tuesday' TIME '04:00'
DENY BETWEEN DAY 'Wednesday' TIME '02:00' AND DAY 'Wednesday' TIME '04:00'
DENY BETWEEN DAY 'Thursday' TIME '02:00' AND DAY 'Thursday' TIME '04:00'
DENY BETWEEN DAY 'Friday' TIME '02:00' AND DAY 'Friday' TIME '04:00'
DENY BETWEEN DAY 'Saturday' TIME '02:00' AND DAY 'Saturday' TIME '04:00'
DENY BETWEEN DAY 'Sunday' TIME '02:00' AND DAY 'Sunday' TIME '04:00'
...

**Example 3 – Alter a Role to Add Time-based Constraints**
No access is allowed Wednesdays or Fridays between 3:00 p.m. and 5:00 p.m.

```
ALTER ROLE generaluser
  DENY DAY 'Wednesday'
  DENY BETWEEN DAY 'Friday' TIME '15:00' AND DAY 'Friday' TIME '17:00'
```

**Dropping a Time-based Restriction**
To remove a time-based restriction, use the ALTER ROLE command. Enter the keywords DROP DENY FOR followed by a day/time specification to drop.

```
DROP DENY FOR DAY 'Sunday'
```

Any constraint containing all or part of the conditions in a DROP clause is removed. For example, if an existing constraint denies access on Mondays and Tuesdays, and the DROP clause removes constraints for Mondays, the existing constraint is completely dropped. The DROP clause completely removes all constraints that overlap with the constraint in the drop clause. The overlapping constraints are completely removed even if they contain more restrictions that the restrictions mentioned in the DROP clause.

**Example 1 - Remove a Time-based Restriction from a Role**

```
ALTER ROLE generaluser
  DROP DENY FOR DAY 'Monday'
...
```

This statement would remove all constraints that overlap with a Monday constraint for the role `generaluser` in Example 2, even if there are additional constraints.
Greenplum Command Center Security

Greenplum Command Center is a web-based application for monitoring and managing Greenplum clusters. Command Center works with data collected by agents running on the segment hosts and saved to the gpperfmon database. Installing Command Center creates the gpperfmon database and the gpmon database role if they do not already exist. It creates the gpmetrics schema in the gpperfmon database, which contains metrics and query history tables populated by the Greenplum Database metrics collector module.

Note: The gpperfmon_install utility also creates the gpperfmon database and gpmon role, but Command Center no longer requires the history tables it creates in the database. Do not use gpperfmon_install unless you need the old query history tables for some other purpose. gpperfmon_install enables the gpmmon and gpsmon agents, which add unnecessary load to the Greenplum Database system if you do not need the old history tables.

The gpmon User

The Command Center installer creates the gpmon database role and adds the role to the pg_hba.conf file with the following entries:

```
local  gpperfmon  gpmon         md5
host   all       gpmon         127.0.0.1/28    md5
host   all       gpmon         ::1/128         md5
```

These entries allow gpmon to establish a local socket connection to the gpperfmon database and a TCP/IP connection to any database.

The gpmon database role is a superuser. In a secure or production environment, it may be desirable to restrict the gpmon user to just the gpperfmon database. Do this by editing the gpmon host entry in the pg_hba.conf file and changing all in the database field to gpperfmon:

```
local  gpperfmon  gpmon                        md5
host   gpperfmon  gpmon    127.0.0.1/28        md5
host   gpperfmon  gpmon    ::1/128             md5
```

The password used to authenticate the gpmon user is stored in the gpadmin home directory in the ~/.pgpass file. The ~/.pgpass file must be owned by the gpadmin user and be RW-accessible only by the gpadmin user. The Command Center installer creates the gpmon role with the default password "changeme". Be sure to change the password immediately after you install Command Center. Use the ALTER ROLE command to change the password in the database, change the password in the ~/.pgpass file, and then restart Command Center with the gpcc start command.

Because the .pgpass file contains the plain-text password of the gpmon user, you may want to remove it and supply the gpmon password using a more secure method. The gpmon password is needed when you run the gpcc start, gpcc stop, or gpcc status commands. You can add the -W option to the gpcc command to have the command prompt you to enter the password. Alternatively, you can set the PGPASSWORD environment variable to the gpmon password before you run the gpcc command.

Command Center does not allow logins from any role configured with trust authentication, including the gpadmin user.

The gpmon user can log in to the Command Center Console and has access to all of the application's features. You can allow other database roles access to Command Center so that you can secure the gpmon user and restrict other users' access to Command Center features. Setting up other Command Center users is described in the next section.
Greenplum Command Center Users

To log in to the Command Center web application, a user must be allowed access to the gpperfmon database in `pg_hba.conf`. For example, to make `user1` a regular Command Center user, edit the `pg_hba.conf` file and either add or edit a line for the user so that the gpperfmon database is included in the database field. For example:

```
host     gpperfmon,accounts   user1     127.0.0.1/28    md5
```

The Command Center web application includes an Admin interface to add, remove, and edit entries in the `pg_hba.conf` file and reload the file into Greenplum Database.

Command Center has the following types of users:

- **Self Only** users can view metrics and view and cancel their own queries. Any Greenplum Database user successfully authenticated through the Greenplum Database authentication system can access Greenplum Command Center with Self Only permission. Higher permission levels are required to view and cancel other’s queries and to access the System and Admin Control Center features.
- **Basic** users can view metrics, view all queries, and cancel their own queries. Users with Basic permission are members of the Greenplum Database `gpcc_basic` group.
- **Operator Basic** users can view metrics, view their own and others’ queries, cancel their own queries, and view the System and Admin screens. Users with Operator Basic permission are members of the Greenplum Database `gpcc_operator_basic` group.
- **Operator** users can view their own and others’ queries, cancel their own and other’s queries, and view the System and Admin screens. Users with Operator permission are members of the Greenplum Database `gpcc_operator` group.
- **Admin** users can access all views and capabilities in the Command Center. Greenplum Database users with the `SUPERUSER` privilege have Admin permissions in Command Center.

The Command Center web application has an Admin interface you can use to change a Command Center user’s access level.

Enabling SSL for Greenplum Command Center

The Command Center web server can be configured to support SSL so that client connections are encrypted. To enable SSL, install a `.pem` file containing the web server’s certificate and private key on the web server host and then enter the full path to the `.pem` file when prompted by the Command Center installer.

Enabling Kerberos Authentication for Greenplum Command Center Users

If Kerberos authentication is enabled for Greenplum Database, Command Center users can also authenticate with Kerberos. Command Center supports three Kerberos authentication modes: strict, normal, and `gpmon-only`.

**Strict**

Command Center has a Kerberos keytab file containing the Command Center service principal and a principal for every Command Center user. If the principal in the client’s connection request is in the keytab file, the web server grants the client access and the web server connects to Greenplum Database using the client’s principal name. If the principal is not in the keytab file, the connection request fails.

**Normal**

The Command Center Kerberos keytab file contains the Command Center principal and may contain principals for Command Center users. If the principal in the client’s connection request is in Command Center’s keytab file, it uses the client’s principal for database connections. Otherwise, Command Center uses the `gpmon` user for database connections.
gpmon-only

The Command Center uses the gpmon database role for all Greenplum Database connections. No client principals are needed in the Command Center’s keytab file.

See the Greenplum Command Center documentation for instructions to enable Kerberos authentication with Greenplum Command Center.
Auditing

Describes Greenplum Database events that are logged and should be monitored to detect security threats.

Greenplum Database is capable of auditing a variety of events, including startup and shutdown of the system, segment database failures, SQL statements that result in an error, and all connection attempts and disconnections. Greenplum Database also logs SQL statements and information regarding SQL statements, and can be configured in a variety of ways to record audit information with more or less detail. The `log_error_verbosity` configuration parameter controls the amount of detail written in the server log for each message that is logged. Similarly, the `log_min_error_statement` parameter allows administrators to configure the level of detail recorded specifically for SQL statements, and the `log_statement` parameter determines the kind of SQL statements that are audited. Greenplum Database records the username for all auditable events, when the event is initiated by a subject outside the Greenplum Database.

Greenplum Database prevents unauthorized modification and deletion of audit records by only allowing administrators with an appropriate role to perform any operations on log files. Logs are stored in a proprietary format using comma-separated values (CSV). Each segment and the master stores its own log files, although these can be accessed remotely by an administrator. Greenplum Database also authorizes overwriting of old log files via the `log_truncate_on_rotation` parameter. This is a local parameter and must be set on each segment and master configuration file.

Greenplum provides an administrative schema called `gp_toolkit` that you can use to query log files, as well as system catalogs and operating environment for system status information. For more information, including usage, refer to The `gp_toolkit` Administrative Schema appendix in the Greenplum Database Reference Guide.

Viewing the Database Server Log Files

Every database instance in Greenplum Database (master and segments) is a running PostgreSQL database server with its own server log file. Daily log files are created in the `pg_log` directory of the master and each segment data directory.

The server log files are written in comma-separated values (CSV) format. Not all log entries will have values for all of the log fields. For example, only log entries associated with a query worker process will have the `slice_id` populated. Related log entries of a particular query can be identified by its session identifier (`gp_session_id`) and command identifier (`gp_command_count`).

<table>
<thead>

</tbody>
</table>
Greenplum provides a utility called gplogfilter that can be used to search through a Greenplum Database log file for entries matching the specified criteria. By default, this utility searches through the Greenplum master log file in the default logging location. For example, to display the last three lines of the master log file:

```
$ gplogfilter -n 3
```

You can also use gplogfilter to search through all segment log files at once by running it through the gpssh utility. For example, to display the last three lines of each segment log file:

```
$ gpssh -f seg_host_file
  => source /usr/local/greenplum-db/greenplum_path.sh
  => gplogfilter -n 3 /gpdata/gp*/pg_log/gpdb*.csv
```

The following are the Greenplum security-related audit (or logging) server configuration parameters that are set in the postgresql.conf configuration file:

<table>
<thead>
<tr>
<th>Field Name</th>
<th>Value Range</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>log_connections</td>
<td>Boolean</td>
<td>off</td>
<td>This outputs a line to the server log detailing each successful connection. Some client programs, like psql, attempt to connect twice while determining if a password is required, so duplicate “connection received” messages do not always indicate a problem.</td>
</tr>
<tr>
<td>log_disconnections</td>
<td>Boolean</td>
<td>off</td>
<td>This outputs a line in the server log at termination of a client session, and includes the duration of the session.</td>
</tr>
<tr>
<td>Field Name</td>
<td>Value Range</td>
<td>Default</td>
<td>Description</td>
</tr>
<tr>
<td>--------------------</td>
<td>------------------------------</td>
<td>---------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>log_statement</td>
<td>NONE, DDL, MOD, ALL</td>
<td>ALL</td>
<td>Controls which SQL statements are logged. DDL logs all data definition commands like CREATE, ALTER, and DROP commands. MOD logs all DDL statements, plus INSERT, UPDATE, DELETE, TRUNCATE, and COPY FROM. PREPARE and EXPLAIN ANALYZE statements are also logged if their contained command is of an appropriate type.</td>
</tr>
<tr>
<td>log_hostname</td>
<td>Boolean</td>
<td>off</td>
<td>By default, connection log messages only show the IP address of the connecting host. Turning on this option causes logging of the host name as well. Note that depending on your host name resolution setup this might impose a non-negligible performance penalty.</td>
</tr>
<tr>
<td>log_duration</td>
<td>Boolean</td>
<td>off</td>
<td>Causes the duration of every completed statement which satisfies log_statement to be logged.</td>
</tr>
<tr>
<td>log_error_verbosity</td>
<td>TERSE, DEFAULT, VERBOSEx</td>
<td>DEFAULT</td>
<td>Controls the amount of detail written in the server log for each message that is logged.</td>
</tr>
<tr>
<td>log_min_duration_statement</td>
<td>number of milliseconds, 0, -1</td>
<td>-1</td>
<td>Logs the statement and its duration on a single log line if its duration is greater than or equal to the specified number of milliseconds. Setting this to 0 will print all statements and their durations. -1 disables the feature. For example, if you set it to 250 then all SQL statements that run 250ms or longer will be logged. Enabling this option can be useful in tracking down unoptimized queries in your applications.</td>

Encrypting Data and Database Connections

Encrypting Data and Database Connections

 Describes how to encrypt data at rest in the database or in transit over the network, to protect from eavesdroppers or man-in-the-middle attacks.

- Connections between clients and the master database can be encrypted with SSL. This is enabled with the `ssl` server configuration parameter, which is `off` by default. Setting the `ssl` parameter to `on` allows client communications with the master to be encrypted. The master database must be set up for SSL. See OpenSSL Configuration for more about encrypting client connections with SSL.
- Greenplum Database allows SSL encryption of data in transit between the Greenplum parallel file distribution server, `gpfdist`, and segment hosts. See Encrypting gpfdist Connections for more information.
- The `pgcrypto` module of encryption/decryptions functions protect data at rest in the database. Encryption at the column level protects sensitive information, such as social security numbers or credit card numbers. See Encrypting Data at Rest with pgcrypto for more information.

Encrypting gpfdist Connections

The `gpfdists` protocol is a secure version of the `gpfdist` protocol that securely identifies the file server and the Greenplum Database and encrypts the communications between them. Using `gpfdists` protects against eavesdropping and man-in-the-middle attacks.

The `gpfdists` protocol implements client/server SSL security with the following notable features:

- Client certificates are required.
- Multilingual certificates are not supported.
- A Certificate Revocation List (CRL) is not supported.
- The TLSv1 protocol is used with the `TLS_RSA_WITH_AES_128_CBC_SHA` encryption algorithm. These SSL parameters cannot be changed.
- SSL renegotiation is supported.
- The SSL ignore host mismatch parameter is set to false.
- Private keys containing a passphrase are not supported for the `gpfdist` file server (server.key) or for the Greenplum Database (client.key).
- It is the user's responsibility to issue certificates that are appropriate for the operating system in use. Generally, converting certificates to the required format is supported, for example using the SSL Converter at https://www.sslshopper.com/ssl-converter.html.

A `gpfdist` server started with the `--ssl` option can only communicate with the `gpfdists` protocol. A `gpfdist` server started without the `--ssl` option can only communicate with the `gpfdist` protocol. For more detail about `gpfdist` refer to the Greenplum Database Administrator Guide.

There are two ways to enable the `gpfdists` protocol:

- Run `gpfdist` with the `--ssl` option and then use the `gpfdists` protocol in the LOCATION clause of a CREATE EXTERNAL TABLE statement.
- Use a YAML control file with the SSL option set to true and run `gpload`. Running `gpload` starts the `gpfdist` server with the `--ssl` option and then uses the `gpfdists` protocol.

When using `gpfdists`, the following client certificates must be located in the `$PGDATA/gpfdists` directory on each segment:

- The client certificate file, `client.crt`
- The client private key file, `client.key`
- The trusted certificate authorities, `root.crt`

**Important:** Do not protect the private key with a passphrase. The server does not prompt for a passphrase for the private key, and loading data fails with an error if one is required.
When using `gpload` with SSL you specify the location of the server certificates in the YAML control file. When using `gpfdist` with SSL, you specify the location of the server certificates with the `--ssl` option.

The following example shows how to securely load data into an external table. The example creates a readable external table named `ext_expenses` from all files with the `.txt` extension, using the `gpfdists` protocol. The files are formatted with a pipe (`|`) as the column delimiter and an empty space as null.

1. Run `gpfdist` with the `--ssl` option on the segment hosts.
2. Log into the database and execute the following command:

```
=## CREATE EXTERNAL TABLE ext_expenses
    ( name text, date date, amount float4, category text, desc1 text )
LOCATION ('gpfdists://etlhost-1:8081/*.txt', 'gpfdists://etlhost-2:8082/*.txt')
FORMAT 'TEXT' ( DELIMITER '|' NULL ' ') ;
```

## Encrypting Data at Rest with pgcrypto

The pgcrypto module for Greenplum Database provides functions for encrypting data at rest in the database. Administrators can encrypt columns with sensitive information, such as social security numbers or credit card numbers, to provide an extra layer of protection. Database data stored in encrypted form cannot be read by users who do not have the encryption key, and the data cannot be read directly from disk.

pgcrypto is installed by default when you install Greenplum Database. You must explicitly enable pgcrypto in each database in which you want to use the module.

pgcrypto allows PGP encryption using symmetric and asymmetric encryption. Symmetric encryption encrypts and decrypts data using the same key and is faster than asymmetric encryption. It is the preferred method in an environment where exchanging secret keys is not an issue. With asymmetric encryption, a public key is used to encrypt data and a private key is used to decrypt data. This is slower than symmetric encryption and it requires a stronger key.

Using pgcrypto always comes at the cost of performance and maintainability. It is important to use encryption only with the data that requires it. Also, keep in mind that you cannot search encrypted data by indexing the data.

Before you implement in-database encryption, consider the following PGP limitations.

- No support for signing. That also means that it is not checked whether the encryption sub-key belongs to the master key.
- No support for encryption key as master key. This practice is generally discouraged, so this limitation should not be a problem.
- No support for several subkeys. This may seem like a problem, as this is common practice. On the other hand, you should not use your regular GPG/PGP keys with pgcrypto, but create new ones, as the usage scenario is rather different.

Greenplum Database is compiled with zlib by default; this allows PGP encryption functions to compress data before encrypting. When compiled with OpenSSL, more algorithms will be available.

Because pgcrypto functions run inside the database server, the data and passwords move between pgcrypto and the client application in clear-text. For optimal security, you should connect locally or use SSL connections and you should trust both the system and database administrators.

pgcrypto configures itself according to the findings of the main PostgreSQL configure script.

When compiled with zlib, pgcrypto encryption functions are able to compress data before encrypting.

Pgcrypto has various levels of encryption ranging from basic to advanced built-in functions. The following table shows the supported encryption algorithms.
Table 60: Pgcrypto Supported Encryption Functions

Creating PGP Keys

To use PGP asymmetric encryption in Greenplum Database, you must first create public and private keys and install them.

This section assumes you are installing Greenplum Database on a Linux machine with the Gnu Privacy Guard (gpg) command line tool. Use the latest version of GPG to create keys. Download and install Gnu Privacy Guard (GPG) for your operating system from https://www.gnupg.org/download/. On the GnuPG website you will find installers for popular Linux distributions and links for Windows and Mac OS X installers.

1. As root, execute the following command and choose option 1 from the menu:

```
# gpg --gen-key
```

```
gpg (GnuPG) 2.0.14; Copyright (C) 2009 Free Software Foundation, Inc.
This is free software: you are free to change and redistribute it.
There is NO WARRANTY, to the extent permitted by law.
gpg: directory '/root/.gnupg' created
gpg: new configuration file '/root/.gnupg/gpg.conf' created
gpg: WARNING: options in '/root/.gnupg/gpg.conf' are not yet active during this run
gpg: keyring '/root/.gnupg/secring.gpg' created
gpg: keyring '/root/.gnupg/pubring.gpg' created
Please select what kind of key you want:
(1) RSA and RSA (default)
(2) DSA and Elgamal
(3) DSA (sign only)
(4) RSA (sign only)
Your selection? 1
```

2. Respond to the prompts and follow the instructions, as shown in this example:

```
RSA keys may be between 1024 and 4096 bits long.
```

---

³ SHA2 algorithms were added to OpenSSL in version 0.9.8. For older versions, pgcrypto will use built-in code.
⁴ Any digest algorithm OpenSSL supports is automatically picked up. This is not possible with ciphers, which need to be supported explicitly.
⁵ AES is included in OpenSSL since version 0.9.7. For older versions, pgcrypto will use built-in code.
What keysize do you want? (2048) Press enter to accept default key size
Requested keysize is 2048 bits
Please specify how long the key should be valid.
 0 = key does not expire
<n> = key expires in n days
<n>w = key expires in n weeks
<n>m = key expires in n months
<n>y = key expires in n years
Key is valid for? (0) 365
Key expires at Wed 13 Jan 2016 10:35:39 AM PST
Is this correct? (y/N) y

GnuPG needs to construct a user ID to identify your key.

Real name: John Doe
Email address: jdoe@email.com
Comment:
You selected this USER-ID:
"John Doe <jdoe@email.com>"

Change (N)ame, (C)omment, (E)mail or (O)kay/(Q)uit? O
You need a Passphrase to protect your secret key.
(For this demo the passphrase is blank.)
can't connect to '/root/.gnupg/S.gpg-agent': No such file or directory
You don't want a passphrase - this is probably a *bad* idea!
I will do it anyway. You can change your passphrase at any time,
using this program with the option "--edit-key".

We need to generate a lot of random bytes. It is a good idea to perform
some other action (type on the keyboard, move the mouse, utilize the
disks) during the prime generation; this gives the random number
generator a better chance to gain enough entropy.
We need to generate a lot of random bytes. It is a good idea to perform
some other action (type on the keyboard, move the mouse, utilize the
disks) during the prime generation; this gives the random number
generator a better chance to gain enough entropy.
gpg: /root/.gnupg/trustdb.gpg: trustdb created
gpg: key 2027CC30 marked as ultimately trusted
public and secret key created and signed.
gpg: checking the trustdb:
   3 marginal(s) needed, 1 complete(s) needed, PGP trust model
gpg: depth: 0  valid: 1  signed: 0  trust: 0-, 0q, 0n, 0m, 0f, 1u
gpg: next trustdb check due at 2016-01-13
pub  2048R/2027CC30 2015-01-13 [expires: 2016-01-13]
    Key fingerprint = 7EDA 6AD0 F5E0 400F 4D45   3259 077D 725E 2027CC30
uid                  John Doe <jdoe@email.com>
sub   2048R/4FD2EFBB 2015-01-13 [expires: 2016-01-13]

3. List the PGP keys by entering the following command:

    gpg --list-secret-keys
    /root/.gnupg/secring.gpg
    ------------------------
    sec  2048R/2027CC30 2015-01-13 [expires: 2016-01-13]
    uid   John Doe <jdoe@email.com>
    ssb  2048R/4FD2EFBB 2015-01-13

2027CC30 is the public key and will be used to encrypt data in the database. 4FD2EFBB is the private
(secret) key and will be used to decrypt data.
4. Export the keys using the following commands:

```
# gpg -a --export 4FD2EFBB > public.key
# gpg -a --export-secret-keys 2027CC30 > secret.key
```

See the `pgcrypto` documentation for more information about PGP encryption functions.

## Encrypting Data in Tables using PGP

This section shows how to encrypt data inserted into a column using the PGP keys you generated.

1. Dump the contents of the `public.key` file and then copy it to the clipboard:

```
# cat public.key
-----BEGIN PGP PUBLIC KEY BLOCK-----

-----END PGP PUBLIC KEY BLOCK-----'));
```

This shows that the PGP key ID used to encrypt the `ssn` column is 9D4D255F4FD2EFBB. It is recommended to perform this step whenever a new key is created and then store the ID for tracking.

You can use this key to see which key pair was used to encrypt the data:

```sql
SELECT username, pgp_key_id(ssn) As key_used
FROM userssn;
```
5. Decrypt the data using the private key.

```
SELECT username, pgp_pub_decrypt(ssn, keys.privkey) AS decrypted_ssn FROM userssn

**Note:** Different keys may have the same ID. This is rare, but is a normal event. The client application should try to decrypt with each one to see which fits — like handling ANYKEY. See `pgp_key_id()` in the pgcrypto documentation.
If you created a key with passphrase, you may have to enter it here. However for the purpose of this example, the passphrase is blank.

**Key Management**

Whether you are using symmetric (single private key) or asymmetric (public and private key) cryptography, it is important to store the master or private key securely. There are many options for storing encryption keys, for example, on a file system, key vault, encrypted USB, trusted platform module (TPM), or hardware security module (HSM).

Consider the following questions when planning for key management:

- Where will the keys be stored?
- When should keys expire?
- How are keys protected?
- How are keys accessed?
- How can keys be recovered and revoked?

The Open Web Application Security Project (OWASP) provides a very comprehensive guide to securing encryption keys.
Security Best Practices

Describes basic security best practices that you should follow to ensure the highest level of system security.

In the default Greenplum Database security configuration:

- Only local connections are allowed.
- Basic authentication is configured for the superuser (gpadmin).
- The superuser is authorized to do anything.
- Only database role passwords are encrypted.

System User (gpadmin)

Secure and limit access to the gpadmin system user.

Greenplum requires a UNIX user id to install and initialize the Greenplum Database system. This system user is referred to as gpadmin in the Greenplum documentation. The gpadmin user is the default database superuser in Greenplum Database, as well as the file system owner of the Greenplum installation and its underlying data files. The default administrator account is fundamental to the design of Greenplum Database. The system cannot run without it, and there is no way to limit the access of the gpadmin user id.

The gpadmin user can bypass all security features of Greenplum Database. Anyone who logs on to a Greenplum host with this user id can read, alter, or delete any data, including system catalog data and database access rights. Therefore, it is very important to secure the gpadmin user id and only allow essential system administrators access to it.

Administrators should only log in to Greenplum as gpadmin when performing certain system maintenance tasks (such as upgrade or expansion).

Database users should never log on as gpadmin, and ETL or production workloads should never run as gpadmin.

Superusers

Roles granted the SUPERUSER attribute are superusers. Superusers bypass all access privilege checks and resource queues. Only system administrators should be given superuser rights.

See "Altering Role Attributes" in the Greenplum Database Administrator Guide.

Login Users

Assign a distinct role to each user who logs in and set the LOGIN attribute.

For logging and auditing purposes, each user who is allowed to log in to Greenplum Database should be given their own database role. For applications or web services, consider creating a distinct role for each application or service. See "Creating New Roles (Users)" in the Greenplum Database Administrator Guide.

Each login role should be assigned to a single, non-default resource queue.

Groups

Use groups to manage access privileges.

Create a group for each logical grouping of object/access permissions.

Every login user should belong to one or more roles. Use the GRANT statement to add group access to a role. Use the REVOKE statement to remove group access from a role.
The **LOGIN** attribute should not be set for group roles.

See "Creating Groups (Role Membership)" in the *Greenplum Database Administrator Guide*.

### Object Privileges

Only the owner and superusers have full permissions to new objects. Permission must be granted to allow other rules (users or groups) to access objects. Each type of database object has different privileges that may be granted. Use the **GRANT** statement to add a permission to a role and the **REVOKE** statement to remove the permission.

You can change the owner of an object using the **REASIGN OWNED BY** statement. For example, to prepare to drop a role, change the owner of the objects that belong to the role. Use the **DROP OWNED BY** to drop objects, including dependent objects, that are owned by a role.

Schemas can be used to enforce an additional layer of object permissions checking, but schema permissions do not override object privileges set on objects contained within the schema.

### Operating System Users and File System

To protect the network from intrusion, system administrators should verify the passwords used within an organization are sufficiently strong. The following recommendations can strengthen a password:

- Minimum password length recommendation: At least 9 characters. MD5 passwords should be 15 characters or longer.
- Mix upper and lower case letters.
- Mix letters and numbers.
- Include non-alphanumeric characters.
- Pick a password you can remember.

The following are recommendations for password cracker software that you can use to determine the strength of a password:

- **John The Ripper.** A fast and flexible password cracking program. It allows the use of multiple word lists and is capable of brute-force password cracking. It is available online at [http://www.openwall.com/john/](http://www.openwall.com/john/).
- **Crack.** Perhaps the most well-known password cracking software, Crack is also very fast, though not as easy to use as John The Ripper. It can be found online at [https://dropsafe.crypticide.com/alecm/software/crack/c50-faq.html](https://dropsafe.crypticide.com/alecm/software/crack/c50-faq.html).

The security of the entire system depends on the strength of the root password. This password should be at least 12 characters long and include a mix of capitalized letters, lowercase letters, special characters, and numbers. It should not be based on any dictionary word.

Password expiration parameters should be configured.

Ensure the following line exists within the file `/etc/libuser.conf` under the **[import]** section.

```
login_defs = /etc/login.defs
```

Ensure no lines in the **[userdefaults]** section begin with the following text, as these words override settings from `/etc/login.defs`:

- **LU_SHADOWMAX**
- **LU_SHADOWMIN**
- **LU_SHADOWWARNING**

Ensure the following command produces no output. Any accounts listed by running this command should be locked.

```
grep "^+:" /etc/passwd /etc/shadow /etc/group
```
Note: We strongly recommend that customers change their passwords after initial setup.

```bash
cd /etc
chown root:root passwd shadow group gshadow
chmod 644 passwd group
chmod 400 shadow gshadow
```

Find all the files that are world-writable and that do not have their sticky bits set.

```bash
find / -xdev -type d \( -perm -0002 -a ! -perm -1000 \) -print
```

Set the sticky bit (# chmod +t {dir}) for all the directories that result from running the previous command.

Find all the files that are world-writable and fix each file listed.

```bash
find / -xdev -type f -perm -0002 -print
```

Set the right permissions (# chmod o-w {file}) for all the files generated by running the aforementioned command.

Find all the files that do not belong to a valid user or group and either assign an owner or remove the file, as appropriate.

```bash
find / -xdev \( -nouser -o nogroup \) -print
```

Find all the directories that are world-writable and ensure they are owned by either root or a system account (assuming only system accounts have a User ID lower than 500). If the command generates any output, verify the assignment is correct or reassign it to root.

```bash
find / -xdev -type d -perm -0002 -uid +500 -print
```

Authentication settings such as password quality, password expiration policy, password reuse, password retry attempts, and more can be configured using the Pluggable Authentication Modules (PAM) framework. PAM looks in the directory `/etc/pam.d` for application-specific configuration information. Running `authconfig` or `system-config-authentication` will re-write the PAM configuration files, destroying any manually made changes and replacing them with system defaults.

The default `pam_cracklib` PAM module provides strength checking for passwords. To configure `pam_cracklib` to require at least one uppercase character, lowercase character, digit, and special character, as recommended by the U.S. Department of Defense guidelines, edit the file `/etc/pam.d/system-auth` to include the following parameters in the line corresponding to password requisite `pam_cracklib.so try_first_pass`.

```bash
retry=3:
dcredit=-1. Require at least one digit
ucredit=-1. Require at least one upper case character
ocredit=-1. Require at least one special character
lcredit=-1. Require at least one lower case character
minlen=14. Require a minimum password length of 14.
```

For example:
password required pam_cracklib.so try_first_pass retry=3\minlen=14
dcredit=-1 ucredit=-1 ocredit=-1 lcredit=-1

These parameters can be set to reflect your security policy requirements. Note that the password restrictions are not applicable to the root password.

The pam_tally2 PAM module provides the capability to lock out user accounts after a specified number of failed login attempts. To enforce password lockout, edit the file /etc/pam.d/system-auth to include the following lines:

- The first of the auth lines should include:
  ```
  auth required pam_tally2.so deny=5 onerr=fail unlock_time=900
  ```
- The first of the account lines should include:
  ```
  account required pam_tally2.so
  ```

Here, the deny parameter is set to limit the number of retries to 5 and the `unlock_time` has been set to 900 seconds to keep the account locked for 900 seconds before it is unlocked. These parameters may be configured appropriately to reflect your security policy requirements. A locked account can be manually unlocked using the `pam_tally2` utility:

```
/sbin/pam_tally2 --user {username} -reset
```

You can use PAM to limit the reuse of recent passwords. The remember option for the `pam_unix` module can be set to remember the recent passwords and prevent their reuse. To accomplish this, edit the appropriate line in `/etc/pam.d/system-auth` to include the remember option.

For example:

```
password sufficient pam_unix.so [ ... existing_options ...] remember=5
```

You can set the number of previous passwords to remember to appropriately reflect your security policy requirements.

```
cd /etc
chown root:root passwd shadow group gshadow
chmod 644 passwd group
chmod 400 shadow gshadow
```
Chapter 10

Greenplum Database Best Practices

A best practice is a method or technique that has consistently shown results superior to those achieved with other means. Best practices are found through experience and are proven to reliably lead to a desired result. Best practices are a commitment to use any product correctly and optimally, by leveraging all the knowledge and expertise available to ensure success.

This document does not teach you how to use Greenplum Database features. Links are provided to other relevant parts of the Greenplum Database documentation for information on how to use and implement specific Greenplum Database features. This document addresses the most important best practices to follow when designing, implementing, and using Greenplum Database.

It is not the intent of this document to cover the entire product or compendium of features, but rather to provide a summary of what matters most in Greenplum Database. This document does not address edge use cases. While edge use cases can further leverage and benefit from Greenplum Database features, they require a proficient knowledge and expertise with these features, as well as a deep understanding of your environment, including SQL access, query execution, concurrency, workload, and other factors.

By mastering these best practices, you will increase the success of your Greenplum Database clusters in the areas of maintenance, support, performance, and scalability.
Best Practices Summary

A summary of best practices for Greenplum Database.

Data Model

Greenplum Database is an analytical MPP shared-nothing database. This model is significantly different from a highly normalized/transactional SMP database. Because of this, the following best practices are recommended.

- Greenplum Database performs best with a denormalized schema design suited for MPP analytical processing for example, Star or Snowflake schema, with large fact tables and smaller dimension tables.
- Use the same data types for columns used in joins between tables.

See Schema Design.

Heap vs. Append-Optimized Storage

- Use heap storage for tables and partitions that will receive iterative batch and singleton UPDATE, DELETE, and INSERT operations.
- Use heap storage for tables and partitions that will receive concurrent UPDATE, DELETE, and INSERT operations.
- Use append-optimized storage for tables and partitions that are updated infrequently after the initial load and have subsequent inserts only performed in large batch operations.
- Avoid performing singleton INSERT, UPDATE, or DELETE operations on append-optimized tables.
- Avoid performing concurrent batch UPDATE or DELETE operations on append-optimized tables. Concurrent batch INSERT operations are acceptable.

See Heap Storage or Append-Optimized Storage.

Row vs. Column Oriented Storage

- Use row-oriented storage for workloads with iterative transactions where updates are required and frequent inserts are performed.
- Use row-oriented storage when selects against the table are wide.
- Use row-oriented storage for general purpose or mixed workloads.
- Use column-oriented storage where selects are narrow and aggregations of data are computed over a small number of columns.
- Use column-oriented storage for tables that have single columns that are regularly updated without modifying other columns in the row.

See Row or Column Orientation.

Compression

- Use compression on large append-optimized and partitioned tables to improve I/O across the system.
- Set the column compression settings at the level where the data resides.
- Balance higher levels of compression with the time and CPU cycles needed to compress and uncompress data.

See Compression.

Distributions

- Explicitly define a column or random distribution for all tables. Do not use the default.
- Use a single column that will distribute data across all segments evenly.
• Do not distribute on columns that will be used in the WHERE clause of a query.
• Do not distribute on dates or timestamps.
• Never distribute and partition tables on the same column.
• Achieve local joins to significantly improve performance by distributing on the same column for large tables commonly joined together.
• To ensure there is no data skew, validate that data is evenly distributed after the initial load and after incremental loads.

See Distributions.

Resource Queue Memory Management

• Set vm.overcommit_memory to 2.
• Do not configure the OS to use huge pages.
• Use gp_vmem_protect_limit to set the maximum memory that the instance can allocate for all work being done in each segment database.
• You can use gp_vmem_protect_limit by calculating:
  
  \[
  \text{gp\_vmem} = \frac{((\text{SWAP} + \text{RAM}) - (7.5\text{GB} + 0.05 \times \text{RAM}))}{1.7}
  \]

  where SWAP is the host's swap space in GB, and RAM is the host's RAM in GB

  \[
  \text{max\_acting\_primary\_segments} - \text{the maximum number of primary segments that could be running on a host when mirror segments are activated due to a host or segment failure}
  \]

  \[
  \text{gp\_vmem\_protect\_limit} = \frac{\text{gp\_vmem}}{\text{acting\_primary\_segments}}
  \]

  Convert to MB to set the value of the configuration parameter.

• In a scenario where a large number of workfiles are generated calculate the \( \text{gp\_vmem} \) factor with this formulat to account for the workfiles:

  \[
  \text{gp\_vmem} = \frac{((\text{SWAP} + \text{RAM}) - (7.5\text{GB} + 0.05 \times \text{RAM} - (300\text{KB} \times \text{total\_#\_workfiles})))}{1.7}
  \]

  • Never set \( \text{gp\_vmem\_protect\_limit} \) too high or larger than the physical RAM on the system.

• Use the calculated \( \text{gp\_vmem} \) value to calculate the setting for the \( \text{vm.\overcommit\_ratio} \) operating system parameter:

  \[
  \text{vm.\overcommit\_ratio} = \frac{\text{RAM} - 0.026 \times \text{gp\_vmem}}{\text{RAM}}
  \]

• Use statement_mem to allocate memory used for a query per segment db.
• Use resource queues to set both the numbers of active queries (ACTIVE_STATEMENTS) and the amount of memory (MEMORY_LIMIT) that can be utilized by queries in the queue.
• Associate all users with a resource queue. Do not use the default queue.
• Set PRIORITY to match the real needs of the queue for the workload and time of day. Avoid using MAX priority.
• Ensure that resource queue memory allocations do not exceed the setting for \( \text{gp\_vmem\_protect\_limit} \).
• Dynamically update resource queue settings to match daily operations flow.

See Setting the Greenplum Recommended OS Parameters and Memory and Resource Management with Resource Queues.
**Partitioning**

- Partition large tables only. Do not partition small tables.
- Use partitioning only if partition elimination (partition pruning) can be achieved based on the query criteria.
- Choose range partitioning over list partitioning.
- Partition the table based on a commonly-used column, such as a date column.
- Never partition and distribute tables on the same column.
- Do not use default partitions.
- Do not use multi-level partitioning; create fewer partitions with more data in each partition.
- Validate that queries are selectively scanning partitioned tables (partitions are being eliminated) by examining the query `EXPLAIN` plan.
- Do not create too many partitions with column-oriented storage because of the total number of physical files on every segment: `physical files = segments x columns x partitions`

See *Partitioning*.

**Indexes**

- In general indexes are not needed in Greenplum Database.
- Create an index on a single column of a columnar table for drill-through purposes for high cardinality tables that require queries with high selectivity.
- Do not index columns that are frequently updated.
- Consider dropping indexes before loading data into a table. After the load, re-create the indexes for the table.
- Create selective B-tree indexes.
- Do not create bitmap indexes on columns that are updated.
- Avoid using bitmap indexes for unique columns, very high or very low cardinality data. Bitmap indexes perform best when the column has a low cardinality—100 to 100,000 distinct values.
- Do not use bitmap indexes for transactional workloads.
- In general do not index partitioned tables. If indexes are needed, the index columns must be different than the partition columns.

See *Indexes*.

**Resource Queues**

- Use resource queues to manage the workload on the cluster.
- Associate all roles with a user-defined resource queue.
- Use the `ACTIVE_STATEMENTS` parameter to limit the number of active queries that members of the particular queue can run concurrently.
- Use the `MEMORY_LIMIT` parameter to control the total amount of memory that queries running through the queue can utilize.
- Alter resource queues dynamically to match the workload and time of day.

See *Configuring Resource Queues*.

**Monitoring and Maintenance**

- Implement the "Recommended Monitoring and Maintenance Tasks" in the *Greenplum Database Administrator Guide*.
- Run `gpcheckperf` at install time and periodically thereafter, saving the output to compare system performance over time.
- Use all the tools at your disposal to understand how your system behaves under different loads.
- Examine any unusual event to determine the cause.
• Monitor query activity on the system by running explain plans periodically to ensure the queries are running optimally.
• Review plans to determine whether index are being used and partition elimination is occurring as expected.
• Know the location and content of system log files and monitor them on a regular basis, not just when problems arise.

See System Monitoring and Maintenance, Query Profiling and Monitoring Greenplum Database Log Files.

ANALYZE
• Determine if analyzing the database is actually needed. Analyzing is not needed if gp_autostats_mode is set to on_no_stats (the default) and the table is not partitioned.
• Use analyzedb in preference to ANALYZE when dealing with large sets of tables, as it does not require analyzing the entire database. The analyzedb utility updates statistics data for the specified tables incrementally and concurrently. For append optimized tables, analyzedb updates statistics incrementally only if the statistics are not current. For heap tables, statistics are always updated. ANALYZE does not update the table metadata that the analyzedb utility uses to determine whether table statistics are up to date.
• Selectively run ANALYZE at the table level when needed.
• Always run ANALYZE after INSERT, UPDATE, and DELETE operations that significantly changes the underlying data.
• Always run ANALYZE after CREATE INDEX operations.
• If ANALYZE on very large tables takes too long, run ANALYZE only on the columns used in a join condition, WHERE clause, SORT, GROUP BY, or HAVING clause.
• When dealing with large sets of tables, use analyzedb instead of ANALYZE.

See Updating Statistics with ANALYZE.

Vacuum
• Run VACUUM after large UPDATE and DELETE operations.
• Do not run VACUUM FULL. Instead run a CREATE TABLE...AS operation, then rename and drop the original table.
• Frequently run VACUUM on the system catalogs to avoid catalog bloat and the need to run VACUUM FULL on catalog tables.
• Never kill VACUUM on catalog tables.

See Managing Bloat in the Database.

Loading
• Maximize the parallelism as the number of segments increase.
• Spread the data evenly across as many ETL nodes as possible.
  • Split very large data files into equal parts and spread the data across as many file systems as possible.
  • Run two gpfdist instances per file system.
  • Run gpfdist on as many interfaces as possible.
  • Use gp_external_max_segs to control the number of segments that will request data from the gpfdist process.
  • Always keep gp_external_max_segs and the number of gpfdist processes an even factor.
• Always drop indexes before loading into existing tables and re-create the index after loading.
• Run VACUUM after load errors to recover space.

See Loading Data.
Security

- Secure the `gpadmin` user id and only allow essential system administrators access to it.
- Administrators should only log in to Greenplum as `gpadmin` when performing certain system maintenance tasks (such as upgrade or expansion).
- Limit users who have the `SUPERUSER` role attribute. Roles that are superusers bypass all access privilege checks in Greenplum Database, as well as resource queuing. Only system administrators should be given superuser rights. See "Altering Role Attributes" in the *Greenplum Database Administrator Guide*.
- Database users should never log on as `gpadmin`, and ETL or production workloads should never run as `gpadmin`.
- Assign a distinct Greenplum Database role to each user, application, or service that logs in.
- For applications or web services, consider creating a distinct role for each application or service.
- Use groups to manage access privileges.
- Protect the root password.
- Enforce a strong password password policy for operating system passwords.
- Ensure that important operating system files are protected.

See Security.

Encryption

- Encrypting and decrypting data has a performance cost; only encrypt data that requires encryption.
- Do performance testing before implementing any encryption solution in a production system.
- Server certificates in a production Greenplum Database system should be signed by a certificate authority (CA) so that clients can authenticate the server. The CA may be local if all clients are local to the organization.
- Client connections to Greenplum Database should use SSL encryption whenever the connection goes through an insecure link.
- A symmetric encryption scheme, where the same key is used to both encrypt and decrypt, has better performance than an asymmetric scheme and should be used when the key can be shared safely.
- Use crytographic functions to encrypt data on disk. The data is encrypted and decrypted in the database process, so it is important to secure the client connection with SSL to avoid transmitting unencrypted data.
- Use the `gpfdists` protocol to secure ETL data as it is loaded into or unloaded from the database.

See Encrypting Data and Database Connections.

High Availability

Note: The following guidelines apply to actual hardware deployments, but not to public cloud-based infrastructure, where high availability solutions may already exist.

- Use a hardware RAID storage solution with 8 to 24 disks.
- Use RAID 1, 5, or 6 so that the disk array can tolerate a failed disk.
- Configure a hot spare in the disk array to allow rebuild to begin automatically when disk failure is detected.
- Protect against failure of the entire disk array and degradation during rebuilds by mirroring the RAID volume.
- Monitor disk utilization regularly and add additional space when needed.
- Monitor segment skew to ensure that data is distributed evenly and storage is consumed evenly at all segments.
- Set up a standby master instance to take over if the primary master fails.
- Plan how to switch clients to the new master instance when a failure occurs, for example, by updating the master address in DNS.
• Set up monitoring to send notifications in a system monitoring application or by email when the primary fails.
• Set up mirrors for all segments.
• Locate primary segments and their mirrors on different hosts to protect against host failure.
• Recover failed segments promptly, using the `gprecoverseg` utility, to restore redundancy and return the system to optimal balance.
• Consider a Dual Cluster configuration to provide an additional level of redundancy and additional query processing throughput.
• Backup Greenplum databases regularly unless the data is easily restored from sources.
• If backups are saved to local cluster storage, move the files to a safe, off-cluster location when the backup is complete.
• If backups are saved to NFS mounts, use a scale-out NFS solution such as Dell EMC Isilon to prevent IO bottlenecks.
• Consider using Greenplum integration to stream backups to the Dell EMC Data Domain enterprise backup platform.

See *High Availability*. 
System Configuration

Requirements and best practices for system administrators who are configuring Greenplum Database cluster hosts.

Configuration of the Greenplum Database cluster is usually performed as root.

Configuring the Timezone

Greenplum Database selects a timezone to use from a set of internally stored PostgreSQL timezones. The available PostgreSQL timezones are taken from the Internet Assigned Numbers Authority (IANA) Time Zone Database, and Greenplum Database updates its list of available timezones as necessary when the IANA database changes for PostgreSQL.

Greenplum selects the timezone by matching a PostgreSQL timezone with the user specified time zone, or the host system time zone if no time zone is configured. For example, when selecting a default timezone, Greenplum uses an algorithm to select a PostgreSQL timezone based on the host system timezone files. If the system timezone includes leap second information, Greenplum Database cannot match the system timezone with a PostgreSQL timezone. In this case, Greenplum Database calculates a “best match” with a PostgreSQL timezone based on information from the host system.

As a best practice, configure Greenplum Database and the host systems to use a known, supported timezone. This sets the timezone for the Greenplum Database master and segment instances, and prevents Greenplum Database from recalculating a “best match” timezone each time the cluster is restarted, using the current system timezone and Greenplum timezone files (which may have been updated from the IANA database since the last restart). Use the `gpconfig` utility to show and set the Greenplum Database timezone. For example, these commands show the Greenplum Database timezone and set the timezone to US/Pacific.

```bash
# gpconfig -s TimeZone
# gpconfig -c TimeZone -v 'US/Pacific'
```

You must restart Greenplum Database after changing the timezone. The command `gpstop -ra` restarts Greenplum Database. The catalog view `pg_timezone_names` provides Greenplum Database timezone information.

File System

XFS is the file system used for Greenplum Database data directories. XFS should be mounted with the following mount options:

```
  rw,nodev,noatime,nobarrier,inode64
```

See the recommended OS parameter settings in the Greenplum Database Installation Guide for further details.

Port Configuration

Set up `ip_local_port_range` so it does not conflict with the Greenplum Database port ranges. For example, setting this range in `/etc/sysctl.conf`:

```bash
  net.ipv4.ip_local_port_range = 10000  65535
```

you could set the Greenplum Database base port numbers to these values.

```
  PORT_BASE = 6000
```
MIRROR_PORT_BASE = 7000

See the Recommended OS Parameters Settings in the Greenplum Database Installation Guide for further details.

I/O Configuration

Set the blockdev read-ahead size to 16384 on the devices that contain data directories. This command sets the read-ahead size for /dev/sdb.

```
# /sbin/blockdev --setra 16384 /dev/sdb
```

This command returns the read-ahead size for /dev/sdb.

```
# /sbin/blockdev --getra /dev/sdb
16384
```

See the Recommended OS Parameters Settings in the Greenplum Database Installation Guide for further details.

The deadline IO scheduler should be set for all data directory devices.

```
# cat /sys/block/sdb/queue/scheduler
noop anticipatory [deadline] cfq
```

The maximum number of OS files and processes should be increased in the /etc/security/limits.conf file.

```
* soft  nofile 524288
* hard  nofile 524288
* soft  nproc 131072
* hard  nproc 131072
```

Enable core files output to a known location and make sure limits.conf allows core files.

```
kernl.core_pattern = /var/core/core.%h.%t
# grep core /etc/security/limits.conf
* soft  core unlimited
```

OS Memory Configuration

The Linux sysctl `vm.overcommit_memory` and `vm.overcommit_ratio` variables affect how the operating system manages memory allocation. See the /etc/sysctl.conf file parameters guidelines in the Greenplum Database Installation Guide for further details.

`vm.overcommit_memory` determines the method the OS uses for determining how much memory can be allocated to processes. This should be always set to 2, which is the only safe setting for the database.

**Note:** For information on configuration of overcommit memory, refer to:

- https://en.wikipedia.org/wiki/Memory_overcommitment

`vm.overcommit_ratio` is the percent of RAM that is used for application processes. The default is 50 on Red Hat Enterprise Linux. See Resource Queue Segment Memory Configuration for a formula to calculate an optimal value.

Do not enable huge pages in the operating system.

See also Memory and Resource Management with Resource Queues.
Shared Memory Settings

Greenplum Database uses shared memory to communicate between `postgres` processes that are part of the same `postgres` instance. The following shared memory settings should be set in `sysctl` and are rarely modified. See the `sysctl.conf` file parameters in the *Greenplum Database Installation Guide* for further details.

```plaintext
kernel.shmmax = 500000000
kernel.shmmni = 4096
kernel.shmall = 4000000000
```

Number of Segments per Host

Determining the number of segments to execute on each segment host has immense impact on overall system performance. The segments share the host's CPU cores, memory, and NICs with each other and with other processes running on the host. Over-estimating the number of segments a server can accommodate is a common cause of suboptimal performance.

The factors that must be considered when choosing how many segments to run per host include the following:

- Number of cores
- Amount of physical RAM installed in the server
- Number of NICs
- Amount of storage attached to server
- Mixture of primary and mirror segments
- ETL processes that will run on the hosts
- Non-Greenplum processes running on the hosts

Resource Queue Segment Memory Configuration

The `gp_vmem_protect_limit` server configuration parameter specifies the amount of memory that all active `postgres` processes for a single segment can consume at any given time. Queries that exceed this amount will fail. Use the following calculations to estimate a safe value for `gp_vmem_protect_limit`.

1. Calculate `gp_vmem`, the host memory available to Greenplum Database, using this formula:

   ```plaintext
   gp_vmem = (((SWAP + RAM) - (7.5GB + 0.05 * RAM)) / 1.7)
   ```

   where `SWAP` is the host's swap space in GB and `RAM` is the RAM installed on the host in GB.

2. Calculate `max_acting_primary_segments`. This is the maximum number of primary segments that can be running on a host when mirror segments are activated due to a segment or host failure on another host in the cluster. With mirrors arranged in a 4-host block with 8 primary segments per host, for example, a single segment host failure would activate two or three mirror segments on each remaining host in the failed host's block. The `max_acting_primary_segments` value for this configuration is 11 (8 primary segments plus 3 mirrors activated on failure).

3. Calculate `gp_vmem_protect_limit` by dividing the total Greenplum Database memory by the maximum number of acting primaries:

   ```plaintext
   gp_vmem_protect_limit = gp_vmem / max_acting_primary_segments
   ```

Convert to megabytes to find the value to set for the `gp_vmem_protect_limit` system configuration parameter.
For scenarios where a large number of workfiles are generated, adjust the calculation for \( gp\_vmem \) to account for the workfiles:

\[
gp\_vmem = \frac{((SWAP + RAM) - (7.5GB + 0.05 \times RAM - (300KB \times total\_#\_workfiles)))}{1.7}
\]

For information about monitoring and managing workfile usage, see the Greenplum Database Administrator Guide.

You can calculate the value of the \( \text{vm}\_\text{overcommit}\_\text{ratio} \) operating system parameter from the value of \( gp\_vmem \):

\[
\text{vm}\_\text{overcommit}\_\text{ratio} = \frac{(RAM - 0.026 \times gp\_vmem)}{RAM}
\]

See OS Memory Configuration for more about \( \text{vm}\_\text{overcommit}\_\text{ratio} \).

See also Memory and Resource Management with Resource Queues.

### Resource Queue Statement Memory Configuration

The \( \text{statement}\_\text{mem} \) server configuration parameter is the amount of memory to be allocated to any single query in a segment database. If a statement requires additional memory it will spill to disk. Calculate the value for \( \text{statement}\_\text{mem} \) with the following formula:

\[
(\text{gp}\_\text{vmem}\_\text{protect}\_\text{limit} \times .9) / \text{max}\_\text{expected}\_\text{concurrent}\_\text{queries}
\]

For example, for 40 concurrent queries with \( \text{gp}\_\text{vmem}\_\text{protect}\_\text{limit} \) set to 8GB (8192MB), the calculation for \( \text{statement}\_\text{mem} \) would be:

\[
(8192MB \times .9) / 40 = 184MB
\]

Each query would be allowed 184MB of memory before it must spill to disk.

To increase \( \text{statement}\_\text{mem} \) safely you must either increase \( \text{gp}\_\text{vmem}\_\text{protect}\_\text{limit} \) or reduce the number of concurrent queries. To increase \( \text{gp}\_\text{vmem}\_\text{protect}\_\text{limit} \), you must add physical RAM and/ or swap space, or reduce the number of segments per host.

Note that adding segment hosts to the cluster cannot help out-of-memory errors unless you use the additional hosts to decrease the number of segments per host.

Spill files are created when there is not enough memory to fit all the mapper output, usually when 80% of the buffer space is occupied.

Also, see Resource Management for best practices for managing query memory using resource queues.

### Resource Queue Spill File Configuration

Greenplum Database creates spill files (also called workfiles) on disk if a query is allocated insufficient memory to execute in memory. A single query can create no more than 100,000 spill files, by default, which is sufficient for the majority of queries.

You can control the maximum number of spill files created per query and per segment with the configuration parameter \( \text{gp}\_\text{workfile}\_\text{limit}\_\text{files}\_\text{per}\_\text{query} \). Set the parameter to 0 to allow queries to create an unlimited number of spill files. Limiting the number of spill files permitted prevents runaway queries from disrupting the system.

A query could generate a large number of spill files if not enough memory is allocated to it or if data skew is present in the queried data. If a query creates more than the specified number of spill files, Greenplum Database returns this error:

ERROR: number of workfiles per query limit exceeded

Before raising the \( \text{gp}\_\text{workfile}\_\text{limit}\_\text{files}\_\text{per}\_\text{query} \), try reducing the number of spill files by changing the query, changing the data distribution, or changing the memory configuration.
The `gp_toolkit` schema includes views that allow you to see information about all the queries that are currently using spill files. This information can be used for troubleshooting and for tuning queries:

- The `gp_workfile_entries` view contains one row for each operator using disk space for workfiles on a segment at the current time. See *How to Read Explain Plans* for information about operators.
- The `gp_workfile_usage_per_query` view contains one row for each query using disk space for workfiles on a segment at the current time.
- The `gp_workfile_usage_per_segment` view contains one row for each segment. Each row displays the total amount of disk space used for workfiles on the segment at the current time.

See the *Greenplum Database Reference Guide* for descriptions of the columns in these views.

The `gp_workfile_compression` configuration parameter specifies whether the spill files are compressed. It is `off` by default. Enabling compression can improve performance when spill files are used.

**Schema Design**

Best practices for designing Greenplum Database schemas.

Greenplum Database is an analytical, shared-nothing database, which is much different than a highly normalized, transactional SMP database. Greenplum Database performs best with a denormalized schema design suited for MPP analytical processing, a star or snowflake schema, with large centralized fact tables connected to multiple smaller dimension tables.

**Data Types**

**Use Types Consistently**

Use the same data types for columns used in joins between tables. If the data types differ, Greenplum Database must dynamically convert the data type of one of the columns so the data values can be compared correctly. With this in mind, you may need to increase the data type size to facilitate joins to other common objects.

**Choose Data Types that Use the Least Space**

You can increase database capacity and improve query execution by choosing the most efficient data types to store your data.

Use `TEXT` or `VARCHAR` rather than `CHAR`. There are no performance differences among the character data types, but using `TEXT` or `VARCHAR` can decrease the storage space used.

Use the smallest numeric data type that will accommodate your data. Using `BIGINT` for data that fits in `INT` or `SMALLINT` wastes storage space.

**Storage Model**

Greenplum Database provides an array of storage options when creating tables. It is very important to know when to use heap storage versus append-optimized (AO) storage, and when to use row-oriented storage versus column-oriented storage. The correct selection of heap versus AO and row versus column is extremely important for large fact tables, but less important for small dimension tables.

The best practices for determining the storage model are:

1. Design and build an insert-only model, truncating a daily partition before load.
2. For large partitioned fact tables, evaluate and use optimal storage options for different partitions. One storage option is not always right for the entire partitioned table. For example, some partitions can be row-oriented while others are column-oriented.
3. When using column-oriented storage, every column is a separate file on every Greenplum Database segment. For tables with a large number of columns consider columnar storage for data often accessed (hot) and row-oriented storage for data not often accessed (cold).
4. Storage options should be set at the partition level.
5. Compress large tables to improve I/O performance and to make space in the cluster.

**Heap Storage or Append-Optimized Storage**

Heap storage is the default model, and is the model PostgreSQL uses for all database tables. Use heap storage for tables and partitions that will receive iterative `UPDATE`, `DELETE`, and singleton `INSERT` operations. Use heap storage for tables and partitions that will receive concurrent `UPDATE`, `DELETE`, and `INSERT` operations.
Use append-optimized storage for tables and partitions that are updated infrequently after the initial load and have subsequent inserts performed only in batch operations. Avoid performing singleton INSERT, UPDATE, or DELETE operations on append-optimized tables. Concurrent batch INSERT operations are acceptable, but never perform concurrent batch UPDATE or DELETE operations.

The append-optimized storage model is inappropriate for frequently updated tables, because space occupied by rows that are updated and deleted in append-optimized tables is not recovered and reused as efficiently as with heap tables. Append-optimized storage is intended for large tables that are loaded once, updated infrequently, and queried frequently for analytical query processing.

**Row or Column Orientation**

Row orientation is the traditional way to store database tuples. The columns that comprise a row are stored on disk contiguously, so that an entire row can be read from disk in a single I/O.

Column orientation stores column values together on disk. A separate file is created for each column. If the table is partitioned, a separate file is created for each column and partition. When a query accesses only a small number of columns in a column-oriented table with many columns, the cost of I/O is substantially reduced compared to a row-oriented table; any columns not referenced do not have to be retrieved from disk.

Row-oriented storage is recommended for transactional type workloads with iterative transactions where updates are required and frequent inserts are performed. Use row-oriented storage when selects against the table are wide, where many columns of a single row are needed in a query. If the majority of columns in the SELECT list or WHERE clause is selected in queries, use row-oriented storage. Use row-oriented storage for general purpose or mixed workloads, as it offers the best combination of flexibility and performance.

Column-oriented storage is optimized for read operations but it is not optimized for write operations; column values for a row must be written to different places on disk. Column-oriented tables can offer optimal query performance on large tables with many columns where only a small subset of columns are accessed by the queries.

Another benefit of column orientation is that a collection of values of the same data type can be stored together in less space than a collection of mixed type values, so column-oriented tables use less disk space (and consequently less disk I/O) than row-oriented tables. Column-oriented tables also compress better than row-oriented tables.

Use column-oriented storage for data warehouse analytic workloads where selects are narrow or aggregations of data are computed over a small number of columns. Use column-oriented storage for tables that have single columns that are regularly updated without modifying other columns in the row. Reading a complete row in a wide columnar table requires more time than reading the same row from a row-oriented table. It is important to understand that each column is a separate physical file on every segment in Greenplum Database.

**Compression**

Greenplum Database offers a variety of options to compress append-optimized tables and partitions. Use compression to improve I/O across the system by allowing more data to be read with each disk read operation. The best practice is to set the column compression settings at the partition level.

Note that new partitions added to a partitioned table do not automatically inherit compression defined at the table level; you must specifically define compression when you add new partitions.

Run-length encoding (RLE) compression provides the best levels of compression. Higher levels of compression usually result in more compact storage on disk, but require additional time and CPU cycles when compressing data on writes and uncompressing on reads. Sorting data, in combination with the various compression options, can achieve the highest level of compression.

Data compression should never be used for data that is stored on a compressed file system.
Test different compression types and ordering methods to determine the best compression for your specific data. For example, you might start zstd compression at level 8 or 9 and adjust for best results. RLE compression works best with files that contain repetitive data.

**Distributions**

An optimal distribution that results in evenly distributed data is the most important factor in Greenplum Database. In an MPP shared nothing environment overall response time for a query is measured by the completion time for all segments. The system is only as fast as the slowest segment. If the data is skewed, segments with more data will take more time to complete, so every segment must have an approximately equal number of rows and perform approximately the same amount of processing. Poor performance and out of memory conditions may result if one segment has significantly more data to process than other segments.

Consider the following best practices when deciding on a distribution strategy:

- Explicitly define a column or random distribution for all tables. Do not use the default.
- Ideally, use a single column that will distribute data across all segments evenly.
- Do not distribute on columns that will be used in the `WHERE` clause of a query.
- Do not distribute on dates or timestamps.
- The distribution key column data should contain unique values or very high cardinality.
- If a single column cannot achieve an even distribution, use a multi-column distribution key with a maximum of two columns. Additional column values do not typically yield a more even distribution and they require additional time in the hashing process.
- If a two-column distribution key cannot achieve an even distribution of data, use a random distribution. Multi-column distribution keys in most cases require motion operations to join tables, so they offer no advantages over a random distribution.

Greenplum Database random distribution is not round-robin, so there is no guarantee of an equal number of records on each segment. Random distributions typically fall within a target range of less than ten percent variation.

Optimal distributions are critical when joining large tables together. To perform a join, matching rows must be located together on the same segment. If data is not distributed on the same join column, the rows needed from one of the tables are dynamically redistributed to the other segments. In some cases a broadcast motion, in which each segment sends its individual rows to all other segments, is performed rather than a redistribution motion, where each segment rehashes the data and sends the rows to the appropriate segments according to the hash key.

**Local (Co-located) Joins**

Using a hash distribution that evenly distributes table rows across all segments and results in local joins can provide substantial performance gains. When joined rows are on the same segment, much of the processing can be accomplished within the segment instance. These are called *local* or *co-located* joins. Local joins minimize data movement; each segment operates independently of the other segments, without network traffic or communications between segments.

To achieve local joins for large tables commonly joined together, distribute the tables on the same column. Local joins require that both sides of a join be distributed on the same columns (and in the same order) and that all columns in the distribution clause are used when joining tables. The distribution columns must also be the same data type—although some values with different data types may appear to have the same representation, they are stored differently and hash to different values, so they are stored on different segments.
Data Skew

Data skew is often the root cause of poor query performance and out of memory conditions. Skewed data affects scan (read) performance, but it also affects all other query execution operations, for instance, joins and group by operations.

It is very important to validate distributions to ensure that data is evenly distributed after the initial load. It is equally important to continue to validate distributions after incremental loads.

The following query shows the number of rows per segment as well as the variance from the minimum and maximum numbers of rows:

```sql
SELECT 'Example Table' AS "Table Name",
       max(c) AS "Max Seg Rows", min(c) AS "Min Seg Rows",
       (max(c) - min(c)) * 100.0 / max(c) AS "Percentage Difference Between Max & Min"
FROM (SELECT count(*) c, gp_segment_id FROM facts GROUP BY 2) AS a;
```

The `gp_toolkit` schema has two views that you can use to check for skew.

- The `gp_toolkit.gp_skew_coefficients` view shows data distribution skew by calculating the coefficient of variation (CV) for the data stored on each segment. The `skccoeff` column shows the coefficient of variation (CV), which is calculated as the standard deviation divided by the average. It takes into account both the average and variability around the average of a data series. The lower the value, the better. Higher values indicate greater data skew.
- The `gp_toolkit.gp_skew_idle_fractions` view shows data distribution skew by calculating the percentage of the system that is idle during a table scan, which is an indicator of computational skew. The `sifraction` column shows the percentage of the system that is idle during a table scan. This is an indicator of uneven data distribution or query processing skew. For example, a value of 0.1 indicates 10% skew, a value of 0.5 indicates 50% skew, and so on. Tables that have more than 10% skew should have their distribution policies evaluated.

Processing Skew

Processing skew results when a disproportionate amount of data flows to, and is processed by, one or a few segments. It is often the culprit behind Greenplum Database performance and stability issues. It can happen with operations such join, sort, aggregation, and various OLAP operations. Processing skew happens in flight while a query is executing and is not as easy to detect as data skew, which is caused by uneven data distribution due to the wrong choice of distribution keys. Data skew is present at the table level, so it can be easily detected and avoided by choosing optimal distribution keys.

If single segments are failing, that is, not all segments on a host, it may be a processing skew issue. Identifying processing skew is currently a manual process. First look for spill files. If there is skew, but not enough to cause spill, it will not become a performance issue. If you determine skew exists, then find the query responsible for the skew. Following are the steps and commands to use. (Change names like the host file name passed to `gpssh` accordingly):

1. Find the OID for the database that is to be monitored for skew processing:

   ```sql
   SELECT oid, datname FROM pg_database;
   ```

   Example output:

<table>
<thead>
<tr>
<th>oid</th>
<th>datname</th>
</tr>
</thead>
<tbody>
<tr>
<td>17088</td>
<td>gpadmin</td>
</tr>
<tr>
<td>10899</td>
<td>postgres</td>
</tr>
<tr>
<td>1</td>
<td>template1</td>
</tr>
<tr>
<td>10898</td>
<td>template0</td>
</tr>
<tr>
<td>38817</td>
<td>pws</td>
</tr>
<tr>
<td>39682</td>
<td>gpperfmon</td>
</tr>
</tbody>
</table>
2. Run a `gpssh` command to check file sizes across all of the segment nodes in the system. Replace `<OID>` with the OID of the database from the prior command:

```
[gpadmin@mdw kend]$ gpssh -f ~/hosts -e 
  "du -b /data[1-2]/primary/gpseg*/base/<OID>/pgsql_tmp/*" | 
  grep -v "du -b" | sort | awk -F" " '{ arr[$1] = arr[$1] + $2 ; tot = 
  tot + $2 }; END 
  { for ( i in arr ) print "Segment node" i, arr[i], "bytes (" arr[i]/
  (1024**3)" GB)"; } 
  print "Total", tot, "bytes (" tot/(1024**3)" GB)" )' -
```

Example output:

```
Segment node[sw1] 2443370457 bytes (2.27557 GB)
Segment node[sw2] 1766575328 bytes (1.64525 GB)
Segment node[sw3] 1761686551 bytes (1.6407 GB)
Segment node[sw4] 1780301617 bytes (1.65804 GB)
Segment node[sw5] 1742543599 bytes (1.62287 GB)
Segment node[sw6] 1830073754 bytes (1.70439 GB)
Segment node[sw7] 1767310099 bytes (1.64594 GB)
Segment node[sw8] 1765105802 bytes (1.64388 GB)
Total 14856967207 bytes (13.8366 GB)
```

If there is a significant and sustained difference in disk usage, then the queries being executed should be investigated for possible skew (the example output above does not reveal significant skew). In monitoring systems, there will always be some skew, but often it is transient and will be short in duration.

3. If significant and sustained skew appears, the next task is to identify the offending query.

The command in the previous step sums up the entire node. This time, find the actual segment directory. You can do this from the master or by logging into the specific node identified in the previous step. Following is an example run from the master.

This example looks specifically for sort files. Not all spill files or skew situations are caused by sort files, so you will need to customize the command:

```
$ gpssh -f ~/hosts -e 
  "ls -l /data[1-2]/primary/gpseg*/base/19979/pgsql_tmp/*" | 
  grep -i sort | awk '{sub(/base.*tmp//, "...", $10); print $1,$6, $10}' | sort -k2 -n
```

Here is output from this command:

```
[sw1] 299718848  
/datal/primary/gpseg2/.../pgsql_tmp_slice0_sort_17758_0001.0[sw1] 
291176448  
/datal/primary/gpseg5/.../pgsql_tmp_slice0_sort_17764_0001.0[sw8] 
924581888  
/datal/primary/gpseg45/.../pgsql_tmp_slice10_sort_15673_0010.9[sw4] 
980582400  
/datal/primary/gpseg18/.../pgsql_tmp_slice10_sort_29425_0001.0[sw6] 
98447872  
/datal/primary/gpseg35/.../pgsql_tmp_slice10_sort_29602_0001.0[sw5] 
999620608  
/datal/primary/gpseg26/.../pgsql_tmp_slice10_sort_28637_0001.0[sw2] 
999751680  
/datal/primary/gpseg9/.../pgsql_tmp_slice10_sort_3969_0001.0[sw3] 
1000112128  
/datal/primary/gpseg13/.../pgsql_tmp_slice10_sort_24723_0001.0[sw5] 
1000898560
```
Scanning this output reveals that segment gpseg45 on host sdw8 is the culprit, as its sort files are larger than the others in the output.

4. Log in to the offending node with ssh and become root. Use the lsof command to find the PID for the process that owns one of the sort files:

   [root@sdw8 ~]# lsof /data2/primary/gpseg45/base/19979/pgsql_tmp/pgsql_tmp_slice10_sort_15673_0002.1
   COMMAND  PID    USER    FD   TYPE DEVICE  SIZE        NODE        NAME
   postgres 15673  gpadmin 11u  REG  8,48    1073741824  64424546751 /data2/
   primary/gpseg45/base/19979/pgsql_tmp/pgsql_tmp_slice10_sort_15673_0002.1

   The PID, 15673, is also part of the file name, but this may not always be the case.

5. Use the ps command with the PID to identify the database and connection information:

   [root@sdw8 ~]# ps -eaf | grep 15673
   gpadmin  15673 27471 28 12:05 ?        00:12:59 postgres: port 40003,
   sbaskin  172.28.12.250(21813) con699238 seg45 cmd32 slice10 MPPEXEC SELECT
   root     29622 29566  0 12:50 pts/16   00:00:00 grep 15673

6. On the master, check the pg_log log file for the user in the previous command (sbaskin), connection (con699238, and command (cmd32). The line in the log file with these three values should be the line that contains the query, but occasionally, the command number may differ slightly. For example, the ps output may show cmd32, but in the log file it is cmd34. If the query is still running, the last query for the user and connection is the offending query.

The remedy for processing skew in almost all cases is to rewrite the query. Creating temporary tables can eliminate skew. Temporary tables can be randomly distributed to force a two-stage aggregation.

**Partitioning**

A good partitioning strategy reduces the amount of data to be scanned by reading only the partitions needed to satisfy a query.
Each partition is a separate physical file or set of tiles (in the case of column-oriented tables) on every segment. Just as reading a complete row in a wide columnar table requires more time than reading the same row from a heap table, reading all partitions in a partitioned table requires more time than reading the same data from a non-partitioned table.

Following are partitioning best practices:

- **Partition large tables only, do not partition small tables.**
- **Use partitioning on large tables only** when partition elimination (partition pruning) can be achieved based on query criteria and is accomplished by partitioning the table based on the query predicate. Whenever possible, use range partitioning instead of list partitioning.
- The query planner can selectively scan partitioned tables only when the query contains a direct and simple restriction of the table using immutable operators, such as `=`, `<`, `<=`, `>`, `>=`, and `<>`.
- Selective scanning recognizes **STABLE and IMMUTABLE functions**, but does not recognize **VOLATILE** functions within a query. For example, `WHERE` clauses such as

  ```
  date > CURRENT_DATE
  ```

  cause the query planner to selectively scan partitioned tables, but a `WHERE` clause such as

  ```
  time > TIMEOFDAY
  ```

does not. It is important to validate that queries are selectively scanning partitioned tables (partitions are being eliminated) by examining the query `EXPLAIN` plan.

- **Do not use default partitions.** The default partition is always scanned but, more importantly, in many environments they tend to overfill resulting in poor performance.
- **Never** partition and distribute tables on the same column.
- **Do not use multi-level partitioning.** While sub-partitioning is supported, it is not recommended because typically subpartitions contain little or no data. It is a myth that performance increases as the number of partitions or subpartitions increases; the administrative overhead of maintaining many partitions and subpartitions will outweigh any performance benefits. For performance, scalability and manageability, balance partition scan performance with the number of overall partitions.
- **Beware of using too many partitions with column-oriented storage.**
- **Consider workload concurrency and the average number of partitions opened and scanned for all concurrent queries.**

### Number of Partition and Columnar Storage Files

The only hard limit for the number of files Greenplum Database supports is the operating system's open file limit. It is important, however, to consider the total number of files in the cluster, the number of files on every segment, and the total number of files on a host. In an MPP shared nothing environment, every node operates independently of other nodes. Each node is constrained by its disk, CPU, and memory. CPU and I/O constraints are not common with Greenplum Database, but memory is often a limiting factor because the query execution model optimizes query performance in memory.

The optimal number of files per segment also varies based on the number of segments on the node, the size of the cluster, SQL access, concurrency, workload, and skew. There are generally six to eight segments per host, but large clusters should have fewer segments per host. When using partitioning and columnar storage it is important to balance the total number of files in the cluster, but it is more important to consider the number of files per segment and the total number of files on a node.

#### Example with 64GB Memory per Node

- Number of nodes: 16
- Number of segments per node: 8
- Average number of files per segment: 10,000
The total number of files per node is \(8 \times 10,000 = 80,000\) and the total number of files for the cluster is \(8 \times 16 \times 10,000 = 1,280,000\). The number of files increases quickly as the number of partitions and the number of columns increase.

As a general best practice, limit the total number of files per node to under 100,000. As the previous example shows, the optimal number of files per segment and total number of files per node depends on the hardware configuration for the nodes (primarily memory), size of the cluster, SQL access, concurrency, workload and skew.

### Indexes

Indexes are not generally needed in Greenplum Database. Most analytical queries operate on large volumes of data, while indexes are intended for locating single rows or small numbers of rows of data. In Greenplum Database, a sequential scan is an efficient method to read data as each segment contains an equal portion of the data and all segments work in parallel to read the data.

If adding an index does not produce performance gains, drop it. Verify that every index you create is used by the optimizer.

For queries with high selectivity, indexes may improve query performance. Create an index on a single column of a columnar table for drill through purposes for high cardinality columns that are required for highly selective queries.

Do not index columns that are frequently updated. Creating an index on a column that is frequently updated increases the number of writes required on updates.

Indexes on expressions should be used only if the expression is used frequently in queries.

An index with a predicate creates a partial index that can be used to select a small number of rows from large tables.

Avoid overlapping indexes. Indexes that have the same leading column are redundant.

Indexes can improve performance on compressed append-optimized tables for queries that return a targeted set of rows. For compressed data, an index access method means only the necessary pages are uncompressed.

Create selective B-tree indexes. Index selectivity is a ratio of the number of distinct values a column has divided by the number of rows in a table. For example, if a table has 1000 rows and a column has 800 distinct values, the selectivity of the index is 0.8, which is considered good.

As a general rule, drop indexes before loading data into a table. The load will run an order of magnitude faster than loading data into a table with indexes. After the load, re-create the indexes.

Bitmap indexes are suited for querying and not updating. Bitmap indexes perform best when the column has a low cardinality—100 to 100,000 distinct values. Do not use bitmap indexes for unique columns, very high, or very low cardinality data. Do not use bitmap indexes for transactional workloads.

If indexes are needed on partitioned tables, the index columns must be different than the partition columns. A benefit of indexing partitioned tables is that because the b-tree performance degrades exponentially as the size of the b-tree grows, creating indexes on partitioned tables creates smaller b-trees that perform better than with non-partitioned tables.

### Column Sequence and Byte Alignment

For optimum performance lay out the columns of a table to achieve data type byte alignment. Lay out the columns in heap tables in the following order:

1. Distribution and partition columns
2. Fixed numeric types
3. Variable data types
Lay out the data types from largest to smallest, so that BIGINT and TIMESTAMP come before INT and DATE, and all of these types come before TEXT, VARCHAR, or NUMERIC(x, y). For example, 8-byte types first (BIGINT, TIMESTAMP), 4-byte types next (INT, DATE), 2-byte types next (SMALLINT), and variable data type last (VARCHAR).

Instead of defining columns in this sequence:

Int, Bigint, Timestamp, Bigint, Timestamp, Int (distribution key), Date (partition key), Bigint, Smallint

define the columns in this sequence:

Int (distribution key), Date (partition key), Bigint, Bigint, Timestamp, Bigint, Timestamp, Int, Smallint
Memory and Resource Management with Resource Groups

Managing Greenplum Database resources with resource groups.

Memory, CPU, and concurrent transaction management have a significant impact on performance in a Greenplum Database cluster. Resource groups are a newer resource management scheme that enforce memory, CPU, and concurrent transaction limits in Greenplum Database.

- Configuring Memory for Greenplum Database
- Memory Considerations when using Resource Groups
- Configuring Resource Groups
- Low Memory Queries
- Administrative Utilities and admin_group Concurrency

Configuring Memory for Greenplum Database

While it is not always possible to increase system memory, you can avoid many out-of-memory conditions by configuring resource groups to manage expected workloads.

The following operating system and Greenplum Database memory settings are significant when you manage Greenplum Database resources with resource groups:

- **vm.overcommit_memory**
  This Linux kernel parameter, set in `/etc/sysctl.conf`, identifies the method that the operating system uses to determine how much memory can be allocated to processes. `vm.overcommit_memory` must always be set to 2 for Greenplum Database systems.

- **vm.overcommit_ratio**
  This Linux kernel parameter, set in `/etc/sysctl.conf`, identifies the percentage of RAM that is used for application processes; the remainder is reserved for the operating system. Tune the setting as necessary. If your memory utilization is too low, increase the value; if your memory or swap usage is too high, decrease the setting.

- **gp_resource_group_memory_limit**
  The percentage of system memory to allocate to Greenplum Database. The default value is .7 (70%).

- **gp_workfile_limit_files_per_query**
  Set `gp_workfile_limit_files_per_query` to limit the maximum number of temporary spill files (workfiles) allowed per query. Spill files are created when a query requires more memory than it is allocated. When the limit is exceeded the query is terminated. The default is zero, which allows an unlimited number of spill files and may fill up the file system.

- **gp_workfile_compression**
  If there are numerous spill files then set `gp_workfile_compression` to compress the spill files. Compressing spill files may help to avoid overloading the disk subsystem with IO operations.

- **memory_spill_ratio**
  Set `memory_spill_ratio` to increase or decrease the amount of query operator memory Greenplum Database allots to a query. When `memory_spill_ratio` is larger than 0, it represents the percentage of resource group memory to allot to query operators. If concurrency is high, this memory amount may be small even when `memory_spill_ratio` is set to the max value of 100. When you set `memory_spill_ratio` to 0, Greenplum Database uses the `statement_mem` setting to determine the initial amount of query operator memory to allot.

- **statement_mem**
When memory_spill_ratio is 0, Greenplum Database uses the statement_mem setting to determine the amount of memory to allocate to a query.

Other considerations:

- Do not configure the operating system to use huge pages. See the Recommended OS Parameters Settings in the Greenplum Installation Guide.
- When you configure resource group memory, consider memory requirements for mirror segments that become primary segments during a failure to ensure that database operations can continue when primary segments or segment hosts fail.

Memory Considerations when using Resource Groups

Available memory for resource groups may be limited on systems that use low or no swap space, and that use the default vm.overcommit_ratio and gp_resource_group_memory_limit settings. To ensure that Greenplum Database has a reasonable per-segment-host memory limit, you may be required to increase one or more of the following configuration settings:

1. The swap size on the system.
2. The system's vm.overcommit_ratio setting.
3. The resource group gp_resource_group_memory_limit setting.

Configuring Resource Groups

Greenplum Database resource groups provide a powerful mechanism for managing the workload of the cluster. Consider these general guidelines when you configure resource groups for your system:

- A transaction submitted by any Greenplum Database role with SUPERUSER privileges runs under the default resource group named admin_group. Keep this in mind when scheduling and running Greenplum administration utilities.
- Ensure that you assign each non-admin role a resource group. If you do not assign a resource group to a role, queries submitted by the role are handled by the default resource group named default_group.
- Use the CONCURRENCY resource group parameter to limit the number of active queries that members of a particular resource group can run concurrently.
- Use the MEMORY_LIMIT and MEMORY_SPILL_RATIO parameters to control the maximum amount of memory that queries running in the resource group can consume.
- Greenplum Database assigns unreserved memory (100 - (sum of all resource group MEMORY_LIMITS)) to a global shared memory pool. This memory is available to all queries on a first-come, first-served basis.
- Alter resource groups dynamically to match the real requirements of the group for the workload and the time of day.
- Use the gp_toolkit views to examine resource group resource usage and to monitor how the groups are working.
- Consider using Pivotal Greenplum Command Center to create and manage resource groups, and to define the criteria under which Command Center dynamically assigns a transaction to a resource group.

Low Memory Queries

A low statement_mem setting (for example, in the 10MB range) has been shown to increase the performance of queries with low memory requirements. Use the memory_spill_ratio and statement_mem server configuration parameters to override the setting on a per-query basis. For example:

```
SET memory_spill_ratio=0;
SET statement_mem='10 MB';
```
Administrative Utilities and admin_group Concurrency

The default resource group for database transactions initiated by Greenplum Database SUPERUSERS is the group named admin_group. The default CONCURRENCY value for the admin_group resource group is 10.

Certain Greenplum Database administrative utilities may use more than one CONCURRENCY slot at runtime, such as gpbackup that you invoke with the --jobs option. If the utility(s) you run require more concurrent transactions than that configured for admin_group, consider temporarily increasing the group's MEMORY_LIMIT and CONCURRENCY values to meet the utility's requirement, making sure to return these parameters back to their original settings when the utility completes.

Note: Memory allocation changes that you initiate with ALTER RESOURCE GROUP may not take affect immediately due to resource consumption by currently running queries. Be sure to alter resource group parameters in advance of your maintenance window.
Memory and Resource Management with Resource Queues

Avoid memory errors and manage Greenplum Database resources.

**Note:** Resource groups are a newer resource management scheme that enforces memory, CPU, and concurrent transaction limits in Greenplum Database. The Managing Resources topic provides a comparison of the resource queue and the resource group management schemes. Refer to Using Resource Groups for configuration and usage information for this resource management scheme.

Memory management has a significant impact on performance in a Greenplum Database cluster. The default settings are suitable for most environments. Do not change the default settings until you understand the memory characteristics and usage on your system.

- Resolving Out of Memory Errors
- Low Memory Queries
- Configuring Memory for Greenplum Database
- Configuring Resource Queues

Resolving Out of Memory Errors

An out of memory error message identifies the Greenplum segment, host, and process that experienced the out of memory error. For example:

```
Out of memory (seg27 host.example.com pid=47093)
VM Protect failed to allocate 4096 bytes, 0 MB available
```

Some common causes of out-of-memory conditions in Greenplum Database are:

- Insufficient system memory (RAM) available on the cluster
- Improperly configured memory parameters
- Data skew at the segment level
- Operational skew at the query level

Following are possible solutions to out of memory conditions:

- Tune the query to require less memory
- Reduce query concurrency using a resource queue
- Validate the `gp_vmem_protect_limit` configuration parameter at the database level. See calculations for the maximum safe setting in Configuring Memory for Greenplum Database.
- Set the memory quota on a resource queue to limit the memory used by queries executed within the resource queue
- Use a session setting to reduce the `statement_mem` used by specific queries
- Decrease `statement_mem` at the database level
- Decrease the number of segments per host in the Greenplum Database cluster. This solution requires a re-initializing Greenplum Database and reloading your data.
- Increase memory on the host, if possible. (Additional hardware may be required.)

Adding segment hosts to the cluster will not in itself alleviate out of memory problems. The memory used by each query is determined by the `statement_mem` parameter and it is set when the query is invoked. However, if adding more hosts allows decreasing the number of segments per host, then the amount of memory allocated in `gp_vmem_protect_limit` can be raised.
Low Memory Queries

A low `statement_mem` setting (for example, in the 1-3MB range) has been shown to increase the performance of queries with low memory requirements. Use the `statement_mem` server configuration parameter to override the setting on a per-query basis. For example:

```sql
SET statement_mem='2MB';
```

Configuring Memory for Greenplum Database

Most out of memory conditions can be avoided if memory is thoughtfully managed.

It is not always possible to increase system memory, but you can prevent out-of-memory conditions by configuring memory use correctly and setting up resource queues to manage expected workloads.

It is important to include memory requirements for mirror segments that become primary segments during a failure to ensure that the cluster can continue when primary segments or segment hosts fail.

The following are recommended operating system and Greenplum Database memory settings:

- **Do not configure the OS to use huge pages.**
- **`vm.overcommit_memory`**
  
  This is a Linux kernel parameter, set in `/etc/sysctl.conf` and it should always be set to 2. It determines the method the OS uses for determining how much memory can be allocated to processes and 2 is the only safe setting for Greenplum Database. Please review the sysctl parameters in the Greenplum Database Installation Guide.

- **`vm.overcommit_ratio`**
  
  This is a Linux kernel parameter, set in `/etc/sysctl.conf`. It is the percentage of RAM that is used for application processes. The remainder is reserved for the operating system. The default on Red Hat is 50.

  Setting `vm.overcommit_ratio` too high may result in not enough memory being reserved for the operating system, which can result in segment host failure or database failure. Setting the value too low reduces the amount of concurrency and query complexity that can be run by reducing the amount of memory available to Greenplum Database. When increasing the setting it is important to remember to always reserve some memory for operating system activities.

  See Greenplum Database Memory Overview for instructions to calculate a value for `vm.overcommit_ratio`.

- **`gp_vmem_protect_limit`**
  
  Use `gp_vmem_protect_limit` to set the maximum memory that the instance can allocate for all work being done in each segment database. Never set this value larger than the physical RAM on the system. If `gp_vmem_protect_limit` is too high, it is possible for memory to become exhausted on the system and normal operations may fail, causing segment failures. If `gp_vmem_protect_limit` is set to a safe lower value, true memory exhaustion on the system is prevented; queries may fail for hitting the limit, but system disruption and segment failures are avoided, which is the desired behavior.

  See Resource Queue Segment Memory Configuration for instructions to calculate a safe value for `gp_vmem_protect_limit`.

- **`runaway_detector_activation_percent`**
  
  Runaway Query Termination, introduced in Greenplum Database 4.3.4, prevents out of memory conditions. The `runaway_detector_activation_percent` system parameter controls the percentage of `gp_vmem_protect_limit` memory utilized that triggers termination of queries. It is set on by default at 90%. If the percentage of `gp_vmem_protect_limit` memory that is utilized for a segment exceeds the specified value, Greenplum Database terminates queries based on memory usage, beginning with the query consuming the largest amount of memory. Queries are terminated until the utilized percentage of `gp_vmem_protect_limit` is below the specified percentage.
• **statement_mem**

  Use `statement_mem` to allocate memory used for a query per segment database. If additional memory is required it will spill to disk. Set the optimal value for `statement_mem` as follows:

  \[
  (\text{vmprotect} \times 0.9) / \text{max\_expected\_concurrent\_queries}
  \]

  The default value of `statement_mem` is 125MB. For example, on a system that is configured with 8 segments per host, a query uses 1GB of memory on each segment server (8 segments # 125MB) with the default `statement_mem` setting. Set `statement_mem` at the session level for specific queries that require additional memory to complete. This setting works well to manage query memory on clusters with low concurrency. For clusters with high concurrency also use resource queues to provide additional control on what and how much is running on the system.

• **gp_workfile_limit_files_per_query**

  Set `gp_workfile_limit_files_per_query` to limit the maximum number of temporary spill files (workfiles) allowed per query. Spill files are created when a query requires more memory than it is allocated. When the limit is exceeded the query is terminated. The default is zero, which allows an unlimited number of spill files and may fill up the file system.

• **gp_workfile_compression**

  If there are numerous spill files then set `gp_workfile_compression` to compress the spill files. Compressing spill files may help to avoid overloading the disk subsystem with IO operations.

### Configuring Resource Queues

Greenplum Database resource queues provide a powerful mechanism for managing the workload of the cluster. Queues can be used to limit both the numbers of active queries and the amount of memory that can be used by queries in the queue. When a query is submitted to Greenplum Database, it is added to a resource queue, which determines if the query should be accepted and when the resources are available to execute it.

• Associate all roles with an administrator-defined resource queue.

  Each login user (role) is associated with a single resource queue; any query the user submits is handled by the associated resource queue. If a queue is not explicitly assigned the user's queries are handed by the default queue, `pg_default`.

• Do not run queries with the gpadmin role or other superuser roles.

  Superusers are exempt from resource queue limits, therefore superuser queries always run regardless of the limits set on their assigned queue.

• Use the `ACTIVE_STATEMENTS` resource queue parameter to limit the number of active queries that members of a particular queue can run concurrently.

• Use the `MEMORY_LIMIT` parameter to control the total amount of memory that queries running through the queue can utilize. By combining the `ACTIVE_STATEMENTS` and `MEMORY_LIMIT` attributes an administrator can fully control the activity emitted from a given resource queue.

  The allocation works as follows: Suppose a resource queue, `sample_queue`, has `ACTIVE_STATEMENTS` set to 10 and `MEMORY_LIMIT` set to 2000MB. This limits the queue to approximately 2 gigabytes of memory per segment. For a cluster with 8 segments per server, the total usage per server is 16 GB for `sample_queue` (2GB * 8 segments/server). If a segment server has 64GB of RAM, there could be no more than four of this type of resource queue on the system before there is a chance of running out of memory (4 queues * 16GB per queue).

  Note that by using `STATEMENT_MEM`, individual queries running in the queue can allocate more than their “share” of memory, thus reducing the memory available for other queries in the queue.

• Resource queue priorities can be used to align workloads with desired outcomes. Queues with MAX priority throttle activity in all other queues until the MAX queue completes running all queries.
• Alter resource queues dynamically to match the real requirements of the queue for the workload and time of day. You can script an operational flow that changes based on the time of day and type of usage of the system and add `crontab` entries to execute the scripts.
• Use gptoolkit to view resource queue usage and to understand how the queues are working.
System Monitoring and Maintenance

Best practices for regular maintenance that will ensure Greenplum Database high availability and optimal performance.

Monitoring

Greenplum Database includes utilities that are useful for monitoring the system.

The gp_toolkit schema contains several views that can be accessed using SQL commands to query system catalogs, log files, and operating environment for system status information.

The gp_stats_missing view shows tables that do not have statistics and require ANALYZE to be run.

For additional information on gpstate and gpcheckperf refer to the Greenplum Database Utility Guide. For information about the gp_toolkit schema, see the Greenplum Database Reference Guide.

gpstate

The gpstate utility program displays the status of the Greenplum system, including which segments are down, master and segment configuration information (hosts, data directories, etc.), the ports used by the system, and mapping of primary segments to their corresponding mirror segments.

Run gpstate -Q to get a list of segments that are marked “down” in the master system catalog.

To get detailed status information for the Greenplum system, run gpstate -s.

gpcheckperf

The gpcheckperf utility tests baseline hardware performance for a list of hosts. The results can help identify hardware issues. It performs the following checks:

- disk I/O test – measures I/O performance by writing and reading a large file using the dd operating system command. It reports read and write rates in megabytes per second.
- memory bandwidth test – measures sustainable memory bandwidth in megabytes per second using the STREAM benchmark.
- network performance test – runs the gpnetbench network benchmark program (optionally netperf) to test network performance. The test is run in one of three modes: parallel pair test (-r N), serial pair test (-r n), or full-matrix test (-r M). The minimum, maximum, average, and median transfer rates are reported in megabytes per second.

To obtain valid numbers from gpcheckperf, the database system must be stopped. The numbers from gpcheckperf can be inaccurate even if the system is up and running with no query activity.

gpcheckperf requires a trusted host setup between the hosts involved in the performance test. It calls gpssh and gpscp, so these utilities must also be in your PATH. Specify the hosts to check individually (-h host1 -h host2 ...) or with -f hosts_file, where hosts_file is a text file containing a list of the hosts to check. If you have more than one subnet, create a separate host file for each subnet so that you can test the subnets separately.

By default, gpcheckperf runs the disk I/O test, the memory test, and a serial pair network performance test. With the disk I/O test, you must use the -d option to specify the file systems you want to test. The following command tests disk I/O and memory bandwidth on hosts listed in the subnet_1_hosts file:

```bash
$ gpcheckperf -f subnet_1_hosts -d /data1 -d /data2 -r ds
```

The -r option selects the tests to run: disk I/O (d), memory bandwidth (s), network parallel pair (N), network serial pair test (n), network full-matrix test (t). Only one network mode can be selected per execution. See the Greenplum Database Reference Guide for the detailed gpcheckperf reference.
Monitoring with Operating System Utilities

The following Linux/UNIX utilities can be used to assess host performance:

- `iostat` allows you to monitor disk activity on segment hosts.
- `top` displays a dynamic view of operating system processes.
- `vmstat` displays memory usage statistics.

You can use `gpssh` to run utilities on multiple hosts.

Best Practices

- Implement the "Recommended Monitoring and Maintenance Tasks" in the *Greenplum Database Administrator Guide*.
- Run `gpcheckperf` at install time and periodically thereafter, saving the output to compare system performance over time.
- Use all the tools at your disposal to understand how your system behaves under different loads.
- Examine any unusual event to determine the cause.
- Monitor query activity on the system by running explain plans periodically to ensure the queries are running optimally.
- Review plans to determine whether index are being used and partition elimination is occurring as expected.

Additional Information

- `gpcheckperf` reference in the *Greenplum Database Utility Guide*.
- "Recommended Monitoring and Maintenance Tasks" in the *Greenplum Database Administrator Guide*.
- [www.netperf.org](http://www.netperf.org) to use netperf, netperf must be installed on each host you test. See `gpcheckperf` reference for more information.

Updating Statistics with **ANALYZE**

The most important prerequisite for good query performance is to begin with accurate statistics for the tables. Updating statistics with the **ANALYZE** statement enables the query planner to generate optimal query plans. When a table is analyzed, information about the data is stored in the system catalog tables. If the stored information is out of date, the planner can generate inefficient plans.

Generating Statistics Selectively

Running **ANALYZE** with no arguments updates statistics for all tables in the database. This can be a very long-running process and it is not recommended. You should **ANALYZE** tables selectively when data has changed or use the `analyzedb` utility.

Running **ANALYZE** on a large table can take a long time. If it is not feasible to run **ANALYZE** on all columns of a very large table, you can generate statistics for selected columns only using `ANALYZE table(column, ...). Be sure to include columns used in joins, WHERE clauses, SORT clauses, GROUP BY clauses, or HAVING clauses.

For a partitioned table, you can run **ANALYZE** on just partitions that have changed, for example, if you add a new partition. Note that for partitioned tables, you can run **ANALYZE** on the parent (main) table, or on the leaf nodes—the partition files where data and statistics are actually stored. The intermediate files for sub-partitioned tables store no data or statistics, so running **ANALYZE** on them does not work. You can find the names of the partition tables in the `pg_partitions` system catalog:

```sql
SELECT partitiontablename from pg_partitions WHERE tablename='parent_table';
```
Improving Statistics Quality

There is a trade-off between the amount of time it takes to generate statistics and the quality, or accuracy, of the statistics.

To allow large tables to be analyzed in a reasonable amount of time, \texttt{ANALYZE} takes a random sample of the table contents, rather than examining every row. To increase the number of sample values for all table columns adjust the \texttt{default_statistics_target} configuration parameter. The target value ranges from 1 to 1000; the default target value is 100. The \texttt{default_statistics_target} variable applies to all columns by default, and specifies the number of values that are stored in the list of common values. A larger target may improve the quality of the query planner’s estimates, especially for columns with irregular data patterns. \texttt{default_statistics_target} can be set at the master/session level and requires a reload.

When to Run \texttt{ANALYZE}

Run \texttt{ANALYZE}:

- after loading data,
- after \texttt{CREATE INDEX} operations,
- and after \texttt{INSERT}, \texttt{UPDATE}, and \texttt{DELETE} operations that significantly change the underlying data.

\texttt{ANALYZE} requires only a read lock on the table, so it may be run in parallel with other database activity, but do not run \texttt{ANALYZE} while performing \texttt{LOAD}, \texttt{INSERT}, \texttt{UPDATE}, \texttt{DELETE}, and \texttt{CREATE INDEX} operations.

Configuring Automatic Statistics Collection

The \texttt{gp_autostats_mode} configuration parameter, together with the \texttt{gp_autostats_on_change_threshold} parameter, determines when an automatic analyze operation is triggered. When automatic statistics collection is triggered, the planner adds an \texttt{ANALYZE} step to the query.

By default, \texttt{gp_autostats_mode} is \texttt{on_no_stats}, which triggers statistics collection for \texttt{CREATE TABLE AS SELECT}, \texttt{INSERT}, or \texttt{COPY} operations on any table that has no existing statistics.

Setting \texttt{gp_autostats_mode} to \texttt{on_change} triggers statistics collection only when the number of rows affected exceeds the threshold defined by \texttt{gp_autostats_on_change_threshold}, which has a default value of 2147483647. Operations that can trigger automatic statistics collection with \texttt{on_change} are: \texttt{CREATE TABLE AS SELECT}, \texttt{UPDATE}, \texttt{DELETE}, \texttt{INSERT}, and \texttt{COPY}.

Setting \texttt{gp_autostats_mode} to \texttt{none} disables automatic statistics collection.

For partitioned tables, automatic statistics collection is not triggered if data is inserted from the top-level parent table of a partitioned table. But automatic statistics collection is triggered if data is inserted directly in a leaf table (where the data is stored) of the partitioned table.

Managing Bloat in the Database

Greenplum Database heap tables use the PostgreSQL Multiversion Concurrency Control (MVCC) storage implementation. A deleted or updated row is logically deleted from the database, but a non-visible image of the row remains in the table. These deleted rows, also called expired rows, are tracked in a free space map. Running \texttt{VACUUM} marks the expired rows as free space that is available for reuse by subsequent inserts.

If the free space map is not large enough to accommodate all of the expired rows, the \texttt{VACUUM} command is unable to reclaim space for expired rows that overflowed the free space map. The disk space may only be recovered by running \texttt{VACUUM FULL}, which locks the table, copies rows one-by-one to the beginning of the file, and truncates the file. This is an expensive operation that can take an exceptional amount of time to complete with a large table. It should be used only on smaller tables. If you attempt to kill a \texttt{VACUUM FULL} operation, the system can be disrupted.
**Important:**

It is very important to run `VACUUM` after large `UPDATE` and `DELETE` operations to avoid the necessity of ever running `VACUUM FULL`.

If the free space map overflows and it is necessary to recover the space it is recommended to use the `CREATE TABLE...AS SELECT` command to copy the table to a new table, which will create a new compact table. Then drop the original table and rename the copied table.

It is normal for tables that have frequent updates to have a small or moderate amount of expired rows and free space that will be reused as new data is added. But when the table is allowed to grow so large that active data occupies just a small fraction of the space, the table has become significantly “bloated.” Bloated tables require more disk storage and additional I/O that can slow down query execution.

Bloat affects heap tables, system catalogs, and indexes.

Running the `VACUUM` statement on tables regularly prevents them from growing too large. If the table does become significantly bloated, the `VACUUM FULL` statement (or an alternative procedure) must be used to compact the file. If a large table becomes significantly bloated, it is better to use one of the alternative methods described in Removing Bloat from Database Tables to remove the bloat.

**Caution:** *Never* run `VACUUM FULL <database_name>` and do not run `VACUUM FULL` on large tables in a Greenplum Database.

### Detecting Bloat

The statistics collected by the `ANALYZE` statement can be used to calculate the expected number of disk pages required to store a table. The difference between the expected number of pages and the actual number of pages is a measure of bloat. The `gp_toolkit` schema provides a `gp_bloat_diag` view that identifies table bloat by comparing the ratio of expected to actual pages. To use it, make sure statistics are up to date for all of the tables in the database, then run the following SQL:

```
gpadmin=# SELECT * FROM gp_toolkit.gp_bloat_diag;
```

<table>
<thead>
<tr>
<th>bdirelid</th>
<th>bdinspname</th>
<th>bdirelname</th>
<th>bdirelpages</th>
<th>bdiexppages</th>
<th>bdidiag</th>
</tr>
</thead>
<tbody>
<tr>
<td>21488</td>
<td>public</td>
<td>t1</td>
<td>97</td>
<td>1</td>
<td>significant amount of bloat suspected</td>
</tr>
</tbody>
</table>

(1 row)

The results include only tables with moderate or significant bloat. Moderate bloat is reported when the ratio of actual to expected pages is greater than four and less than ten. Significant bloat is reported when the ratio is greater than ten.

The `gp_toolkit.gp_bloat_expected_pages` view lists the actual number of used pages and expected number of used pages for each database object.

```
gpadmin=# SELECT * FROM gp_toolkit.gp_bloat_expected_pages LIMIT 5;
```

<table>
<thead>
<tr>
<th>btdrelid</th>
<th>btdrelpages</th>
<th>btdexppages</th>
</tr>
</thead>
<tbody>
<tr>
<td>10789</td>
<td>1</td>
<td>1</td>
</tr>
<tr>
<td>10794</td>
<td>1</td>
<td>1</td>
</tr>
<tr>
<td>10799</td>
<td>1</td>
<td>1</td>
</tr>
<tr>
<td>5004</td>
<td>1</td>
<td>1</td>
</tr>
<tr>
<td>7175</td>
<td>1</td>
<td>1</td>
</tr>
</tbody>
</table>

(5 rows)

The `btdrelid` is the object ID of the table. The `btdrelpages` column reports the number of pages the table uses; the `btdexppages` column is the number of pages expected. Again, the numbers reported are based on the table statistics, so be sure to run `ANALYZE` on tables that have changed.
Removing Bloat from Database Tables

The **VACUUM** command adds expired rows to the free space map so that the space can be reused. When **VACUUM** is run regularly on a table that is frequently updated, the space occupied by the expired rows can be promptly reused, preventing the table file from growing larger. It is also important to run **VACUUM** before the free space map is filled. For heavily updated tables, you may need to run **VACUUM** at least once a day to prevent the table from becoming bloated.

*Warning:* When a table is significantly bloated, it is better to run **VACUUM** before running **ANALYZE**. Analyzing a severely bloated table can generate poor statistics if the sample contains empty pages, so it is good practice to vacuum a bloated table before analyzing it.

When a table accumulates significant bloat, running the **VACUUM** command is insufficient. For small tables, running **VACUUM FULL** `<table_name>` can reclaim space used by rows that overflowed the free space map and reduce the size of the table file. However, a **VACUUM FULL** statement is an expensive operation that requires an **ACCESS EXCLUSIVE** lock and may take an exceptionally long and unpredictable amount of time to finish. Rather than run **VACUUM FULL** on a large table, an alternative method is required to remove bloat from a large file. Note that every method for removing bloat from large tables is resource intensive and should be done only under extreme circumstances.

The first method to remove bloat from a large table is to create a copy of the table excluding the expired rows, drop the original table, and rename the copy. This method uses the **CREATE TABLE** `<table_name>` **AS SELECT** statement to create the new table, for example:

```
gpadmin=# CREATE TABLE mytable_tmp AS SELECT * FROM mytable;
gpadmin=# DROP TABLE mytable;
gpadmin=# ALTER TABLE mytabe_tmp RENAME TO mytable;
```

A second way to remove bloat from a table is to redistribute the table, which rebuilds the table without the expired rows. Follow these steps:

1. Make a note of the table's distribution columns.
2. Change the table's distribution policy to random:

   ```
   ALTER TABLE mytable SET WITH (REORGANIZE=false) DISTRIBUTED randomly;
   ```

   This changes the distribution policy for the table, but does not move any data. The command should complete instantly.

3. Change the distribution policy back to its initial setting:

   ```
   ALTER TABLE mytable SET WITH (REORGANIZE=true) DISTRIBUTED BY ("original distribution columns");
   ```

   This step redistributes the data. Since the table was previously distributed with the same distribution key, the rows are simply rewritten on the same segment, excluding expired rows.

Removing Bloat from Indexes

The **VACUUM** command only recovers space from tables. To recover the space from indexes, recreate them using the **REINDEX** command.

To rebuild all indexes on a table run **REINDEX** `<table_name>`. To rebuild a particular index, run **REINDEX** `<index_name>`. **REINDEX** sets the `reltuples` and `relnpages` to 0 (zero) for the index. To update those statistics, run **ANALYZE** on the table after reindexing.

Removing Bloat from System Catalogs

Greenplum Database system catalogs are also heap tables and can become bloated over time. As database objects are created, altered, or dropped, expired rows are left in the system catalogs. Using
gpload to load data contributes to the bloat since gpload creates and drops external tables. (Rather than use gpload, it is recommended to use gpfdist to load data.)

Bloat in the system catalogs increases the time require to scan the tables, for example, when creating explain plans. System catalogs are scanned frequently and if they become bloated, overall system performance is degraded.

It is recommended to run VACUUM on the system catalog nightly and at least weekly. At the same time, running REINDEX SYSTEM removes bloat from the indexes. Alternatively, you can reindex system tables using the reindexdb utility with the \(-s\) \(--system\) option. After removing catalog bloat, run ANALYZE to update catalog table statistics.

These are Greenplum Database system catalog maintenance steps.

1. Perform a REINDEX on the system catalog tables to rebuild the system catalog indexes. This removes bloat in the indexes and improves VACUUM performance.

   **Note:** When performing REINDEX on the system catalog tables, locking will occur on the tables and might have an impact on currently running queries. You can schedule the REINDEX operation during a period of low activity to avoid disrupting ongoing business operations.

2. Perform a VACUUM on system catalog tables.

3. Perform an ANALYZE on the system catalog tables to update the table statistics.

If you are performing catalog maintenance during a maintenance period and you need to stop a process due to time constraints, run the Greenplum Database function pg_cancel_backend\((<\text{PID}>)\) to safely stop a Greenplum Database process.

The following script runs REINDEX, VACUUM, and ANALYZE on the system catalogs.

```bash
#!/bin/bash
DBNAME="<database_name>"
SYSTABLES="' pg_catalog.' || relname || ' '; from pg_class a, pg_namespace b \
where a.relnamespace=b.oid and b.nspname='pg_catalog' and a.relkind='r'"
reindexdb -s -d $DBNAME
psql -tc "SELECT 'VACUUM' || $SYSTABLES" $DBNAME | psql -a $DBNAME
analyzedb -s pg_catalog -d $DBNAME
```

If the system catalogs become significantly bloated, you must perform an intensive system catalog maintenance procedure. The CREATE TABLE AS SELECT and redistribution key methods for removing bloat cannot be used with system catalogs. You must instead run VACUUM FULL during a scheduled downtime period. During this period, stop all catalog activity on the system; VACUUM FULL takes exclusive locks against the system catalog. Running VACUUM regularly can prevent the need for this more costly procedure.

These are steps for intensive system catalog maintenance.

1. Stop all catalog activity on the Greenplum Database system.
2. Perform a REINDEX on the system catalog tables to rebuild the system catalog indexes. This removes bloat in the indexes and improves VACUUM performance.
3. Perform a VACUUM FULL on the system catalog tables. See the following Note.
4. Perform an ANALYZE on the system catalog tables to update the catalog table statistics.

   **Note:** The system catalog table pg_attribute is usually the largest catalog table. If the pg_attribute table is significantly bloated, a VACUUM FULL operation on the table might require a significant amount of time and might need to be performed separately. The presence of both of these conditions indicate a significantly bloated pg_attribute table that might require a long VACUUM FULL time:

   • The pg_attribute table contains a large number of records.
   • The diagnostic message for pg_attribute is significant amount of bloat in the gp_toolkit.gp_bloat_diag view.
Removing Bloat from Append-Optimized Tables

Append-optimized tables are handled much differently than heap tables. Although append-optimized tables allow updates, inserts, and deletes, they are not optimized for these operations and it is recommended to not use them with append-optimized tables. If you heed this advice and use append-optimized for load-once/read-many workloads, VACUUM on an append-optimized table runs almost instantaneously.

If you do run UPDATE or DELETE commands on an append-optimized table, expired rows are tracked in an auxiliary bitmap instead of the free space map. VACUUM is the only way to recover the space. Running VACUUM on an append-optimized table with expired rows compacts a table by rewriting the entire table without the expired rows. However, no action is performed if the percentage of expired rows in the table exceeds the value of the gp_appendonly_compaction_threshold configuration parameter, which is 10 (10%) by default. The threshold is checked on each segment, so it is possible that a VACUUM statement will compact an append-only table on some segments and not others. Compacting append-only tables can be disabled by setting the gp_appendonly_compaction parameter to no.

Monitoring Greenplum Database Log Files

Know the location and content of system log files and monitor them on a regular basis and not just when problems arise.

The following table shows the locations of the various Greenplum Database log files. In file paths:

- $GPADMIN_HOME refers to the home directory of the gpadmin operating system user.
- $MASTER_DATA_DIRECTORY refers to the master data directory on the Greenplum Database master host.
- $GPDATA_DIR refers to a data directory on the Greenplum Database segment host.
- host identifies the Greenplum Database segment host name.
- segprefix identifies the segment prefix.
- N identifies the segment instance number.
- date is a date in the format YYYYMMDD.

<table>
<thead>
<tr>
<th>Path</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>$GPADMIN_HOME/gpAdminLogs/*</td>
<td>Many different types of log files, directory on each server. $GPADMIN_HOME is the default location for the gpAdminLogs/ directory. You can specify a different location when you run an administrative utility command.</td>
</tr>
<tr>
<td>$GPADMIN_HOME/gpAdminLogs/gpinitsystem_date.log</td>
<td>system initialization log</td>
</tr>
<tr>
<td>$GPADMIN_HOME/gpAdminLogs/gpstart_date.log</td>
<td>start log</td>
</tr>
<tr>
<td>$GPADMIN_HOME/gpAdminLogs/gpstop_date.log</td>
<td>stop log</td>
</tr>
<tr>
<td>$GPADMIN_HOME/gpAdminLogs/gpsegstart.py_host:gpadmin_date.log</td>
<td>segment host start log</td>
</tr>
<tr>
<td>$GPADMIN_HOME/gpAdminLogs/gpsegstop.py_host:gpadmin_date.log</td>
<td>segment host stop log</td>
</tr>
<tr>
<td>$MASTER_DATA_DIRECTORY/pg_log/startup.log, $PGDATA_DIR/segprefixN/pg_log/startup.log</td>
<td>segment instance start log</td>
</tr>
</tbody>
</table>
Use `gplogfilter -t (--trouble)` first to search the master log for messages beginning with `ERROR:`, `FATAL:`, or `PANIC:`. Messages beginning with `WARNING` may also provide useful information.

To search log files on the segment hosts, use the Greenplum `gplogfilter` utility with `gpssh` to connect to segment hosts from the master host. You can identify corresponding log entries in segment logs by the `statement_id`.

Greenplum Database can be configured to rotate database logs based on the size and/or age of the current log file. The `log_rotation_size` configuration parameter sets the size of an individual log file that triggers rotation. When the current log file size is equal to or greater than this size, the file is closed and a new log file is created. The `log_rotation_age` configuration parameter specifies the age of the current log file that triggers rotation. When the specified time has elapsed since the current log file was created, a new log file is created. The default `log_rotation_age`, 1d, creates a new log file 24 hours after the current log file was created.

<table>
<thead>
<tr>
<th>Path</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>$MASTER_DATA_DIRECTORY/gpperfmon/logs/gpmon.*.log</td>
<td>gpperfmon logs</td>
</tr>
<tr>
<td>$MASTER_DATA_DIRECTORY/pg_log/<em>.csv, $GPDATA_DIR/segprefixN/pg_log/</em>.csv</td>
<td>master and segment database logs</td>
</tr>
<tr>
<td>$GPDATA_DIR/mirror/segprefixN/pg_log/*.csv</td>
<td>mirror segment database logs</td>
</tr>
<tr>
<td>$GPDATA_DIR/primary/segprefixN/pg_log/*.csv</td>
<td>primary segment database logs</td>
</tr>
<tr>
<td>/var/log/messages</td>
<td>Global Linux system messages</td>
</tr>
</tbody>
</table>
Loading Data

Description of the different ways to add data to Greenplum Database.

**INSERT Statement with Column Values**

A singleton `INSERT` statement with values adds a single row to a table. The row flows through the master and is distributed to a segment. This is the slowest method and is not suitable for loading large amounts of data.

**COPY Statement**

The PostgreSQL `COPY` statement copies data from an external file into a database table. It can insert multiple rows more efficiently than an `INSERT` statement, but the rows are still passed through the master. All of the data is copied in one command; it is not a parallel process.

Data input to the `COPY` command is from a file or the standard input. For example:

```
COPY table FROM '/data/mydata.csv' WITH CSV HEADER;
```

Use `COPY` to add relatively small sets of data, for example dimension tables with up to ten thousand rows, or one-time data loads.

Use `COPY` when scripting a process that loads small amounts of data, less than 10 thousand rows.

Since `COPY` is a single command, there is no need to disable autocommit when you use this method to populate a table.

You can run multiple concurrent `COPY` commands to improve performance.

**External Tables**

External tables provide access to data in sources outside of Greenplum Database. They can be accessed with `SELECT` statements and are commonly used with the Extract, Load, Transform (ELT) pattern, a variant of the Extract, Transform, Load (ETL) pattern that takes advantage of Greenplum Database’s fast parallel data loading capability.

With ETL, data is extracted from its source, transformed outside of the database using external transformation tools, such as Informatica or Datastage, and then loaded into the database.

With ELT, Greenplum external tables provide access to data in external sources, which could be read-only files (for example, text, CSV, or XML files), Web servers, Hadoop file systems, executable OS programs, or the Greenplum `gpfdist` file server, described in the next section. External tables support SQL operations such as select, sort, and join so the data can be loaded and transformed simultaneously, or loaded into a `load table` and transformed in the database into target tables.

The external table is defined with a `CREATE EXTERNAL TABLE` statement, which has a `LOCATION` clause to define the location of the data and a `FORMAT` clause to define the formatting of the source data so that the system can parse the input data. Files use the `file://` protocol, and must reside on a segment host in a location accessible by the Greenplum superuser. The data can be spread out among the segment hosts with no more than one file per primary segment on each host. The number of files listed in the `LOCATION` clause is the number of segments that will read the external table in parallel.

**External Tables with Gpfdist**

The fastest way to load large fact tables is to use external tables with `gpdist`. `gpdist` is a file server program using an HTTP protocol that serves external data files to Greenplum Database segments.
in parallel. A gpfdist instance can serve 200 MB/second and many gpfdist processes can run simultaneously, each serving up a portion of the data to be loaded. When you begin the load using a statement such as INSERT INTO <table> SELECT * FROM <external_table>, the INSERT statement is parsed by the master and distributed to the primary segments. The segments connect to the gpfdist servers and retrieve the data in parallel, parse and validate the data, calculate a hash from the distribution key data and, based on the hash key, send the row to its destination segment. By default, each gpfdist instance will accept up to 64 connections from segments. With many segments and gpfdist servers participating in the load, data can be loaded at very high rates.

Primary segments access external files in parallel when using gpfdist up to the value of gp_external_max_segments. When optimizing gpfdist performance, maximize the parallelism as the number of segments increase. Spread the data evenly across as many ETL nodes as possible. Split very large data files into equal parts and spread the data across as many file systems as possible.

Run two gpfdist instances per file system. gpfdist tends to be CPU bound on the segment nodes when loading. But if, for example, there are eight racks of segment nodes, there is lot of available CPU on the segments to drive more gpfdist processes. Run gpfdist on as many interfaces as possible. Be aware of bonded NICs and be sure to start enough gpfdist instances to work them.

It is important to keep the work even across all these resources. The load is as fast as the slowest node. Skew in the load file layout will cause the overall load to bottleneck on that resource.

The gp_external_max_segs configuration parameter controls the number of segments each gpfdist process serves. The default is 64. You can set a different value in the postgresql.conf configuration file on the master. Always keep gp_external_max_segs and the number of gpfdist processes an even factor; that is, the gp_external_max_segs value should be a multiple of the number of gpfdist processes. For example, if there are 12 segments and 4 gpfdist processes, the planner round robin the segment connections as follows:

<table>
<thead>
<tr>
<th>Segment 1</th>
<th>gpfdist 1</th>
</tr>
</thead>
<tbody>
<tr>
<td>Segment 2</td>
<td>gpfdist 2</td>
</tr>
<tr>
<td>Segment 3</td>
<td>gpfdist 3</td>
</tr>
<tr>
<td>Segment 4</td>
<td>gpfdist 4</td>
</tr>
<tr>
<td>Segment 5</td>
<td>gpfdist 1</td>
</tr>
<tr>
<td>Segment 6</td>
<td>gpfdist 2</td>
</tr>
<tr>
<td>Segment 7</td>
<td>gpfdist 3</td>
</tr>
<tr>
<td>Segment 8</td>
<td>gpfdist 4</td>
</tr>
<tr>
<td>Segment 9</td>
<td>gpfdist 1</td>
</tr>
<tr>
<td>Segment 10</td>
<td>gpfdist 2</td>
</tr>
<tr>
<td>Segment 11</td>
<td>gpfdist 3</td>
</tr>
<tr>
<td>Segment 12</td>
<td>gpfdist 4</td>
</tr>
</tbody>
</table>

Drop indexes before loading into existing tables and re-create the index after loading. Creating an index on pre-existing data is faster than updating it incrementally as each row is loaded.

Run ANALYZE on the table after loading. Disable automatic statistics collection during loading by setting gp_autostats_mode to NONE. Run VACUUM after load errors to recover space.

Performing small, high frequency data loads into heavily partitioned column-oriented tables can have a high impact on the system because of the number of physical files accessed per time interval.

Gpload

gpload is a data loading utility that acts as an interface to the Greenplum external table parallel loading feature.

Beware of using gpload as it can cause catalog bloat by creating and dropping external tables. Use gpfdist instead, since it provides the best performance.

gpload executes a load using a specification defined in a YAML-formatted control file. It performs the following operations:
Invokes gpfdist processes
Creates a temporary external table definition based on the source data defined
Executes an INSERT, UPDATE, or MERGE operation to load the source data into the target table in the database
Drops the temporary external table
Cleans up gpfdist processes

The load is accomplished in a single transaction.

**Best Practices**

- Drop any indexes on an existing table before loading data and recreate the indexes after loading. Newly creating an index is faster than updating an index incrementally as each row is loaded.
- Disable automatic statistics collection during loading by setting the `gp_autostats_mode` configuration parameter to `NONE`.
- External tables are not intended for frequent or ad hoc access.
- External tables have no statistics to inform the optimizer. You can set rough estimates for the number of rows and disk pages for the external table in the `pg_class` system catalog with a statement like the following:

  ```sql
  UPDATE pg_class SET reltuples=400000, relpages=400
  WHERE relname='myexttable';
  ```
- When using gpfdist, maximize network bandwidth by running one gpfdist instance for each NIC on the ETL server. Divide the source data evenly between the gpfdist instances.
- When using gpload, run as many simultaneous gpload instances as resources allow. Take advantage of the CPU, memory, and networking resources available to increase the amount of data that can be transferred from ETL servers to the Greenplum Database.
- Use the `SEGMENT REJECT LIMIT` clause of the `COPY` statement to set a limit for the number or percentage of rows that can have errors before the `COPY` FROM command is aborted. The reject limit is per segment; when any one segment exceeds the limit, the command is aborted and no rows are added. Use the `LOG ERRORS` clause to save error rows. If a row has errors in the formatting—for example missing or extra values, or incorrect data types—Greenplum Database stores the error information and row internally. Use the `gp_read_error_log()` built-in SQL function to access this stored information.
- If the load has errors, run VACUUM on the table to recover space.
- After you load data into a table, run VACUUM on heap tables, including system catalogs, and ANALYZE on all tables. It is not necessary to run VACUUM on append-optimized tables. If the table is partitioned, you can vacuum and analyze just the partitions affected by the data load. These steps clean up any rows from aborted loads, deletes, or updates and update statistics for the table.
- Recheck for segment skew in the table after loading a large amount of data. You can use a query like the following to check for skew:

- By default, gpfdist assumes a maximum record size of 32K. To load data records larger than 32K, you must increase the maximum row size parameter by specifying the `-m <bytes>` option on the gpfdist command line. If you use gpload, set the `MAX_LINE_LENGTH` parameter in the gpload control file.

  **Note:** Integrations with Informatica Power Exchange are currently limited to the default 32K record length.

**Additional Information**

See the *Greenplum Database Reference Guide* for detailed instructions for loading data using gpfdist and gpload.
Security

Best practices to ensure the highest level of system security.

Basic Security Best Practices

• Secure the gpadmin system user. Greenplum requires a UNIX user id to install and initialize the Greenplum Database system. This system user is referred to as gpadmin in the Greenplum documentation. The gpadmin user is the default database superuser in Greenplum Database, as well as the file system owner of the Greenplum installation and its underlying data files. The default administrator account is fundamental to the design of Greenplum Database. The system cannot run without it, and there is no way to limit the access of the gpadmin user id. This gpadmin user can bypass all security features of Greenplum Database. Anyone who logs on to a Greenplum host with this user id can read, alter, or delete any data, including system catalog data and database access rights. Therefore, it is very important to secure the gpadmin user id and only allow essential system administrators access to it. Administrators should only log in to Greenplum as gpadmin when performing certain system maintenance tasks (such as upgrade or expansion). Database users should never log on as gpadmin, and ETL or production workloads should never run as gpadmin.

• Assign a distinct role to each user who logs in. For logging and auditing purposes, each user who is allowed to log in to Greenplum Database should be given their own database role. For applications or web services, consider creating a distinct role for each application or service. See "Creating New Roles (Users)" in the Greenplum Database Administrator Guide.

• Use groups to manage access privileges. See "Creating Groups (Role Membership)" in the Greenplum Database Administrator Guide.

• Limit users who have the SUPERUSER role attribute. Roles that are superusers bypass all access privilege checks in Greenplum Database, as well as resource queuing. Only system administrators should be given superuser rights. See "Altering Role Attributes" in the Greenplum Database Administrator Guide.

Password Strength Guidelines

To protect the network from intrusion, system administrators should verify the passwords used within an organization are strong ones. The following recommendations can strengthen a password:

• Minimum password length recommendation: At least 9 characters. MD5 passwords should be 15 characters or longer.
• Mix upper and lower case letters.
• Mix letters and numbers.
• Include non-alphanumeric characters.
• Pick a password you can remember.

The following are recommendations for password cracker software that you can use to determine the strength of a password.

• John The Ripper. A fast and flexible password cracking program. It allows the use of multiple word lists and is capable of brute-force password cracking. It is available online at http://www.openwall.com/john/.
• Crack. Perhaps the most well-known password cracking software, Crack is also very fast, though not as easy to use as John The Ripper. It can be found online at http://www.crypticide.com/alecm/security/crack/c50-faq.html.

The security of the entire system depends on the strength of the root password. This password should be at least 12 characters long and include a mix of capitalized letters, lowercase letters, special characters, and numbers. It should not be based on any dictionary word.

Password expiration parameters should be configured.
Ensure the following line exists within the file /etc/libuser.conf under the [import] section.

login_defs = /etc/login.defs

Ensure no lines in the [userdefaults] section begin with the following text, as these words override settings from /etc/login.defs:

- LU_SHADOWMAX
- LU_SHADOWMIN
- LU_SHADOWWARNING

Ensure the following command produces no output. Any accounts listed by running this command should be locked.

grep "^+:" /etc/passwd /etc/shadow /etc/group

Note: We strongly recommend that customers change their passwords after initial setup.

cd /etc
cp root:root passwd shadow group gshadow
chmod 644 passwd group
cchmod 400 shadow gshadow

Find all the files that are world-writable and that do not have their sticky bits set.

find / -xdev -type d \( -perm -0002 -a ! -perm -1000 \) -print

Set the sticky bit (# chmod +t {dir}) for all the directories that result from running the previous command.

Find all the files that are world-writable and fix each file listed.

find / -xdev -type f -perm -0002 -print

Set the right permissions (# chmod o-w {file}) for all the files generated by running the aforementioned command.

Find all the files that do not belong to a valid user or group and either assign an owner or remove the file, as appropriate.

find / -xdev \( -nouser -o nogroup \) -print

Find all the directories that are world-writable and ensure they are owned by either root or a system account (assuming only system accounts have a User ID lower than 500). If the command generates any output, verify the assignment is correct or reassign it to root.

find / -xdev -type d -perm -0002 -uid +500 -print

Authentication settings such as password quality, password expiration policy, password reuse, password retry attempts, and more can be configured using the Pluggable Authentication Modules (PAM) framework. PAM looks in the directory /etc/pam.d for application-specific configuration information. Running authconfig or system-config-authentication will re-write the PAM configuration files, destroying any manually made changes and replacing them with system defaults.
The default `pam_cracklib` PAM module provides strength checking for passwords. To configure `pam_cracklib` to require at least one uppercase character, lowercase character, digit, and special character, as recommended by the U.S. Department of Defense guidelines, edit the file `/etc/pam.d/system-auth` to include the following parameters in the line corresponding to password requisite `pam_cracklib.so try_first_pass`.

```
retry=3:
  dcredit=-1. Require at least one digit
  ucredit=-1. Require at least one upper case character
  ocredit=-1. Require at least one special character
  lcredit=-1. Require at least one lower case character
  minlen-14. Require a minimum password length of 14.
```

For example:

```
password required pam_cracklib.so try_first_pass retry=3\minlen=14
  dcredit=-1 ucredit=-1 ocredit=-1 lcredit=-1
```

These parameters can be set to reflect your security policy requirements. Note that the password restrictions are not applicable to the root password.

The `pam_tally2` PAM module provides the capability to lock out user accounts after a specified number of failed login attempts. To enforce password lockout, edit the file `/etc/pam.d/system-auth` to include the following lines:

- The first of the auth lines should include:
  ```
  auth required pam_tally2.so deny=5 onerr=fail unlock_time=900
  ```

- The first of the account lines should include:
  ```
  account required pam_tally2.so
  ```

Here, the deny parameter is set to limit the number of retries to 5 and the `unlock_time` has been set to 900 seconds to keep the account locked for 900 seconds before it is unlocked. These parameters may be configured appropriately to reflect your security policy requirements. A locked account can be manually unlocked using the `pam_tally2` utility:

```
/sbin/pam_tally2 --user {username} -reset
```

You can use PAM to limit the reuse of recent passwords. The remember option for the `pam_unix` module can be set to remember the recent passwords and prevent their reuse. To accomplish this, edit the appropriate line in `/etc/pam.d/system-auth` to include the remember option.

For example:

```
password sufficient pam_unix.so [ ... existing_options ...]
  remember=5
```

You can set the number of previous passwords to remember to appropriately reflect your security policy requirements.

```
cd /etc
cchown root:root passwd shadow group gshadow
chmod 644 passwd group
chmod 400 shadow gshadow
```
Encrypting Data and Database Connections

Best practices for implementing encryption and managing keys.

Encryption can be used to protect data in a Greenplum Database system in the following ways:

- Connections between clients and the master database can be encrypted with SSL. This is enabled by setting the `ssl` server configuration parameter to `on` and editing the `pg_hba.conf` file. See "Encrypting Client/Server Connections" in the Greenplum Database Administrator Guide for information about enabling SSL in Greenplum Database.
- Greenplum Database 4.2.1 and above allow SSL encryption of data in transit between the Greenplum parallel file distribution server, `gpfdist`, and segment hosts. See Encrypting `gpfdist` Connections for more information.
- Network communications between hosts in the Greenplum Database cluster can be encrypted using IPsec. An authenticated, encrypted VPN is established between every pair of hosts in the cluster. Check your operating system documentation for IPsec support, or consider a third-party solution such as that provided by Zettaset.
- The `pgcrypto` module of encryption/decryption functions protects data at rest in the database. Encryption at the column level protects sensitive information, such as passwords, Social Security numbers, or credit card numbers. See Encrypting Data in Tables using PGP for an example.

Best Practices

- Encryption ensures that data can be seen only by users who have the key required to decrypt the data.
- Encrypting and decrypting data has a performance cost; only encrypt data that requires encryption.
- Do performance testing before implementing any encryption solution in a production system.
- Server certificates in a production Greenplum Database system should be signed by a certificate authority (CA) so that clients can authenticate the server. The CA may be local if all clients are local to the organization.
- Client connections to Greenplum Database should use SSL encryption whenever the connection goes through an insecure link.
- A symmetric encryption scheme, where the same key is used to both encrypt and decrypt, has better performance than an asymmetric scheme and should be used when the key can be shared safely.
- Use functions from the `pgcrypto` module to encrypt data on disk. The data is encrypted and decrypted in the database process, so it is important to secure the client connection with SSL to avoid transmitting unencrypted data.
- Use the `gpfdists` protocol to secure ETL data as it is loaded into or unloaded from the database. See Encrypting `gpfdist` Connections.

Key Management

Whether you are using symmetric (single private key) or asymmetric (public and private key) cryptography, it is important to store the master or private key securely. There are many options for storing encryption keys, for example, on a file system, key vault, encrypted USB, trusted platform module (TPM), or hardware security module (HSM).

Consider the following questions when planning for key management:

- Where will the keys be stored?
- When should keys expire?
- How are keys protected?
- How are keys accessed?
- How can keys be recovered and revoked?
The Open Web Application Security Project (OWASP) provides a very comprehensive guide to securing encryption keys.

**Encrypting Data at Rest with pgcrypto**

The pgcrypto module for Greenplum Database provides functions for encrypting data at rest in the database. Administrators can encrypt columns with sensitive information, such as social security numbers or credit card numbers, to provide an extra layer of protection. Database data stored in encrypted form cannot be read by users who do not have the encryption key, and the data cannot be read directly from disk.

pgcrypto is installed by default when you install Greenplum Database. You must explicitly enable pgcrypto in each database in which you want to use the module.

pgcrypto allows PGP encryption using symmetric and asymmetric encryption. Symmetric encryption encrypts and decrypts data using the same key and is faster than asymmetric encryption. It is the preferred method in an environment where exchanging secret keys is not an issue. With asymmetric encryption, a public key is used to encrypt data and a private key is used to decrypt data. This is slower than symmetric encryption and it requires a stronger key.

Using pgcrypto always comes at the cost of performance and maintainability. It is important to use encryption only with the data that requires it. Also, keep in mind that you cannot search encrypted data by indexing the data.

Before you implement in-database encryption, consider the following PGP limitations.

- No support for signing. That also means that it is not checked whether the encryption sub-key belongs to the master key.
- No support for encryption key as master key. This practice is generally discouraged, so this limitation should not be a problem.
- No support for several subkeys. This may seem like a problem, as this is common practice. On the other hand, you should not use your regular GPG/PGP keys with pgcrypto, but create new ones, as the usage scenario is rather different.

Greenplum Database is compiled with zlib by default; this allows PGP encryption functions to compress data before encrypting. When compiled with OpenSSL, more algorithms will be available.

Because pgcrypto functions run inside the database server, the data and passwords move between pgcrypto and the client application in clear-text. For optimal security, you should connect locally or use SSL connections and you should trust both the system and database administrators.

pgcrypto configures itself according to the findings of the main PostgreSQL configure script.

When compiled with zlib, pgcrypto encryption functions are able to compress data before encrypting.

Pgcrypto has various levels of encryption ranging from basic to advanced built-in functions. The following table shows the supported encryption algorithms.

<table>
<thead>
<tr>
<th>Value Functionality</th>
<th>Built-in</th>
<th>With OpenSSL</th>
</tr>
</thead>
<tbody>
<tr>

## Creating PGP Keys

To use PGP asymmetric encryption in Greenplum Database, you must first create public and private keys and install them.

This section assumes you are installing Greenplum Database on a Linux machine with the Gnu Privacy Guard (gpg) command line tool. Pivotal recommends using the latest version of GPG to create keys. Download and install Gnu Privacy Guard (GPG) for your operating system from [https://www.gnupg.org/download/](https://www.gnupg.org/download/). On the GnuPG website you will find installers for popular Linux distributions and links for Windows and Mac OS X installers.

1. As root, execute the following command and choose option 1 from the menu:

```bash
# gpg --gen-key
```

   gpg (GnuPG) 2.0.14; Copyright (C) 2009 Free Software Foundation, Inc.
   This is free software: you are free to change and redistribute it.
   There is NO WARRANTY, to the extent permitted by law.

   gpg: directory `/root/.gnupg' created
   gpg: new configuration file `/root/.gnupg/gpg.conf' created
   gpg: WARNING: options in `/root/.gnupg/gpg.conf' are not yet active during
   this run
   gpg: keyring `/root/.gnupg/secring.gpg' created
   gpg: keyring `/root/.gnupg/pubring.gpg' created
   Please select what kind of key you want:
   (1) RSA and RSA (default)
   (2) DSA and Elgamal
   (3) DSA (sign only)
   (4) RSA (sign only)
   Your selection? 1

2. Respond to the prompts and follow the instructions, as shown in this example:

   RSA keys may be between 1024 and 4096 bits long.
   What keysize do you want? (2048) Press enter to accept default key size
   Requested keysize is 2048 bits
   Please specify how long the key should be valid.
   0 = key does not expire
   <n> = key expires in n days
   <n>w = key expires in n weeks
   <n>m = key expires in n months
   <n>y = key expires in n years
   Key is valid for? (0) 365

---

\(^7\) Any digest algorithm OpenSSL supports is automatically picked up. This is not possible with ciphers, which need to be supported explicitly.

\(^8\) AES is included in OpenSSL since version 0.9.7. For older versions, pgcrypto will use built-in code.
Key expires at Wed 13 Jan 2016 10:35:39 AM PST
Is this correct? (y/N)  y

GnuPG needs to construct a user ID to identify your key.

Real name: **John Doe**
Email address: **jdoe@email.com**
Comment:
You selected this USER-ID:
"John Doe <jdoe@email.com>"

Change (N)ame, (C)omment, (E)mail or (O)kay/(Q)uit?  O
You need a Passphrase to protect your secret key.
*(For this demo the passphrase is blank.)*
can't connect to `/root/.gnupg/S.gpg-agent': No such file or directory
You don't want a passphrase - this is probably a *bad* idea!
I will do it anyway. You can change your passphrase at any time,
using this program with the option "--edit-key".

We need to generate a lot of random bytes. It is a good idea to perform
some other action (type on the keyboard, move the mouse, utilize the
disks) during the prime generation; this gives the random number
generator a better chance to gain enough entropy.
We need to generate a lot of random bytes. It is a good idea to perform
some other action (type on the keyboard, move the mouse, utilize the
disks) during the prime generation; this gives the random number
generator a better chance to gain enough entropy.
gpg: /root/.gnupg/trustdb.gpg: trustdb created
gpg: key 2027CC30 marked as ultimately trusted
public and secret key created and signed.
gpg: checking the trustdb
  3 marginal(s) needed, 1 complete(s) needed, PGP trust model
gpg: depth: 0  valid:  1  signed:  0  trust: 0-, 0q, 0n, 0m, 0f, 1u
gpg: next trustdb check due at 2016-01-13
pub  2048R/2027CC30 2015-01-13 [expires: 2016-01-13]
    Key fingerprint = 7EDA 6AD0 F5E0 400F 4D45   3259 077D 725E 2027
    CC30
    uid                  John Doe <jdoe@email.com>
    sub   2048R/4FD2EFBB 2015-01-13 [expires: 2016-01-13]

3. List the PGP keys by entering the following command:

    gpg --list-secret-keys
    /root/.gnupg/secring.gpg
    ------------------------
    sec  2048R/2027CC30 2015-01-13 [expires: 2016-01-13]
    uid                  John Doe <jdoe@email.com>
    ssb  2048R/4FD2EFBB 2015-01-13

2027CC30 is the public key and will be used to *encrypt* data in the database. 4FD2EFBB is the private
(secret) key and will be used to *decrypt* data.

4. Export the keys using the following commands:

    # gpg -a --export 4FD2EFBB > public.key
    # gpg -a --export-secret-keys 2027CC30 > secret.key

See the *pgcrypto* documentation for for more information about PGP encryption functions.
Encrypting Data in Tables using PGP

This section shows how to encrypt data inserted into a column using the PGP keys you generated.

1. Dump the contents of the public.key file and then copy it to the clipboard:

   ```
   # cat public.key
   -----BEGIN PGP PUBLIC KEY BLOCK-----
   Version: GnuPG v2.0.14 (GNU/Linux)
   mQENBFS1zF0BCADNw8Qvk1V1c3kfcwd3Kpm/diJpfRyyEwB6PqKyA05jtWiXZTh
   2HIslojSP6LI0cSkIQMU9LAlnecce2hRINhvuVgKiLSgd9tewg2nnST1AdmqiK/yX
   RSyvVKG+qcdWuy729gO0Omyehrhc3n+kkdBfTMuM3flbMs8shOwzvMvstCUVmHU/V
   . . .
   WH+N2lasuoAuoJjb2kQGhLOnFbJuevkyBy1Rz+hI/+8rJKc2OjQkmmK8Hkk8qb5x/
   HMUC5S5H0q2qOYAOBnPnHjGg0Q45Q6pk3G2/7Dbek5WJ6K1wUrPy5lsN1GWE8pvgEx
   /UUEB+dYyCtvx0nnBu1KNCmK2AkEcFK3YoliCxm0dOxhFOv9AKjjojDyC65KJci
   Pz2MikPS2fK0Ag1R73pMa8ZdET14w3vckPQNrQNnYuU6fj6Z0Cv
   =XZ8J
   -----END PGP PUBLIC KEY BLOCK-----
   ```

2. Create a table called userssn and insert some sensitive data, social security numbers for Bob and Alice, in this example. Paste the public.key contents after "dearmor(".

   ```
   CREATE TABLE userssn( ssn_id SERIAL PRIMARY KEY, 
   username varchar(100), ssn bytea);
   INSERT INTO userssn(username, ssn)
   SELECT robotccs.username, pgp_pub_encrypt(robotccs.ssn, keys.pubkey) AS ssn
   FROM (  
   VALUES ('Alice', '123-45-6788'), ('Bob', '123-45-6799'))
   AS robotccs(username, ssn)
   CROSS JOIN  (SELECT  dearmor('-----BEGIN PGP PUBLIC KEY BLOCK-----' AS pubkey) AS keys;
   ```

3. Verify that the ssn column is encrypted.

   ```
   test_db=# select * from userssn;
   ssn_id | 1
   username | Alice
   ssn     | \
   -----|-------
   30\n1300\nL0003\n235M%_O
| 32|357|273|01|00|00272|227|010|341|216|360|17C|020|261|_367
| 1229|03|13|C35d4<1337|006Q\|351|('\|2330|0311|263Qf
| 34\1262|200|3015|235|036AK|242fl\|315g\|32
| 70|2170|304|361|355|220|021|320|200%|264|274|B
| 21|377|363|235|365|03|230|364|331|303|237t|27=  \
| f\|015|004|224|231|263|225|032|271a|001|035|277|021|375X|323|304|305|  \
| 30|34\|334|0131\|325|34\|3\|362|0
| 37\|251|336|303|340|377\|011275\|301|MY\|334|343|245|244|372y|257S
| 374\|230|346|277|373W|346|230|276
| 017fi|\226q\|307\|012|326|3646|000\|326|005\|E\|364W\|252=zz|010\|(:343
\|237|2571qO\|0326|350|v0|362|327|350|
```
4. Extract the public.key ID from the database:

```sql
SELECT pgp_key_id(dearmor('-----BEGIN PGP PUBLIC KEY BLOCK-----
Version: GnuPG v2.0.14 (GNU/Linux)
mQENBFS1zF0BCADNwQvk1V1C36Kfcwd3Kpm/dijPfRyyEwB6pQyA05jtWixZTh
2HislojzSP6Li0cSkIqMU09ALnecce2rHRiHvuVgK1G9gd9texg2nnSL9Admkqk/yX
RSvyVKG+qcdWuyyZ9gO0OoMeyyjgc3n+kkbRTEmuM3f7ibMs8shOwZMvstCUVmuHU/V
... WH+N2lasOauJhb2kQRhLOnFbJuevkyBy1Rz+iH+/+RrJKc2OjQkmmK8HKhkq5bq5x/
HMUC55Hq02qQAyO0BpnJHg0QOQ45q6pk3GZ/7Dbek5WJ6KUfY5lsaNieGE8pvgEx
/UU2B+YqCwtyx0innBuIKNCmkzAKkEcFk3YoliCiXmdOxhFOv9AKjjojDyC65Kjci
PV2M1PfSkFOAg1R3pMa8zDEt14w3VckPQNrQuYuTfj6ZozCvv
=XZ8J
-----END PGP PUBLIC KEY BLOCK-----'));
pgp_key_id | 9D4D255F4FD2EFBB
```

This shows that the PGP key ID used to encrypt the `ssn` column is `9D4D255F4FD2EFBB`. It is recommended to perform this step whenever a new key is created and then store the ID for tracking.
You can use this key to see which key pair was used to encrypt the data:

```
SELECT username, pgp_key_id(ssn) AS key_used
FROM userssn;
```

```
username | Alice
---------+-----------------
key_used | 9D4D255F4FD2EFBB
```

**Note:** Different keys may have the same ID. This is rare, but is a normal event. The client application should try to decrypt with each one to see which fits — like handling ANYKEY. See `pgp_key_id()` in the pgcrypto documentation.

5. Decrypt the data using the private key.

```
SELECT username, pgp_pub_decrypt(ssn, keys.privkey)
AS decrypted_ssn FROM userssn
CROSS JOIN
(SELECT dearmor('-----BEGIN PGP PRIVATE KEY BLOCK-----
Version: GnuPG v2.0.14 (GNU/Linux)

Encrypted gpdist Connections

The gpdist protocol is a secure version of the gpfdist protocol that securely identifies the file server and the Greenplum Database and encrypts the communications between them. Using gpdist protects against eavesdropping and man-in-the-middle attacks.

The gpdist protocol implements client/server SSL security with the following notable features:

- Client certificates are required.
- Multilingual certificates are not supported.
- A Certificate Revocation List (CRL) is not supported.
- The TLSv1 protocol is used with the TLS_RSA_WITH_AES_128_CBC_SHA encryption algorithm. These SSL parameters cannot be changed.
- SSL renegotiation is supported.
- The SSL ignore host mismatch parameter is set to false.
- Private keys containing a passphrase are not supported for the gpdist file server (server.key) or for the Greenplum Database (client.key).
- It is the user's responsibility to issue certificates that are appropriate for the operating system in use. Generally, converting certificates to the required format is supported, for example using the SSL Converter at https://www.sslshopper.com/ssl-converter.html.

A gpdist server started with the --ssl option can only communicate with the gpdist protocol. A gpfdist server started without the --ssl option can only communicate with the gpdist protocol. For more detail about gpdist refer to the Greenplum Database Administrator Guide.

There are two ways to enable the gpdist protocol:

- Run gpdist with the --ssl option and then use the gpdist protocol in the LOCATION clause of a CREATE EXTERNAL TABLE statement.
- Use a YAML control file with the SSL option set to true and run gpload. Running gpload starts the gpdist server with the --ssl option and then uses the gpdist protocol.

When using gpdist, the following client certificates must be located in the $PGDATA/gpdist directory on each segment.
- The client certificate file, `client.crt`
- The client private key file, `client.key`
- The trusted certificate authorities, `root.crt`

**Important:** Do not protect the private key with a passphrase. The server does not prompt for a passphrase for the private key, and loading data fails with an error if one is required.

When using `gpload` with SSL you specify the location of the server certificates in the YAML control file. When using `gpfdist` with SSL, you specify the location of the server certificates with the `--ssl` option.

The following example shows how to securely load data into an external table. The example creates a readable external table named `ext_expenses` from all files with the `.txt` extension, using the `gpfdists` protocol. The files are formatted with a pipe (|) as the column delimiter and an empty space as null.

1. Run `gpfdist` with the `--ssl` option on the segment hosts.
2. Log into the database and execute the following command:

```sql
=# CREATE EXTERNAL TABLE ext_expenses
   ( name text, date date, amount float4, category text, desc1 text )
  LOCATION ('gpfdists://etlhost-1:8081/*.txt', 'gpfdists://etlhost-2:8082/*.txt')
 FORMAT 'TEXT' ( DELIMITER '|' NULL ' ' ) ;
```
Tuning SQL Queries

The Greenplum Database cost-based optimizer evaluates many strategies for executing a query and chooses the least costly method.

Like other RDBMS optimizers, the Greenplum optimizer takes into account factors such as the number of rows in tables to be joined, availability of indexes, and cardinality of column data when calculating the costs of alternative execution plans. The optimizer also accounts for the location of the data, preferring to perform as much of the work as possible on the segments and to minimize the amount of data that must be transmitted between segments to complete the query.

When a query runs slower than you expect, you can view the plan the optimizer selected as well as the cost it calculated for each step of the plan. This will help you determine which steps are consuming the most resources and then modify the query or the schema to provide the optimizer with more efficient alternatives. You use the SQL EXPLAIN statement to view the plan for a query.

The optimizer produces plans based on statistics generated for tables. It is important to have accurate statistics to produce the best plan. See Updating Statistics with ANALYZE in this guide for information about updating statistics.

How to Generate Explain Plans

The EXPLAIN and EXPLAIN ANALYZE statements are useful tools to identify opportunities to improve query performance. EXPLAIN displays the query plan and estimated costs for a query, but does not execute the query. EXPLAIN ANALYZE executes the query in addition to displaying the query plan. EXPLAIN ANALYZE discards any output from the SELECT statement; however, other operations in the statement are performed (for example, INSERT, UPDATE, or DELETE). To use EXPLAIN ANALYZE on a DML statement without letting the command affect the data, explicitly use EXPLAIN ANALYZE in a transaction (BEGIN; EXPLAIN ANALYZE ...; ROLLBACK;).

EXPLAIN ANALYZE runs the statement in addition to displaying the plan with additional information as follows:
- Total elapsed time (in milliseconds) to run the query
- Number of workers (segments) involved in a plan node operation
- Maximum number of rows returned by the segment (and its segment ID) that produced the most rows for an operation
- The memory used by the operation
- Time (in milliseconds) it took to retrieve the first row from the segment that produced the most rows, and the total time taken to retrieve all rows from that segment.

How to Read Explain Plans

An explain plan is a report detailing the steps the Greenplum Database optimizer has determined it will follow to execute a query. The plan is a tree of nodes, read from bottom to top, with each node passing its result to the node directly above. Each node represents a step in the plan, and one line for each node identifies the operation performed in that step—for example, a scan, join, aggregation, or sort operation. The node also identifies the method used to perform the operation. The method for a scan operation, for example, may be a sequential scan or an index scan. A join operation may perform a hash join or nested loop join.

Following is an explain plan for a simple query. This query finds the number of rows in the contributions table stored at each segment.
This plan has eight nodes – Seq Scan, Sort, GroupAggregate, Result, Redistribute Motion, Sort, GroupAggregate, and finally Gather Motion. Each node contains three cost estimates: cost (in sequential page reads), the number of rows, and the width of the rows.

The cost is a two-part estimate. A cost of 1.0 is equal to one sequential disk page read. The first part of the estimate is the start-up cost, which is the cost of getting the first row. The second estimate is the total cost, the cost of getting all of the rows.

The rows estimate is the number of rows output by the plan node. The number may be lower than the actual number of rows processed or scanned by the plan node, reflecting the estimated selectivity of WHERE clause conditions. The total cost assumes that all rows will be retrieved, which may not always be the case (for example, if you use a LIMIT clause).

The width estimate is the total width, in bytes, of all the columns output by the plan node.

The cost estimates in a node include the costs of all its child nodes, so the top-most node of the plan, usually a Gather Motion, has the estimated total execution costs for the plan. This is this number that the query planner seeks to minimize.

Scan operators scan through rows in a table to find a set of rows. There are different scan operators for different types of storage. They include the following:

- Seq Scan on tables — scans all rows in the table.
- Index Scan — traverses an index to fetch the rows from the table.
- Bitmap Heap Scan — gathers pointers to rows in a table from an index and sorts by location on disk. (The operator is called a Bitmap Heap Scan, even for append-only tables.)
- Dynamic Seq Scan — chooses partitions to scan using a partition selection function.

Join operators include the following:

- Hash Join – builds a hash table from the smaller table with the join column(s) as hash key. Then scans the larger table, calculating the hash key for the join column(s) and probing the hash table to find the rows with the same hash key. Hash joins are typically the fastest joins in Greenplum Database. The Hash Cond in the explain plan identifies the columns that are joined.
- Nested Loop – iterates through rows in the larger dataset, scanning the rows in the smaller dataset on each iteration. The Nested Loop join requires the broadcast of one of the tables so that all rows in one table can be compared to all rows in the other table. It performs well for small tables or tables that are limited by using an index. It is also used for Cartesian joins and range joins. There are performance implications when using a Nested Loop join operator, validate the SQL and ensure that the results are what is intended. Set the enable_nestloop server configuration parameter to OFF (default) to favor Hash Join.
- Merge Join – sorts both datasets and merges them together. A merge join is fast for pre-ordered data, but is very rare in the real world. To favor Merge Joins over Hash Joins, set the enable_mergejoin system configuration parameter to ON.

Some query plan nodes specify motion operations. Motion operations move rows between segments when required to process the query. The node identifies the method used to perform the motion operation. Motion operators include the following:

- Broadcast motion – each segment sends its own, individual rows to all other segments so that every segment instance has a complete local copy of the table. A Broadcast motion may not be as optimal as a Redistribute motion, so the optimizer typically only selects a Broadcast motion for small tables. A Broadcast motion is not acceptable for large tables. In the case where data was not distributed on the join key, a dynamic redistribution of the needed rows from one of the tables to another segment is performed.
- Redistribute motion – each segment rehashes the data and sends the rows to the appropriate segments according to hash key.
- Gather motion – result data from all segments is assembled into a single stream. This is the final operation for most query plans.

Other operators that occur in query plans include the following:
- **Materialize** – the planner materializes a subselect once so it does not have to repeat the work for each top-level row.
- **InitPlan** – a pre-query, used in dynamic partition elimination, performed when the values the planner needs to identify partitions to scan are unknown until execution time.
- **Sort** – sort rows in preparation for another operation requiring ordered rows, such as an Aggregation or Merge Join.
- **Group By** – groups rows by one or more columns.
- **Group/Hash Aggregate** – aggregates rows using a hash.
- **Append** – concatenates data sets, for example when combining rows scanned from partitions in a partitioned table.
- **Filter** – selects rows using criteria from a `WHERE` clause.
- **Limit** – limits the number of rows returned.

**Optimizing Greenplum Queries**

This topic describes Greenplum Database features and programming practices that can be used to enhance system performance in some situations.

To analyze query plans, first identify the plan nodes where the estimated cost to perform the operation is very high. Determine if the estimated number of rows and cost seems reasonable relative to the number of rows for the operation performed.

If using partitioning, validate that partition elimination is achieved. To achieve partition elimination the query predicate (`WHERE` clause) must be the same as the partitioning criteria. Also, the `WHERE` clause must not contain an explicit value and cannot contain a subquery.

Review the execution order of the query plan tree. Review the estimated number of rows. You want the execution order to build on the smaller tables or hash join result and probe with larger tables. Optimally, the largest table is used for the final join or probe to reduce the number of rows being passed up the tree to the topmost plan nodes. If the analysis reveals that the order of execution builds and/or probes is not optimal ensure that database statistics are up to date. Running `ANALYZE` will likely address this and produce an optimal query plan.

Look for evidence of computational skew. Computational skew occurs during query execution when execution of operators such as Hash Aggregate and Hash Join cause uneven execution on the segments. More CPU and memory are used on some segments than others, resulting in less than optimal execution. The cause could be joins, sorts, or aggregations on columns that have low cardinality or non-uniform distributions. You can detect computational skew in the output of the `EXPLAIN ANALYZE` statement for a query. Each node includes a count of the maximum rows processed by any one segment and the average rows processed by all segments. If the maximum row count is much higher than the average, at least one segment has performed much more work than the others and computational skew should be suspected for that operator.

Identify plan nodes where a Sort or Aggregate operation is performed. Hidden inside an Aggregate operation is a Sort. If the Sort or Aggregate operation involves a large number of rows, there is an opportunity to improve query performance. A HashAggregate operation is preferred over Sort and Aggregate operations when a large number of rows are required to be sorted. Usually a Sort operation is chosen by the optimizer due to the SQL construct; that is, due to the way the SQL is written. Most Sort operations can be replaced with a HashAggregate if the query is rewritten. To favor a HashAggregate operation over a Sort and Aggregate operation ensure that the `enable_groupagg` server configuration parameter is set to `ON`.

When an explain plan shows a broadcast motion with a large number of rows, you should attempt to eliminate the broadcast motion. One way to do this is to use the `gp_segments_for_planner` server configuration parameter to increase the cost estimate of the motion so that alternatives are favored. The `gp_segments_for_planner` variable tells the query planner how many primary segments to use in its calculations. The default value is zero, which tells the planner to use the actual number of primary segments in estimates. Increasing the number of primary segments increases the cost...
of the motion, thereby favoring a redistribute motion over a broadcast motion. For example, setting `gp_segments_for_planner = 100000` tells the planner that there are 100,000 segments. Conversely, to influence the optimizer to broadcast a table and not redistribute it, set `gp_segments_for_planner` to a low number, for example 2.

**Greenplum Grouping Extensions**

Greenplum Database aggregation extensions to the `GROUP BY` clause can perform some common calculations in the database more efficiently than in application or procedure code:

- `GROUP BY ROLLUP(col1, col2, col3)`
- `GROUP BY CUBE(col1, col2, col3)`
- `GROUP BY GROUPING SETS((col1, col2), (col1, col3))`

A `ROLLUP` grouping creates aggregate subtotals that roll up from the most detailed level to a grand total, following a list of grouping columns (or expressions). `ROLLUP` takes an ordered list of grouping columns, calculates the standard aggregate values specified in the `GROUP BY` clause, then creates progressively higher-level subtotals, moving from right to left through the list. Finally, it creates a grand total.

A `CUBE` grouping creates subtotals for all of the possible combinations of the given list of grouping columns (or expressions). In multidimensional analysis terms, `CUBE` generates all the subtotals that could be calculated for a data cube with the specified dimensions.

You can selectively specify the set of groups that you want to create using a `GROUPING SETS` expression. This allows precise specification across multiple dimensions without computing a whole `ROLLUP` or `CUBE`.

Refer to the *Greenplum Database Reference Guide* for details of these clauses.

**Window Functions**

Window functions apply an aggregation or ranking function over partitions of the result set—for example, `sum(population) over (partition by city)`. Window functions are powerful and, because they do all of the work in the database, they have performance advantages over front-end tools that produce similar results by retrieving detail rows from the database and reprocessing them.

- The `row_number()` window function produces row numbers for the rows in a partition, for example, `row_number() over (order by id)`.
- When a query plan indicates that a table is scanned in more than one operation, you may be able to use window functions to reduce the number of scans.
- It is often possible to eliminate self joins by using window functions.
High Availability

Greenplum Database supports highly available, fault-tolerant database services when you enable and properly configure Greenplum high availability features. To guarantee a required level of service, each component must have a standby ready to take its place if it should fail.

Disk Storage

With the Greenplum Database "shared-nothing" MPP architecture, the master host and segment hosts each have their own dedicated memory and disk storage, and each master or segment instance has its own independent data directory. For both reliability and high performance, Pivotal recommends a hardware RAID storage solution with from 8 to 24 disks. A larger number of disks improves I/O throughput when using RAID 5 (or 6) because striping increases parallel disk I/O. The RAID controller can continue to function with a failed disk because it saves parity data on each disk in a way that it can reconstruct the data on any failed member of the array. If a hot spare is configured (or an operator replaces the failed disk with a new one) the controller rebuilds the failed disk automatically.

RAID 1 exactly mirrors disks, so if a disk fails, a replacement is immediately available with performance equivalent to that before the failure. With RAID 5 each I/O for data on the failed array member must be reconstructed from data on the remaining active drives until the replacement disk is rebuilt, so there is a temporary performance degradation. If the Greenplum master and segments are mirrored, you can switch any affected Greenplum instances to their mirrors during the rebuild to maintain acceptable performance.

A RAID disk array can still be a single point of failure, for example, if the entire RAID volume fails. At the hardware level, you can protect against a disk array failure by mirroring the array, using either host operating system mirroring or RAID controller mirroring, if supported.

It is important to regularly monitor available disk space on each segment host. Query the `gp_disk_free` external table in the `gptoolkit` schema to view disk space available on the segments. This view runs the Linux `df` command. Be sure to check that there is sufficient disk space before performing operations that consume large amounts of disk, such as copying a large table.

See `gp_toolkit.gp_disk_free` in the Greenplum Database Reference Guide.

Best Practices

• Use a hardware RAID storage solution with 8 to 24 disks.
• Use RAID 1, 5, or 6 so that the disk array can tolerate a failed disk.
• Configure a hot spare in the disk array to allow rebuild to begin automatically when disk failure is detected.
• Protect against failure of the entire disk array and degradation during rebuilds by mirroring the RAID volume.
• Monitor disk utilization regularly and add additional space when needed.
• Monitor segment skew to ensure that data is distributed evenly and storage is consumed evenly at all segments.

Master Mirroring

The Greenplum Database master instance is clients' single point of access to the system. The master instance stores the global system catalog, the set of system tables that store metadata about the database instance, but no user data. If an unmirrored master instance fails or becomes inaccessible, the Greenplum instance is effectively off-line, since the entry point to the system has been lost. For this reason, a standby master must be ready to take over if the primary master fails.

Master mirroring uses two processes, a sender on the active master host and a receiver on the mirror host, to synchronize the mirror with the master. As changes are applied to the master system catalogs,
the active master streams its write-ahead log (WAL) to the mirror so that each transaction applied on the
master is applied on the mirror.

The mirror is a warm standby. If the primary master fails, switching to the standby requires an
administrative user to run the `gpactivatestandby` utility on the standby host so that it begins to
accept client connections. Clients must reconnect to the new master and will lose any work that was not
committed when the primary failed.

See "Enabling High Availability Features" in the *Greenplum Database Administrator Guide* for more
information.

**Best Practices**

- Set up a standby master instance—a mirror—to take over if the primary master fails.
- The standby can be on the same host or on a different host, but it is best practice to place it on a
different host from the primary master to protect against host failure.
- Plan how to switch clients to the new master instance when a failure occurs, for example, by updating
the master address in DNS.
- Set up monitoring to send notifications in a system monitoring application or by email when the primary
fails.

**Segment Mirroring**

Greenplum Database segment instances each store and manage a portion of the database data, with
coordination from the master instance. If any unmirrored segment fails, the database may have to be
shutdown and recovered, and transactions occurring after the most recent backup could be lost. Mirroring
segments is, therefore, an essential element of a high availability solution.

A segment mirror is a hot standby for a primary segment. Greenplum Database detects when a segment
is unavailable and automatically activates the mirror. During normal operation, when the primary segment
instance is active, data is replicated from the primary to the mirror in two ways:

- The transaction commit log is replicated from the primary to the mirror before the transaction is
committed. This ensures that if the mirror is activated, the changes made by the last successful
transaction at the primary are present at the mirror. When the mirror is activated, transactions in the log
are applied to tables in the mirror.
- Second, segment mirroring uses physical file replication to update heap tables. Greenplum Server
stores table data on disk as fixed-size blocks packed with tuples. To optimize disk I/O, blocks are
cached in memory until the cache fills and some blocks must be evicted to make room for newly
updated blocks. When a block is evicted from the cache it is written to disk and replicated over the
network to the mirror. Because of the caching mechanism, table updates at the mirror can lag behind
the primary. However, because the transaction log is also replicated, the mirror remains consistent
with the primary. If the mirror is activated, the activation process updates the tables with any unapplied
changes in the transaction commit log.

When the acting primary is unable to access its mirror, replication stops and state of the primary changes
to "Change Tracking." The primary saves changes that have not been replicated to the mirror in a system
table to be replicated to the mirror when it is back on-line.

The master automatically detects segment failures and activates the mirror. Transactions in progress at the
time of failure are restarted using the new primary. Depending on how mirrors are deployed on the hosts,
the database system may be unbalanced until the original primary segment is recovered. For example, if
each segment host has four primary segments and four mirror segments, and a mirror is activated on one
host, that host will have five active primary segments. Queries are not complete until the last segment has
finished its work, so performance can be degraded until the balance is restored by recovering the original
primary.

Administrators perform the recovery while Greenplum Database is up and running by running the
`gprecoverseg` utility. This utility locates the failed segments, verifies they are valid, and compares the
transactional state with the currently active segment to determine changes made while the segment was offline. `gprecoverseg` synchronizes the changed database files with the active segment and brings the segment back online.

It is important to reserve enough memory and CPU resources on segment hosts to allow for increased activity from mirrors that assume the primary role during a failure. The formulas provided in Configuring Memory for Greenplum Database for configuring segment host memory include a factor for the maximum number of primary hosts on any one segment during a failure. The arrangement of mirrors on the segment hosts affects this factor and how the system will respond during a failure. See Segment Mirroring Configuration for a discussion of segment mirroring options.

**Best Practices**

- Set up mirrors for all segments.
- Locate primary segments and their mirrors on different hosts to protect against host failure.
- Mirrors can be on a separate set of hosts or co-located on hosts with primary segments.
- Set up monitoring to send notifications in a system monitoring application or by email when a primary segment fails.
- Recover failed segments promptly, using the `gprecoverseg` utility, to restore redundancy and return the system to optimal balance.

**Dual Clusters**

For some use cases, an additional level of redundancy can be provided by maintaining two Greenplum Database clusters that store the same data. The decision to implement dual clusters should be made with business requirements in mind.

There are two recommended methods for keeping the data synchronized in a dual cluster configuration. The first method is called Dual ETL. ETL (extract, transform, and load) is the common data warehousing process of cleansing, transforming, validating, and loading data into a data warehouse. With Dual ETL, the ETL processes are performed twice, in parallel on each cluster, and validated each time. Dual ETL provides for a complete standby cluster with the same data. It also provides the capability to query the data on both clusters, doubling the processing throughput. The application can take advantage of both clusters as needed and also ensure that the ETL is successful and validated on both sides.

The second mechanism for maintaining dual clusters is backup and restore. The data is backed up on the primary cluster, then the backup is replicated to and restored on the second cluster. The backup and restore mechanism has higher latency than Dual ETL, but requires less application logic to be developed. Backup and restore is ideal for use cases where data modifications and ETL are done daily or less frequently.

**Best Practices**

- Consider a Dual Cluster configuration to provide an additional level of redundancy and additional query processing throughput.

**Backup and Restore**

Backups are recommended for Greenplum Database databases unless the data in the database can be easily and cleanly regenerated from source data. Backups protect from operational, software, or hardware errors.

The `gpbackup` utility makes backups in parallel across the segments, so that backups scale as the cluster grows in hardware size.

A backup strategy must consider where the backups will be written and where they will be stored. Backups can be taken to the local cluster disks, but they should not be stored there permanently. If the database and its backup are on the same storage, they can be lost simultaneously. The backup also occupies space
that could be used for database storage or operations. After performing a local backup, the files should be copied to a safe, off-cluster location.

An alternative is to back up directly to an NFS mount. If each host in the cluster has an NFS mount, the backups can be written directly to NFS storage. A scale-out NFS solution is recommended to ensure that backups do not bottleneck on the IO throughput of the NFS device. Dell EMC Isilon is an example of this type of solution and can scale alongside the Greenplum cluster.

Finally, through native API integration, Greenplum Database can stream backups directly to the Dell EMC Data Domain enterprise backup platform.

**Best Practices**

- Back up Greenplum databases regularly unless the data is easily restored from sources.
- Use the `gpbackup` command to specify only the schema and tables that you want backed up. See the `gpbackup` reference in the *Greenplum Database Utility Reference Guide* for more information.
- `gpbackup` places SHARED ACCESS locks on the set of tables to back up. Backups with fewer tables are more efficient for selectively restoring schemas and tables, since `gprestore` does not have to search through the entire database.
- If backups are saved to local cluster storage, move the files to a safe, off-cluster location when the backup is complete. Backup files and database files that reside on the same storage can be lost simultaneously.
- If backups are saved to NFS mounts, use a scale-out NFS solution such as Dell EMC Isilon to prevent IO bottlenecks.
- Consider using Pivotal Greenplum Database integration to stream backups to the Dell EMC Data Domain enterprise backup platform.

**Detecting Failed Master and Segment Instances**

Recovering from system failures requires intervention from a system administrator, even when the system detects a failure and activates a standby for the failed component. In each case, the failed component must be replaced or recovered to restore full redundancy. Until the failed component is recovered, the active component lacks a standby, and the system may not be executing optimally. For these reasons, it is important to perform recovery operations promptly. Constant system monitoring ensures that administrators are aware of failures that demand their attention.

The Greenplum Database server `ftsprobe` subprocess handles fault detection. `ftsprobe` connects to and scans all segments and database processes at intervals that you can configure with the `gp_fts_probe_interval` configuration parameter. If `ftsprobe` cannot connect to a segment, it marks the segment “down” in the Greenplum Database system catalog. The segment remains down until an administrator runs the `gprecoverseg` recovery utility.

**Best Practices**

- Run the `gpstate` utility to see the overall state of the Greenplum system.

*Greenplum Database Utility Guide*:

- `gpstate`—view state of the Greenplum system
- `gprecoverseg`—recover a failed segment
- `gpactivatestandby`—make the standby master the active master

*RDBMS MIB Specification*
Segment Mirroring Configuration

Segment mirroring allows database queries to fail over to a backup segment if the primary segment fails or becomes unavailable. Pivotal requires mirroring for supported production Greenplum Database systems.

A primary segment and its mirror must be on different hosts to ensure high availability. Each host in a Greenplum Database system has the same number of primary segments and mirror segments. Multi-homed hosts should have the same numbers of primary and mirror segments on each interface. This ensures that segment hosts and network resources are equally loaded when all primary segments are operational and brings the most resources to bear on query processing.

When a segment becomes unavailable, its mirror segment on another host becomes the active primary and processing continues. The additional load on the host creates skew and degrades performance, but should allow the system to continue. A database query is not complete until all segments return results, so a single host with an additional active primary segment has the same effect as adding an additional primary segment to every host in the cluster.

The least amount of performance degradation in a failover scenario occurs when no host has more than one mirror assuming the primary role. If multiple segments or hosts fail, the amount of degradation is determined by the host or hosts with the largest number of mirrors assuming the primary role. Spreading a host's mirrors across the remaining hosts minimizes degradation when any single host fails.

It is important, too, to consider the cluster's tolerance for multiple host failures and how to maintain a mirror configuration when expanding the cluster by adding hosts. There is no mirror configuration that is ideal for every situation.

You can allow Greenplum Database to arrange mirrors on the hosts in the cluster using one of two standard configurations, or you can design your own mirroring configuration.

The two standard mirroring arrangements are group mirroring and spread mirroring:

- **Group mirroring** — Each host mirrors another host's primary segments. This is the default for `gpinitsystem` and `gpaddmirrors`.
- **Spread mirroring** — Mirrors are spread across the available hosts. This requires that the number of hosts in the cluster is greater than the number of segments per host.

You can design a custom mirroring configuration and use the Greenplum `gpaddmirrors` or `gpaddmirrors` utilities to set up the configuration.

*Block mirroring* is a custom mirror configuration that divides hosts in the cluster into equally sized blocks and distributes mirrors evenly to hosts within the block. If a primary segment fails, its mirror on another host within the same block becomes the active primary. If a segment host fails, mirror segments on each of the other hosts in the block become active.

The following sections compare the group, spread, and block mirroring configurations.

**Group Mirroring**

Group mirroring is easiest to set up and is the default Greenplum mirroring configuration. It is least expensive to expand, since it can be done by adding as few as two hosts. There is no need to move mirrors after expansion to maintain a consistent mirror configuration.

The following diagram shows a group mirroring configuration with eight primary segments on four hosts.
Unless both the primary and mirror of the same segment instance fail, up to half of your hosts can fail and the cluster will continue to run as long as resources (CPU, memory, and IO) are sufficient to meet the needs.

Any host failure will degrade performance by half or more because the host with the mirrors will have twice the number of active primaries. If your resource utilization is normally greater than 50%, you will have to adjust your workload until the failed host is recovered or replaced. If you normally run at less than 50% resource utilization the cluster can continue to operate at a degraded level of performance until the failure is corrected.

**Spread Mirroring**

With spread mirroring, mirrors for each host's primary segments are spread across as many hosts as there are segments per host. Spread mirroring is easy to set up when the cluster is initialized, but requires that the cluster have at least one more host than there are segments per host.

The following diagram shows the spread mirroring configuration for a cluster with three primaries on four hosts.
Expanding a cluster with spread mirroring requires more planning and may take more time. You must either add a set of hosts equal to the number of primaries per host plus one, or you can add two nodes in a group mirroring configuration and, when the expansion is complete, move mirrors to recreate the spread mirror configuration.

Spread mirroring has the least performance impact for a single failed host because each host's mirrors are spread across the maximum number of hosts. Load is increased by $1/Nth$, where $N$ is the number of primaries per host. Spread mirroring is, however, the most likely configuration to suffer catastrophic failure if two or more hosts fail simultaneously.

**Block Mirroring**

With block mirroring, nodes are divided into blocks, for example a block of four or eight hosts, and the mirrors for segments on each host are placed on other hosts within the block. Depending on the number of hosts in the block and the number of primary segments per host, each host maintains more than one mirror for each other host's segments.

The following diagram shows a single block mirroring configuration for a block of four hosts, each with eight primary segments:
If there are eight hosts, an additional four-host block is added with the mirrors for primary segments 32 through 63 set up in the same pattern.

A cluster with block mirroring is easy to expand because each block is a self-contained primary mirror group. The cluster is expanded by adding one or more blocks. There is no need to move mirrors after expansion to maintain a consistent mirror setup. This configuration is able to survive multiple host failures as long as the failed hosts are in different blocks.

Because each host in a block has multiple mirror instances for each other host in the block, block mirroring has a higher performance impact for host failures than spread mirroring, but a lower impact than group mirroring. The expected performance impact varies by block size and primary segments per node. As with group mirroring, if the resources are available, performance will be negatively impacted but the cluster will remain available. If resources are insufficient to accommodate the added load you must reduce the workload until the failed node is replaced.

**Implementing Block Mirroring**

Block mirroring is not one of the automatic options Greenplum Database offers when you set up or expand a cluster. To use it, you must create your own configuration.
For a new Greenplum system, you can initialize the cluster without mirrors, and then run `gpaddmirrors -i mirror_config_file` with a custom mirror configuration file to create the mirrors for each block. You must create the file system locations for the mirror segments before you run `gpaddmirrors`. See the `gpaddmirrors` reference page in the *Greenplum Database Management Utility Guide* for details.

If you expand a system that has block mirroring or you want to implement block mirroring at the same time you expand a cluster, it is recommended that you complete the expansion first, using the default grouping mirror configuration, and then use the `gpmovemirrors` utility to move mirrors into the block configuration.

To implement block mirroring with an existing system that has a different mirroring scheme, you must first determine the desired location for each mirror according to your block configuration, and then determine which of the existing mirrors must be relocated. Follow these steps:

1. Run the following query to find the current locations of the primary and mirror segments:

   ```sql
   SELECT dbid, content, role, port, hostname, datadir FROM gp_segment_configuration WHERE content > -1 ;
   ```

   The `gp_segment_configuration` system catalog table contains the current segment configuration.

2. Create a list with the current mirror location and the desired block mirroring location, then remove any mirrors from the list that are already on the correct host.

3. Create an input file for the `gpmovemirrors` utility with an entry for each mirror that must be moved. The `gpmovemirrors` input file has the following format:

   ```text
   contentID|address|port|data_dir new_address|port|data_dir
   ```

   Where `contentID` is the segment instance content ID, `address` is the host name or IP address of the segment host, `port` is the communication port, and `data_dir` is the segment instance data directory.

   The following example `gpmovemirrors` input file specifies three mirror segments to move.

   ```text
   1|sdw2|50001|/data2/mirror/gpseg1 sdw3|50001|/data/mirror/gpseg1
   2|sdw2|50001|/data2/mirror/gpseg2 sdw4|50001|/data/mirror/gpseg2
   3|sdw3|50001|/data2/mirror/gpseg3 sdw1|50001|/data/mirror/gpseg3
   ```

4. Run `gpmovemirrors` with a command like the following:

   ```bash
   gpmovemirrors -i mirror_config_file
   ```

   The `gpmovemirrors` utility validates the input file, calls `gprecoverseg` to relocate each specified mirror, and removes the original mirror. It creates a backout configuration file which can be used as input to `gpmovemirrors` to undo the changes that were made. The backout file has the same name as the input file, with the suffix `_backout_timestamp` added.

   See the *Greenplum Database Management Utility Reference* for complete information about the `gpmovemirrors` utility.
Chapter 12

Greenplum Database Utility Guide

Reference information for Greenplum Database utility programs.
About the Greenplum Database Utilities

General information about using the Greenplum Database utility programs.

Referencing IP Addresses

When you reference IPv6 addresses in Greenplum Database utility programs, or when you use numeric IP addresses instead of hostnames in any management utility, always enclose the IP address in brackets. When specifying an IP address at the command line, the best practice is to escape any brackets or enclose them in single quotes. For example, use either:

\[2620:0:170:610::11\]

Or:

'\[2620:0:170:610::11\]'

Running Backend Server Programs

Greenplum Database has modified certain PostgreSQL backend server programs to handle the parallelism and distribution of a Greenplum Database system. You access these programs only through the Greenplum Database management tools and utilities. *Do not run these programs directly.*

The following table identifies certain PostgreSQL backend server programs and the Greenplum Database utility command to run instead.

Table 62: Greenplum Database Backend Server Programs

<table>
<thead>
<tr>
<th>PostgreSQL Program Name</th>
<th>Description</th>
<th>Use Instead</th>
</tr>
</thead>
<tbody>
<tr>
<td>initdb</td>
<td>This program is called by gpinitsystem when initializing a Greenplum Database array. It is used internally to create the individual segment instances and the master instance.</td>
<td>gpinitsystem</td>
</tr>
<tr>
<td>ipcclean</td>
<td>Not used in Greenplum Database</td>
<td>N/A</td>
</tr>
<tr>
<td>pg_basebackup</td>
<td>This program makes a binary copy of a single database instance. Greenplum Database uses it for tasks such as creating a standby master instance, or recovering a mirror segment when a full copy is needed. Do not use this utility to back up Greenplum Database segment instances because it does not produce MPP-consistent backups.</td>
<td>gpinitstandby, gprecoverseg</td>
</tr>
<tr>
<td>pg_controldata</td>
<td>Not used in Greenplum Database</td>
<td>gpstate</td>
</tr>
<tr>
<td>PostgreSQL Program Name</td>
<td>Description</td>
<td>Use Instead</td>
</tr>
<tr>
<td>-------------------------</td>
<td>-------------</td>
<td>-------------</td>
</tr>
<tr>
<td><strong>pg_ctl</strong></td>
<td>This program is called by <code>gpstart</code> and <code>gpstop</code> when starting or stopping a Greenplum Database array. It is used internally to stop and start the individual segment instances and the master instance in parallel and with the correct options.</td>
<td><code>gpstart</code>, <code>gpstop</code></td>
</tr>
</tbody>
</table>
| **pg_resetxlog**        | **DO NOT USE**  
**Warning:** This program might cause data loss or cause data to become unavailable. If this program is used, the Pivotal Greenplum Database cluster is not supported. The cluster must be reinitialized and restored by the customer. | N/A |
| **postgres**            | The `postgres` executable is the actual PostgreSQL server process that processes queries. | The main `postgres` process (postmaster) creates other `postgres` subprocesses and `postgres` session as needed to handle client connections. |
| **postmaster**          | `postmaster` starts the `postgres` database server listener process that accepts client connections. In Greenplum Database, a `postgres` database listener process runs on the Greenplum master Instance and on each Segment Instance. | In Greenplum Database, you use `gpstart` and `gpstop` to start all postmasters (`postgres` processes) in the system at once in the correct order and with the correct options. |
Utility Reference

The command-line utilities provided with Greenplum Database.

Greenplum Database uses the standard PostgreSQL client and server programs and provides additional management utilities for administering a distributed Greenplum Database DBMS.

Several utilities are installed when you install the Greenplum Database server. These utilities reside in $GPHOME/bin. Other utilities must be downloaded from Pivotal Network and installed separately. These include:

- The Pivotal Greenplum Backup and Restore utilities.
- The Pivotal Greenplum gpcopy utility.

Additionally, the Pivotal Greenplum Client and Loader Tools is a separate download from Pivotal Network that includes selected utilities from the Greenplum Database server installation that you can install on a client system.

Greenplum Database provides the following utility programs. Superscripts identify those utilities that require separate downloads, as well as those utilities that are also installed with the Client and Loader Tools Packages. (See the Note following the table.) All utilities are installed when you install the Greenplum Database server, unless specifically identified by a superscript.

Note:

1 The utility program can be obtained from the Greenplum Backup and Restore tile on Pivotal Network.
2 The utility program can be obtained from the Greenplum Data Copy Utility tile on Pivotal Network.
3 The utility program is also installed with the Greenplum Client and Loader Tools Packages for Linux and Windows. You can obtain these packages from the Greenplum Database Greenplum Clients filegroup on Pivotal Network.
4 The utility program is also installed with the Greenplum Client and Loader Tools Package for Linux.

analyzedb

A utility that performs ANALYZE operations on tables incrementally and concurrently. For append optimized tables, analyzedb updates statistics only if the statistics are not current.

Synopsis

analyzedb -d dbname
{ -s schema | 
{ -t schema.table
 [ -i col|[, , ...] | 
 -x col|[, , ...] ] } | 
( -f | --file) config-file
 [ -l | --list ]
 [ --gen_profile_only ]
 [ -p parallel-level ]
 [ --full ]
 [ --skip_root_stats ]
 [ -v | --verbose ]
 [ --debug ]
 [ -a ]

analyzedb { --clean_last | --clean_all }
analyzedb --version
analyzedb { --? | -h | --help }

Description
The `analyzedb` utility updates statistics on table data for the specified tables in a Greenplum database incrementally and concurrently.

While performing `ANALYZE` operations, `analyzedb` creates a snapshot of the table metadata and stores it on disk on the master host. An `ANALYZE` operation is performed only if the table has been modified. If a table or partition has not been modified since the last time it was analyzed, `analyzedb` automatically skips the table or partition because it already contains up-to-date statistics.

- For append optimized tables, `analyzedb` updates statistics incrementally, if the statistics are not current. For example, if table data is changed after statistics were collected for the table. If there are no statistics for the table, statistics are collected.
- For heap tables, statistics are always updated.

Specify the `--full` option to update append-optimized table statistics even if the table statistics are current.

By default, `analyzedb` creates a maximum of 5 concurrent sessions to analyze tables in parallel. For each session, `analyzedb` issues an `ANALYZE` command to the database and specifies different table names. The `--p` option controls the maximum number of concurrent sessions.

Partitioned Append-Optimized Tables
For a partitioned, append-optimized table, `analyzedb` checks the partitioned table root partition and leaf partitions. If needed, the utility updates statistics for non-current partitions and the root partition.

The root partition statistics is required by GPORCA. By default, the `analyzedb` utility collects statistics on the root partition of a partitioned table if the statistics do not exist. If any of the leaf partitions have stale statistics, `analyzedb` also refreshes the root partition statistics. The cost of refreshing the root level statistics is comparable to analyzing one leaf partition. You can specify the option `--skip_root_stats` to disable collection of statistics on the root partition of a partitioned table.

Notes
The `analyzedb` utility updates append optimized table statistics if the table has been modified by DML or DDL commands, including `INSERT`, `DELETE`, `UPDATE`, `CREATE TABLE`, `ALTER TABLE` and `TRUNCATE`. The utility determines if a table has been modified by comparing catalog metadata of tables with the previous snapshot of metadata taken during a previous `analyzedb` operation. The snapshots of table metadata are stored as state files in the directory `db_analyze/<db_name>/<timestamp>` in the Greenplum Database master data directory.

The utility does not automatically remove old snapshot information. Over time, the snapshots can consume a large amount of disk space. To recover disk space, you can keep the most recent snapshot information and remove the older snapshots. You can also specify the `--clean_last` or `--clean_all` option to remove state files generated by `analyzedb`.

If you do not specify a table, set of tables, or schema, the `analyzedb` utility collects the statistics as needed on all system catalog tables and user-defined tables in the database.

External tables are not affected by `analyzedb`.

Table names that contain spaces are not supported.

Running the `ANALYZE` command on a table, not using the `analyzedb` utility, does not update the table metadata that the `analyzedb` utility uses to determine whether table statistics are up to date.

Options
`--clean_last`
Remove the state files generated by last `analyzedb` operation. All other options except `-d` are ignored.

`--clean_all`
Remove all the state files generated by `analyzedb`. All other options except `-d` are ignored.

`-d dbname`
Specifies the name of the database that contains the tables to be analyzed. If this option is not specified, the database name is read from the environment variable `PGDATABASE`. If `PGDATABASE` is not set, the user name specified for the connection is used.

`--debug`
If specified, sets the logging level to debug. During command execution, debug level information is written to the log file and to the command line. The information includes the commands executed by the utility and the duration of each `ANALYZE` operation.

`-f config-file | --file config-file`
Text file that contains a list of tables to be analyzed. A relative file path from current directory can be specified.

The file lists one table per line. Table names must be qualified with a schema name. Optionally, a list of columns can be specified using the `-i` or `-x`. No other options are allowed in the file. Other options such as `--full` must be specified on the command line.

Only one of the options can be used to specify the files to be analyzed: `-f` or `--file`, `-t`, or `-s`.

When performing `ANALYZE` operations on multiple tables, `analyzedb` creates concurrent sessions to analyze tables in parallel. The `-p` option controls the maximum number of concurrent sessions.

In the following example, the first line performs an `ANALYZE` operation on the table `public.nation`, the second line performs an `ANALYZE` operation only on the columns `l_shipdate` and `l_receiptdate` in the table `public.lineitem`.

```
public.nation
public.lineitem -i l_shipdate, l_receiptdate
```

`--full`
Perform an `ANALYZE` operation on all the specified tables. The operation is performed even if the statistics are up to date.

`--gen_profile_only`
Update the `analyzedb` snapshot of table statistics information without performing any `ANALYZE` operations. If other options specify tables or a schema, the utility updates the snapshot information only for the specified tables.

Specify this option if the `ANALYZE` command was run on database tables and you want to update the `analyzedb` snapshot for the tables.

`-i col1, col2, ...`
Optional. Must be specified with the `-t` option. For the table specified with the `-t` option, collect statistics only for the specified columns.

Only `-i`, or `-x` can be specified. Both options cannot be specified.

`-l | --list`
Lists the tables that would have been analyzed with the specified options. The `ANALYZE` operations are not performed.

`-p parallel-level`
The number of tables that are analyzed in parallel. parallel level can be an integer between 1 and 10, inclusive. Default value is 5.

--skip_root_stats
For a partitioned table, skip refreshing root partition statistics if only some of the leaf partitions statistics require updating.

When updating statistics for a partitioned table and you know which leaf partition statistics require updating, you can specify those partitions and this option to improve performance.

For information about how statistics are collected for partitioned tables, see ANALYZE.

GPORCA uses root partition statistics. If you use --skip-root-partition option, you should ensure that root partition statistics are up to date so that GPORCA does not produce inferior query plans due to stale root partition statistics.

-s schema
Specify a schema to analyze. All tables in the schema will be analyzed. Only a single schema name can be specified on the command line.

Only one of the options can be used to specify the files to be analyzed: -f or --file, -t, or -s.

-t schema.table
Collect statistics only on schema.table. The table name must be qualified with a schema name. Only a single table name can be specified on the command line. You can specify the -f option to specify multiple tables in a file or the -s option to specify all the tables in a schema.

Only one of these options can be used to specify the files to be analyzed: -f or --file, -t, or -s.

-x col1, col2, ...
Optional. Must be specified with the -t option. For the table specified with the -t option, exclude statistics collection for the specified columns. Statistics are collected only on the columns that are not listed.

Only -i, or -x can be specified. Both options cannot be specified.

-a
Quiet mode. Do not prompt for user confirmation.

-h | -? | --help
Displays the online help.

-v | --verbose
If specified, sets the logging level to verbose to write additional information the log file and to the command line during command execution. The information includes a list of all the tables to be analyzed (including child leaf partitions of partitioned tables). Output also includes the duration of each ANALYZE operation.

--version
Displays the version of this utility.

Examples
An example that collects statistics only on a set of table columns. In the database mytest, collect statistics on the columns shipdate and receiptdate in the table public.orders:

analyzedb -d mytest -t public.orders -i shipdate, receiptdate
An example that collects statistics on a table and exclude a set of columns. In the database `mytest`,
collect statistics on the table `public.foo`, and do not collect statistics on the columns `bar` and `test2`.

```
analyzedb -d mytest -t public.foo -x bar, test2
```

An example that specifies a file that contains a list of tables. This command collect statistics on the tables
listed in the file `analyze-tables` in the database named `mytest`.

```
analyzedb -d mytest -f analyze-tables
```

If you do not specify a table, set of tables, or schema, the `analyzedb` utility collects the statistics as
needed on all catalog tables and user-defined tables in the specified database. This command refreshes
table statistics on the system catalog tables and user-defined tables in the database `mytest`.

```
analyzedb -d mytest
```

You can create a PL/Python function to run the `analyzedb` utility as a Greenplum Database function.
This example `CREATE FUNCTION` command creates a user defined PL/Python function that runs the
`analyzedb` utility and displays output on the command line. Specify `analyzedb` options as the function
parameter.

```sql
CREATE OR REPLACE FUNCTION analyzedb(params TEXT)
RETURNS VOID AS $BODYS$
    import subprocess
    cmd = ['analyzedb', '-a'] + params.split()
    p = subprocess.Popen(cmd, stdout=subprocess.PIPE, stderr=subprocess.STDOUT)

    # verbose output of process
    for line in iter(p.stdout.readline, ''):
        plpy.info(line);

    p.wait()
$BODYS$
LANGUAGE plpythonu VOLATILE;
```

When this `SELECT` command is run by the gpadmin user, the `analyzedb` utility performs an analyze
operation on the table `public.mytable` that is in the database `mytest`.

```
SELECT analyzedb('-d mytest -t public.mytable') ;
```

**Note:** To create a PL/Python function, the PL/Python procedural language must be registered
as a language in the database. For example, this `CREATE LANGUAGE` command run as gpadmin
registers PL/Python as an untrusted language:

```
CREATE LANGUAGE plpythonu;
```

**See Also**

`ANALYZE` in the Greenplum Database Reference Guide

**clusterdb**

Reclusters tables that were previously clustered with `CLUSTER`. 
Synopsis

```
```

```
clusterdb [connection-option ...] [--all | -a] [--verbose | -v]
```

```
clusterdb -? | --help
```

```
clusterdb -V | --version
```

Description

To cluster a table means to physically reorder a table on disk according to an index so that index scan operations can access data on disk in a somewhat sequential order, thereby improving index seek performance for queries that use that index.

The `clusterdb` utility will find any tables in a database that have previously been clustered with the `CLUSTER` SQL command, and clusters them again on the same index that was last used. Tables that have never been clustered are not affected.

`clusterdb` is a wrapper around the SQL command `CLUSTER`. Although clustering a table in this way is supported in Greenplum Database, it is not recommended because the `CLUSTER` operation itself is extremely slow.

If you do need to order a table in this way to improve your query performance, use a `CREATE TABLE AS` statement to reorder the table on disk rather than using `CLUSTER`. If you do 'cluster' a table in this way, then `clusterdb` would not be relevant.

Options

```
-a | --all
```

Cluster all databases.

```
[[-d] dbname | [--dbname=] dbname]
```

Specifies the name of the database to be clustered. If this is not specified, the database name is read from the environment variable `PGDATABASE`. If that is not set, the user name specified for the connection is used.

```
-e | --echo
```

Echo the commands that `clusterdb` generates and sends to the server.

```
-q | --quiet
```

Do not display a response.

```
-t table | --table=table
```

Cluster the named table only. Multiple tables can be clustered by writing multiple `-t` switches.

```
-v | --verbose
```

Print detailed information during processing.

```
-V | --version
```

Print the `clusterdb` version and exit.

```
-? | --help
```

Show help about `clusterdb` command line arguments, and exit.

Connection Options

```
-h host | --host=host
```

```
The host name of the machine on which the Greenplum master database server is running. If not specified, reads from the environment variable `PGHOST` or defaults to localhost.

```
-p port | --port=port
```

The TCP port on which the Greenplum master database server is listening for connections. If not specified, reads from the environment variable `PGPORT` or defaults to 5432.

```
-U username | --username=username
```

The database role name to connect as. If not specified, reads from the environment variable `PGUSER` or defaults to the current system role name.

```
-w | --no-password
```

Never issue a password prompt. If the server requires password authentication and a password is not available by other means such as a `.pgpass` file, the connection attempt will fail. This option can be useful in batch jobs and scripts where no user is present to enter a password.

```
-W | --password
```

Force a password prompt.

```
--maintenance-db=dbname
```

Specifies the name of the database to connect to discover what other databases should be clustered. If not specified, the `postgres` database will be used, and if that does not exist, `template1` will be used.

**Examples**

To cluster the database *test*:

```
clusterdb test
```

To cluster a single table *foo* in a database named *xyzzy*:

```
clusterdb --table foo xyzzyb
```

**See Also**

`CLUSTER` in the *Greenplum Database Reference Guide*

`createdb`

Creates a new database.

**Synopsis**

```
createdb [connection-option ...] [option ...] [dbname ['description']]
createdb -? | --help
createdb -V | --version
```

**Description**

`createdb` creates a new database in a Greenplum Database system.
Normally, the database user who executes this command becomes the owner of the new database. However, a different owner can be specified via the -o option, if the executing user has appropriate privileges.

createdb is a wrapper around the SQL command \texttt{CREATE DATABASE}.

\textbf{Options}

\textit{dbname}

The name of the database to be created. The name must be unique among all other databases in the Greenplum system. If not specified, reads from the environment variable \texttt{PGDATABASE}, then \texttt{PGUSER} or defaults to the current system user.

\textit{description}

A comment to be associated with the newly created database. Descriptions containing white space must be enclosed in quotes.

\textit{--tablespace} | \texttt{--tablespace=tablespace}

Specifies the default tablespace for the database. (This name is processed as a double-quoted identifier.)

\textbf{--echo}

Echo the commands that \texttt{createdb} generates and sends to the server.

\textbf{--encoding} | \texttt{--encoding encoding}

Character set encoding to use in the new database. Specify a string constant (such as 'UTF8'), an integer encoding number, or \texttt{DEFAULT} to use the default encoding. See the Greenplum Database Reference Guide for information about supported character sets.

\textbf{--locale} | \texttt{--locale locale}

Specifies the locale to be used in this database. This is equivalent to specifying both \texttt{--lc-collate} and \texttt{--lc-ctype}.

\textbf{--lc-collate} locale

Specifies the \texttt{LC_COLLATE} setting to be used in this database.

\textbf{--lc-ctype} locale

Specifies the \texttt{LC_CTYPE} setting to be used in this database.

\textbf{--maintenance-db=dbname}

Specifies the name of the database to connect to when creating the new database. If not specified, the \texttt{postgres} database will be used; if that does not exist (or if it is the name of the new database being created), \texttt{template1} will be used.

\textbf{--owner} | \texttt{--owner=owner}

The name of the database user who will own the new database. Defaults to the user executing this command. (This name is processed as a double-quoted identifier.)

\textbf{--template} | \texttt{--template=template}

The name of the template from which to create the new database. Defaults to \texttt{template1}. (This name is processed as a double-quoted identifier.)

\textbf{--version} | \texttt{--version}

Print the \texttt{createdb} version and exit.

\textbf{--help} | \textbf{--help}

Show help about \texttt{createdb} command line arguments, and exit.

The options \texttt{-D}, \texttt{-1}, \texttt{-E}, \texttt{-O}, and \texttt{-T} correspond to options of the underlying SQL command \texttt{CREATE DATABASE}; see \texttt{CREATE DATABASE} in the \textit{Greenplum Database Reference Guide} for more information about them.
Connection Options

- **h host | --host=host**
  The host name of the machine on which the Greenplum master database server is running. If not specified, reads from the environment variable `PGHOST` or defaults to localhost.

- **p port | --port=port**
  The TCP port on which the Greenplum master database server is listening for connections. If not specified, reads from the environment variable `PGPORT` or defaults to 5432.

- **U username | --username=username**
  The database role name to connect as. If not specified, reads from the environment variable `PGUSER` or defaults to the current system role name.

- **w | --no-password**
  Never issue a password prompt. If the server requires password authentication and a password is not available by other means such as a `.pgpass` file, the connection attempt will fail. This option can be useful in batch jobs and scripts where no user is present to enter a password.

- **W | --password**
  Force a password prompt.

Examples

To create the database **test** using the default options:

```
createdb test
```

To create the database **demo** using the Greenplum master on host **gpmaster**, port 54321, using the **LATIN1** encoding scheme:

```
createdb -p 54321 -h gpmaster -E LATIN1 demo
```

See Also

**CREATE DATABASE** in the *Greenplum Database Reference Guide*

**createlang**

Defines a new procedural language for a database.

Synopsis

```
createlang [connection_option ...] [-e] langname [[-d] dbname]
createlang [connection-option ...] -l dbname
createlang -? | --help
createlang -V | --version
```

Description

The **createlang** utility adds a new procedural language to a database. **createlang** is a wrapper around the **SQL** command **CREATE EXTENSION**.
**Note:** `createlang` is deprecated and may be removed in a future release. From Greenplum Database 6.x, using `createlang` to add a procedural language package generates an error. Use the `CREATE EXTENSION` command instead.

The procedural language packages included in the standard Greenplum Database distribution are:

- PL/pgSQL
- PL/Perl
- PL/Python

The PL/pgSQL language is registered in all databases by default.

Greenplum Database also has language handlers for PL/Java and PL/R, but those languages are not pre-installed with Greenplum Database. See the [Greenplum PL/Java Language Extension](#) and [Greenplum PL/R Language Extension](#) sections in the documentation for more information.

**Options**

`langname`  
Specifies the name of the procedural language to be installed. (This name is lower-cased.)

`[-d] dbname | [--dbname=]dbname`  
Specifies the database to which the language should be added. The default is to use the `PGDATABASE` environment variable setting, or the same name as the current system user.

`-e | --echo`  
Echo the commands that `createlang` generates and sends to the server.

`-l dbname | --list dbname`  
Show a list of already installed languages in the target database.

`-V | --version`  
Print the `createlang` version and exit.

`-? | --help`  
Show help about `createlang` command line arguments, and exit.

**Connection Options**

`-h host | --host=host`  
The host name of the machine on which the Greenplum master database server is running. If not specified, reads from the environment variable `PGHOST` or defaults to localhost.

`-p port | --port=port`  
The TCP port on which the Greenplum master database server is listening for connections. If not specified, reads from the environment variable `PGPORT` or defaults to 5432.

`-U username | --username=username`  
The database role name to connect as. If not specified, reads from the environment variable `PGUSER` or defaults to the current system role name.

`-w | --no-password`  
Never issue a password prompt. If the server requires password authentication and a password is not available by other means such as a `.pgpass` file, the connection attempt will fail. This option can be useful in batch jobs and scripts where no user is present to enter a password.

`-W | --password`  
Force a password prompt.
Examples
To install the language plperl into the database mytestdb:

createlang plperl mytestdb

See Also

createuser
 Creates a new database role.

Synopsis

createuser [connection-option ...] [role_attribute ...] [-e] role_name
createuser -? | --help
createuser -V | --version

Description

createuser creates a new Greenplum Database role. You must be a superuser or have the
CREATEROLE privilege to create new roles. You must connect to the database as a superuser to create
new superusers.

Superusers can bypass all access permission checks within the database, so superuser privileges should
not be granted lightly.

createuser is a wrapper around the SQL command CREATE ROLE.

Options

role_name
 The name of the role to be created. This name must be different from all existing roles in
this Greenplum Database installation.

-c number | --connection-limit=number
 Set a maximum number of connections for the new role. The default is to set no limit.

-d | --createdb
 The new role will be allowed to create databases.

-D | --no-createdb
 The new role will not be allowed to create databases. This is the default.

-e | --echo
 Echo the commands that createuser generates and sends to the server.

-E | --encrypted
 Encrypts the role's password stored in the database. If not specified, the default password
behavior is used.

-i | --inherit
 The new role will automatically inherit privileges of roles it is a member of. This is the
default.

-I | --no-inherit
 The new role will not automatically inherit privileges of roles it is a member of.
--interactive
Prompt for the user name if none is specified on the command line, and also prompt for whichever of the options -d/-D, -r/-R, -s/-S is not specified on the command line.

-l | --login
The new role will be allowed to log in to Greenplum Database. This is the default.

-L | --no-login
The new role will not be allowed to log in (a group-level role).

-N | --unencrypted
Does not encrypt the role’s password stored in the database. If not specified, the default password behavior is used.

-P | --pwprompt
If given, createuser will issue a prompt for the password of the new role. This is not necessary if you do not plan on using password authentication.

-r | --createrole
The new role will be allowed to create new roles (CREATEROLE privilege).

-R | --no-createrole
The new role will not be allowed to create new roles. This is the default.

-s | --superuser
The new role will be a superuser.

-S | --no-superuser
The new role will not be a superuser. This is the default.

-V | --version
Print the createuser version and exit.

--replication
The new user will have the REPLICATION privilege, which is described more fully in the documentation for CREATE ROLE.

--no-replication
The new user will not have the REPLICATION privilege, which is described more fully in the documentation for CREATE ROLE.

-? | --help
Show help about createuser command line arguments, and exit.

Connection Options
-h host | --host=host
The host name of the machine on which the Greenplum master database server is running. If not specified, reads from the environment variable PGHOST or defaults to localhost.

-p port | --port=port
The TCP port on which the Greenplum master database server is listening for connections. If not specified, reads from the environment variable PGPORT or defaults to 5432.

-U username | --username=username
The database role name to connect as. If not specified, reads from the environment variable PGUSER or defaults to the current system role name.

-w | --no-password
Never issue a password prompt. If the server requires password authentication and a password is not available by other means such as a .pgpass file, the connection attempt
will fail. This option can be useful in batch jobs and scripts where no user is present to enter a password.

-w | --password
Force a password prompt.

Examples
To create a role joe on the default database server:

$ createuser joe

To create a role joe on the default database server with prompting for some additional attributes:

$ createuser --interactive joe
Shall the new role be a superuser? (y/n) n
Shall the new role be allowed to create databases? (y/n) n
Shall the new role be allowed to create more new roles? (y/n) n
CREATE ROLE

To create the same role joe using connection options, with attributes explicitly specified, and taking a look at the underlying command:

createuser -h masterhost -p 54321 -S -D -R -e joe
CREATE ROLE joe NOSUPERUSER NOCREATEDB NOCREATEROLE INHERIT
LOGIN;
CREATE ROLE

To create the role joe as a superuser, and assign password admin123 immediately:

createuser -P -s -e joe
Enter password for new role: admin123
Enter it again: admin123
CREATE ROLE joe PASSWORD 'admin123' SUPERUSER CREATEDB
CREATEROLE INHERIT LOGIN;
CREATE ROLE

In the above example, the new password is not actually echoed when typed, but we show what was typed for clarity. However the password will appear in the echoed command, as illustrated if the -e option is used.

CREATE ROLE in the Greenplum Database Reference Guide

dropdb
Removes a database.

Synopsis

dropdb [connection-option ...] [-e] [-i] dbname
dropdb -? | --help
dropdb -V | --version
Description

dropdb destroys an existing database. The user who executes this command must be a superuser or the owner of the database being dropped.

dropdb is a wrapper around the SQL command DROP DATABASE. See the Greenplum Database Reference Guide for information about DROP DATABASE.

Options

dbname

The name of the database to be removed.

-e | --echo

Echo the commands that dropdb generates and sends to the server.

-i | --interactive

Issues a verification prompt before doing anything destructive.

-V | --version

Print the dropdb version and exit.

--if-exists

Do not throw an error if the database does not exist. A notice is issued in this case.

-? | --help

Show help about dropdb command line arguments, and exit.

Connection Options

-h host | --host=host

The host name of the machine on which the Greenplum master database server is running. If not specified, reads from the environment variable PGHOST or defaults to localhost.

-p port | --port=port

The TCP port on which the Greenplum master database server is listening for connections. If not specified, reads from the environment variable PGPORT or defaults to 5432.

-U username | --username=username

The database role name to connect as. If not specified, reads from the environment variable PGUSER or defaults to the current system role name.

-w | --no-password

Never issue a password prompt. If the server requires password authentication and a password is not available by other means such as a .pgpass file, the connection attempt will fail. This option can be useful in batch jobs and scripts where no user is present to enter a password.

-W | --password

Force a password prompt.

--maintenance-db=dbname

Specifies the name of the database to connect to in order to drop the target database. If not specified, the postgres database will be used; if that does not exist (or if it is the name of the database being dropped), template1 will be used.

Examples

To destroy the database named demo using default connection parameters:

dropdb demo
To destroy the database named demo using connection options, with verification, and a peek at the underlying command:

```
dropdb -p 54321 -h masterhost -i -e demo
Database "demo" will be permanently deleted.
Are you sure? (y/n) y
DROP DATABASE "demo"
DROP DATABASE
```

DROP DATABASE in the Greenplum Database Reference Guide

droplang

Removes a procedural language.

Synopsis

```
droplang [connection-option ...] [-e] langname [[-d] dbname]
droplang [connection-option ...] [-e] -l dbname
droplang -? | --help
droplang -V | --version
```

Description

droplang removes an existing procedural language from a database.

droplang is a wrapper for the SQL command DROP EXTENSION.

Note: droplang is deprecated and may be removed in a future release. From Greenplum Database 6.x using droplang to remove a procedural language package generates an error. Use the DROP EXTENSION command instead.

Options

langname

Specifies the name of the procedural language to be removed. (This name is lower-cased.)

[-d] dbname | [--dbname=] dbname

Specifies from which database the language should be removed. The default is to use the PGDATABASE environment variable setting, or the same name as the current system user.

-e | --echo

Echo the commands that droplang generates and sends to the server.

-l | --list

Show a list of already installed languages in the target database.

-V | --version

Print the droplang version and exit.

-? | --help

Show help about droplang command line arguments, and exit.

Connection Options

-h host | --host=host
The host name of the machine on which the Greenplum master database server is running. If not specified, reads from the environment variable `PGHOST` or defaults to localhost.

```
-p port | --port=port
```

The TCP port on which the Greenplum master database server is listening for connections. If not specified, reads from the environment variable `PGPORT` or defaults to 5432.

```
-U username | --username=username
```

The database role name to connect as. If not specified, reads from the environment variable `PGUSER` or defaults to the current system role name.

```
-w | --no-password
```

Never issue a password prompt. If the server requires password authentication and a password is not available by other means such as a `.pgpass` file, the connection attempt will fail. This option can be useful in batch jobs and scripts where no user is present to enter a password.

```
-W | --password
```

Force a password prompt.

### Examples

To remove the language `pltcl` from the `mydatabase` database:

```
droplang pltcl mydatabase
```

### See Also

**dropuser**

Removes a database role.

#### Synopsis

```
dropuser [connection-option ...] [-e] [-i] role_name
```

```
dropuser -? | --help
```

```
dropuser -V | --version
```

#### Description

`dropuser` removes an existing role from Greenplum Database. Only superusers and users with the `CREATEROLE` privilege can remove roles. To remove a superuser role, you must yourself be a superuser. `dropuser` is a wrapper around the SQL command `DROP ROLE`.

#### Options

- `role_name`:

  The name of the role to be removed. You will be prompted for a name if not specified on the command line and the `-i/--interactive` option is used.

- `e | --echo`:

  Echo the commands that `dropuser` generates and sends to the server.

- `i | --interactive`
Prompt for confirmation before actually removing the role, and prompt for the role name if none is specified on the command line.

`--if-exists`

Do not throw an error if the user does not exist. A notice is issued in this case.

`-V | --version`

Print the `dropuser` version and exit.

`-? | --help`

Show help about `dropuser` command line arguments, and exit.

**Connection Options**

`-h host | --host=host`

The host name of the machine on which the Greenplum master database server is running. If not specified, reads from the environment variable `PGHOST` or defaults to localhost.

`-p port | --port=port`

The TCP port on which the Greenplum master database server is listening for connections. If not specified, reads from the environment variable `PGPORT` or defaults to 5432.

`-U username | --username=username`

The database role name to connect as. If not specified, reads from the environment variable `PGUSER` or defaults to the current system role name.

`-w | --no-password`

Never issue a password prompt. If the server requires password authentication and a password is not available by other means such as a `.pgpass` file, the connection attempt will fail. This option can be useful in batch jobs and scripts where no user is present to enter a password.

`-W | --password`

Force a password prompt.

**Examples**

To remove the role `joe` using default connection options:

```
dropuser joe
DROP ROLE
```

To remove the role `joe` using connection options, with verification, and a peek at the underlying command:

```
dropuser -p 54321 -h masterhost -i -e joe
Role "joe" will be permanently removed.
Are you sure? (y/n) y
DROP ROLE "joe"
DROP ROLE
```

**See Also**

`DROP ROLE` in the *Greenplum Database Reference Guide*

**gpactivatestandby**

Activates a standby master host and makes it the active master for the Greenplum Database system.
Synopsis

```
gpactivatestandby [-d standby_master_datadir] [-f] [-a] [-q]
       [-l logfile_directory]
gpactivatestandby -v

gpactivatestandby -?  |  -h  |  --help
```

Description

The `gpactivatestandby` utility activates a backup, standby master host and brings it into operation as the active master instance for a Greenplum Database system. The activated standby master effectively becomes the Greenplum Database master, accepting client connections on the master port.

When you initialize a standby master, the default is to use the same port as the active master. For information about the master port for the standby master, see `gpinitstandby`.

You must run this utility from the master host you are activating, not the failed master host you are disabling. Running this utility assumes you have a standby master host configured for the system (see `gpinitstandby`).

The utility will perform the following steps:

- Stops the synchronization process (`walreceiver`) on the standby master
- Updates the system catalog tables of the standby master using the logs
- Activates the standby master to be the new active master for the system
- Restarts the Greenplum Database system with the new master host

A backup, standby Greenplum master host serves as a 'warm standby' in the event of the primary Greenplum master host becoming non-operational. The standby master is kept up to date by transaction log replication processes (`walsender` and `walreceiver`), which run on the primary master and standby master hosts and keep the data between the primary and standby master hosts synchronized.

If the primary master fails, the log replication process is shutdown, and the standby master can be activated in its place by using the `gpactivatestandby` utility. Upon activation of the standby master, the replicated logs are used to reconstruct the state of the Greenplum master host at the time of the last successfully committed transaction.

In order to use `gpactivatestandby` to activate a new primary master host, the master host that was previously serving as the primary master cannot be running. The utility checks for a `postmaster.pid` file in the data directory of the disabled master host, and if it finds it there, it will assume the old master host is still active. In some cases, you may need to remove the `postmaster.pid` file from the disabled master host data directory before running `gpactivatestandby` (for example, if the disabled master host process was terminated unexpectedly).

After activating a standby master, run `ANALYZE` to update the database query statistics. For example:

```
psql dbname -c 'ANALYZE;'
```

After you activate the standby master as the primary master, the Greenplum Database system no longer has a standby master configured. You might want to specify another host to be the new standby with the `gpinitstandby` utility.

Options

- `-a` (do not prompt)
  Do not prompt the user for confirmation.

- `-d standby_master_datadir`
  The absolute path of the data directory for the master host you are activating.
If this option is not specified, `gpactivatestandby` uses the value of the `MASTER_DATA_DIRECTORY` environment variable setting on the master host you are activating. If this option is specified, it overrides any setting of `MASTER_DATA_DIRECTORY`. If a directory cannot be determined, the utility returns an error.

```
-f (force activation)
Use this option to force activation of the backup master host. Use this option only if you are sure that the standby and primary master hosts are consistent.
```

```
-l logfile_directory
The directory to write the log file. Defaults to `~/gpAdminLogs`.
```

```
-q (no screen output)
Run in quiet mode. Command output is not displayed on the screen, but is still written to the log file.
```

```
-v (show utility version)
Displays the version, status, last updated date, and check sum of this utility.
```

```
-? | -h | --help (help)
Displays the online help.
```

**Example**

Activate the standby master host and make it the active master instance for a Greenplum Database system (run from backup master host you are activating):

```
gpactivatestandby -d /gpdata
```

**See Also**

`gpinitsystem`, `gpinitstandby`  
`gpaddmirrors`

Adds mirror segments to a Greenplum Database system that was initially configured without mirroring.

**Synopsis**

```
```

```
```

```
gpaddmirrors -o output_sample_mirror_config [-s] [-m datadir_config_file]
```

```
gpaddmirrors -?
```

```
gpaddmirrors --version
```

**Description**

The `gpaddmirrors` utility configures mirror segment instances for an existing Greenplum Database system that was initially configured with primary segment instances only. The utility will create the mirror instances and begin the online replication process between the primary and mirror segment instances.
Once all mirrors are synchronized with their primaries, your Greenplum Database system is fully data redundant.

**Important:** During the online replication process, Greenplum Database should be in a quiescent state, workloads and other queries should not be running.

By default, the utility will prompt you for the file system location(s) where it will create the mirror segment data directories. If you do not want to be prompted, you can pass in a file containing the file system locations using the \( -m \) option.

The mirror locations and ports must be different than your primary segment data locations and ports.

The utility creates a unique data directory for each mirror segment instance in the specified location using the predefined naming convention. There must be the same number of file system locations declared for mirror segment instances as for primary segment instances. It is OK to specify the same directory name multiple times if you want your mirror data directories created in the same location, or you can enter a different data location for each mirror. Enter the absolute path. For example:

```
Enter mirror segment data directory location 1 of 2 > /gpdb/mirror
Enter mirror segment data directory location 2 of 2 > /gpdb/mirror
```

OR

```
Enter mirror segment data directory location 1 of 2 > /gpdb/m1
Enter mirror segment data directory location 2 of 2 > /gpdb/m2
```

Alternatively, you can run the `gpaddmirrors` utility and supply a detailed configuration file using the \( -i \) option. This is useful if you want your mirror segments on a completely different set of hosts than your primary segments. The format of the mirror configuration file is:

```
<row_id>=<contentID>|<address>|<port>|<data_dir>
```

Where `row_id` is the row in the file, `contentID` is the segment instance content ID, `address` is the host name or IP address of the segment host, `port` is the communication port, and `data_dir` is the segment instance data directory.

For example:

```
0=0|sdw1-1|60000|/gpdata/mir1/gp0
1=1|sdw1-1|60001|/gpdata/mir2/gp1
```

The `gp_segment_configuration` system catalog table can help you determine your current primary segment configuration so that you can plan your mirror segment configuration. For example, run the following query:

```
=# SELECT dbid, content, address as host_address, port, datadir
   FROM gp_segment_configuration
   ORDER BY dbid;
```

If creating your mirrors on alternate mirror hosts, the new mirror segment hosts must be pre-installed with the Greenplum Database software and configured exactly the same as the existing primary segment hosts.

You must make sure that the user who runs `gpaddmirrors` (the `gpadmin` user) has permissions to write to the data directory locations specified. You may want to create these directories on the segment hosts and chown them to the appropriate user before running `gpaddmirrors`.

**Note:** This utility uses secure shell (SSH) connections between systems to perform its tasks. In large Greenplum Database deployments, cloud deployments, or deployments with a large number of segments per host, this utility may exceed the host's maximum threshold for unauthenticated connections. Consider updating the SSH MaxStartups configuration parameter to increase this.
threshold. For more information about SSH configuration options, refer to the SSH documentation for your Linux distribution.

**Options**

- **-a (do not prompt)**
  
  Run in quiet mode - do not prompt for information. Must supply a configuration file with either `-m` or `-i` if this option is used.

- **-B parallel_processes**
  
  The number of mirror setup processes to start in parallel. If not specified, the utility will start up to 10 parallel processes depending on how many mirror segment instances it needs to set up.

- **-d master_data_directory**
  
  The master data directory. If not specified, the value set for `$MASTER_DATA_DIRECTORY` will be used.

- **-i mirror_config_file**
  
  A configuration file containing one line for each mirror segment you want to create. You must have one mirror segment listed for each primary segment in the system. The format of this file is as follows (as per attributes in the `gp_segment_configuration` catalog table):

  `<row_id>=<contentID>|<address>|<port>|<data_dir>`

  Where `row_id` is the row in the file, `contentID` is the segment instance content ID, `address` is the host name or IP address of the segment host, `port` is the communication port, and `data_dir` is the segment instance data directory.

- **-l logfile_directory**
  
  The directory to write the log file. Defaults to `~/gpAdminLogs`.

- **-m datadir_config_file**
  
  A configuration file containing a list of file system locations where the mirror data directories will be created. If not supplied, the utility prompts you for locations. Each line in the file specifies a mirror data directory location. For example:

  `/gpdata/m1
  /gpdata/m2
  /gpdata/m3
  /gpdata/m4`

- **-o output_sample_mirror_config**
  
  If you are not sure how to lay out the mirror configuration file used by the `-i` option, you can run `gpaddmirrors` with this option to generate a sample mirror configuration file based on your primary segment configuration. The utility will prompt you for your mirror segment data directory locations (unless you provide these in a file using `-m`). You can then edit this file to change the host names to alternate mirror hosts if necessary.

- **-p port_offset**
  
  Optional. This number is used to calculate the database ports used for mirror segments. The default offset is 1000. Mirror port assignments are calculated as follows:

  primary port + offset = mirror database port

  For example, if a primary segment has port 50001, then its mirror will use a database port of 51001, by default.

- **-s (spread mirrors)**
Spreads the mirror segments across the available hosts. The default is to group a set of mirror segments together on an alternate host from their primary segment set. Mirror spreading will place each mirror on a different host within the Greenplum Database array. Spreading is only allowed if there is a sufficient number of hosts in the array (number of hosts is greater than the number of segment instances per host).

-v (verbose)
Sets logging output to verbose.

--version (show utility version)
Displays the version of this utility.

-? (help)
Displays the online help.

Examples
Add mirroring to an existing Greenplum Database system using the same set of hosts as your primary data. Calculate the mirror database ports by adding 100 to the current primary segment port numbers:

```
$ gpaddmirrors -p 100
```

Add mirroring to an existing Greenplum Database system using a different set of hosts from your primary data:

```
$ gpaddmirrors -i mirror_config_file
```

Where `mirror_config_file` looks something like this:

```
0=0|sdw1-1|52001|/gpdata/mir1/gp0
1=1|sdw1-2|52002|/gpdata/mir2/gp1
2=2|sdw2-1|52001|/gpdata/mir1/gp2
3=3|sdw2-2|52002|/gpdata/mir2/gp3
```

Generate a sample mirror configuration file with the -o option to use with `gpaddmirrors -i`:

```
$ gpaddmirrors -o /home/gpadmin/sample_mirror_config
```

See Also
`gpinitsystem`, `gpinitstandby`, `gpactivatestandby`

**gpbackup**

Create a Greenplum Database backup for use with the `gprestore` utility.

Synopsis

```
gpbackup --dbname database_name
       [--backup-dir directory]
       [--compression-level level]
       [--data-only]
       [--debug]
       [--exclude-schema schema_name]
       [--exclude-table schema.table]
       [--exclude-table-file file_name]
       [--include-schema schema_name]
       [--include-table schema.table]
       [--include-table-file file_name]
```
gpbackup --help

**Description**

The `gpbackup` utility backs up the contents of a database into a collection of metadata files and data files that can be used to restore the database at a later time using `gprestore`. When you back up a database, you can specify table level and schema level filter options to back up specific tables. For example, you can combine schema level and table level options to back up all the tables in a schema except for a single table.

By default, `gpbackup` backs up objects in the specified database as well as global Greenplum Database system objects. You can optionally supply the `--with-globals` option with `gprestore` to restore global objects. See Objects Included in a Backup or Restore for additional information.

`gpbackup` stores the object metadata files and DDL files for a backup in the Greenplum Database master data directory by default. Greenplum Database segments use the `COPY ... ON SEGMENT` command to store their data for backed-up tables in compressed CSV data files, located in each segment's data directory. See Understanding Backup Files for additional information.

You can add the `--backup-dir` option to copy all backup files from the Greenplum Database master and segment hosts to an absolute path for later use. Additional options are provided to filter the backup set in order to include or exclude specific tables.

You can create an incremental backup with the `--incremental` option. Incremental backups are efficient when the total amount of data in append-optimized tables or table partitions that changed is small compared to the data that has not changed. See Creating Incremental Backups with gpbackup and gprestore for information about incremental backups.

With the default `--jobs` option (1 job), each `gpbackup` operation uses a single transaction on the Greenplum Database master host. The `COPY ... ON SEGMENT` command performs the backup task in parallel on each segment host. The backup process acquires an `ACCESS SHARE` lock on each table that is backed up. During the table locking process, the database should be in a quiescent state.

When a backup operation completes, `gpbackup` returns a status code. See Return Codes.

The `gpbackup` utility cannot be run while `gpexpand` is initializing new segments. Backups created before the expansion cannot be restored with `gprestore` after the cluster expansion is completed.

`gpbackup` can send status email notifications after a backup operation completes. You specify when the utility sends the mail and the email recipients in a configuration file. See Configuring Email Notifications.

**Note:** This utility uses secure shell (SSH) connections between systems to perform its tasks. In large Greenplum Database deployments, cloud deployments, or deployments with a large number of segments per host, this utility may exceed the host's maximum threshold for unauthenticated connections. Consider updating the SSH MaxStartups and MaxSessions configuration parameters to increase this threshold. For more information about SSH configuration options, refer to the SSH documentation for your Linux distribution.

**Options**

--dbname database_name
Required. Specifies the database to back up.

--backup-dir directory
Optional. Copies all required backup files (metadata files and data files) to the specified directory. You must specify directory as an absolute path (not relative). If you do not supply this option, metadata files are created on the Greenplum Database master host in the $MASTER_DATA_DIRECTORY/backups/YYYYMMDD/YYYYMMDDhhmms directory. Segment hosts create CSV data files in the <seg_dir>/backups/YYYYMMDD/YYYYMMDDhhmms directory. When you specify a custom backup directory, files are copied to these paths in subdirectories of the backup directory.

You cannot combine this option with the option --plugin-config.

--compression-level level
Optional. Specifies the gzip compression level (from 1 to 9) used to compress data files. The default is 1. Note that gpbackup uses compression by default.

--data-only
Optional. Backs up only the table data into CSV files, but does not backup metadata files needed to recreate the tables and other database objects.

--debug
Optional. Displays verbose debug messages during operation.

--exclude-schema schema_name
Optional. Specifies a database schema to exclude from the backup. You can specify this option multiple times to exclude multiple schemas. You cannot combine this option with the option --include-schema, or a table filtering option such as --include-table. See Filtering the Contents of a Backup or Restore for more information.

--exclude-table schema.table
Optional. Specifies a table to exclude from the backup. The table must be in the format <schema-name>,<table-name>. If a table or schema name uses any character other than a lowercase letter, number, or an underscore character, then you must include that name in double quotes. You can specify this option multiple times. You cannot combine this option with the option --exclude-schema, or another a table filtering option such as --include-table.

You cannot use this option in combination with --leaf-partition-data. Although you can specify leaf partition names, gpbackup ignores the partition names. See Filtering the Contents of a Backup or Restore for more information.

--exclude-table-file file_name
Optional. Specifies a text file containing a list of tables to exclude from the backup. Each line in the text file must define a single table using the format <schema-name>,<table-name>. The file must not include trailing lines. If a table or schema name uses any character other than a lowercase letter, number, or an underscore character, then you must include that name in double quotes. You cannot combine this option with the option --exclude-schema, or another a table filtering option such as --include-table.

You cannot use this option in combination with --leaf-partition-data. Although you can specify leaf partition names in a file specified with --exclude-table-file, gpbackup ignores the partition names. See Filtering the Contents of a Backup or Restore for more information.

--include-schema schema_name
Optional. Specifies a database schema to include in the backup. You can specify this option multiple times to include multiple schemas. If you specify this option, any schemas that are not included in subsequent --include-schema options are omitted from the backup set. You cannot combine this option with the options --exclude-schema, --
include-table, or --include-table-file. See Filtering the Contents of a Backup or Restore for more information.

--include-table schema.table
Optional. Specifies a table to include in the backup. The table must be in the format <schema-name>.<table-name>. If a table or schema name uses any character other than a lowercase letter, number, or an underscore character, then you must include that name in single quotes. See Schema and Table Names for information about characters that are supported in schema and table names.

You can specify this option multiple times. You cannot combine this option with a schema filtering option such as --include-schema, or another table filtering option such as --exclude-table-file.

You can also specify the qualified name of a sequence or a view.

If you specify this option, the utility does not automatically back up dependent objects. You must also explicitly specify dependent objects that are required. For example if you back up a view, you must also back up the tables that the view uses. If you back up a table that uses a sequence, you must also back up the sequence.

You can optionally specify a table leaf partition name in place of the table name, to include only specific leaf partitions in a backup with the --leaf-partition-data option. When a leaf partition is backed up, the leaf partition data is backed up along with the metadata for the partitioned table.

See Filtering the Contents of a Backup or Restore for more information.

--include-table-file file_name
Optional. Specifies a text file containing a list of tables to include in the backup. Each line in the text file must define a single table using the format <schema-name>.<table-name>. The file must not include trailing lines. See Schema and Table Names for information about characters that are supported in schema and table names.

Any tables not listed in this file are omitted from the backup set. You cannot combine this option with a schema filtering option such as --include-schema, or another table filtering option such as --exclude-table-file.

You can also specify the qualified name of a sequence or a view.

If you specify this option, the utility does not automatically back up dependent objects. You must also explicitly specify dependent objects that are required. For example if you back up a view, you must also specify the tables that the view uses. If you specify a table that uses a sequence, you must also specify the sequence.

You can optionally specify a table leaf partition name in place of the table name, to include only specific leaf partitions in a backup with the --leaf-partition-data option. When a leaf partition is backed up, the leaf partition data is backed up along with the metadata for the partitioned table.

See Filtering the Contents of a Backup or Restore for more information.

--incremental
Specify this option to add an incremental backup to an incremental backup set. A backup set is a full backup and one or more incremental backups. The backups in the set must be created with a consistent set of backup options to ensure that the backup set can be used in a restore operation.

By default, gpbackup attempts to find the most recent existing backup with a consistent set of options. If the backup is a full backup, the utility creates a backup set. If the backup is an incremental backup, the utility adds the backup to the existing backup set. The incremental backup is added as the latest backup in the backup set. You can specify --from-timestamp to override the default behavior.
**--from-timestamp backup-timestamp**
Optional. Specifies the timestamp of a backup. The specified backup must have backup options that are consistent with the incremental backup that is being created. If the specified backup is a full backup, the utility creates a backup set. If the specified backup is an incremental backup, the utility adds the incremental backup to the existing backup set.

You must specify `--leaf-partition-data` with this option. You cannot combine this option with `--data-only` or `--metadata-only`.

A backup is not created and the utility returns an error if the backup cannot add the backup to an existing incremental backup set or cannot use the backup to create a backup set.

For information about creating and using incremental backups, see *Creating Incremental Backups with gpbackup and gprestore*.

**--jobs int**
Optional. Specifies the number of jobs to run in parallel when backing up tables. By default, `gpbackup` uses 1 job (database connection). Increasing this number can improve the speed of backing up data. When running multiple jobs, each job backs up tables in a separate transaction. For example, if you specify `--jobs 2`, the utility creates two processes, each process starts a single transaction, and the utility backs up the tables in parallel using the two processes.

**Important**: If you specify a value higher than 1, the database must be in a quiescent state while the utility acquires a lock on the tables that are being backed up. If database operations are being performed on tables that are being backed up during the table locking process, consistency between tables that are backed up in different transactions cannot be guaranteed.

You cannot use this option in combination with the options `--metadata-only`, `--single-data-file`, or `--plugin-config`.

**--leaf-partition-data**
Optional. For partitioned tables, creates one data file per leaf partition instead of one data file for the entire table (the default). Using this option also enables you to specify individual leaf partitions to include in a backup, with the `--include-table-file` option. You cannot use this option in combination with `--exclude-table-file` or `--exclude-table`.

**--metadata-only**
Optional. Creates only the metadata files (DDL) needed to recreate the database objects, but does not back up the actual table data.

**--no-compression**
Optional. Do not compress the table data CSV files.

**--plugin-config config-file_location**
Specify the location of the `gpbackup` plugin configuration file, a YAML-formatted text file. The file contains configuration information for the plugin application that `gpbackup` uses during the backup operation.

If you specify the `--plugin-config` option when you back up a database, you must specify this option with configuration information for a corresponding plugin application when you restore the database from the backup.

You cannot combine this option with the option `--backup-dir`.

For information about using storage plugin applications, see *Using gpbackup Storage Plugins*.

**--quiet**
Optional. Suppress all non-warning, non-error log messages.
--single-data-file
Optional. Create a single data file on each segment host for all tables backed up on that segment. By default, each gpbackup creates one compressed CSV file for each table that is backed up on the segment.

Note: If you use the --single-data-file option to combine table backups into a single file per segment, you cannot set the gprestore option --jobs to a value higher than 1 to perform a parallel restore operation.

--verbose
Optional. Print verbose log messages.

--version
Optional. Print the version number and exit.

--with-stats
Optional. Include query plan statistics in the backup set.

--help
Displays the online help.

Return Codes
One of these codes is returned after gpbackup completes.

• 0 – Backup completed with no problems.
• 1 – Backup completed with non-fatal errors. See log file for more information.
• 2 – Backup failed with a fatal error. See log file for more information.

Schema and Table Names
When specifying the table filtering option --include-table or --include-table-file to list tables to be backed up, the gpbackup utility supports backing up schemas or tables when the name contains upper-case characters or these special characters.

~ # $ % ^ & * ( ) _ - + [ ] { } > < \ | ; : / ? ! ,

If a name contains an upper-case or special character and is specified on the command line with --include-table, the name must be enclosed in single quotes.

```
gpbackup --dbname test --include-table 'my#1schema'.my_$42_Table'
```

When the table is listed in a file for use with --include-table-file, single quotes are not required. For example, this is the contents of a text file that is used with --include-table-file to back up two tables.

```
my#1schema.my_$42_Table
my#1schema.my_$590_Table
```

Note: The --include-table and --include-table-file options do not support schema or table names that contain the character double quote ("), period (.), newline (\n), or space ( ).

Examples
Backup all schemas and tables in the "demo" database, including global Greenplum Database system objects statistics:

```
$ gpbackup --dbname demo
```
Backup all schemas and tables in the "demo" database except for the "twitter" schema:

```
$ gpbackup --dbname demo --exclude-schema twitter
```

Backup only the "twitter" schema in the "demo" database:

```
$ gpbackup --dbname demo --include-schema twitter
```

Backup all schemas and tables in the "demo" database, including global Greenplum Database system objects and query statistics, and copy all backup files to the /home/gpadmin/backup directory:

```
$ gpbackup --dbname demo --with-stats --backup-dir /home/gpadmin/backup
```

This example uses --include-schema with --exclude-table to back up a schema except for a single table.

```
$ gpbackup --dbname demo --include-schema mydata --exclude-table mydata.addresses
```

You cannot use the option --exclude-schema with a table filtering option such as --include-table.

**See Also**

`gprestore`, `Parallel Backup with gpbackup and gprestore` and `Using the S3 Storage Plugin with gpbackup and gprestore`

**gpcheckcat**

The `gpcheckcat` utility tests Greenplum Database catalog tables for inconsistencies.

The utility is in `$GPHOME/bin/lib`.

**Synopsis**

```
gpcheckcat [ options] [ dbname]
```

**Options:**

- `-g` dir
- `-p` port
- `-P` password
- `-U` user_name
- `-S` {none | only}
- `-O`
- `-R` test_name
- `-C` catalog_name
- `-B` parallel_processes
- `-v`
- `-A`

```
gpcheckcat -l
```

```
gpcheckcat -?
```

**Description**

The `gpcheckcat` utility runs multiple tests that check for database catalog inconsistencies. Some of the tests cannot be run concurrently with other workload statements or the results will not be usable. Restart the database in restricted mode when running `gpcheckcat`, otherwise `gpcheckcat` might report
inconsistencies due to ongoing database operations rather than the actual number of inconsistencies. If you run `gpcheckcat` without stopping database activity, run it with `-o` option.

**Note:** Any time you run the utility, it checks for and deletes orphaned, temporary database schemas (temporary schemas without a session ID) in the specified databases. The utility displays the results of the orphaned, temporary schema check on the command line and also logs the results.

Catalog inconsistencies are inconsistencies that occur between Greenplum Database system tables. In general, there are three types of inconsistencies:

- Inconsistencies in system tables at the segment level. For example, an inconsistency between a system table that contains table data and a system table that contains column data. As another, a system table that contains duplicates in a column that should be unique.

- Inconsistencies between same system table across segments. For example, a system table is missing row on one segment, but other segments have this row. As another example, the values of specific row column data are different across segments, such as table owner or table access privileges.

- Inconsistency between a catalog table and the filesystem. For example, a file exists in database directory, but there is no entry for it in the `pg_class` table.

**Options**

- `-A`
  Run `gpcheckcat` on all databases in the Greenplum Database installation.

- `-B parallel_processes`
  The number of processes to run in parallel.

  The `gpcheckcat` utility attempts to determine the number of simultaneous processes (the batch size) to use. The utility assumes it can use a buffer with a minimum of 20MB for each process. The maximum number of parallel processes is the number of Greenplum Database segment instances. The utility displays the number of parallel processes that it uses when it starts checking the catalog.

  **Note:** The utility might run out of memory if the number of errors returned exceeds the buffer size. If an out of memory error occurs, you can lower the batch size with the `-B` option. For example, if the utility displays a batch size of 936 and runs out of memory, you can specify `-B 468` to run 468 processes in parallel.

- `-C catalog_table`
  Run cross consistency, foreign key, and ACL tests for the specified catalog table.

- `-g data_directory`
  Generate SQL scripts to fix catalog inconsistencies. The scripts are placed in `data_directory`.

- `-l`
  List the `gpcheckcat` tests.

- `-o`
  Run only the `gpcheckcat` tests that can be run in online (not restricted) mode.

- `-p port`
  This option specifies the port that is used by the Greenplum Database.

- `-P password`
  The password of the user connecting to Greenplum Database.

- `-R test_name`
Specify a test to run. Some tests can be run only when Greenplum Database is in restricted mode.

These are the tests that can be performed:

- acl - Cross consistency check for access control privileges
- duplicate - Check for duplicate entries
- foreign_key - Check foreign keys
- inconsistent - Cross consistency check for master segment inconsistency
- missing_extraneous - Cross consistency check for missing or extraneous entries
- owner - Check table ownership that is inconsistent with the master database
- orphaned_toast_tables - Check for orphaned TOAST tables.

**Note:** There are several ways a TOAST table can become orphaned where a repair script cannot be generated and a manual catalog change is required. One way is if the reltoastrelid entry in pg_class points to an incorrect TOAST table (a TOAST table mismatch). Another way is if both the reltoastrelid in pg_class is missing and the pg_depend entry is missing (a double orphan TOAST table). If a manual catalog change is needed, gpcheckcat will display detailed steps you can follow to update the catalog. Contact Pivotal Support if you need help with the catalog change.

- part_integrity - Check pg_partition branch integrity, partition with OIDs, partition distribution policy
- part_constraint - Check constraints on partitioned tables
- unique_index_violation - Check tables that have columns with the unique index constraint for duplicate entries
- dependency - Check for dependency on non-existent objects (restricted mode only)
- distribution_policy - Check constraints on randomly distributed tables (restricted mode only)
- namespace - Check for schemas with a missing schema definition (restricted mode only)
- pgclass - Check pg_class entry that does not have any corresponding pg_attribute entry (restricted mode only)

**-S {none | only}**

Specify this option to control the testing of catalog tables that are shared across all databases in the Greenplum Database installation, such as pg_database.

The value none disables testing of shared catalog tables. The value only tests only the shared catalog tables.

**-U user_name**

The user connecting to Greenplum Database.

**-? (help)**

Displays the online help.

**-v (verbose)**

Displays detailed information about the tests that are performed.

**Notes**

The utility identifies tables with missing attributes and displays them in various locations in the output and in a non-standardized format. The utility also displays a summary list of tables with missing attributes in the format database.schema.table.segment_id after the output information is displayed.
If `gpcheckcat` detects inconsistent OID (Object ID) information, it generates one or more verification files that contain an SQL query. You can run the SQL query to see details about the OID inconsistencies and investigate the inconsistencies. The files are generated in the directory where `gpcheckcat` is invoked.

This is the format of the file:

```
gpcheckcat.verify.dbname.catalog_table_name.test_name.TIMESTAMP.sql
```

This is an example verification filename created by `gpcheckcat` when it detects inconsistent OID (Object ID) information in the catalog table `pg_type` in the database `mydb`:

```
gpcheckcat.verify.mydb.pg_type.missing_extraneous.20150420102715.sql
```

This is an example query from a verification file:

```sql
SELECT *
FROM (  
    SELECT relname, oid FROM pg_class WHERE reltype
    IN (1305822,1301043,1301069,1301095)
    UNION ALL
    SELECT relname, oid FROM gp_dist_random('pg_class') WHERE reltype
    IN (1305822,1301043,1301069,1301095)
) alltyprelids
GROUP BY relname, oid ORDER BY count(*) desc ;
```

`gpcheckperf`

Verifies the baseline hardware performance of the specified hosts.

**Synopsis**

```
gpcheckperf -d test_directory [-d test_directory ...]  
{-f hostfile_gpcheckperf | - h hostname [-h hostname ...]}  
[-r ds] [-B block_size] [-S file_size] [-D] [-v|-V]  
gpcheckperf -d temp_directory  
{-f hostfile_gpchecknet | - h hostname [-h hostname ...]}  
[ -r n|N|M [--duration time] [--netperf] ] [-D] [-v | -V]  
gpcheckperf -?  
gpcheckperf --version
```

**Description**

The `gpcheckperf` utility starts a session on the specified hosts and runs the following performance tests:

- **Disk I/O Test (dd test)** — To test the sequential throughput performance of a logical disk or file system, the utility uses the `dd` command, which is a standard UNIX utility. It times how long it takes to write and read a large file to and from disk and calculates your disk I/O performance in megabytes (MB) per second. By default, the file size that is used for the test is calculated at two times the total random access memory (RAM) on the host. This ensures that the test is truly testing disk I/O and not using the memory cache.

- **Memory Bandwidth Test (stream)** — To test memory bandwidth, the utility uses the STREAM benchmark program to measure sustainable memory bandwidth (in MB/s). This tests that your system is not limited in performance by the memory bandwidth of the system in relation to the computational performance of the CPU. In applications where the data set is large (as in Greenplum Database), low memory bandwidth is a major performance issue. If memory bandwidth is significantly lower than the theoretical bandwidth of the CPU, then it can cause the CPU to spend significant amounts of time waiting for data to arrive from system memory.
• **Network Performance Test (gpnetbench*)** — To test network performance (and thereby the performance of the Greenplum Database interconnect), the utility runs a network benchmark program that transfers a 5-second stream of data from the current host to each remote host included in the test. The data is transferred in parallel to each remote host and the minimum, maximum, average and median network transfer rates are reported in megabytes (MB) per second. If the summary transfer rate is slower than expected (less than 100 MB/s), you can run the network test serially using the `-r n` option to obtain per-host results. To run a full-matrix bandwidth test, you can specify `-r M` which will cause every host to send and receive data from every other host specified. This test is best used to validate if the switch fabric can tolerate a full-matrix workload.

To specify the hosts to test, use the `-f` option to specify a file containing a list of host names, or use the `-h` option to name single host names on the command-line. If running the network performance test, all entries in the host file must be for network interfaces within the same subnet. If your segment hosts have multiple network interfaces configured on different subnets, run the network test once for each subnet.

You must also specify at least one test directory (`-d`). The user who runs `gpcheckperf` must have write access to the specified test directories on all remote hosts. For the disk I/O test, the test directories should correspond to your segment data directories (primary and/or mirrors). For the memory bandwidth and network tests, a temporary directory is required for the test program files.

Before using `gpcheckperf`, you must have a trusted host setup between the hosts involved in the performance test. You can use the utility `gpssh-exkeys` to update the known host files and exchange public keys between hosts if you have not done so already. Note that `gpcheckperf` calls to `gpssh` and `gpscp`, so these Greenplum utilities must also be in your `$PATH`.

**Options**

- **-B block_size**
  Specifies the block size (in KB or MB) to use for disk I/O test. The default is 32KB, which is the same as the Greenplum Database page size. The maximum block size is 1 MB.

- **-d test_directory**
  For the disk I/O test, specifies the file system directory locations to test. You must have write access to the test directory on all hosts involved in the performance test. You can use the `-d` option multiple times to specify multiple test directories (for example, to test disk I/O of your primary and mirror data directories).

- **-d temp_directory**
  For the network and stream tests, specifies a single directory where the test program files will be copied for the duration of the test. You must have write access to this directory on all hosts involved in the test.

- **-D (display per-host results)**
  Reports performance results for each host for the disk I/O tests. The default is to report results for just the hosts with the minimum and maximum performance, as well as the total and average performance of all hosts.

- **--duration time**
  Specifies the duration of the network test in seconds (s), minutes (m), hours (h), or days (d). The default is 15 seconds.

- **-f hostfile_gpcheckperf**
  For the disk I/O and stream tests, specifies the name of a file that contains one host name per host that will participate in the performance test. The host name is required, and you can optionally specify an alternate user name and/or SSH port number per host. The syntax of the host file is one host per line as follows:

  ```
  [username@]hostname[:ssh_port]
  ```

- **-f hostfile_gpchecknet**
For the network performance test, all entries in the host file must be for host addresses within the same subnet. If your segment hosts have multiple network interfaces configured on different subnets, run the network test once for each subnet. For example (a host file containing segment host address names for interconnect subnet 1):

```
sdw1-1
sdw2-1
sdw3-1
```

- **h hostname**  
  Specifies a single host name (or host address) that will participate in the performance test. You can use the -h option multiple times to specify multiple host names.

- **--netperf**  
  Specifies that the netperf binary should be used to perform the network test instead of the Greenplum network test. To use this option, you must download netperf from [http://www.netperf.org](http://www.netperf.org) and install it into $GPHOME/bin/lib on all Greenplum hosts (master and segments).

- **r ds{n|N|M}**  
  Specifies which performance tests to run. The default is dsn:

  - Disk I/O test (d)
  - Stream test (s)
  - Network performance test in sequential (n), parallel (N), or full-matrix (M) mode. The optional --duration option specifies how long (in seconds) to run the network test. To use the parallel (N) mode, you must run the test on an even number of hosts.

  If you would rather use netperf ([http://www.netperf.org](http://www.netperf.org)) instead of the Greenplum network test, you can download it and install it into $GPHOME/bin/lib on all Greenplum hosts (master and segments). You would then specify the optional --netperf option to use the netperf binary instead of the default gpnetbench* utilities.

- **-S file_size**  
  Specifies the total file size to be used for the disk I/O test for all directories specified with -d. file_size should equal two times total RAM on the host. If not specified, the default is calculated at two times the total RAM on the host where gpcheckperf is executed. This ensures that the test is truly testing disk I/O and not using the memory cache. You can specify sizing in KB, MB, or GB.

- **v (verbose) | -V (very verbose)**  
  Verbose mode shows progress and status messages of the performance tests as they are run. Very verbose mode shows all output messages generated by this utility.

- **--version**  
  Displays the version of this utility.

- **-? (help)**  
  Displays the online help.

**Examples**

Run the disk I/O and memory bandwidth tests on all the hosts in the file host_file using the test directory of /data1 and /data2:

```
$ gpcheckperf -f hostfile_gpcheckperf -d /data1 -d /data2 -r ds
```
Run only the disk I/O test on the hosts named sdw1 and sdw2 using the test directory of /data1. Show individual host results and run in verbose mode:

```
$ gpcheckperf -h sdw1 -h sdw2 -d /data1 -r d -D -v
```

Run the parallel network test using the test directory of /tmp, where hostfile_gpchecknet_ic* specifies all network interface host address names within the same interconnect subnet:

```
$ gpcheckperf -f hostfile_gpchecknet_ic1 -r N -d /tmp
$ gpcheckperf -f hostfile_gpchecknet_ic2 -r N -d /tmp
```

Run the same test as above, but use netperf instead of the Greenplum network test (note that netperf must be installed in $GPHOME/bin/lib on all Greenplum hosts):

```
$ gpcheckperf -f hostfile_gpchecknet_ic1 -r N --netperf -d /tmp
$ gpcheckperf -f hostfile_gpchecknet_ic2 -r N --netperf -d /tmp
```

See Also
gpssh, gpscp

gpconfig

Sets server configuration parameters on all segments within a Greenplum Database system.

**Synopsis**

```
gpconfig -c param_name -v value [-m master_value | --masteronly]
   [-r param_name [--masteronly]]
   [-l [--skipvalidation] [--verbose] [--debug]]
gpconfig -s param_name [--file | --file-compare] [--verbose] [--debug]
gpconfig --help
```

**Description**

The gpconfig utility allows you to set, unset, or view configuration parameters from the postgresql.conf files of all instances (master, segments, and mirrors) in your Greenplum Database system. When setting a parameter, you can also specify a different value for the master if necessary. For example, parameters such as max_connections require a different setting on the master than what is used for the segments. If you want to set or unset a global or master only parameter, use the --masteronly option.

gpconfig can only be used to manage certain parameters. For example, you cannot use it to set parameters such as port, which is required to be distinct for every segment instance. Use the -l (list) option to see a complete list of configuration parameters supported by gpconfig.

When gpconfig sets a configuration parameter in a segment postgresql.conf file, the new parameter setting always displays at the bottom of the file. When you use gpconfig to remove a configuration parameter setting, gpconfig comments out the parameter in all segment postgresql.conf files, thereby restoring the system default setting. For example, if you use gpconfig to remove (comment out) a parameter and later add it back (set a new value), there will be two instances of the parameter; one that is commented out, and one that is enabled and inserted at the bottom of the postgresql.conf file.
After setting a parameter, you must restart your Greenplum Database system or reload the postgresql.conf files in order for the change to take effect. Whether you require a restart or a reload depends on the parameter.

For more information about the server configuration parameters, see the Greenplum Database Reference Guide.

To show the currently set values for a parameter across the system, use the -s option.

gpconfig uses the following environment variables to connect to the Greenplum Database master instance and obtain system configuration information:

- PGHOST
- PGPORT
- PGUSER
- PGPASSWORD
- PGDATABASE

**Options**

-c | --change param_name

Changes a configuration parameter setting by adding the new setting to the bottom of the postgresql.conf files.

-v | --value value

The value to use for the configuration parameter you specified with the -c option. By default, this value is applied to all segments, their mirrors, the master, and the standby master.

The utility correctly quotes the value when adding the setting to the postgresql.conf files.

To set the value to an empty string, enter empty single quotes ("'").

-m | --mastervalue master_value

The master value to use for the configuration parameter you specified with the -c option. If specified, this value only applies to the master and standby master. This option can only be used with -v.

--masteronly

When specified, gpconfig will only edit the master postgresql.conf file.

-r | --remove param_name

Removes a configuration parameter setting by commenting out the entry in the postgresql.conf files.

-l | --list

Lists all configuration parameters supported by the gpconfig utility.

-s | --show param_name

Shows the value for a configuration parameter used on all instances (master and segments) in the Greenplum Database system. If there is a difference in a parameter value among the instances, the utility displays an error message. Running gpconfig with the -s option reads parameter values directly from the database, and not the postgresql.conf file. If you are using gpconfig to set configuration parameters across all segments, then running gpconfig -s to verify the changes, you might still see the previous (old) values. You must reload the configuration files (gpstop -u) or restart the system (gpstop -r) for changes to take effect.

--file

For a configuration parameter, shows the value from the postgresql.conf file on all instances (master and segments) in the Greenplum Database system. If there is a
difference in a parameter value among the instances, the utility displays a message. Must be specified with the --s option.

For example, the configuration parameter statement_mem is set to 64MB for a user with the ALTER ROLE command, and the value in the postgresql.conf file is 128MB. Running the command gpconfig --s statement_mem --file displays 128MB. The command gpconfig --s statement_mem run by the user displays 64MB.

Not valid with the --file-compare option.

--file-compare
For a configuration parameter, compares the current Greenplum Database value with the value in the postgresql.conf files on hosts (master and segments). The values in the postgresql.conf files represent the value when Greenplum Database is restarted.

If the values are not the same, the utility displays the values from all hosts. If all hosts have the same value, the utility displays a summary report.

Not valid with the --file option.

--skipvalidation
Overrides the system validation checks of gpconfig and allows you to operate on any server configuration parameter, including hidden parameters and restricted parameters that cannot be changed by gpconfig. When used with the -l option (list), it shows the list of restricted parameters.

Warning: Use extreme caution when setting configuration parameters with this option.

--verbose
Displays additional log information during gpconfig command execution.

--debug
Sets logging output to debug level.

-? | -h | --help
Displays the online help.

Examples
Set the max_connections setting to 100 on all segments and 10 on the master:

```
gpconfig -c max_connections -v 100 -m 10
```

These examples shows the syntax required due to bash shell string processing.

```
gpconfig -c search_path -v '"$user",public'
gpconfig -c dynamic_library_path -v '"$libdir'
```

The configuration parameters are added to the postgresql.conf file.

```
search_path='"$user",public'
dynamic_library_path='$libdir'
```

Comment out all instances of the default_statistics_target configuration parameter, and restore the system default:

```
gpconfig -r default_statistics_target
```
List all configuration parameters supported by `gpconfig`:

```
gpconfig -l
```

Show the values of a particular configuration parameter across the system:

```
gpconfig -s max_connections
```

See Also

gpstop

gpcopy

The `gpcopy` utility copies objects from databases in a source Greenplum Database system to databases in a destination Greenplum Database system.

Note: The `gpcopy` utility is available as a separate download for the commercial release of Pivotal Greenplum Database. See the Pivotal gpcopy Documentation.

gpdeletesystem

Deletes a Greenplum Database system that was initialized using `gpinitdb`.

Synopsis

```
gpdeletesystem -?
gpdeletesystem -v
```

Description

The `gpdeletesystem` utility performs the following actions:

- Stop all `postgres` processes (the segment instances and master instance).
- Deletes all data directories.

Before running `gpdeletesystem`:

- Move any backup files out of the master and segment data directories.
- Make sure that Greenplum Database is running.
- If you are currently in a segment data directory, change directory to another location. The utility fails with an error when run from within a segment data directory.

This utility will not uninstall the Greenplum Database software.

Options

- **d master_data_directory**
  
  Specifies the master host data directory. If this option is not specified, the setting for the environment variable `MASTER_DATA_DIRECTORY` is used. If this option is specified, it overrides any setting of `MASTER_DATA_DIRECTORY`. If `master_data_directory` cannot be determined, the utility returns an error.

- B parallel_processes
The number of segments to delete in parallel. If not specified, the utility will start up to 60 parallel processes depending on how many segment instances it needs to delete.

-\f (force)
  Force a delete even if backup files are found in the data directories. The default is to not delete Greenplum Database instances if backup files are present.

-\l logfile_directory
  The directory to write the log file. Defaults to ~/gpAdminLogs.

-\D (debug)
  Sets logging level to debug.

-? (help)
  Displays the online help.

-v (show utility version)
  Displays the version, status, last updated date, and check sum of this utility.

Examples
Delete a Greenplum Database system:

```
gpdeletesystem -d /gpdata/gp-1
```

Delete a Greenplum Database system even if backup files are present:

```
gpdeletesystem -d /gpdata/gp-1 -f
```

See Also

```
gpinitsystem
```

**gpexpand**

Expands an existing Greenplum Database across new hosts in the system.

**Synopsis**

```
gpexpand [-f --hosts-file] hosts_file
         [-i --input] input_file [-B batch_size]
         [-d --duration] hh:mm:ss | {-e|--end} 'YYYY-MM-DD hh:mm:ss'
         [-a --analyze]
         [-n parallel_processes]
         [-r --rollback]
         [-c --clean]
         [-v --verbose] [-s --silent]
         [{-t --tardir} directory ]
         [-S --simple-progress ]
```

```
gpexpand -? | -h | --help
```

```
gpexpand --version
```

**Prerequisites**

- You are logged in as the Greenplum Database superuser (gpadmin).
- The new segment hosts have been installed and configured as per the existing segment hosts. This involves:
- Configuring the hardware and OS
- Installing the Greenplum software
- Creating the `gpadmin` user account
- Exchanging SSH keys.
- Enough disk space on your segment hosts to temporarily hold a copy of your largest table.
- When redistributing data, Greenplum Database must be running in production mode. Greenplum Database cannot be running in restricted mode or in master mode. The `gpstart` options `-R` or `-m` cannot be specified to start Greenplum Database.

**Note:** These utilities cannot be run while `gpexpand` is performing segment initialization.

- `gpbackup`
- `gpcheckcat`
- `gpconfig`
- `gppkg`
- `gprestore`

For information about preparing a system for expansion, see *Expanding a Greenplum System* in the *Greenplum Database Administrator Guide*.

**Description**

The `gpexpand` utility performs system expansion in two phases: segment instance initialization and then table data redistribution.

In the initialization phase, `gpexpand` runs with an input file that specifies data directories, `dbid` values, and other characteristics of the new segment instances. You can create the input file manually, or by following the prompts in an interactive interview.

If you choose to create the input file using the interactive interview, you can optionally specify a file containing a list of expansion system hosts. If your platform or command shell limits the length of the list of hostnames that you can type when prompted in the interview, specifying the hosts with `-f` may be mandatory.

In addition to initializing the segment instances, the initialization phase performs these actions:

- Creates an expansion schema named `gpexpand` in the `postgres` database to store the status of the expansion operation, including detailed status for tables.

In the table data redistribution phase, `gpexpand` redistributes table data to rebalance the data across the old and new segment instances.

**Note:** Data redistribution should be performed during low-use hours. Redistribution can be divided into batches over an extended period.

To begin the redistribution phase, run `gpexpand` with either the `-d` (duration) or `-e` (end time) options, or with no options. If you specify an end time or duration, then the utility redistributes tables in the expansion schema until the specified end time or duration is reached. If you specify no options, then the utility redistribution phase continues until all tables in the expansion schema are reorganized. Each table is reorganized using `ALTER TABLE` commands to rebalance the tables across new segments, and to set tables to their original distribution policy. If `gpexpand` completes the reorganization of all tables, it displays a success message and ends.

**Note:** This utility uses secure shell (SSH) connections between systems to perform its tasks. In large Greenplum Database deployments, cloud deployments, or deployments with a large number of segments per host, this utility may exceed the host's maximum threshold for unauthenticated connections. Consider updating the SSH `MaxStartups` and `MaxSessions` configuration parameters to increase this threshold. For more information about SSH configuration options, refer to the SSH documentation for your Linux distribution.
Options

-a | --analyze
  Run ANALYZE to update the table statistics after expansion. The default is to not run ANALYZE.

-B batch_size
  Batch size of remote commands to send to a given host before making a one-second pause. Default is 16. Valid values are 1-128.

  The gpexpand utility issues a number of setup commands that may exceed the host's maximum threshold for unauthenticated connections as defined by MaxStartups in the SSH daemon configuration. The one-second pause allows authentications to be completed before gpexpand issues any more commands.

  The default value does not normally need to be changed. However, it may be necessary to reduce the maximum number of commands if gpexpand fails with connection errors such as 'ssh_exchange_identification: Connection closed by remote host.'

-c | --clean
  Remove the expansion schema.

-d | --duration hh:mm:ss
  Duration of the expansion session from beginning to end.

-e | --end 'YYYY-MM-DD hh:mm:ss'
  Ending date and time for the expansion session.

-f | --hosts-file filename
  Specifies the name of a file that contains a list of new hosts for system expansion. Each line of the file must contain a single host name.

  This file can contain hostnames with or without network interfaces specified. The gpexpand utility handles either case, adding interface numbers to end of the hostname if the original nodes are configured with multiple network interfaces.

  Note: The Greenplum Database segment host naming convention is sdwN where sdw is a prefix and N is an integer. For example, sdw1, sdw2 and so on. For hosts with multiple interfaces, the convention is to append a dash (-) and number to the host name. For example, sdw1-1 and sdw1-2 are the two interface names for host sdw1.

-i | --input input_file
  Specifies the name of the expansion configuration file, which contains one line for each segment to be added in the format of:

  hostname|address|port|datadir|dbid|content|preferred_role

-n parallel_processes
  The number of tables to redistribute simultaneously. Valid values are 1 - 96.

  Each table redistribution process requires two database connections: one to alter the table, and another to update the table's status in the expansion schema. Before increasing -n, check the current value of the server configuration parameter max_connections and make sure the maximum connection limit is not exceeded.

-r | --rollback
  Roll back a failed expansion setup operation.

-s | --silent
  Runs in silent mode. Does not prompt for confirmation to proceed on warnings.

-S | --simple-progress
If specified, the `gpexpand` utility records only the minimum progress information in the Greenplum Database table `gpexpand.expansion_progress`. The utility does not record the relation size information and status information in the table `gpexpand.status_detail`. Specifying this option can improve performance by reducing the amount of progress information written to the `gpexpand` tables.

`[-t | --tardir] directory`

The fully qualified path to a directory on segment hosts where the `gpexpand` utility copies a temporary tar file. The file contains Greenplum Database files that are used to create segment instances. The default directory is the user home directory.

`-v | --verbose`

Verbose debugging output. With this option, the utility will output all DDL and DML used to expand the database.

`--version`

Display the utility's version number and exit.

`-? | -h | --help`

Displays the online help.

**Examples**

Run `gpexpand` with an input file to initialize new segments and create the expansion schema in the `postgres` database:

```
$ gpexpand -i input_file
```

Run `gpexpand` for sixty hours maximum duration to redistribute tables to new segments:

```
$ gpexpand -d 60:00:00
```

**gpfdist**

Serves data files to or writes data files out from Greenplum Database segments.

**Synopsis**

```
        [-t timeout] [-S] [-w time] [-v | -V] [-s] [-m max_length]
        [--ssl certificate_path] [--sslclean wait_time] ]
        [-c config.yml]
```

```
gpfdist -? | --help
```

```
gpfdist --version
```

**Description**

gpfdist is Greenplum Database parallel file distribution program. It is used by readable external tables and `gpload` to serve external table files to all Greenplum Database segments in parallel. It is used by writable external tables to accept output streams from Greenplum Database segments in parallel and write them out to a file.
Note: gpfdist and gpload are compatible only with the Greenplum Database major version in which they are shipped. For example, a gpfdist utility that is installed with Greenplum Database 4.x cannot be used with Greenplum Database 5.x or 6.x.

In order for gpfdist to be used by an external table, the LOCATION clause of the external table definition must specify the external table data using the gpfdist:// protocol (see the Greenplum Database command CREATE EXTERNAL TABLE).

Note: If the --ssl option is specified to enable SSL security, create the external table with the gpfdists:// protocol.

The benefit of using gpfdist is that you are guaranteed maximum parallelism while reading from or writing to external tables, thereby offering the best performance as well as easier administration of external tables.

For readable external tables, gpfdist parses and serves data files evenly to all the segment instances in the Greenplum Database system when users SELECT from the external table. For writable external tables, gpfdist accepts parallel output streams from the segments when users INSERT into the external table, and writes to an output file.

Note: When gpfdist reads data and encounters a data formatting error, the error message includes a row number indicating the location of the formatting error. gpfdist attempts to capture the row that contains the error. However, gpfdist might not capture the exact row for some formatting errors.

For readable external tables, if load files are compressed using gzip or bzip2 (have a .gz or .bz2 file extension), gpfdist uncompressed the files before loading. For writable external tables, gpfdist compresses the data using gzip if the target file has a .gz extension.

Note: Compression is not supported for readable and writeable external tables when the gpfdist utility runs on Windows platforms.

When reading or writing data with the gpfdist or gpfdists protocol, Greenplum Database includes X-GP-PROTO in the HTTP request header to indicate that the request is from Greenplum Database. The utility rejects HTTP requests that do not include X-GP-PROTO in the request header.

Most likely, you will want to run gpfdist on your ETL machines rather than the hosts where Greenplum Database is installed. To install gpfdist on another host, simply copy the utility over to that host and add gpfdist to your $PATH.

Note: When using IPv6, always enclose the numeric IP address in brackets.

Options

-d directory
The directory from which gpfdist will serve files for readable external tables or create output files for writable external tables. If not specified, defaults to the current directory.

-l log_file
The fully qualified path and log file name where standard output messages are to be logged.

-p http_port
The HTTP port on which gpfdist will serve files. Defaults to 8080.

-P last_http_port
The last port number in a range of HTTP port numbers (http_port to last_http_port, inclusive) on which gpfdist will attempt to serve files. gpfdist serves the files on the first port number in the range to which it successfully binds.

-t timeout
Sets the time allowed for Greenplum Database to establish a connection to a `gpfdist` process. Default is 5 seconds. Allowed values are 2 to 7200 seconds (2 hours). May need to be increased on systems with a lot of network traffic.

`-m max_length`

Sets the maximum allowed data row length in bytes. Default is 32768. Should be used when user data includes very wide rows (or when `line too long` error message occurs). Should not be used otherwise as it increases resource allocation. Valid range is 32K to 256MB. (The upper limit is 1MB on Windows systems.)

**Note:** Memory issues might occur if you specify a large maximum row length and run a large number of `gpfdist` concurrent connections. For example, setting this value to the maximum of 256MB with 96 concurrent `gpfdist` processes requires approximately 24GB of memory \((96 + 1) \times 246MB\).

`-s`

Enables simplified logging. When this option is specified, only messages with `WARN` level and higher are written to the `gpfdist` log file. `INFO` level messages are not written to the log file. If this option is not specified, all `gpfdist` messages are written to the log file.

You can specify this option to reduce the information written to the log file.

`-S (use O_SYNC)`

Opens the file for synchronous I/O with the `O_SYNC` flag. Any writes to the resulting file descriptor block `gpfdist` until the data is physically written to the underlying hardware.

`-w time`

Sets the number of seconds that Greenplum Database delays before closing a target file such as a named pipe. The default value is 0, no delay. The maximum value is 7200 seconds (2 hours).

For a Greenplum Database with multiple segments, there might be a delay between segments when writing data from different segments to the file. You can specify a time to wait before Greenplum Database closes the file to ensure all the data is written to the file.

`--ssl certificate_path`

Adds SSL encryption to data transferred with `gpfdist`. After executing `gpfdist` with the `--ssl certificate_path` option, the only way to load data from this file server is with the `gpfdist://` protocol. For information on the `gpfdist://` protocol, see "Loading and Unloading Data" in the `Greenplum Database Administrator Guide`.

The location specified in `certificate_path` must contain the following files:

- The server certificate file, `server.crt`
- The server private key file, `server.key`
- The trusted certificate authorities, `root.crt`

The root directory (`/`) cannot be specified as `certificate_path`.

`--sslclean wait_time`

When the utility is run with the `--ssl` option, sets the number of seconds that the utility delays before closing an SSL session and cleaning up the SSL resources after it completes writing data to or from a Greenplum Database segment. The default value is 0, no delay. The maximum value is 500 seconds. If the delay is increased, the transfer speed decreases.

In some cases, this error might occur when copying large amounts of data: `gpfdist server closed connection`. To avoid the error, you can add a delay, for example `--sslclean 5`.

`-c config.yaml`
Specifies rules that gpfdist uses to select a transform to apply when loading or extracting data. The gpfdist configuration file is a YAML 1.1 document.

For information about the file format, see Configuration File Format in the Greenplum Database Administrator Guide. For information about configuring data transformation with gpfdist, see Transforming External Data with gpfdist and gpload in the Greenplum Database Administrator Guide.

This option is not available on Windows platforms.

-v (verbose)
Verbese mode shows progress and status messages.

-V (very verbose)
Verbese mode shows all output messages generated by this utility.

-? (help)
Displays the online help.

--version
Displays the version of this utility.

Notes
The server configuration parameter verify_gpfdists_cert controls whether SSL certificate authentication is enabled when Greenplum Database communicates with the gpfdist utility to either read data from or write data to an external data source. You can set the parameter value to false to disable authentication when testing the communication between the Greenplum Database external table and the gpfdist utility that is serving the external data. If the value is false, these SSL exceptions are ignored:

- The self-signed SSL certificate that is used by gpfdist is not trusted by Greenplum Database.
- The host name contained in the SSL certificate does not match the host name that is running gpfdist.

Warning: Disabling SSL certificate authentication exposes a security risk by not validating the gpfdists SSL certificate.

If the gpfdist utility hangs with no read or write activity occurring, you can generate a core dump the next time a hang occurs to help debug the issue. Set the environment variable GPFDIST_WATCHDOG_TIMER to the number of seconds of no activity to wait before gpfdist is forced to exit. When the environment variable is set and gpfdist hangs, the utility aborts after the specified number of seconds, creates a core dump, and sends abort information to the log file.

This example sets the environment variable on a Linux system so that gpfdist exits after 300 seconds (5 minutes) of no activity.

export GPFDIST_WATCHDOG_TIMER=300

Examples
To serve files from a specified directory using port 8081 (and start gpfdist in the background):

gpfdist -d /var/load_files -p 8081 &

To start gpfdist in the background and redirect output and errors to a log file:

gpfdist -d /var/load_files -p 8081 -l /home/gpadmin/log &

To stop gpfdist when it is running in the background:
--First find its process id:

```
ps ax | grep gpfdist
```

--Then kill the process, for example:

```
kill 3456
```

**See Also**

gpload, CREATE EXTERNAL TABLE in the *Greenplum Database Reference Guide*

**gpinitstandby**

Adds and/or initializes a standby master host for a Greenplum Database system.

**Synopsis**

```
gpinitstandby { -s standby_hostname [-P port] | -r | -n } [-a] [-q]
               [-D] [-S standby_data_directory] [-l logfile_directory]
```

```
gpinitstandby -v
```

```
gpinitstandby -?
```

**Description**

The `gpinitstandby` utility adds a backup, standby master instance to your Greenplum Database system. If your system has an existing standby master instance configured, use the `-r` option to remove it before adding the new standby master instance.

Before running this utility, make sure that the Greenplum Database software is installed on the standby master host and that you have exchanged SSH keys between the hosts. It is recommended that the master port is set to the same port number on the master host and the standby master host.

This utility should be run on the currently active primary master host. See the *Greenplum Database Installation Guide* for instructions.

The utility performs the following steps:

- Updates the Greenplum Database system catalog to remove the existing standby master information (if the `-r` option is supplied)
- Updates the Greenplum Database system catalog to add the new standby master instance information
- Edits the `pg_hba.conf` file of the Greenplum Database master to allow access from the newly added standby master
- Sets up the standby master instance on the alternate master host
- Starts the synchronization process

A backup, standby master instance serves as a ‘warm standby’ in the event of the primary master becoming non-operational. The standby master is kept up to date by transaction log replication processes (the `walsender` and `walreceiver`), which run on the primary master and standby master hosts and keep the data between the primary and standby master instances synchronized. If the primary master fails, the log replication process is shut down, and the standby master can be activated in its place by using the `gpactivatestandby` utility. Upon activation of the standby master, the replicated logs are used to reconstruct the state of the master instance at the time of the last successfully committed transaction.

The activated standby master effectively becomes the Greenplum Database master, accepting client connections on the master port and performing normal master operations such as SQL command processing and resource management.
Important: If the gpinitstandby utility previously failed to initialize the standby master, you must delete the files in the standby master data directory before running gpinitstandby again. The standby master data directory is not cleaned up after an initialization failure because it contains log files that can help in determining the reason for the failure.

If an initialization failure occurs, a summary report file is generated in the standby host directory /tmp. The report file lists the directories on the standby host that require clean up.

Options

-a (do not prompt)
Do not prompt the user for confirmation.

-D (debug)
Sets logging level to debug.

-l logfile_directory
The directory to write the log file. Defaults to ~/gpAdminLogs.

-n (restart standby master)
Specify this option to start a Greenplum Database standby master that has been configured but has stopped for some reason.

-P port
This option specifies the port that is used by the Greenplum Database standby master. The default is the same port used by the active Greenplum Database master.

If the Greenplum Database standby master is on the same host as the active master, the ports must be different. If the ports are the same for the active and standby master and the host is the same, the utility returns an error.

-q (no screen output)
Run in quiet mode. Command output is not displayed on the screen, but is still written to the log file.

-r (remove standby master)
Removes the currently configured standby master instance from your Greenplum Database system.

-s standby_hostname
The host name of the standby master host.

-S standby_data_directory
The data directory to use for a new standby master. The default is the same directory used by the active master.

If the standby master is on the same host as the active master, a different directory must be specified using this option.

-v (show utility version)
Displays the version, status, last updated date, and checksum of this utility.

-? (help)
Displays the online help.

Examples

Add a standby master instance to your Greenplum Database system and start the synchronization process:

    gpinitstandby -s host09
Start an existing standby master instance and synchronize the data with the current primary master instance:

```bash
gpinitstandby -n
```

**Note:** Do not specify the `-n` and `-s` options in the same command.

Add a standby master instance to your Greenplum Database system specifying a different port:

```bash
gpinitstandby -s myhost -P 2222
```

If you specify the same host name as the active Greenplum Database master, you must also specify a different port number with the `-P` option and a standby data directory with the `-S` option.

Remove the existing standby master from your Greenplum system configuration:

```bash
gpinitstandby -r
```

See Also

`gpinitsystem`, `gpaddmirrors`, `gpactivatestandby`

### gpinitsystem

Initializes a Greenplum Database system using configuration parameters specified in the `gpinitsystem_config` file.

#### Synopsis

```bash
```

#### Description

The `gpinitsystem` utility creates a Greenplum Database instance or writes an input configuration file using the values defined in a cluster configuration file and any command-line options that you provide. See `Initialization Configuration File Format` for more information about the configuration file. Before running this utility, make sure that you have installed the Greenplum Database software on all the hosts in the array.
With the -O output_configuration_file option, gpinitsystem does not create a new database instance but instead writes all provided configuration information to the specified output file. This file uses the QD_PRIMARY_ARRAY and PRIMARY_ARRAY parameters to define each member using its hostname, port, data directory, segment prefix, segment ID, and content ID. Details of the array configuration can be modified as necessary to match values available in a Greenplum Database backup, or can simply be used to recreate the same cluster configuration at a later time. Configuration files that use QD_PRIMARY_ARRAY and PRIMARY_ARRAY must be passed into gpinitsystem using the -I input_configuration_file option. See Initialization Configuration File Format for more information.

In a Greenplum Database DBMS, each database instance (the master and all segments) must be initialized across all of the hosts in the system in such a way that they can all work together as a unified DBMS. The gpinitsystem utility takes care of initializing the Greenplum master and each segment instance, and configuring the system as a whole.

Before running gpinitsystem, you must set the $GPHOME environment variable to point to the location of your Greenplum Database installation on the master host and exchange SSH keys between all host addresses in the array using gpssh-exkeys.

This utility performs the following tasks:

- Verifies that the parameters in the configuration file are correct.
- Ensures that a connection can be established to each host address. If a host address cannot be reached, the utility will exit.
- Verifies the locale settings.
- Displays the configuration that will be used and prompts the user for confirmation.
- Initializes the master instance.
- Initializes the standby master instance (if specified).
- Initializes the primary segment instances.
- Initializes the mirror segment instances (if mirroring is configured).
- Configures the Greenplum Database system and checks for errors.
- Starts the Greenplum Database system.

Note: This utility uses secure shell (SSH) connections between systems to perform its tasks. In large Greenplum Database deployments, cloud deployments, or deployments with a large number of segments per host, this utility may exceed the host's maximum threshold for unauthenticated connections. Consider updating the SSH MaxStartups and MaxSessions configuration parameters to increase this threshold. For more information about SSH configuration options, refer to the SSH documentation for your Linux distribution.

Options

-a
Do not prompt the user for confirmation.

-B parallel_processes
The number of segments to create in parallel. If not specified, the utility will start up to 4 parallel processes at a time.

-c cluster_configuration_file
Required. The full path and filename of the configuration file, which contains all of the defined parameters to configure and initialize a new Greenplum Database system. See Initialization Configuration File Format for a description of this file. You must provide either the -c cluster_configuration_file option or the -I input_configuration_file option to gpinitsystem.

-D
Sets log output level to debug.

-h hostfile_gpinitsystem
Optional. The full path and filename of a file that contains the host addresses of your segment hosts. If not specified on the command line, you can specify the host file using the MACHINE_LIST_FILE parameter in the gpinitSystem_config file.

-\textbf{I \textit{input}\_configuration\_file}

The full path and filename of an input configuration file, which defines the Greenplum Database members and segments using the QD\_PRIMARY\_ARRAY and PRIMARY\_ARRAY parameters. The input configuration file is typically created by using gpinitSystem with the -O output\_configuration\_file option. You must provide either the -c cluster\_configuration\_file option or the -I input\_configuration\_file option to gpinitSystem.

-\textbf{n locale} | --locale=locale

Sets the default locale used by Greenplum Database. If not specified, the LC\_ALL, LC\_COLLATE, or LANG environment variable of the master host determines the locale. If these are not set, the default locale is C (POSIX). A locale identifier consists of a language identifier and a region identifier, and optionally a character set encoding. For example, sv\_SE is Swedish as spoken in Sweden, en\_US is U.S. English, and fr\_CA is French Canadian. If more than one character set can be useful for a locale, then the specifications look like this: en\_US.UTF-8 (locale specification and character set encoding). On most systems, the command locale will show the locale environment settings and locale -a will show a list of all available locales.

-\textbf{--lc-collate=locale}

Similar to --locale, but sets the locale used for collation (sorting data). The sort order cannot be changed after Greenplum Database is initialized, so it is important to choose a collation locale that is compatible with the character set encodings that you plan to use for your data. There is a special collation name of C or POSIX (byte-order sorting as opposed to dictionary-order sorting). The C collation can be used with any character encoding.

-\textbf{--lc-ctype=locale}

Similar to --locale, but sets the locale used for character classification (what character sequences are valid and how they are interpreted). This cannot be changed after Greenplum Database is initialized, so it is important to choose a character classification locale that is compatible with the data you plan to store in Greenplum Database.

-\textbf{--lc-messages=locale}

Similar to --locale, but sets the locale used for messages output by Greenplum Database. The current version of Greenplum Database does not support multiple locales for output messages (all messages are in English), so changing this setting will not have any effect.

-\textbf{--lc-monetary=locale}

Similar to --locale, but sets the locale used for formatting currency amounts.

-\textbf{--lc-numeric=locale}

Similar to --locale, but sets the locale used for formatting numbers.

-\textbf{--lc-time=locale}

Similar to --locale, but sets the locale used for formatting dates and times.

-\textbf{l logfile\_directory}

The directory to write the log file. Defaults to ~/gpAdminLogs.

-\textbf{m number} | --max\_connections=number

Sets the maximum number of client connections allowed to the master. The default is 250.

-\textbf{O output\_configuration\_file}

When used with the -O option, gpinitSystem does not create a new Greenplum Database cluster but instead writes the supplied cluster configuration.
information to the specified `output_configuration_file`. This file defines Greenplum Database members and segments using the `QD_PRIMARY_ARRAY`, `PRIMARY_ARRAY`, and `MIRROR_ARRAY` parameters, and can be later used with `-i input_configuration_file` to initialize a new cluster.

```
-p postgresql_conf_param_file
```
Optional. The name of a file that contains `postgresql.conf` parameter settings that you want to set for Greenplum Database. These settings will be used when the individual master and segment instances are initialized. You can also set parameters after initialization using the `gpconfig` utility.

```
-q
```
Run in quiet mode. Command output is not displayed on the screen, but is still written to the log file.

```
-b size | --shared_buffers=size
```
Sets the amount of memory a Greenplum server instance uses for shared memory buffers. You can specify sizing in kilobytes (kB), megabytes (MB) or gigabytes (GB). The default is 125MB.

```
-s standby_master_host
```
Optional. If you wish to configure a backup master instance, specify the host name using this option. The Greenplum Database software must already be installed and configured on this host.

```
-P standby_master_port
```
If you configure a standby master instance with `-s`, specify its port number using this option. The default port is the same as the master port. To run the standby and master on the same host, you must use this option to specify a different port for the standby. The Greenplum Database software must already be installed and configured on the standby host.

```
-S standby_master_datadir | --standby_dir=standby_master_datadir
```
If you configure a standby master host with `-s`, use this option to specify its data directory. If you configure a standby on the same host as the master instance, the master and standby must have separate data directories.

```
-e superuser_password | --su_password=superuser_password
```
Use this option to specify the password to set for the Greenplum Database superuser account (such as `gpadmin`). If this option is not specified, the default password `gparray` is assigned to the superuser account. You can use the `ALTER ROLE` command to change the password at a later time.

Recommended security best practices:

- Do not use the default password option for production environments.
- Change the password immediately after installation.

```
--mirror_mode={group|spread}
```
Use this option to specify the placement of mirror segment instances on the segment hosts. The default, `group`, groups the mirror segments for all of a host’s primary segments on a single alternate host. `spread` spreads mirror segments for the primary segments on a host across different hosts in the Greenplum Database array. Spreading is only allowed if the number of hosts is greater than the number of segment instances per host. See `Overview of Segment Mirroring` for information about Greenplum Database mirroring strategies.

```
-v | --version
```
Print the `gpinitsystem` version and exit.
Initialization Configuration File Format

gpinitsystem requires a cluster configuration file with the following parameters defined. An example initialization configuration file can be found in $GPHOME/docs/cli_help/gpconfigs/gpinitsystem_config.

To avoid port conflicts between Greenplum Database and other applications, the Greenplum Database port numbers should not be in the range specified by the operating system parameter net.ipv4.ip_local_port_range. For example, if net.ipv4.ip_local_port_range = 10000 65535, you could set Greenplum Database base port numbers to these values.

```
PORT_BASE = 6000
MIRROR_PORT_BASE = 7000
```

**ARRAY_NAME**

Required. A name for the array you are configuring. You can use any name you like. Enclose the name in quotes if the name contains spaces.

**MACHINE_LIST_FILE**

Optional. Can be used in place of the --help option. This specifies the file that contains the list of segment host address names that comprise the Greenplum Database system. The master host is assumed to be the host from which you are running the utility and should not be included in this file. If your segment hosts have multiple network interfaces, then this file would include all addresses for the host. Give the absolute path to the file.

**SEG_PREFIX**

Required. This specifies a prefix that will be used to name the data directories on the master and segment instances. The naming convention for data directories in a Greenplum Database system is SEG_PREFIX$number where $number starts with 0 for segment instances (the master is always -1). So for example, if you choose the prefix gpseg, your master instance data directory would be named gpseg-1, and the segment instances would be named gpseg0, gpseg1, gpseg2, gpseg3, and so on.

**PORT_BASE**

Required. This specifies the base number by which primary segment port numbers are calculated. The first primary segment port on a host is set as PORT_BASE, and then incremented by one for each additional primary segment on that host. Valid values range from 1 through 65535.

**DATA_DIRECTORY**

Required. This specifies the data storage location(s) where the utility will create the primary segment data directories. The number of locations in the list dictate the number of primary segments that will get created per physical host (if multiple addresses for a host are listed in the host file, the number of segments will be spread evenly across the specified interface addresses). It is OK to list the same data storage area multiple times if you want your data directories created in the same location. The user who runs gpinitsystem (for example, the gpadmin user) must have permission to write to these directories. For example, this will create six primary segments per host:

```
declare -a DATA_DIRECTORY=('/data1/primary /data1/primary /data1/primary /data2/primary /data2/primary /data2/primary')
```

**MASTER_HOSTNAME**
**Required.** The host name of the master instance. This host name must exactly match the configured host name of the machine (run the `hostname` command to determine the correct hostname).

**MASTER_DIRECTORY**

**Required.** This specifies the location where the data directory will be created on the master host. You must make sure that the user who runs `gpinitsystem` (for example, the `gpadmin` user) has permissions to write to this directory.

**MASTER_PORT**

**Required.** The port number for the master instance. This is the port number that users and client connections will use when accessing the Greenplum Database system.

**TRUSTED_SHELL**

**Required.** The shell the `gpinitsystem` utility uses to execute commands on remote hosts. Allowed values are `ssh`. You must set up your trusted host environment before running the `gpinitsystem` utility (you can use `gpssh-exkeys` to do this).

**CHECK_POINT_SEGMENTS**

**Required.** Maximum distance between automatic write ahead log (WAL) checkpoints, in log file segments (each segment is normally 16 megabytes). This will set the `checkpoint_segments` parameter in the `postgresql.conf` file for each segment instance in the Greenplum Database system.

**ENCODING**

**Required.** The character set encoding to use. This character set must be compatible with the `--locale` settings used, especially `--lc-collate` and `--lc-ctype`. Greenplum Database supports the same character sets as PostgreSQL.

**DATABASE_NAME**

**Optional.** The name of a Greenplum Database database to create after the system is initialized. You can always create a database later using the `CREATE DATABASE` command or the `createdb` utility.

**MIRROR_PORT_BASE**

**Optional.** This specifies the base number by which mirror segment port numbers are calculated. The first mirror segment port on a host is set as `MIRROR_PORT_BASE`, and then incremented by one for each additional mirror segment on that host. Valid values range from 1 through 65535 and cannot conflict with the ports calculated by `PORT_BASE`.

**MIRROR_DATA_DIRECTORY**

**Optional.** This specifies the data storage location(s) where the utility will create the mirror segment data directories. There must be the same number of data directories declared for mirror segment instances as for primary segment instances (see the `DATA_DIRECTORY` parameter). The user who runs `gpinitsystem` (for example, the `gpadmin` user) must have permission to write to these directories. For example:

```bash
declare -a MIRROR_DATA_DIRECTORY=('/data1/mirror /data1/mirror /data1/mirror /data2/mirror /data2/mirror')
```

**QD_PRIMARY_ARRAY, PRIMARY_ARRAY, MIRROR_ARRAY**

These parameters can only be provided using an input configuration file, with the `gpinitsystem -I input_configuration_file` option. `QD_PRIMARY_ARRAY, PRIMARY_ARRAY, MIRROR_ARRAY` define the Greenplum Database master host and the primary and mirror instances on the segment hosts, respectively, using the format:

```
host~port~data_directory/seg_prefix<segment_id>~dbid~content_id
```
The Greenplum Database master always uses the value -1 for the segment ID and content ID. For example:

```
QD_PRIMARY_ARRAY=127.0.0.1~5432~/gpmaster/gpmsne-1~1~-1~0
declare -a PRIMARY_ARRAY=(
  127.0.0.1~40000~/gpdata1/gpmsne0~2~0
  127.0.0.1~40001~/gpdata2/gpmsne1~3~1
)
declare -a MIRROR_ARRAY=(
  127.0.0.1~50000~/gpmirror1/gpmsne0~4~0
  127.0.0.1~50001~/gpmirror2/gpmsne1~5~1
)
```

You can use the `gpinitsystem -O output_configuration_file` to populate QD_PRIMARY_ARRAY, PRIMARY_ARRAY, MIRROR_ARRAY using the hosts, data directories, segment prefix, and base port values that you provide to the command. For recovery purposes, you can edit the segment and content IDs to match the values of an existing Greenplum Database backup.

**HEAP_CHECKSUM**

Optional. This parameter specifies if checksums are enabled for heap data. When enabled, checksums are calculated for heap storage in all databases, enabling Greenplum Database to detect corruption in the I/O system. This option is set when the system is initialized and cannot be changed later.

The HEAP_CHECKSUM option is on by default and turning it off is strongly discouraged. If you set this option to off, data corruption in storage can go undetected and make recovery much more difficult.

To determine if heap checksums are enabled in a Greenplum Database system, you can query the `data_checksums` server configuration parameter with the `gpconfig` management utility:

```
$ gpconfig -s data_checksums
```

**HBA_HOSTNAMES**

Optional. This parameter controls whether `gpinitsystem` uses IP addresses or host names in the `pg_hba.conf` file when updating the file with addresses that can connect to Greenplum Database. The default value is 0, the utility uses IP addresses when updating the file. When initializing a Greenplum Database system, specify HBA_HOSTNAMES=1 to have the utility use host names in the `pg_hba.conf` file.

For information about how Greenplum Database resolves host names in the `pg_hba.conf` file, see Configuring Client Authentication.

### Examples

Initialize a Greenplum Database array by supplying a cluster configuration file and a segment host address file, and set up a spread mirroring (--mirror-mode=spread) configuration:

```
$ gpinitsystem -c gpinitsystem_config -h hostfile_gpinitsystem --mirror-mode=spread
```

Initialize a Greenplum Database array and set the superuser remote password:

```
$ gpinitsystem -c gpinitsystem_config -h hostfile_gpinitsystem --su-password=mypassword
```
Initialize a Greenplum Database array with an optional standby master host:

```bash
$ gpinitsystem -c gpinitsystem_config -h hostfile_gpinitsystem -s host09
```

Instead of initializing a Greenplum Database array, write the provided configuration to an output file. The output file uses the `QD_PRIMARY_ARRAY` and `PRIMARY_ARRAY` parameters to define master and segment hosts:

```bash
$ gpinitsystem -c gpinitsystem_config -h hostfile_gpinitsystem --mirror-mode=spread -O cluster_init.config
```

Initialize a Greenplum Database using an input configuration file (a file that defines the Greenplum Database array) using `QD_PRIMARY_ARRAY` and `PRIMARY_ARRAY` parameters:

```bash
$ gpinitsystem -I cluster_init.config
```

### gpload

Runs a load job as defined in a YAML formatted control file.

**Synopsis**

```bash
gpload -?
gpload --version
```

**Requirements**

The client machine where `gpload` is executed must have the following:

- The `gpfdist` parallel file distribution program installed and in your `$PATH`. This program is located in `$GPHOME/bin` of your Greenplum Database server installation.
- Network access to and from all hosts in your Greenplum Database array (master and segments).
- Network access to and from the hosts where the data to be loaded resides (ETL servers).

**Description**

`gpload` is a data loading utility that acts as an interface to the Greenplum Database external table parallel loading feature. Using a load specification defined in a YAML formatted control file, `gpload` executes a load by invoking the Greenplum Database parallel file server (`gpfdist`), creating an external table definition based on the source data defined, and executing an `INSERT`, `UPDATE` or `MERGE` operation to load the source data into the target table in the database.

**Note:** `gpfdist` is compatible only with the Greenplum Database major version in which it is shipped. For example, a `gpfdist` utility that is installed with Greenplum Database 4.x cannot be used with Greenplum Database 5.x or 6.x.

**Note:** The Greenplum Database 5.22 and later `gpload` for Linux is compatible with Greenplum Database 6.x. The Greenplum Database 6.x `gpload` for both Linux and Windows is compatible with Greenplum 5.x.
**Note:** MERGE and UPDATE operations are not supported if the target table column name is a reserved keyword, has capital letters, or includes any character that requires quotes (" ") to identify the column.

The operation, including any SQL commands specified in the SQL collection of the YAML control file (see *Control File Format*), are performed as a single transaction to prevent inconsistent data when performing multiple, simultaneous load operations on a target table.

**Options**

---

**-f control_file**  
*Required.* A YAML file that contains the load specification details. See *Control File Format*.

**--gpfdist_timeout seconds**  
Sets the timeout for the gpfdist parallel file distribution program to send a response. Enter a value from 0 to 30 seconds (entering "0" to disables timeouts). Note that you might need to increase this value when operating on high-traffic networks.

**-l log_file**  
Specifies where to write the log file. Defaults to ~/.gpAdminLogs/gpload_YYYYMMDD. For more information about the log file, see *Log File Format*.

**--no_auto_trans**  
Specify --no_auto_trans to disable processing the load operation as a single transaction if you are performing a single load operation on the target table. By default, gpload processes each load operation as a single transaction to prevent inconsistent data when performing multiple, simultaneous operations on a target table.

**-q (no screen output)**  
Run in quiet mode. Command output is not displayed on the screen, but is still written to the log file.

**-D (debug mode)**  
Check for error conditions, but do not execute the load.

**-v (verbose mode)**  
Show verbose output of the load steps as they are executed.

**-V (very verbose mode)**  
Shows very verbose output.

**-? (show help)**  
Show help, then exit.

**--version**  
Show the version of this utility, then exit.

**Connection Options**

---

**-d database**  
The database to load into. If not specified, reads from the load control file, the environment variable $PGDATABASE or defaults to the current system user name.

**-h hostname**  
Specifies the host name of the machine on which the Greenplum Database master database server is running. If not specified, reads from the load control file, the environment variable $PGHOST or defaults to localhost.

**-p port**
Specifies the TCP port on which the Greenplum Database master database server is
listening for connections. If not specified, reads from the load control file, the environment
variable $PGPORT or defaults to 5432.

- **U username**
  The database role name to connect as. If not specified, reads from the load control file, the
  environment variable $PGUSER or defaults to the current system user name.

- **W (force password prompt)**
  Force a password prompt. If not specified, reads the password from the environment
  variable $PGPASSWORD or from a password file specified by $PGPASSFILE or in
  ~/.pgpass. If these are not set, then gpload will prompt for a password even if -W is not
  supplied.

**Control File Format**

The gpload control file uses the **YAML 1.1** document format and then implements its own schema for
defining the various steps of a Greenplum Database load operation. The control file must be a valid YAML
document.

The gpload program processes the control file document in order and uses indentation (spaces) to
determine the document hierarchy and the relationships of the sections to one another. The use of white
space is significant. White space should not be used simply for formatting purposes, and tabs should not
be used at all.

The basic structure of a load control file is:

```yaml
---
VERSION: 1.0.0.1
DATABASE: db_name
USER: db_username
HOST: master_hostname
PORT: master_port
GPLOAD:
  INPUT:
    - SOURCE:
      LOCAL_HOSTNAME:
      - hostname_or_ip
      PORT: http_port
      PORT_RANGE: [start_port_range, end_port_range]
    FILE:
      - /path/to/input_file
      SSL: true | false
      CERTIFICATES_PATH: /path/to/certificates
    FULLY_QUALIFIED_DOMAIN_NAME: true | false
  COLUMNS:
    - field_name: data_type
  TRANSFORM: 'transformation'
  TRANSFORM_CONFIG: 'configuration-file-path'
  MAX_LINE_LENGTH: integer
  FORMAT: text | csv
  DELIMITER: 'delimiter_character'
  ESCAPE: 'escape_character' | 'OFF'
  NULL_AS: 'null_string'
  FORCE_NOT_NULL: true | false
  QUOTE: 'csv_quote_character'
  HEADER: true | false
  ENCODING: database_encoding
  ERROR_LIMIT: integer
  LOG_ERRORS: true | false
EXTERNAL:
  - SCHEMA: schema | '%'
```
OUTPUT:
- **TABLE**: `schema.table_name`
- **MODE**: `insert` | `update` | `merge`
- **MATCH_COLUMNS**:
  - `target_column_name`
- **UPDATE_COLUMNS**:
  - `target_column_name`
- **UPDATE_CONDITION**: `'boolean_condition'`
- **MAPPING**:
  - `target_column_name`: `source_column_name` | `'expression'`

PRELOAD:
- **TRUNCATE**: `true` | `false`
- **REUSE_TABLES**: `true` | `false`
- **STAGING_TABLE**: `external_table_name`
- **FAST_MATCH**: `true` | `false`

SQL:
- **BEFORE**: `"sql_command"`
- **AFTER**: `"sql_command"`

**VERSION**
Optional. The version of the `gpload` control file schema. The current version is 1.0.0.1.

**DATABASE**
Optional. Specifies which database in the Greenplum Database system to connect to. If not specified, defaults to `$PGDATABASE` if set or the current system user name. You can also specify the database on the command line using the `-d` option.

**USER**
Optional. Specifies which database role to use to connect. If not specified, defaults to the current user or `$PGUSER` if set. You can also specify the database role on the command line using the `-U` option.

If the user running `gpload` is not a Greenplum Database superuser, then the appropriate rights must be granted to the user for the load to be processed. See the Greenplum Database Reference Guide for more information.

**HOST**
Optional. Specifies Greenplum Database master host name. If not specified, defaults to localhost or `$PGHOST` if set. You can also specify the master host name on the command line using the `-h` option.

**PORT**
Optional. Specifies Greenplum Database master port. If not specified, defaults to 5432 or `$PGPORT` if set. You can also specify the master port on the command line using the `-p` option.

**GPLOAD**
Required. Begins the load specification section. A `GPLOAD` specification must have an `INPUT` and an `OUTPUT` section defined.

**INPUT**
Required. Defines the location and the format of the input data to be loaded. `gpload` will start one or more instances of the `gpfdist` file distribution program on the current host and create the required external table definition(s) in Greenplum Database that point to the source data. Note that the host from which you run `gpload` must be accessible over the network by all Greenplum Database hosts (master and segments).

**SOURCE**
Required. The `SOURCE` block of an `INPUT` specification defines the location of a source file. An `INPUT` section can have more than one `SOURCE` block defined. Each `SOURCE` block defined corresponds to one instance of the `gpfdist` file distribution program that will be started on the local machine. Each `SOURCE` block defined must have a `FILE` specification.
For more information about using the `gpfdist` parallel file server and single and multiple `gpfdist` instances, see "Loading and Unloading Data" in the *Greenplum Database Administrator Guide*.

**LOCAL_HOSTNAME**

Optional. Specifies the host name or IP address of the local machine on which `gpload` is running. If this machine is configured with multiple network interface cards (NICs), you can specify the host name or IP of each individual NIC to allow network traffic to use all NICs simultaneously. The default is to use the local machine’s primary host name or IP only.

**PORT**

Optional. Specifies the specific port number that the `gpfdist` file distribution program should use. You can also supply a `PORT_RANGE` to select an available port from the specified range. If both `PORT` and `PORT_RANGE` are defined, then `PORT` takes precedence. If neither `PORT` or `PORT_RANGE` are defined, the default is to select an available port between 8000 and 9000.

If multiple host names are declared in `LOCAL_HOSTNAME`, this port number is used for all hosts. This configuration is desired if you want to use all NICs to load the same file or set of files in a given directory location.

**PORT_RANGE**

Optional. Can be used instead of `PORT` to supply a range of port numbers from which `gpload` can choose an available port for this instance of the `gpfdist` file distribution program.

**FILE**

Required. Specifies the location of a file, named pipe, or directory location on the local file system that contains data to be loaded. You can declare more than one file so long as the data is of the same format in all files specified.

If the files are compressed using `gzip` or `bzip2` (have a `.gz` or `.bz2` file extension), the files will be uncompressed automatically (provided that `gunzip` or `bunzip2` is in your path).

When specifying which source files to load, you can use the wildcard character (`*`) or other C-style pattern matching to denote multiple files. The files specified are assumed to be relative to the current directory from which `gpload` is executed (or you can declare an absolute path).

**SSL**

Optional. Specifies usage of SSL encryption. If `SSL` is set to `true`, `gpload` starts the `gpfdist` server with the `--ssl` option and uses the `gpfdists://` protocol.

**CERTIFICATES_PATH**

Required when `SSL` is `true`; cannot be specified when `SSL` is `false` or unspecified. The location specified in `CERTIFICATES_PATH` must contain the following files:

- The server certificate file, `server.crt`
- The server private key file, `server.key`
- The trusted certificate authorities, `root.crt`

The root directory (`/`) cannot be specified as `CERTIFICATES_PATH`.

**FULLY_QUALIFIED_DOMAIN_NAME**

Optional. Specifies whether `gpload` resolve hostnames to the fully qualified domain name (FQDN) or the local hostname. If the value is set to `true`, names are resolved to the FQDN. If the value is set to `false`, resolution is to the local hostname. The default is `false`. 
A fully qualified domain name might be required in some situations. For example, if the Greenplum Database system is in a different domain than an ETL application that is being accessed by gpload.

**COLUMNS**
Optional. Specifies the schema of the source data file(s) in the format of
`field_name: data_type`. The DELIMITER character in the source file is what separates two data value fields (columns). A row is determined by a line feed character (\x0a).

If the input COLUMNS are not specified, then the schema of the output TABLE is implied, meaning that the source data must have the same column order, number of columns, and data format as the target table.

The default source-to-target mapping is based on a match of column names as defined in this section and the column names in the target TABLE. This default mapping can be overridden using the MAPPING section.

**TRANSFORM**
Optional. Specifies the name of the input transformation passed to gpload. For information about XML transformations, see "Loading and Unloading Data" in the Greenplum Database Administrator Guide.

**TRANSFORM_CONFIG**
Required when TRANSFORM is specified. Specifies the location of the transformation configuration file that is specified in the TRANSFORM parameter, above.

**MAX_LINE_LENGTH**
Optional. An integer that specifies the maximum length of a line in the XML transformation data passed to gpload.

**FORMAT**
Optional. Specifies the format of the source data file(s) - either plain text (TEXT) or comma separated values (CSV) format. Defaults to TEXT if not specified. For more information about the format of the source data, see "Loading and Unloading Data" in the Greenplum Database Administrator Guide.

**DELIMITER**
Optional. Specifies a single ASCII character that separates columns within each row (line) of data. The default is a tab character in TEXT mode, a comma in CSV mode. You can also specify a non- printable ASCII character or a non-printable unicode character, for example: "\x1b" or "\u001B". The escape string syntax, `E'character-code'`, is also supported for non-printable characters. The ASCII or unicode character must be enclosed in single quotes. For example: `E'\x1b'` or `E'\u001B'`.

**ESCAPE**
Specifies the single character that is used for C escape sequences (such as \n, \t, \\00, and so on) and for escaping data characters that might otherwise be taken as row or column delimiters. Make sure to choose an escape character that is not used anywhere in your actual column data. The default escape character is a \ (backslash) for text-formatted files and a " (double quote) for csv-formatted files, however it is possible to specify another character to represent an escape. It is also possible to disable escaping in text-formatted files by specifying the value 'OFF' as the escape value. This is very useful for data such as text-formatted web log data that has many embedded backslashes that are not intended to be escapes.

**NULL_AS**
Optional. Specifies the string that represents a null value. The default is \N (backslash-N) in TEXT mode, and an empty value with no quotations in CSV mode. You might prefer an empty string even in TEXT mode for cases where you do not want to distinguish nulls
from empty strings. Any source data item that matches this string will be considered a null value.

**FORCE_NOT_NULL**
Optional. In CSV mode, processes each specified column as though it were quoted and hence not a NULL value. For the default null string in CSV mode (nothing between two delimiters), this causes missing values to be evaluated as zero-length strings.

**QUOTE**
Required when FORMAT is CSV. Specifies the quotation character for CSV mode. The default is double-quote (").

**HEADER**
Optional. Specifies that the first line in the data file(s) is a header row (contains the names of the columns) and should not be included as data to be loaded. If using multiple data source files, all files must have a header row. The default is to assume that the input files do not have a header row.

**ENCODING**
Optional. Character set encoding of the source data. Specify a string constant (such as 'SQL_ASCII'), an integer encoding number, or 'DEFAULT' to use the default client encoding. If not specified, the default client encoding is used. For information about supported character sets, see the Greenplum Database Reference Guide.

**Note:** If you change the ENCODING value in an existing gpload control file, you must manually drop any external tables that were creating using the previous ENCODING configuration. gpload does not drop and recreate external tables to use the new ENCODING if REUSE_TABLES is set to true.

**ERROR_LIMIT**
Optional. Enables single row error isolation mode for this load operation. When enabled, input rows that have format errors will be discarded provided that the error limit count is not reached on any Greenplum Database segment instance during input processing. If the error limit is not reached, all good rows will be loaded and any error rows will either be discarded or captured as part of error log information. The default is to abort the load operation on the first error encountered. Note that single row error isolation only applies to data rows with format errors; for example, extra or missing attributes, attributes of a wrong data type, or invalid client encoding sequences. Constraint errors, such as primary key violations, will still cause the load operation to abort if encountered. For information about handling load errors, see “Loading and Unloading Data” in the Greenplum Database Administrator Guide.

**LOG_ERRORS**
Optional when ERROR_LIMIT is declared. Value is either true or false. The default value is false. If the value is true, rows with formatting errors are logged internally when running in single row error isolation mode. You can examine formatting errors with the Greenplum Database built-in SQL function gp_read_error_log('table_name'). If formatting errors are detected when loading data, gpload generates a warning message with the name of the table that contains the error information similar to this message.

```
timestamp|WARN|1 bad row, please use GPDB built-in function
gp_read_error_log('table_name')
to access the detailed error row
```

If LOG_ERRORS: true is specified, REUSE_TABLES: true must be specified to retain the formatting errors in Greenplum Database error logs. If REUSE_TABLES: true is not specified, the error information is deleted after the gpload operation. Only summary information about formatting errors is returned. You can delete the formatting errors from the error logs with the Greenplum Database function gp_truncate_error_log().
Note: When `gpfdist` reads data and encounters a data formatting error, the error message includes a row number indicating the location of the formatting error. `gpfdist` attempts to capture the row that contains the error. However, `gpfdist` might not capture the exact row for some formatting errors.

For more information about handling load errors, see "Loading and Unloading Data" in the Greenplum Database Administrator Guide. For information about the `gp_read_error_log()` function, see the CREATE EXTERNAL TABLE command in the Greenplum Database Reference Guide.

**EXTERNAL**

Optional. Defines the schema of the external table database objects created by `gpload`. The default is to use the Greenplum Database `search_path`.

**SCHEMA**

Required when `EXTERNAL` is declared. The name of the schema of the external table. If the schema does not exist, an error is returned.

If `%` (percent character) is specified, the schema of the table name specified by `TABLE` in the `OUTPUT` section is used. If the table name does not specify a schema, the default schema is used.

**OUTPUT**

Required. Defines the target table and final data column values that are to be loaded into the database.

**TABLE**

Required. The name of the target table to load into.

**MODE**

Optional. Defaults to `INSERT` if not specified. There are three available load modes:

- **INSERT** - Loads data into the target table using the following method:

  ```
  INSERT INTO target_table SELECT * FROM input_data;
  ```

- **UPDATE** - Updates the `UPDATE_COLUMNS` of the target table where the rows have `MATCH_COLUMNS` attribute values equal to those of the input data, and the optional `UPDATE_CONDITION` is true. `UPDATE` is not supported if the target table column name is a reserved keyword, has capital letters, or includes any character that requires quotes (" ") to identify the column.

- **MERGE** - Inserts new rows and updates the `UPDATE_COLUMNS` of existing rows where `FOOBAR` attribute values are equal to those of the input data, and the optional `MATCH_COLUMNS` is true. New rows are identified when the `MATCH_COLUMNS` value in the source data does not have a corresponding value in the existing data of the target table. In those cases, the entire row from the source file is inserted, not only the `MATCH` and `UPDATE` columns. If there are multiple new `MATCH_COLUMNS` values that are the same, only one new row for that value will be inserted. Use `UPDATE_CONDITION` to filter out the rows to discard. `MERGE` is not supported if the target table column name is a reserved keyword, has capital letters, or includes any character that requires quotes (" ") to identify the column.

**MATCH_COLUMNS**

Required if `MODE` is `UPDATE` or `MERGE`. Specifies the column(s) to use as the join condition for the update. The attribute value in the specified target column(s) must be equal to that of the corresponding source data column(s) in order for the row to be updated in the target table.

**UPDATE_COLUMNS**
Required if **MODE** is **UPDATE** or **MERGE**. Specifies the column(s) to update for the rows that meet the **MATCH_COLUMNS** criteria and the optional **UPDATE_CONDITION**.

**UPDATE_CONDITION**
Optional. Specifies a Boolean condition (similar to what you would declare in a **WHERE** clause) that must be met in order for a row in the target table to be updated (or inserted in the case of a **MERGE**).

**MAPPING**
Optional. If a mapping is specified, it overrides the default source-to-target column mapping. The default source-to-target mapping is based on a match of column names as defined in the source **COLUMNS** section and the column names of the target **TABLE**. A mapping is specified as either:

```plaintext
target_column_name: source_column_name
```

or

```plaintext
target_column_name: 'expression'
```

Where **expression** is any expression that you would specify in the **SELECT** list of a query, such as a constant value, a column reference, an operator invocation, a function call, and so on.

**PRELOAD**
Optional. Specifies operations to run prior to the load operation. Right now the only preload operation is **TRUNCATE**.

**TRUNCATE**
Optional. If set to true, **gpload** will remove all rows in the target table prior to loading it. Default is false.

**REUSE_TABLES**
Optional. If set to true, **gpload** will not drop the external table objects and staging table objects it creates. These objects will be reused for future load operations that use the same load specifications. This improves performance of trickle loads (ongoing small loads to the same target table).

If **LOG_ERRORS**: true is specified, **REUSE_TABLES**: true must be specified to retain the formatting errors in Greenplum Database error logs. If **REUSE_TABLES**: true is not specified, formatting error information is deleted after the **gpload** operation.

If the **external_table_name** exists, the utility uses the existing table. The utility returns an error if the table schema does not match the **OUTPUT** table schema.

**STAGING_TABLE**
Optional. Specify the name of the temporary external table that is created during a **gpload** operation. The external table is used by **gpfdist**. **REUSE_TABLES**: true must also be specified. If **REUSE_TABLES** is false or not specified, **STAGING_TABLE** is ignored. By default, **gpload** creates a temporary external table with a randomly generated name.

If **external_table_name** contains a period (**.**), **gpload** returns an error. If the table exists, the utility uses the table. The utility returns an error if the existing table schema does not match the **OUTPUT** table schema.

The utility uses the value of **SCHEMA** in the **EXTERNAL** section as the schema for **external_table_name**. If the **SCHEMA** value is **%**, the schema for **external_table_name** is the same as the schema of the target table, the schema of **TABLE** in the **OUTPUT** section.

If **SCHEMA** is not set, the utility searches for the table (using the schemas in the database **search_path**). If the table is not found, **external_table_name** is created in the default **PUBLIC** schema.

**FAST_MATCH**
Optional. If set to true, `gpload` only searches the database for matching external table objects when reusing external tables. The utility does not check the external table column names and column types in the catalog table `pg_attribute` to ensure that the table can be used for a `gpload` operation. Set the value to true to improve `gpload` performance when reusing external table objects and the database catalog table `pg_attribute` contains a large number of rows. The utility returns an error and quits if the column definitions are not compatible.

The default value is false, the utility checks the external table definition column names and column types.

`REUSE_TABLES: true` must also specified. If `REUSE_TABLES` is false or not specified and `FAST_MATCH: true` is specified, `gpload` returns a warning message.

### SQL

Optional. Defines SQL commands to run before and/or after the load operation. You can specify multiple `BEFORE` and/or `AFTER` commands. List commands in the order of desired execution.

#### BEFORE

Optional. An SQL command to run before the load operation starts. Enclose commands in quotes.

#### AFTER

Optional. An SQL command to run after the load operation completes. Enclose commands in quotes.

### Log File Format

Log files output by `gpload` have the following format:

```
timestamp|level|message
```

Where `timestamp` takes the form: `YYYY-MM-DD HH:MM:SS`, `level` is one of `DEBUG`, `LOG`, `INFO`, `ERROR`, and `message` is a normal text message.

Some `INFO` messages that may be of interest in the log files are (where `#` corresponds to the actual number of seconds, units of data, or failed rows):

```
INFO|running time: #.## seconds
INFO|transferred #.# kB of #.# kB.
INFO|gpload succeeded
INFO|gpload succeeded with warnings
INFO|gpload failed
INFO|1 bad row
INFO|# bad rows
```

### Notes

If your database object names were created using a double-quoted identifier (delimited identifier), you must specify the delimited name within single quotes in the `gpload` control file. For example, if you create a table as follows:

```
CREATE TABLE "MyTable" ("MyColumn" text);
```

Your YAML-formatted `gpload` control file would refer to the above table and column names as follows:

```
- COLUMNS:
  - ""MyColumn": text
```

```
If the YAML control file contains the ERROR_TABLE element that was available in Greenplum Database 4.3.x, gpload logs a warning stating that ERROR_TABLE is not supported, and load errors are handled as if the LOG_ERRORS and REUSE_TABLE elements were set to true. Rows with formatting errors are logged internally when running in single row error isolation mode.

Examples

Run a load job as defined in my_load.yml:

```
gpload -f my_load.yml
```

Example load control file:

```yaml
---
VERSION: 1.0.0.1
DATABASE: ops
USER: gpadmin
HOST: mdw-1
PORT: 5432
GPLOAD:
  INPUT:
    - SOURCE:
      LOCAL_HOSTNAME:
        - etl1-1
        - etl1-2
        - etl1-3
        - etl1-4
      PORT: 8081
      FILE:
        - /var/load/data/*
    - COLUMNS:
      - name: text
      - amount: float4
      - category: text
      - descr: text
      - date: date
      - FORMAT: text
      - DELIMITER: '|
      - ERROR_LIMIT: 25
      - LOG_ERRORS: true
  OUTPUT:
    - TABLE: payables.expenses
    - MODE: INSERT
  PRELOAD:
    - REUSE_TABLES: true
  SQL:
    - BEFORE: "INSERT INTO audit VALUES('start', current_timestamp)"
    - AFTER: "INSERT INTO audit VALUES('end', current_timestamp)"
```

`gpfdist`, `CREATE EXTERNAL TABLE` in the Greenplum Database Reference Guide

`gplogfilter`

Searches through Greenplum Database log files for specified entries.
Synopsis

```
gplogfilter [timestamp_options] [pattern_options] [output_options] [input_options] [input_file]
gplogfilter --help
gplogfilter --version
```

Description

The `gplogfilter` utility can be used to search through a Greenplum Database log file for entries matching the specified criteria. If an input file is not supplied, then `gplogfilter` will use the `$MASTER_DATA_DIRECTORY` environment variable to locate the Greenplum master log file in the standard logging location. To read from standard input, use a dash (`-`) as the input file name. Input files may be compressed using `gzip`. In an input file, a log entry is identified by its timestamp in `YYYY-MM-DD [hh:mm[:ss]]` format.

You can also use `gplogfilter` to search through all segment log files at once by running it through the `gpssh` utility. For example, to display the last three lines of each segment log file:

```
gpssh -f seg_host_file
=> source /usr/local/greenplum-db/greenplum_path.sh
=> gplogfilter -n 3 /gpdata/*/pg_log/gpdb*.csv
```

By default, the output of `gplogfilter` is sent to standard output. Use the `-o` option to send the output to a file or a directory. If you supply an output file name ending in `.gz`, the output file will be compressed by default using maximum compression. If the output destination is a directory, the output file is given the same name as the input file.

Options

**Timestamp Options**

- `-b datetime | --begin=datetime`

  Specifies a starting date and time to begin searching for log entries in the format of `YYYY-MM-DD [hh:mm[:ss]]`.

  If a time is specified, the date and time must be enclosed in either single or double quotes. This example encloses the date and time in single quotes:

  ```
gplogfilter -b '2013-05-23 14:33'
```

- `-e datetime | --end=datetime`

  Specifies an ending date and time to stop searching for log entries in the format of `YYYY-MM-DD [hh:mm[:ss]]`.

  If a time is specified, the date and time must be enclosed in either single or double quotes. This example encloses the date and time in single quotes:

  ```
gplogfilter -e '2013-05-23 14:33'
```

- `-d time | --duration=time`

  Specifies a time duration to search for log entries in the format of `[hh][:mm[:ss]]`. If used without either the `-b` or `-e` option, will use the current time as a basis.

**Pattern Matching Options**

- `-c i [gnore] | r [espect] | --case=i [gnore] | r [espect]`

  Matching of alphabetic characters is case sensitive by default unless proceeded by the `--case=ignore` option.
-C 'string' | --columns='string'
Selects specific columns from the log file. Specify the desired columns as a comma-delimited string of column numbers beginning with 1, where the second column from left is 2, the third is 3, and so on. See "Viewing the Database Server Log Files" in the Greenplum Database Administrator Guide for details about the log file format and for a list of the available columns and their associated number.

-f 'string' | --find='string'
Finds the log entries containing the specified string.

-F 'string' | --nofind='string'
Rejects the log entries containing the specified string.

-m regex | --match=regex
Finds log entries that match the specified Python regular expression. See https://docs.python.org/library/re.html for Python regular expression syntax.

-M regex | --nomatch=regex
Rejects log entries that match the specified Python regular expression. See https://docs.python.org/library/re.html for Python regular expression syntax.

-t | --trouble
Finds only the log entries that have ERROR:, FATAL:, or PANIC: in the first line.

Output Options

-n integer | --tail=integer
Limits the output to the last integer of qualifying log entries found.

-s offset [limit] | --slice=offset [limit]
From the list of qualifying log entries, returns the limit number of entries starting at the offset entry number, where an offset of zero (0) denotes the first entry in the result set and an offset of any number greater than zero counts back from the end of the result set.

-o output_file | --out=output_file
Writes the output to the specified file or directory location instead of STDOUT.

-z 0-9 | --zip=0-9
Compresses the output file to the specified compression level using gzip, where 0 is no compression and 9 is maximum compression. If you supply an output file name ending in .gz, the output file will be compressed by default using maximum compression.

-a | --append
If the output file already exists, appends to the file instead of overwriting it.

Input Options

input_file
The name of the input log file(s) to search through. If an input file is not supplied, gplogfilter will use the $MASTER_DATA_DIRECTORY environment variable to locate the Greenplum Database master log file. To read from standard input, use a dash (-) as the input file name.

-u | --unzip
Uncompress the input file using gunzip. If the input file name ends in .gz, it will be uncompressed by default.

--help
Displays the online help.

--version
Displays the version of this utility.
Examples

Display the last three error messages in the master log file:

```
gplogfilter -t -n 3
```

Display all log messages in the master log file timestamped in the last 10 minutes:

```
gplogfilter -d :10
```

Display log messages in the master log file containing the string `|con6 cmd11|`:

```
gplogfilter -f '|con6 cmd11|'
```

Using `gpssh`, run `gplogfilter` on the segment hosts and search for log messages in the segment log files containing the string `con6` and save output to a file.

```
gpssh -f seg_hosts_file -e 'source /usr/local/greenplum-db/greenplum_path.sh ; gplogfilter -f con6 /gpdata/*/pg_log/gpdb*.csv' > seglog.out
```

`gpssh, gpscp`

gpmapreduce

Runs Greenplum MapReduce jobs as defined in a YAML specification document.

Synopsis

```
gpmapreduce -f config.yaml [dbname [username]]
        [-k name=value | --key name=value]
        [-h hostname | --host hostname] [-p port | --port port]
        [-U username | --username username] [-W] [-v]
```

```
gpmapreduce -x | --explain
```

```
gpmapreduce -X | --explain-analyze
```

```
gpmapreduce -V | --version
```

```
gpmapreduce -h | --help
```

Requirements

The following are required prior to running this program:

- You must have your MapReduce job defined in a YAML file. See `gpmapreduce.yaml` for more information about the format of, and keywords supported in, the Greenplum MapReduce YAML configuration file.
- You must be a Greenplum Database superuser to run MapReduce jobs written in untrusted Perl or Python.
- You must be a Greenplum Database superuser to run MapReduce jobs with EXEC and FILE inputs.
- You must be a Greenplum Database superuser to run MapReduce jobs with GPFDIST input unless the user has the appropriate rights granted.
Description

MapReduce is a programming model developed by Google for processing and generating large data sets on an array of commodity servers. Greenplum MapReduce allows programmers who are familiar with the MapReduce paradigm to write map and reduce functions and submit them to the Greenplum Database parallel engine for processing.

gpmapreduce is the Greenplum MapReduce program. You configure a Greenplum MapReduce job via a YAML-formatted configuration file that you pass to the program for execution by the Greenplum Database parallel engine. The Greenplum Database system distributes the input data, executes the program across a set of machines, handles machine failures, and manages the required inter-machine communication.

Options

\texttt{-f config.yaml}

Required. The YAML file that contains the Greenplum MapReduce job definitions. Refer to \texttt{gpmapreduce.yaml} for the format and content of the parameters that you specify in this file.

\texttt{-? | --help}

Show help, then exit.

\texttt{-v | --version}

Show version information, then exit.

\texttt{-v | --verbose}

Show verbose output.

\texttt{-x | --explain}

Do not run MapReduce jobs, but produce explain plans.

\texttt{-X | --explain-analyze}

Run MapReduce jobs and produce explain-analyze plans.

\texttt{-k | --keyname=value}

Sets a YAML variable. A value is required. Defaults to "key" if no variable name is specified.

Connection Options

\texttt{-h host | --host host}

Specifies the host name of the machine on which the Greenplum master database server is running. If not specified, reads from the environment variable \texttt{PGHOST} or defaults to localhost.

\texttt{-p port | --port port}

Specifies the TCP port on which the Greenplum master database server is listening for connections. If not specified, reads from the environment variable \texttt{PGPORT} or defaults to 5432.

\texttt{-U username | --username username}

The database role name to connect as. If not specified, reads from the environment variable \texttt{PGUSER} or defaults to the current system user name.

\texttt{-W | --password}

Force a password prompt.

Examples

Run a MapReduce job as defined in \texttt{my_mrjob.yaml} and connect to the database \texttt{mydatabase}:

\texttt{gpmapreduce -f my_mrjob.yaml mydatabase}

Description
You specify the input, map and reduce tasks, and the output for the Greenplum MapReduce gpmapreduce program in a YAML-formatted configuration file. (This reference page uses the name gpmapreduce.yaml when referring to this file; you may choose your own name for the file.)

The gpmapreduce utility processes the YAML configuration file in order, using indentation (spaces) to determine the document hierarchy and the relationships between the sections. The use of white space in the file is significant.

Keys and Values

VERSION
Required. The version of the Greenplum MapReduce YAML specification. Current supported versions are 1.0.0.1, 1.0.0.2, and 1.0.0.3.

DATABASE
Optional. Specifies which database in Greenplum to connect to. If not specified, defaults to the default database or $PGDATABASE if set.

USER
Optional. Specifies which database role to use to connect. If not specified, defaults to the current user or $PGUSER if set. You must be a Greenplum superuser to run functions written in untrusted Python and Perl. Regular database users can run functions written in trusted Perl. You also must be a database superuser to run MapReduce jobs that contain FILE, GPFDIST and EXEC input types.
HOST
Optional. Specifies Greenplum master host name. If not specified, defaults to localhost or $PGHOST if set.

PORT
Optional. Specifies Greenplum master port. If not specified, defaults to 5432 or $PGPORT if set.

DEFINE
Required. A sequence of definitions for this MapReduce document. The DEFINE section must have at least one INPUT definition.

INPUT
Required. Defines the input data. Every MapReduce document must have at least one input defined. Multiple input definitions are allowed in a document, but each input definition can specify only one of these access types: a file, a gpfdist file reference, a table in the database, an SQL command, or an operating system command. See gpfdist for information about this reference.

NAME
A name for this input. Names must be unique with regards to the names of other objects in this MapReduce job (such as map function, task, reduce function and output names). Also, names cannot conflict with existing objects in the database (such as tables, functions or views).

FILE
A sequence of one or more input files in the format: seghostname:/path/to/filename. You must be a Greenplum Database superuser to run MapReduce jobs with FILE input. The file must reside on a Greenplum segment host.

GPFDIST
A sequence identifying one or more running gpfdist file servers in the format: hostname[:port]/file_pattern. You must be a Greenplum Database superuser to run MapReduce jobs with GPFDIST input.

TABLE
The name of an existing table in the database.

QUERY
A SQL SELECT command to run within the database.

EXEC
An operating system command to run on the Greenplum segment hosts. The command is run by all segment instances in the system by default. For example, if you have four segment instances per segment host, the command will be run four times on each host. You must be a Greenplum Database superuser to run MapReduce jobs with EXEC input.

COLUMNS
Optional. Columns are specified as: column_name [data_type]. If not specified, the default is value text. The DELIMITER character is what separates two data value fields (columns). A row is determined by a line feed character (0x0a).

FORMAT
Optional. Specifies the format of the data - either delimited text (TEXT) or comma separated values (CSV) format. If the data format is not specified, defaults to TEXT.

DELIMITER
Optional for FILE, GPFDIST and EXEC inputs. Specifies a single character that separates data values. The default is a tab character in TEXT mode, a comma in CSV mode. The
delimiter character must only appear between any two data value fields. Do not place a delimiter at the beginning or end of a row.

ESCAPE
Optional for FILE, GPFDIST and EXEC inputs. Specifies the single character that is used for C escape sequences (such as \n, \t, \100, and so on) and for escaping data characters that might otherwise be taken as row or column delimiters. Make sure to choose an escape character that is not used anywhere in your actual column data. The default escape character is a \ (backslash) for text-formatted files and a " (double quote) for csv-formatted files, however it is possible to specify another character to represent an escape. It is also possible to disable escaping by specifying the value 'OFF' as the escape value. This is very useful for data such as text-formatted web log data that has many embedded backslashes that are not intended to be escapes.

NULL
Optional for FILE, GPFDIST and EXEC inputs. Specifies the string that represents a null value. The default is \N in TEXT format, and an empty value with no quotations in CSV format. You might prefer an empty string even in TEXT mode for cases where you do not want to distinguish nulls from empty strings. Any input data item that matches this string will be considered a null value.

QUOTE
Optional for FILE, GPFDIST and EXEC inputs. Specifies the quotation character for CSV formatted files. The default is a double quote ("). In CSV formatted files, data value fields must be enclosed in double quotes if they contain any commas or embedded new lines. Fields that contain double quote characters must be surrounded by double quotes, and the embedded double quotes must each be represented by a pair of consecutive double quotes. It is important to always open and close quotes correctly in order for data rows to be parsed correctly.

ERROR_LIMIT
If the input rows have format errors they will be discarded provided that the error limit count is not reached on any Greenplum segment instance during input processing. If the error limit is not reached, all good rows will be processed and any error rows discarded.

ENCODING
Character set encoding to use for the data. Specify a string constant (such as 'SQL_ASCII'), an integer encoding number, or DEFAULT to use the default client encoding. See Character Set Support for more information.

OUTPUT
Optional. Defines where to output the formatted data of this MapReduce job. If output is not defined, the default is STDOUT (standard output of the client). You can send output to a file on the client host or to an existing table in the database.

NAME
A name for this output. The default output name is STDOUT. Names must be unique with regards to the names of other objects in this MapReduce job (such as map function, task, reduce function and input names). Also, names cannot conflict with existing objects in the database (such as tables, functions or views).

FILE
Specifies a file location on the MapReduce client machine to output data in the format: /path/to/filename.

TABLE
Specifies the name of a table in the database to output data. If this table does not exist prior to running the MapReduce job, it will be created using the distribution policy specified with KEYS.
KEYS
Optional for TABLE output. Specifies the column(s) to use as the Greenplum Database distribution key. If the EXECUTE task contains a REDUCE definition, then the REDUCE keys will be used as the table distribution key by default. Otherwise, the first column of the table will be used as the distribution key.

MODE
Optional for TABLE output. If not specified, the default is to create the table if it does not already exist, but error out if it does exist. Declaring APPEND adds output data to an existing table (provided the table schema matches the output format) without removing any existing data. Declaring REPLACE will drop the table if it exists and then recreate it. Both APPEND and REPLACE will create a new table if one does not exist.

MAP
Required. Each MAP function takes data structured in (key, value) pairs, processes each pair, and generates zero or more output (key, value) pairs. The Greenplum MapReduce framework then collects all pairs with the same key from all output lists and groups them together. This output is then passed to the REDUCE task, which is comprised of TRANSITION | CONSOLIDATE | FINALIZE functions. There is one predefined MAP function named IDENTITY that returns (key, value) pairs unchanged. Although (key, value) are the default parameters, you can specify other prototypes as needed.

TRANSITION | CONSOLIDATE | FINALIZE
TRANSITION, CONSOLIDATE and FINALIZE are all component pieces of REDUCE. A TRANSITION function is required. CONSOLIDATE and FINALIZE functions are optional. By default, all take state as the first of their input PARAMETERS, but other prototypes can be defined as well.

A TRANSITION function iterates through each value of a given key and accumulates values in a state variable. When the transition function is called on the first value of a key, the state is set to the value specified by INITIALIZE of a REDUCE job (or the default state value for the data type). A transition takes two arguments as input; the current state of the key reduction, and the next value, which then produces a new state.

If a CONSOLIDATE function is specified, TRANSITION processing is performed at the segment-level before redistributing the keys across the Greenplum interconnect for final aggregation (two-phase aggregation). Only the resulting state value for a given key is redistributed, resulting in lower interconnect traffic and greater parallelism. CONSOLIDATE is handled like a TRANSITION, except that instead of (state + value) => state, it is (state + state) => state.

If a FINALIZE function is specified, it takes the final state produced by CONSOLIDATE (if present) or TRANSITION and does any final processing before emitting the final result. TRANSITION and CONSOLIDATE functions cannot return a set of values. If you need a REDUCE job to return a set, then a FINALIZE is necessary to transform the final state into a set of output values.

NAME
Required. A name for the function. Names must be unique with regards to the names of other objects in this MapReduce job (such as function, task, input and output names). You can also specify the name of a function built-in to Greenplum Database. If using a built-in function, do not supply LANGUAGE or a FUNCTION body.

FUNCTION
Optional. Specifies the full body of the function using the specified LANGUAGE. If FUNCTION is not specified, then a built-in database function corresponding to NAME is used.

LANGUAGE
Required when **FUNCTION** is used. Specifies the implementation language used to interpret the function. This release has language support for **perl**, **python**, and C. If calling a built-in database function, **LANGUAGE** should not be specified.

**LIBRARY**
Required when **LANGUAGE** is C (not allowed for other language functions). To use this attribute, **VERSION** must be 1.0.0.2. The specified library file must be installed prior to running the MapReduce job, and it must exist in the same file system location on all Greenplum hosts (master and segments).

**PARAMETERS**
Optional. Function input parameters. The default type is **text**.

- **MAP** default - key **text**, value **text**
- **TRANSITION** default - state **text**, value **text**
- **CONSOLIDATE** default - state1 **text**, state2 **text** (must have exactly two input parameters of the same data type)
- **FINALIZE** default - state **text** (single parameter only)

**RETURNS**
Optional. The default return type is **text**.

- **MAP** default - key **text**, value **text**
- **TRANSITION** default - state **text** (single return value only)
- **CONSOLIDATE** default - state **text** (single return value only)
- **FINALIZE** default - value **text**

**OPTIMIZE**
Optional optimization parameters for the function:

- **STRICT** - function is not affected by NULL values
- **IMMUTABLE** - function will always return the same value for a given input

**MODE**
Optional. Specifies the number of rows returned by the function.

- **MULTI** - returns 0 or more rows per input record. The return value of the function must be an array of rows to return, or the function must be written as an iterator using **yield** in Python or **return_next** in Perl. **MULTI** is the default mode for **MAP** and **FINALIZE** functions.
- **SINGLE** - returns exactly one row per input record. **SINGLE** is the only mode supported for **TRANSITION** and **CONSOLIDATE** functions. When used with **MAP** and **FINALIZE** functions, **SINGLE** mode can provide modest performance improvement.

**REDUCE**
Required. A **REDUCE** definition names the **TRANSITION** | **CONSOLIDATE** | **FINALIZE** functions that comprise the reduction of (key, value) pairs to the final result set. There are also several predefined **REDUCE** jobs you can execute, which all operate over a column named value:

- **IDENTITY** - returns (key, value) pairs unchanged
- **SUM** - calculates the sum of numeric data
- **AVG** - calculates the average of numeric data
- **COUNT** - calculates the count of input data
**MIN** - calculates minimum value of numeric data

**MAX** - calculates maximum value of numeric data

**NAME**

Required. The name of this **REDUCE** job. Names must be unique with regards to the names of other objects in this MapReduce job (function, task, input and output names). Also, names cannot conflict with existing objects in the database (such as tables, functions or views).

**TRANSITION**

Required. The name of the **TRANSITION** function.

**CONSOLIDATE**

Optional. The name of the **CONSOLIDATE** function.

**FINALIZE**

Optional. The name of the **FINALIZE** function.

**INITIALIZE**

Optional for **text** and **float** data types. Required for all other data types. The default value for **text** is `' '`. The default value for **float** is `0.0`. Sets the initial **state** value of the **TRANSITION** function.

**KEYS**

Optional. Defaults to `[key, *]`. When using a multi-column reduce it may be necessary to specify which columns are key columns and which columns are value columns. By default, any input columns that are not passed to the **TRANSITION** function are key columns, and a column named **key** is always a key column even if it is passed to the **TRANSITION** function. The special indicator `*` indicates all columns not passed to the **TRANSITION** function. If this indicator is not present in the list of keys then any unmatched columns are discarded.

**TASK**

Optional. A **TASK** defines a complete end-to-end **INPUT/MAP/REDUCE** stage within a Greenplum MapReduce job pipeline. It is similar to **EXECUTE** except it is not immediately executed. A task object can be called as **INPUT** to further processing stages.

**NAME**

Required. The name of this task. Names must be unique with regards to the names of other objects in this MapReduce job (such as map function, reduce function, input and output names). Also, names cannot conflict with existing objects in the database (such as tables, functions or views).

**SOURCE**

The name of an **INPUT** or another **TASK**.

**MAP**

Optional. The name of a **MAP** function. If not specified, defaults to **IDENTITY**.

**REDUCE**

Optional. The name of a **REDUCE** function. If not specified, defaults to **IDENTITY**.

**EXECUTE**

Required. **EXECUTE** defines the final **INPUT/MAP/REDUCE** stage within a Greenplum MapReduce job pipeline.

**RUN**

**SOURCE**

Required. The name of an **INPUT** or **TASK**.
TARGET
Optional. The name of an OUTPUT. The default output is STDOUT.

MAP
Optional. The name of a MAP function. If not specified, defaults to IDENTITY.

REDUCE
Optional. The name of a REDUCE function. Defaults to IDENTITY.

See Also

gpmapreduce

gpmovemirrors
Moves mirror segment instances to new locations.

Synopsis

gpmovemirrors -i move_config_file [-d master_data_directory]
[-l logfile_directory]
[-B parallel_processes] [-v]
gpmovemirrors -?
gpmovemirrors --version

Description
The gpmovemirrors utility moves mirror segment instances to new locations. You may want to move mirrors to new locations to optimize distribution or data storage.

Before moving segments, the utility verifies that they are mirrors, and that their corresponding primary segments are up and are in synchronizing or resynchronizing mode.

By default, the utility will prompt you for the file system location(s) where it will move the mirror segment data directories.

You must make sure that the user who runs gpmovemirrors (the gpadmin user) has permissions to write to the data directory locations specified. You may want to create these directories on the segment hosts and chown them to the appropriate user before running gpmovemirrors.

Options

-B parallel_processes
The number of mirror segments to move in parallel. If not specified, the utility will start up to 4 parallel processes depending on how many mirror segment instances it needs to move.

-d master_data_directory
The master data directory. If not specified, the value set for $MASTER_DATA_DIRECTORY will be used.

-i move_config_file
A configuration file containing information about which mirror segments to move, and where to move them.
You must have one mirror segment listed for each primary segment in the system. Each line inside the configuration file has the following format (as per attributes in the `gp_segment_configuration` catalog table):

```
contentID|address|port|data_dir new_address|port|data_dir
```

Where `contentID` is the segment instance content ID, `address` is the host name or IP address of the segment host, `port` is the communication port, and `data_dir` is the segment instance data directory.

```
-l logfile_directory
```

The directory to write the log file. Defaults to `~/.gpAdminLogs`.

```
-v (verbose)
```

Sets logging output to verbose.

```
--version (show utility version)
```

Displays the version of this utility.

```
-? (help)
```

Displays the online help.

**Examples**

Moves mirrors from an existing Greenplum Database system to a different set of hosts:

```
$ gpmovemirrors -i move_config_file
```

Where the `move_config_file` looks something like this:

```
1|sdw2|50001|/data2/mirror/gpseg1 sdw3|50001|/data/mirror/gpseg1
2|sdw2|50001|/data2/mirror/gpseg2 sdw4|50001|/data/mirror/gpseg2
3|sdw3|50001|/data2/mirror/gpseg3 sdw1|50001|/data/mirror/gpseg3
```

**gpperfmon_install**

Installs the `gpperfmon` database and optionally enables the data collection agents.

**Synopsis**

```
gpperfmon_install --port gpdb_port
    [--enable --password gpmon_password [--pgpass path_to_file]]
    [--verbose]
```

```
gpperfmon_install --help | -h | -?
```

**Description**

**Note:** Do not run the `gpperfmon_install` utility if you plan to use Pivotal Greenplum Command Center to manage your Greenplum Database system. Command Center no longer uses the history tables that `gpperfmon_install` creates. Enabling the `gpperfmon` data collection agents (`gpmmon` and `gpsmon`) adds unnecessary load to the system. Instead, run the Command Center installer. The installer creates the `gpperfmon` database with the `gpmetrics` schema Command Center needs and enables the Command Center agent (`ccagent`) to collect real-time system metrics and query information from the Greenplum Database metrics collector module. See the Greenplum Command Center documentation for more information.
The `gpperfmon_install` utility automates the steps required to enable the data collection agents. You must be the Greenplum Database system user (`gpadmin`) to run this utility. The `--port` option is required. When using the `--enable` option, the `--password` option is also required. Use the `--port` option to supply the port of the Greenplum Database master instance. If using the `--enable` option, Greenplum Database must be restarted after the utility completes.

When run without the `--enable` option, the utility just creates the `gpperfmon` database (the database used to store system metrics collected by the data collection agents). When run with the `--enable` option, the utility also runs the following additional tasks necessary to enable the performance monitor data collection agents:

1. Creates the `gpmon` superuser role in Greenplum Database. The data collection agents require this role to connect to the database and write their data. The `gpmon` superuser role uses MD5-encrypted password authentication by default. Use the `--password` option to set the `gpmon` superuser’s password.
2. Updates the `$MASTER_DATA_DIRECTORY/pg_hba.conf` file. The utility adds these lines to the host-based authentication file (`pg_hba.conf`):

```plaintext
local  gpperfmon gpmon 127.0.0.1/28 md5
host   all       gpmon 127.0.0.1/28 md5
host   all       gpmon ::1/128 md5
```

The second and third lines, the host entries, give `gpmon` access to all Greenplum Database databases.

**Note:** It might be necessary to edit the lines in the `pg_hba.conf` file after running the `gpperfmon_install` utility to limit the `gpmon` role’s access to databases or to change the authentication method. After you edit the file, run `gpstop -u` to reload the file in Greenplum Database.

- To limit `gpmon` access to just the `gpperfmon` database, edit the host entries in the `pg_hba.conf` file. For the `gpmon` user change the second field from `all` to `gpperfmon`:

```plaintext
local  gpperfmon gpmon 127.0.0.1/28 md5
host   gpperfmon gpmon 127.0.0.1/28 md5
host   gpperfmon gpmon ::1/128 md5
```

- The `gpperfmon_install` utility assumes the default MD5 authentication method. Greenplum Database can optionally be configured to use the SHA-256 hash algorithm to compute the password hashes saved in the system catalog. This is incompatible with the MD5 authentication method, which expects an MD5 hash or clear text password in the system catalog. Because of this, if you have enabled the SHA-256 hash algorithm in the database, you must edit the `pg_hba.conf` file after running the `gpperfmon_install` utility. For the host entries, change the authentication method for the `gpmon` role from `md5` to `password`:

```plaintext
local  gpperfmon gpmon 127.0.0.1/28 password
host   all       gpmon 127.0.0.1/28 password
host   all       gpmon ::1/128 password
```

The password authentication method submits the user’s clear text password for authentication and should not be used on an untrusted network. See “Protecting Passwords in Greenplum Database” in the *Greenplum Database Administrator Guide* for more information about configuring password hashing.

3. Updates the password file (`.pgpass`). In order to allow the data collection agents to connect as the `gpmon` role without a password prompt, you must have a password file that has an entry for the `gpmon`
user. The utility adds the following entry to your password file (if the file does not exist, the utility will create it):

```
*:5432:gpperfmon:gpmon:gpmon_password
```

If your password file is not located in the default location (~/.pgpass), use the --pgpass option to specify the file location.

4. Sets the server configuration parameters for the `gpperfmon` database. The following parameters must be enabled for the data collection agents to begin collecting data. The utility sets the following parameters in the Greenplum Database `postgresql.conf` configuration files:

- `gp_enable_gpperfmon=on` (in all `postgresql.conf` files)
- `gpperfmon_port=8888` (in all `postgresql.conf` files)
- `gp_external_enable_exec=on` (in the master `postgresql.conf` file)

Data collection agents can be configured by setting parameters in the `gpperfmon.conf` configuration file. See Data Collection Agent Configuration for details.

For information about Greenplum Command Center, see the Greenplum Command Center Documentation.

Options

**--enable**

In addition to creating the `gpperfmon` database, performs the additional steps required to enable the data collection agents. When --enable is specified the utility will also create and configure the `gpmon` superuser account and set the `gpperfmon` server configuration parameters in the `postgresql.conf` files.

**--password gpmon_password**

Required if --enable is specified. Sets the password of the `gpmon` superuser. Disallowed if --enable is not specified.

**--port gpdb_port**

Required. Specifies the connection port of the Greenplum Database master.

**--pgpass path_to_file**

Optional if --enable is specified. If the password file is not in the default location of ~/.pgpass, specifies the location of the password file.

**--verbose**

Sets the logging level to verbose.

**--help | -h | -?**

Displays the online help.

Data Collection Agent Configuration

The `$MASTER_DATA_DIRECTORY/gpperfmon/conf/gpperfmon.conf` file stores configuration parameters for the data collection agents. For configuration changes to these options to take effect, you must save `gpperfmon.conf` and then restart Greenplum Database server (gpstop -r).

The `gpperfmon.conf` file contains the following configuration parameters.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>log_location</td>
<td>Specifies a directory location for <code>gpperfmon</code> log files. Default is <code>$MASTER_DATA_DIRECTORY/gpperfmon/logs</code>.</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>min_query_time</td>
<td>Specifies the minimum query run time in seconds for statistics collection. All queries that run longer than this value are logged in the queries_history table. For queries with shorter run times, no historical data is collected. Defaults to 20 seconds. If you know that you want to collect data for all queries, you can set this parameter to a low value. Setting the minimum query run time to zero, however, collects data for even trivial queries and can create a large amount of data that may not be useful.</td>
</tr>
<tr>
<td>max_log_size</td>
<td>This parameter is not included in gpperfmon.conf, but it may be added to this file. To prevent the log files from growing to excessive size, you can add the max_log_size parameter to gpperfmon.conf. The value of this parameter is measured in bytes. For example: max_log_size = 10485760 With this setting, the log files will grow to 10MB before the system rolls over to a new log file.</td>
</tr>
<tr>
<td>partition_age</td>
<td>The number of months that gpperfmon statistics data will be retained. The default value is 0, which means that partitions are never dropped automatically.</td>
</tr>
<tr>
<td>quantum</td>
<td>Specifies the time in seconds between updates from data collection agents on all segments. Valid values are 10, 15, 20, 30, and 60. Defaults to 15 seconds. If you prefer a less granular view of performance, or want to collect and analyze minimal amounts of data for system metrics, choose a higher quantum. To collect data more frequently, choose a lower value.</td>
</tr>
<tr>
<td>harvest_interval</td>
<td>The time, in seconds, between data harvests. A data harvest moves recent data from the gpperfmon external (_tail) tables to their corresponding history files. The default is 120. The minimum value is 30.</td>
</tr>
<tr>
<td>ignore_gexec_packet</td>
<td>(Deprecated) When set to true, data collection agents do not collect performance data in the gpperfmon database queries_* tables: rows_out, cpu_elapsed, cpu_currpct, skew_cpu, and skew_rows. The default setting, true, reduces the amount of memory consumed by</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
</tr>
<tr>
<td>--------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td></td>
<td>the gpmon process. Set this parameter to false if you require this additional performance data.</td>
</tr>
<tr>
<td>smdw_aliases</td>
<td>This parameter allows you to specify additional host names for the standby master. For example, if the standby master has two NICs, you can enter: smdw_aliases=smdw-1,smdw-2</td>
</tr>
</tbody>
</table>

Notes

The gpperfmon database requires the gpmon role. After the gpperfmon database and gpmon role have been created, you can change the password for the gpmon role:

1. Log in to Greenplum Database as a superuser and change the gpmon password with the ALTER ROLE command.

   ```
   # ALTER ROLE gpmon WITH PASSWORD 'new_password' ;
   ```

2. Update the password in the .pgpass file. The default file location is the gpadmin home directory (~/.pgpass). The .pgpass file contains a line with the gpmon password.

   ```
   *:5432:gpperfmon:gpmon:new_password
   ```

The gpperfmon monitoring system requires some initialization after startup. Monitoring information appears after a few minutes have passed, and not immediately after installation and startup of the gpperfmon system.

Examples

Create the gpperfmon database only:

```
$ su - gpadmin
$ gpperfmon_install --port 5432
```

Create the gpperfmon database, create the gpmon superuser, and enable the data collection agents:

```
$ su - gpadmin
$ gpperfmon_install --enable --password changeme --port 5432
$ gpstop -r
```

See Also

```
gpstop
```

**gppkg**

Installs Greenplum Database extensions in .gppkg format, such as PL/Java, PL/R, PostGIS, and MADlib, along with their dependencies, across an entire cluster.

Synopsis

```
gppkg [ -i package | -u package | -r name-version | -c ]
   [ -d master_data_directory ] [ -a ] [ -v ]
gppkg --migrate GPHOME_old GPHOME_new [ -a ] [ -v ]
```
gppkg [-q | --query] query_option

```
gppkg -? | --help | -h
gppkg --version
```

**Description**

The Greenplum Package Manager (gppkg) utility installs Greenplum Database extensions, along with any dependencies, on all hosts across a cluster. It will also automatically install extensions on new hosts in the case of system expansion and segment recovery.

**Note:** After a major upgrade to Greenplum Database, you must download and install all gppkg extensions again.

Examples of database extensions and packages software that are delivered using the Greenplum Package Manager are:

- PL/Java
- PL/R
- PostGIS
- MADlib

**Options**

-\a (do not prompt)

  Do not prompt the user for confirmation.

-\c | --clean

  Reconciles the package state of the cluster to match the state of the master host. Running this option after a failed or partial install/uninstall ensures that the package installation state is consistent across the cluster.

-\d master_data_directory

  The master data directory. If not specified, the value set for \$MASTER\_DATA\_DIRECTORY will be used.

-\i package | --install=package

  Installs the given package. This includes any pre/post installation steps and installation of any dependencies.

--migrate GPHOME\_old GPHOME\_new

  Migrates packages from a separate \$GPHOME. Carries over packages from one version of Greenplum Database to another.

  For example: gppkg --migrate /usr/local/greenplum-db-<old-version> /usr/local/greenplum-db-<new-version>

  When migrating packages, these requirements must be met.

  - At least the master instance of the destination Greenplum Database must be started (the instance installed in GPHOME\_new). Before running the gppkg command start the Greenplum Database master with the command gpstart -m.
  - Run the gppkg utility from the GPHOME\_new installation. The migration destination installation directory.

-\q | --query query_option

  Provides information specified by query_option about the installed packages. Only one query_option can be specified at a time. The following table lists the possible values for query_option. <package_file> is the name of a package.
### Table 63: Query Options for gppkg

<table>
<thead>
<tr>
<th>query_option</th>
<th>Returns</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt;package_file&gt;</td>
<td>Whether the specified package is installed.</td>
</tr>
<tr>
<td>--info &lt;package_file&gt;</td>
<td>The name, version, and other information about the specified package.</td>
</tr>
<tr>
<td>--list &lt;package_file&gt;</td>
<td>The file contents of the specified package.</td>
</tr>
<tr>
<td>--all</td>
<td>List of all installed packages.</td>
</tr>
</tbody>
</table>

--r name-version | --remove=name-version
Removes the specified package.

--u package | --update=package
Updates the given package.

Warning: The process of updating a package includes removing all previous versions of the system objects related to the package. For example, previous versions of shared libraries are removed. After the update process, a database function will fail when it is called if the function references a package file that has been removed.

--version (show utility version)
Displays the version of this utility.

-v | --verbose
Sets the logging level to verbose.

-? | -h | --help
Displays the online help.

---

**gprecoverseg**

Recovers a primary or mirror segment instance that has been marked as down (if mirroring is enabled).

**Synopsis**

```
gprecoverseg [-p new_recover_host[,...]] [-i recover_config_file] [-d master_data_directory]
[-B parallel_processes] [-F [-s]] [-a] [-q]
[--no-progress] [-l logfile_directory]
gprecoverseg -r

gprecoverseg -o output_recover_config_file
[-p new_recover_host[,...]]
gprecoverseg -? | --help

gprecoverseg --version
```

**Description**

In a system with mirrors enabled, the **gprecoverseg** utility reactivates a failed segment instance and identifies the changed database files that require resynchronization. Once **gprecoverseg** completes this
process, the system goes into resynchronizing mode until the recovered segment is brought up to date. The system is online and fully operational during resynchronization.

During an incremental recovery (the -F option is not specified), if gprecoverseg detects a segment instance with mirroring disabled in a system with mirrors enabled, the utility reports that mirroring is disabled for the segment, does not attempt to recover that segment instance, and continues the recovery process.

A segment instance can fail for several reasons, such as a host failure, network failure, or disk failure. When a segment instance fails, its status is marked as down in the Greenplum Database system catalog, and its mirror is activated in change tracking mode. In order to bring the failed segment instance back into operation again, you must first correct the problem that made it fail in the first place, and then recover the segment instance in Greenplum Database using gprecoverseg.

**Note:** If incremental recovery was not successful and the down segment instance data is not corrupted, contact Pivotal Support.

Segment recovery using gprecoverseg requires that you have an active mirror to recover from. For systems that do not have mirroring enabled, or in the event of a double fault (a primary and mirror pair both down at the same time) — you must take manual steps to recover the failed segment instances and then perform a system restart to bring the segments back online. For example, this command restarts a system.

```
gpstop -r
```

By default, a failed segment is recovered in place, meaning that the system brings the segment back online on the same host and data directory location on which it was originally configured. In this case, use the following format for the recovery configuration file (using -i).

```
<failed_host_address>|<port>|<data_directory>
```

In some cases, this may not be possible (for example, if a host was physically damaged and cannot be recovered). In this situation, gprecoverseg allows you to recover failed segments to a completely new host (using -p), on an alternative data directory location on your remaining live segment hosts (using -s), or by supplying a recovery configuration file (using -i) in the following format. The word SPACE indicates the location of a required space. Do not add additional spaces.

```
<failed_host_address>|<port>|<data_directory> SPACE
<recovery_host_address>|<port>|<data_directory>
```

See the -i option below for details and examples of a recovery configuration file.

The gp_segment_configuration system catalog table can help you determine your current segment configuration so that you can plan your mirror recovery configuration. For example, run the following query:

```
=# SELECT dbid, content, address, port, datadir
    FROM gp_segment_configuration
    ORDER BY dbid;
```

The new recovery segment host must be pre-installed with the Greenplum Database software and configured exactly the same as the existing segment hosts. A spare data directory location must exist on all currently configured segment hosts and have enough disk space to accommodate the failed segments.

The recovery process marks the segment as up again in the Greenplum Database system catalog, and then initiates the resynchronization process to bring the transactional state of the segment up-to-date with the latest changes. The system is online and available during resynchronization. To check the status of the resynchronization process run:

```
gpstate -m
```
Options
- **a** (do not prompt)
  Do not prompt the user for confirmation.

- **B parallel_processes**
  The number of segments to recover in parallel. If not specified, the utility will start up to 16 parallel processes depending on how many segment instances it needs to recover.

- **d master_data_directory**
  Optional. The master host data directory. If not specified, the value set for $MASTER_DATA_DIRECTORY will be used.

- **F (full recovery)**
  Optional. Perform a full copy of the active segment instance in order to recover the failed segment. The default is to only copy over the incremental changes that occurred while the segment was down.

  **Warning:** A full recovery deletes the data directory of the down segment instance before copying the data from the active (current primary) segment instance. Before performing a full recovery, ensure that the segment failure did not cause data corruption and that any host segment disk issues have been fixed.

  Also, for a full recovery, the utility does not restore custom files that are stored in the segment instance data directory even if the custom files are also in the active segment instance. You must restore the custom files manually. For example, when using the gpfdists protocol (gpfdist with SSL encryption) to manage external data, client certificate files are required in the segment instance $PGDATA/gpfdists directory. These files are not restored. For information about configuring gpfdists, see Encrypting gpfdist Connections.

  Full recovery can take a long time for large databases, so gprecoverseg displays a running estimate of the completion progress of the copy for each segment. Progress for each segment is updated once per second, using ANSI escape codes to update the line for each segment in-place. If you are redirecting the gprecoverseg output to a file, or if the ANSI escape codes do not work correctly on your terminal, you can include the **-s** option on the command line to omit the ANSI escape codes. This outputs a new line once per second for each segment. Include the **--no-progress** option to completely disable the progress reports.

- **i recover_config_file**
  Specifies the name of a file with the details about failed segments to recover. Each line in the file is in the following format. The word **SPACE** indicates the location of a required space. Do not add additional spaces.

  ```
  <failed_host_address>|<port>|<data_directory>SPACE
  <recovery_host_address>|<port>|<data_directory>
  ```

Comments
Lines beginning with # are treated as comments and ignored.

Segments to Recover
Each line after the first specifies a segment to recover. This line can have one of two formats. In the event of in-place recovery, enter one group of colon delimited fields in the line. For example:

```
failedAddress|failedPort|failedDataDirectory
```
For recovery to a new location, enter two groups of fields separated by a space in the line. The required space is indicated by `SPACE`. Do not add additional spaces.

```
failedAddress|failedPort|failedDataDirectory SPACE newAddress|newPort|newDataDirectory
```

### Examples

**In-place recovery of a single mirror**

```
sdw1-1|50001|/data1/mirror/gpseg16
```

**Recovery of a single mirror to a new host**

```
sdw1-1|50001|/data1/mirror/gpseg16 SPACE sdw4-1|50001|/data1/recover1/gpseg16
```

### Obtaining a Sample File

You can use the `-o` option to output a sample recovery configuration file to use as a starting point.

```
-l logfile_directory
```

The directory to write the log file. Defaults to `~/gpAdminLogs`.

```
-o output_recover_config_file
```

Specifies a file name and location to output a sample recovery configuration file. The output file lists the currently invalid segments and their default recovery location in the format that is required by the `-i` option. Use together with the `-p` option to output a sample file for recovering on a different host. This file can be edited to supply alternate recovery locations if needed.

```
-p new_recover_host[,...]
```

Specifies a spare host outside of the currently configured Greenplum Database array on which to recover invalid segments. In the case of multiple failed segment hosts, you can specify a comma-separated list. The spare host must have the Greenplum Database software installed and configured, and have the same hardware and OS configuration as the current segment hosts (same OS version, locales, `gpadmin` user account, data directory locations created, ssh keys exchanged, number of network interfaces, network interface naming convention, and so on.).

```
-q (no screen output)
```

Run in quiet mode. Command output is not displayed on the screen, but is still written to the log file.

```
-r (rebalance segments)
```

After a segment recovery, segment instances may not be returned to the preferred role that they were given at system initialization time. This can leave the system in a potentially unbalanced state, as some segment hosts may have more active segments than is optimal for top system performance. This option rebalances primary and mirror segments by returning them to their preferred roles. All segments must be valid and synchronized before running `gprecoverseg -r`. If there are any in progress queries, they will be cancelled and rolled back.

```
-s
```

Show `pg_basebackup` progress sequentially instead of in-place. Useful when writing to a file, or if a tty does not support escape sequences. The default is to show progress in-place.

```
--no-progress
```
Suppresses progress reports from the `pg_basebackup` utility. The default is to display progress of base backups.

```
-v (verbose)
Sets logging output to verbose.

--version (version)
Displays the version of this utility.

-? (help)
Displays the online help.
```

**Examples**

Recover any failed segment instances in place:

```
$ gprecoverseg
```

Rebalance your Greenplum Database system after a recovery by resetting all segments to their preferred role. First check that all segments are up and synchronized.

```
$ gpstate -m
$ gprecoverseg -r
```

Recover any failed segment instances to a newly configured spare segment host:

```
$ gprecoverseg -i recover_config_file
```

Output the default recovery configuration file:

```
$ gprecoverseg -o /home/gpadmin/recover_config_file
```

**See Also**

`gpstart`, `gpstop`

**gpreload**

Reloads Greenplum Database table data sorting the data based on specified columns.

**Synopsis**

```
gpreload -d database [-p port] [-t | --table-file] path_to_file [-a]
gpreload -h
gpreload --version
```

**Description**

The `gpreload` utility reloads table data with column data sorted. For tables that were created with the table storage option `appendoptimized=TRUE` and compression enabled, reloading the data with sorted data can improve table compression. You specify a list of tables to be reloaded and the table columns to be sorted in a text file.

Compression is improved by sorting data when the data in the column has a relatively low number of distinct values when compared to the total number of rows.
For a table being reloaded, the order of the columns to be sorted might affect compression. The columns with the fewest distinct values should be listed first. For example, listing state then city would generally result in better compression than listing city then state.

```plaintext
public.cust_table: state, city
public.cust_table: city, state
```

For information about the format of the file used with `gpreload`, see the `--table-file` option.

**Notes**

To improve reload performance, indexes on tables being reloaded should be removed before reloading the data.

Running the `ANALYZE` command after reloading table data might query performance because of a change in the data distribution of the reloaded data.

For each table, the utility copies table data to a temporary table, truncates the existing table data, and inserts data from the temporary table to the table in the specified sort order. Each table reload is performed in a single transaction.

For a partitioned table, you can reload the data of a leaf child partition. However, data is inserted from the root partition table, which acquires a `ROW EXCLUSIVE` lock on the entire table.

**Options**

`-a` *(do not prompt)*

Optional. If specified, the `gpreload` utility does not prompt the user for confirmation.

`-d database`

The database that contains the tables to be reloaded. The `gpreload` utility connects to the database as the user running the utility.

`-p port`

The Greenplum Database master port. If not specified, the value of the `PGPORT` environment variable is used. If the value is not available, an error is returned.

`{-t | --table-file } path_to_file`

The location and name of file containing list of schema qualified table names to reload and the column names to reorder from the Greenplum Database. Only user defined tables are supported. Views or system catalog tables are not supported.

If indexes are defined on table listed in the file, `gpreload` prompts to continue.

Each line specifies a table name and the list of columns to sort. This is the format of each line in the file:

```plaintext
schema.table_name: column [desc] [, column2 [desc] ... ]
```

The table name is followed by a colon (:) and then at least one column name. If you specify more than one column, separate the column names with a comma. The columns are sorted in ascending order. Specify the keyword `desc` after the column name to sort the column in descending order.

Wildcard characters are not supported.

If there are errors in the file, `gpreload` reports the first error and exits. No data is reloaded.

The following example reloads three tables:

```plaintext
public.clients: region, state, rep_id desc
public.merchants: region, state
```
In the first table `public.clients`, the data in the `rep_id` column is sorted in descending order. The data in the other columns are sorted in ascending order.

```plaintext
--version (show utility version)
  Displays the version of this utility.

-? (help)  
  Displays the online help.
```

### Example

This example command reloads the tables in the database `mytest` that are listed in the file `data-tables.txt`.

```bash
gpreload -d mytest --table-file data-tables.txt
```

`CREATE TABLE` in the *Greenplum Database Reference Guide*

### gprestore

`gprestore` restore a Greenplum Database backup that was created using the `gpbackup` utility. By default, `gprestore` uses backed up metadata files and DDL files located in the Greenplum Database master host data directory, with table data stored locally on segment hosts in CSV data files.

### Synopsis

```bash
gprestore --timestamp YYYYMMDDHHMMSS
  [--backup-dir directory]
  [--create-db]
  [--debug]
  [--exclude-schema schema_name]
  [--exclude-table schema.table]
  [--exclude-table-file file_name]
  [--include-schema schema_name]
  [--include-table schema.table]
  [--include-table-file file_name]
  [--data-only | --metadata-only]
  [--jobs int]
  [--on-error-continue]
  [--plugin-config config_file_location]
  [--quiet]
  [--redirect-db database_name]
  [--verbose]
  [--version]
  [--with-globals]
  [--with-stats]

gprestore --help
```

### Description

To use `gprestore` to restore from a backup set, you must include the `--timestamp` option to specify the exact timestamp value (`YYYYMMDDHHMMSS`) of the backup set to restore. If you specified a custom `--backup-dir` to consolidate the backup files, include the same `--backup-dir` option with `gprestore` to locate the backup files.
If the backup you specify is an incremental backup, you need a complete set of backup files (a full backup and any required incremental backups). `gprestore` ensures that the complete backup set is available before attempting to restore a backup.

**Important:** For incremental backup sets, the backups must be on a single device. For example, a backup set must all be on a Data Domain system.

For information about incremental backups, see [Creating Incremental Backups with gpbackup and gprestore](#).

When restoring from a backup set, `gprestore` restores to a database with the same name as the name specified when creating the backup set. If the target database exists and a table being restored exists in the database, the restore operation fails. Include the `--create-db` option if the target database does not exist in the cluster. You can optionally restore a backup set to a different database by using the `--redirect-db` option.

When restoring a backup set that contains data from some leaf partitions of a partitioned table, the partitioned table is restored along with the data for the leaf partitions. For example, you create a backup with the `gpbackup` option `--include-table-file` and the text file lists some leaf partitions of a partitioned table. Restoring the backup creates the partitioned table and restores the data only for the leaf partitions listed in the file.

Greenplum Database system objects are automatically included in a `gpbackup` backup set, but these objects are only restored if you include the `--with-globals` option to `gprestore`. Similarly, if you backed up query plan statistics using the `--with-stats` option, you can restore those statistics by providing `--with-stats` to `gprestore`. By default, only database objects in the backup set are restored.

Performance of restore operations can be improved by creating multiple parallel connections to restore table data and metadata. By default `gprestore` uses 1 connection, but you can increase this number with the `--jobs` option for large restore operations.

When a restore operation completes, `gprestore` returns a status code. See [Return Codes](#).

`gprestore` can send status email notifications after a backup operation completes. You specify when the utility sends the mail and the email recipients in a configuration file. See [Configuring Email Notifications](#).

**Note:** This utility uses secure shell (SSH) connections between systems to perform its tasks. In large Greenplum Database deployments, cloud deployments, or deployments with a large number of segments per host, this utility may exceed the host's maximum threshold for unauthenticated connections. Consider updating the SSH `MaxStartups` and `MaxSessions` configuration parameters to increase this threshold. For more information about SSH configuration options, refer to the SSH documentation for your Linux distribution.

### Options

**--timestamp YYYYMDDHHMMSS**

Required. Specifies the timestamp of the `gpbackup` backup set to restore. By default `gprestore` tries to locate metadata files for the timestamp on the Greenplum Database master host in the `$MASTER_DATA_DIRECTORY/backups/YYYYMDD/YYYYMDDhhmmss/` directory, and CSV data files in the `<seg_dir>/backups/YYYYMDD/YYYYMDDhhmmss/` directory of each segment host.

**--backup-dir directory**

Optional. Sources all backup files (metadata files and data files) from the specified directory. You must specify `directory` as an absolute path (not relative). If you do not supply this option, `gprestore` tries to locate metadata files for the timestamp on the Greenplum Database master host in the `$MASTER_DATA_DIRECTORY/backups/YYYYMDD/YYYYMDDhhmmss/` directory. CSV data files must be available on each segment in the `<seg_dir>/backups/YYYYMDD/YYYYMDDhhmmss/` directory. Include this option when you specify a custom backup directory with `gpbackup`.

You cannot combine this option with the option `--plugin-config`. 

---

---
--create-db
Optional. Creates the database before restoring the database object metadata.
The database is created by cloning the empty standard system database template0.

--data-only
Optional. Restores table data from a backup created with the gpbackup utility, without
creating the database tables. This option assumes the tables exist in the target database.
To restore data for a specific set of tables from a backup set, you can specify an option
to include tables or schemas or exclude tables or schemas. Specify the --with-stats
option to restore table statistics from the backup.

The backup set must contain the table data to be restored. For example, a backup created
with the gpbackup option --metadata-only does not contain table data.

To restore only database tables, without restoring the table data, see the option --
metadata-only.

--debug
Optional. Displays verbose and debug log messages during a restore operation.

--exclude-schema schema_name
Optional. Specifies a database schema to exclude from the restore operation. You can
specify this option multiple times to exclude multiple schemas. You cannot combine
this option with the option --include-schema, or a table filtering option such as --
include-table.

--exclude-table schema.table
Optional. Specifies a table to exclude from the restore operation. The table must be in the
format <schema-name>.<table-name>. If a table or schema name uses any character
other than a lowercase letter, number, or an underscore character, then you must include
that name in double quotes. You can specify this option multiple times. If the table is
not in the backup set, the restore operation fails. You cannot specify a leaf partition of a
partitioned table.

You cannot combine this option with the option --exclude-schema, or another a table
filtering option such as --include-table.

--exclude-table-file file_name
Optional. Specifies a text file containing a list of tables to exclude from the restore
operation. Each line in the text file must define a single table using the format <schema-
name>.<table-name>. The file must not include trailing lines. If a table or schema name
uses any character other than a lowercase letter, number, or an underscore character,
then you must include that name in double quotes. If a table is not in the backup set, the
restore operation fails. You cannot specify a leaf partition of a partitioned table.

You cannot combine this option with the option --exclude-schema, or another a table
filtering option such as --include-table.

--include-schema schema_name
Optional. Specifies a database schema to restore. You can specify this option multiple
times to include multiple schemas. If you specify this option, any schemas that you specify
must be available in the backup set. Any schemas that are not included in subsequent --
include-schema options are omitted from the restore operation.

If a schema that you specify for inclusion exists in the database, the utility issues an error
and continues the operation. The utility fails if a table being restored exists in the database.

You cannot use this option if objects in the backup set have dependencies on multiple
schemas.

See Filtering the Contents of a Backup or Restore for more information.
--include-table schema.table
Optional. Specifies a table to restore. The table must be in the format <schema-name>.<table-name>. If a table or schema name uses any character other than a lowercase letter, number, or an underscore character, then you must include that name in double quotes. You can specify this option multiple times. You cannot specify a leaf partition of a partitioned table.

You can also specify the qualified name of a sequence or a view.

If you specify this option, the utility does not automatically restore dependent objects. You must also explicitly specify the dependent objects that are required. For example if you restore a view, you must also restore the tables that the view uses. If you restore a table that uses a sequence, you must also restore the sequence. The dependent objects must exist in the backup set.

You cannot combine this option with a schema filtering option such as --include-schema, or another table filtering option such as --exclude-table-file.

--include-table-file file_name
Optional. Specifies a text file containing a list of tables to restore. Each line in the text file must define a single table using the format <schema-name>.<table-name>. The file must not include trailing lines. If a table or schema name uses any character other than a lowercase letter, number, or an underscore character, then you must include that name in double quotes. Any tables not listed in this file are omitted from the restore operation. You cannot specify a leaf partition of a partitioned table.

You can also specify the qualified name of a sequence or a view.

If you specify this option, the utility does not automatically restore dependent objects. You must also explicitly specify dependent objects that are required. For example if you restore a view, you must also specify the tables that the view uses. If you specify a table that uses a sequence, you must also specify the sequence. The dependent objects must exist in the backup set.

If you use the --include-table-file option, gprestore does not create roles or set the owner of the tables. The utility restores table indexes and rules. Triggers are also restored but are not supported in Greenplum Database.

See Filtering the Contents of a Backup or Restore for more information.

--jobs int
Optional. Specifies the number of parallel connections to use when restoring table data and metadata. By default, gprestore uses 1 connection. Increasing this number can improve the speed of restoring data.

Note: If you used the gpbackup --single-data-file option to combine table backups into a single file per segment, you cannot set --jobs to a value higher than 1 to perform a parallel restore operation.

--metadata-only
Optional. Creates database tables from a backup created with the gpbackup utility, but does not restore the table data. This option assumes the tables do not exist in the target database. To create a specific set of tables from a backup set, you can specify an option to include tables or schemas or exclude tables or schemas. Specify the option --with-globals to restore the Greenplum Database system objects.

The backup set must contain the DDL for tables to be restored. For example, a backup created with the gpbackup option --data-only does not contain the DDL for tables.

To restore table data after you create the database tables, see the option --data-only.

--on-error-continue
Optional. Specify this option to continue the restore operation if an SQL error occurs when creating database metadata (such as tables, roles, or functions) or restoring data. If another type of error occurs, the utility exits. The utility displays an error summary and writes error information to the gprestore log file and continues the restore operation.

The default is to exit on the first error.

```
--plugin-config config-file_location
```

Specify the location of the gpbackup plugin configuration file, a YAML-formatted text file. The file contains configuration information for the plugin application that gprestore uses during the restore operation.

If you specify the --plugin-config option when you back up a database, you must specify this option with configuration information for a corresponding plugin application when you restore the database from the backup.

You cannot combine this option with the option --backup-dir.

For information about using storage plugin applications, see Using gpbackup Storage Plugins.

```
--quiet
```

Optional. Suppress all non-warning, non-error log messages.

```
--redirect-db database_name
```

Optional. Restore to the specified database_name instead of to the database that was backed up.

```
--verbose
```

Optional. Displays verbose log messages during a restore operation.

```
--version
```

Optional. Print the version number and exit.

```
--with-globals
```

Optional. Restores Greenplum Database system objects in the backup set, in addition to database objects. See Objects Included in a Backup or Restore.

```
--with-stats
```

Optional. Restore query plan statistics from the backup set.

```
--help
```

Displays the online help.

**Return Codes**

One of these codes is returned after gprestore completes.

- **0** – Restore completed with no problems.
- **1** – Restore completed with non-fatal errors. See log file for more information.
- **2** – Restore failed with a fatal error. See log file for more information.

**Examples**

Create the demo database and restore all schemas and tables in the backup set for the indicated timestamp:

```
$ dropdb demo
$ gprestore --timestamp 20171103152558 --create-db
```
Restore the backup set to the "demo2" database instead of the "demo" database that was backed up:

```
$ createdb demo2
$ gprestore --timestamp 20171103152558 --redirect-db demo2
```

Restore global Greenplum Database metadata and query plan statistics in addition to the database objects:

```
$ gprestore --timestamp 20171103152558 --create-db --with-globals --with-stats
```

Restore, using backup files that were created in the `/home/gpadmin/backup` directory, creating 8 parallel connections:

```
$ gprestore --backup-dir /home/gpadmin/backups/ --timestamp 20171103153156 --create-db --jobs 8
```

Restore only the "wikipedia" schema included in the backup set:

```
$ dropdb demo
$ gprestore --include-schema wikipedia --backup-dir /home/gpadmin/backups/ --timestamp 20171103153156 --create-db
```

If you restore from an incremental backup set, all the required files in the backup set must be available to gprestore. For example, the following timestamp keys specify an incremental backup set. 20170514054532 is the full backup and the others are incremental backups.

```
20170514054532 (full backup)
201707014095512
20170914081205
20171114064330
20180114051246
```

The following gprestore command specifies the timestamp 20121114064330. The incremental backup with the timestamps 20120714095512 and 20120914081205 and the full backup must be available to perform a restore.

```
gprestore --timestamp 20121114064330 --redirect-db mystest --create-db
```

**See Also**

`gpbackup`, *Parallel Backup with gpbackup and gprestore* and *Using the S3 Storage Plugin with gpbackup and gprestore*

**gpscp**

Copies files between multiple hosts at once.

**Synopsis**

```
gscp { -f hostfile_gpssh | -h hostname [-h hostname ...] } 
[-J character] [-v] [[user@]hostname:]file_to_copy [...] 
[[user@]hostname:]copy_to_path
```

```
gscp -?
gscp --version
```
Description

The `gpscp` utility allows you to copy one or more files from the specified hosts to other specified hosts in one command using SCP (secure copy). For example, you can copy a file from the Greenplum Database master host to all of the segment hosts at the same time.

To specify the hosts involved in the SCP session, use the `-f` option to specify a file containing a list of host names, or use the `-h` option to name single host names on the command-line. At least one host name (-h) or a host file (-f) is required. The `-J` option allows you to specify a single character to substitute for the `hostname` in the copy from and copy to destination strings. If `-J` is not specified, the default substitution character is an equal sign (=). For example, the following command will copy `.bashrc` from the local host to `/home/gpadmin` on all hosts named in `hostfile_gpssh`:

```
gpscp -f hostfile_gpssh .bashrc =:/home/gpadmin
```

If a user name is not specified in the host list or with `user@` in the file path, `gpscp` will copy files as the currently logged in user. To determine the currently logged in user, do a `whoami` command. By default, `gpscp` goes to `$HOME` of the session user on the remote hosts after login. To ensure the file is copied to the correct location on the remote hosts, it is recommended that you use absolute paths.

Before using `gpscp`, you must have a trusted host setup between the hosts involved in the SCP session. You can use the utility `gpssh-exkeys` to update the known host files and exchange public keys between hosts if you have not done so already.

Options

```
-f hostfile_gpssh
```

Specifies the name of a file that contains a list of hosts that will participate in this SCP session. The syntax of the host file is one host per line as follows:

```
<hostname>
```

```
-h hostname
```

Specifies a single host name that will participate in this SCP session. You can use the `-h` option multiple times to specify multiple host names.

```
-J character
```

The `-J` option allows you to specify a single character to substitute for the `hostname` in the copy from and copy to destination strings. If `-J` is not specified, the default substitution character is an equal sign (=).

```
-v (verbose mode)
```

Optional. Reports additional messages in addition to the SCP command output.

```
file_to_copy
```

Required. The file name (or absolute path) of a file that you want to copy to other hosts (or file locations). This can be either a file on the local host or on another named host.

```
copy_to_path
```

Required. The path where you want the file(s) to be copied on the named hosts. If an absolute path is not used, the file will be copied relative to `$HOME` of the session user. You can also use the equal sign `=` (or another character that you specify with the `-J` option) in place of a `hostname`. This will then substitute in each host name as specified in the supplied host file (-f) or with the `-h` option.

```
-? (help)
```

Displays the online help.

```
--version
```

Displays the version of this utility.
Examples

Copy the file named installer.tar to / on all the hosts in the file hostfile_gpssh.

```
gpscp -f hostfile_gpssh installer.tar =:/
```

Copy the file named myfuncs.so to the specified location on the hosts named sdw1 and sdw2:

```
gpscp -h sdw1 -h sdw2 myfuncs.so =:/usr/local/greenplum-db/lib
```

### gpssh

Provides SSH access to multiple hosts at once.

#### Synopsis

```
gpssh (-f hostfile_gpssh | -h hostname [-h hostname ...]) [-s] [-e] [-d seconds] [-t multiplier] [-v] [bash_command]
```

```
gpssh -?
gpssh --version
```

#### Description

The `gpssh` utility allows you to run bash shell commands on multiple hosts at once using SSH (secure shell). You can execute a single command by specifying it on the command-line, or omit the command to enter into an interactive command-line session.

To specify the hosts involved in the SSH session, use the `-f` option to specify a file containing a list of host names, or use the `-h` option to name single host names on the command-line. At least one host name (`-h`) or a host file (`-f`) is required. Note that the current host is not included in the session by default — to include the local host, you must explicitly declare it in the list of hosts involved in the session.

Before using `gpssh`, you must have a trusted host setup between the hosts involved in the SSH session. You can use the utility `gpssh-exkeys` to update the known host files and exchange public keys between hosts if you have not done so already.

If you do not specify a command on the command-line, `gpssh` will go into interactive mode. At the `gpssh` command prompt (`=`), you can enter a command as you would in a regular bash terminal command-line, and the command will be executed on all hosts involved in the session. To end an interactive session, press `CTRL+D` on the keyboard or type `exit` or `quit`.

If a user name is not specified in the host file, `gpssh` will execute commands as the currently logged in user. To determine the currently logged in user, do a `whoami` command. By default, `gpssh` goes to `$HOME` of the session user on the remote hosts after login. To ensure commands are executed correctly on all remote hosts, you should always enter absolute paths.

If you encounter network timeout problems when using `gpssh`, you can use `-d` and `-t` options or set parameters in the `gpssh.conf` file to control the timing that `gpssh` uses when validating the initial `ssh` connection. For information about the configuration file, see `gpssh Configuration File`.

#### Options

`bash_command`
A bash shell command to execute on all hosts involved in this session (optionally enclosed in quotes). If not specified, gpssh starts an interactive session.

\[ -d \text{ (delay) seconds} \]
Optional. Specifies the time, in seconds, to wait at the start of a gpssh interaction with ssh. Default is 0.05. This option overrides the delaybeforesend value that is specified in the gpssh.conf configuration file.

Increasing this value can cause a long wait time during gpssh startup.

\[ -e \text{ (echo)} \]
Optional. Echoes the commands passed to each host and their resulting output while running in non-interactive mode.

\[ -f \text{ hostfile_gpssh} \]
Specifies the name of a file that contains a list of hosts that will participate in this SSH session. The syntax of the host file is one host per line.

\[ -h \text{ hostname} \]
Specifies a single host name that will participate in this SSH session. You can use the \(-h\) option multiple times to specify multiple host names.

\[ -s \]
Optional. If specified, before executing any commands on the target host, gpssh sources the file greenplum_path.sh in the directory specified by the \$GPHOME environment variable.

This option is valid for both interactive mode and single command mode.

\[ -t \text{ multiplier} \]
Optional. A decimal number greater than 0 (zero) that is the multiplier for the timeout that gpssh uses when validating the ssh prompt. Default is 1. This option overrides the prompt_validation_timeout value that is specified in the gpssh.conf configuration file.

Increasing this value has a small impact during gpssh startup.

\[ -v \text{ (verbose mode)} \]
Optional. Reports additional messages in addition to the command output when running in non-interactive mode.

\[ --version \]
Displays the version of this utility.

\[ -? \text{ (help)} \]
Displays the online help.

**gpssh Configuration File**

The gpssh.conf file contains parameters that let you adjust the timing that gpssh uses when validating the initial ssh connection. These parameters affect the network connection before the gpssh session executes commands with ssh. The location of the file is specified by the environment variable MASTER_DATA_DIRECTORY. If the environment variable is not defined or the gpssh.conf file does not exist, gpssh uses the default values or the values set with the \(-d\) and \(-t\) options. For information about the environment variable, see the *Greenplum Database Reference Guide*.

The gpssh.conf file is a text file that consists of a [gpssh] section and parameters. On a line, the # (pound sign) indicates the start of a comment. This is an example gpssh.conf file.

```
[gpssh]
delaybeforesend = 0.05
prompt_validation_timeout = 1.0
```
sync_retries = 5

These are the gpssh.conf parameters.

delaybeforesend = seconds

Specifies the time, in seconds, to wait at the start of a gpssh interaction with ssh. Default is 0.05. Increasing this value can cause a long wait time during gpssh startup. The -d option overrides this parameter.

prompt_validation_timeout = multiplier

A decimal number greater than 0 (zero) that is the multiplier for the timeout that gpssh uses when validating the ssh prompt. Increasing this value has a small impact during gpssh startup. Default is 1. The -t option overrides this parameter.

sync_retries = attempts

A non-negative integer that specifies the maximum number of times that gpssh attempts to connect to a remote Greenplum Database host. The default is 3. If the value is 0, gpssh returns an error if the initial connection attempt fails. Increasing the number of attempts also increases the time between retry attempts. This parameter cannot be configured with a command-line option.

The -t option also affects the time between retry attempts.

Increasing this value can compensate for slow network performance or segment host performance issues such as heavy CPU or I/O load. However, when a connection cannot be established, an increased value also increases the delay when an error is returned.

Examples

Start an interactive group SSH session with all hosts listed in the file hostfile_gpssh:

$ gpssh -f hostfile_gpssh

At the gpssh interactive command prompt, run a shell command on all the hosts involved in this session.

=> ls -a /data/primary/*

Exit an interactive session:

=> exit
=> quit

Start a non-interactive group SSH session with the hosts named sdw1 and sdw2 and pass a file containing several commands named command_file to gpssh:

$ gpssh -h sdw1 -h sdw2 -v -e < command_file

Execute single commands in non-interactive mode on hosts sdw2 and localhost:

$ gpssh -h sdw2 -h localhost -v -e 'ls -a /data/primary/*'
$ gpssh -h sdw2 -h localhost -v -e 'echo $GPHOME'
$ gpssh -h sdw2 -h localhost -v -e 'ls -l | wc -l'

**Description**

The `gpssh-exkeys` utility exchanges SSH keys between the specified host names (or host addresses). This allows SSH connections between Greenplum hosts and network interfaces without a password prompt. The utility is used to initially prepare a Greenplum Database system for passwordless SSH access, and also to prepare additional hosts for passwordless SSH access when expanding a Greenplum Database system.

Keys are exchanged as the currently logged in user. You run the utility on the master host as the `gpadmin` user (the user designated to own your Greenplum Database installation). Greenplum Database management utilities require that the `gpadmin` user be created on all hosts in the Greenplum Database system, and the utilities must be able to connect as that user to all hosts without a password prompt.

You can also use `gpssh-exkeys` to enable passwordless SSH for additional users, `root`, for example.

The `gpssh-exkeys` utility has the following prerequisites:

- The user must have an account on the master, standby, and every segment host in the Greenplum Database cluster.
- The user must have an `id_rsa` SSH key pair installed on the master host.
- The user must be able to connect with SSH from the master host to every other host machine without entering a password. (This is called "1-n passwordless SSH.")

You can enable 1-n passwordless SSH using the `ssh-copy-id` command to add the user's public key to each host's `authorized_keys` file. The `gpssh-exkeys` utility enables "n-n passwordless SSH," which allows the user to connect with SSH from any host to any other host in the cluster without a password.

To specify the hosts involved in an SSH key exchange, use the `-f` option to specify a file containing a list of host names (recommended), or use the `-h` option to name single host names on the command-line. At least one host name (-h) or a host file (-f) is required. Note that the local host is included in the key exchange by default.

To specify new expansion hosts to be added to an existing Greenplum Database system, use the `-e` and `-x` options. The `-e` option specifies a file containing a list of existing hosts in the system that have already exchanged SSH keys. The `-x` option specifies a file containing a list of new hosts that need to participate in the SSH key exchange.

The `gpssh-exkeys` utility performs key exchange using the following steps:

- Adds the user's public key to the user's own `authorized_keys` file on the current host.
- Updates the `known_hosts` file of the current user with the host key of each host specified using the `-h`, `-f`, `-e`, and `-x` options.
- Connects to each host using `ssh` and obtains the user's `authorized_keys`, `known_hosts`, and `id_rsa.pub` files.
- Adds keys from the `id_rsa.pub` files obtained from each host to the `authorized_keys` file of the current user.
- Updates the `authorized_keys`, `known_hosts`, and `id_rsa.pub` files on all hosts with new host information (if any).

**Options**

- **-e hostfile_exkeys**
  When doing a system expansion, this is the name and location of a file containing all configured host names and host addresses (interface names) for each host in your current Greenplum system (master, standby master, and segments), one name per line without blank lines or extra spaces. Hosts specified in this file cannot be specified in the host file used with `-x`.

- **-f hostfile_exkeys**
  Specifies the name and location of a file containing all configured host names and host addresses (interface names) for each host in your Greenplum system (master, standby master and segments), one name per line without blank lines or extra spaces.

- **-h hostname**
  Specifies a single host name (or host address) that will participate in the SSH key exchange. You can use the `-h` option multiple times to specify multiple host names and host addresses.

- **--version**
  Displays the version of this utility.

- **-x hostfile_gpexpand**
  When doing a system expansion, this is the name and location of a file containing all configured host names and host addresses (interface names) for each new segment host you are adding to your Greenplum system, one name per line without blank lines or extra spaces. Hosts specified in this file cannot be specified in the host file used with `-e`.

- **-? (help)**
  Displays the online help.

**Examples**

Exchange SSH keys between all host names and addresses listed in the file `hostfile_exkeys`:

```bash
$ gpssh-exkeys -f hostfile_exkeys
```

Exchange SSH keys between the hosts `sdw1`, `sdw2`, and `sdw3`:

```bash
$ gpssh-exkeys -h sdw1 -h sdw2 -h sdw3
```

Exchange SSH keys between existing hosts `sdw1`, `sdw2`, and `sdw3`, and new hosts `sdw4` and `sdw5` as part of a system expansion operation:

```bash
$ cat hostfile_exkeys
mdw
mdw-1
mdw-2
smdw
smdw-1
smdw-2
sdw1
sdw1-1
sdw1-2
sdw2
```
The `gpstart` utility is used to start the Greenplum Database server processes. When you start a Greenplum Database system, you are actually starting several `postgres` database server listener processes at once (the master and all of the segment instances). The `gpstart` utility handles the startup of the individual instances. Each instance is started in parallel.

The first time an administrator runs `gpstart`, the utility creates a hosts cache file named `.gphostcache` in the user’s home directory. Subsequently, the utility uses this list of hosts to start the system more efficiently. If new hosts are added to the system, you must manually remove this file from the `gpadmin` user’s home directory. The utility will create a new hosts cache file at the next startup.

As part of the startup process, the utility checks the consistency of heap checksum setting among the Greenplum Database master and segment instances, either enabled or disabled on all instances. If the heap checksum setting is different among the instances, an error is returned and Greenplum Database does not start. The validation can be disabled by specifying the option `--skip-heap-checksum-validation`. For more information about heap checksums, see `Enabling High Availability and Data Consistency Features` in the *Greenplum Database Administrator Guide*.

**Note:** Before you can start a Greenplum Database system, you must have initialized the system using `gpinitsystem`. Enabling or disabling heap checksums is set when you initialize the system and cannot be changed after initialization.

### Options

- `-a`

  Do not prompt the user for confirmation.
-B parallel_processes
  The number of segments to start in parallel. If not specified, the utility will start up to 64 parallel processes depending on how many segment instances it needs to start.

-d master_data_directory
  Optional. The master host data directory. If not specified, the value set for $MASTER_DATA_DIRECTORY will be used.

-l logfile_directory
  The directory to write the log file. Defaults to ~/gpAdminLogs.

-m
  Optional. Starts the master instance only, which may be useful for maintenance tasks. This mode only allows connections to the master in utility mode. For example:

  PGOPTIONS='c gp_session_role=utility' psql

  The consistency of the heap checksum setting on master and segment instances is not checked.

-q
  Run in quiet mode. Command output is not displayed on the screen, but is still written to the log file.

-R
  Starts Greenplum Database in restricted mode (only database superusers are allowed to connect).

--skip-heap-checksum-validation
  During startup, the utility does not validate the consistency of the heap checksum setting among the Greenplum Database master and segment instances. The default is to ensure that the heap checksum setting is the same on all instances, either enabled or disabled.

  Warning: Starting Greenplum Database without this validation could lead to data loss. Use this option to start Greenplum Database only when it is necessary to ignore the heap checksum verification errors to recover data or to troubleshoot the errors.

-t timeout_seconds
  Specifies a timeout in seconds to wait for a segment instance to start up. If a segment instance was shutdown abnormally (due to power failure or killing its postgres database listener process, for example), it may take longer to start up due to the database recovery and validation process. If not specified, the default timeout is 60 seconds.

-v
  Displays detailed status, progress and error messages output by the utility.

-y
  Optional. Do not start the standby master host. The default is to start the standby master host and synchronization process.

-? | -h | --help
  Displays the online help.

--version
  Displays the version of this utility.
**Examples**

Start a Greenplum Database system:

```
gpstart
```

Start a Greenplum Database system in restricted mode (only allow superuser connections):

```
gpstart -R
```

Start the Greenplum master instance only and connect in utility mode:

```
gpstart -m PGOPTIONS='-c gp_session_role=utility' psql
```

---

**gpstate**

Shows the status of a running Greenplum Database system.

**Synopsis**

```
gpstate [-d master_data_directory] [-B parallel_processes]
[-l log_directory]
gpstate -? | -h | --help
```

**Description**

The `gpstate` utility displays information about a running Greenplum Database instance. There is additional information you may want to know about a Greenplum Database system, since it is comprised of multiple PostgreSQL database instances (segments) spanning multiple machines. The `gpstate` utility provides additional status information for a Greenplum Database system, such as:

- Which segments are down.
- Master and segment configuration information (hosts, data directories, etc.).
- The ports used by the system.
- A mapping of primary segments to their corresponding mirror segments.

**Options**

- `-b` (*brief status*)
  Optional. Display a brief summary of the state of the Greenplum Database system. This is the default option.

- `-B parallel_processes`
  The number of segments to check in parallel. If not specified, the utility will start up to 60 parallel processes depending on how many segment instances it needs to check.

- `-c` (*show primary to mirror mappings*)
  Optional. Display mapping of primary segments to their corresponding mirror segments.

- `-d master_data_directory`
  Optional. The master data directory. If not specified, the value set for $MASTER_DATA_DIRECTORY will be used.
-e (show segments with mirror status issues)
   Show details on primary/mirror segment pairs that have potential issues such as 1) the
   active segment is running in change tracking mode, meaning a segment is down 2) the
   active segment is in resynchronization mode, meaning it is catching up changes to the
   mirror 3) a segment is not in its preferred role, for example a segment that was a primary
   at system initialization time is now acting as a mirror, meaning you may have one or more
   segment hosts with unbalanced processing load.

-f (show standby master details)
   Display details of the standby master host if configured.

-i (show Greenplum Database version)
   Display the Greenplum Database software version information for each instance.

-l logfile_directory
   The directory to write the log file. Defaults to ~/gpAdminLogs.

-m (list mirrors)
   Optional. List the mirror segment instances in the system, their current role, and
   synchronization status.

-p (show ports)
   List the port numbers used throughout the Greenplum Database system.

-q (no screen output)
   Optional. Run in quiet mode. Except for warning messages, command output is not
   displayed on the screen. However, this information is still written to the log file.

-Q (quick status)
   Optional. Checks segment status in the system catalog on the master host. Does not poll
   the segments for status.

-s (detailed status)
   Optional. Displays detailed status information for the Greenplum Database system.

-v (verbose output)
   Optional. Displays error messages and outputs detailed status and progress information.

-x (expand)
   Optional. Displays detailed information about the progress and state of a Greenplum
   system expansion.

-? | -h | --help (help)
   Displays the online help.

Output Field Definitions
The following output fields are reported by gpstate -s for the master:

**Examples**

Show detailed status information of a Greenplum Database system:

```
gpstate -s
```
Do a quick check for down segments in the master host system catalog:

```
gpstate -Q
```

Show information about mirror segment instances:

```
gpstate -m
```

Show information about the standby master configuration:

```
gpstate -f
```

Display the Greenplum software version information:

```
gpstate -i
```

### See Also

`gpstart, gpexpandgplogfilter`

## gpstop

Stops or restarts a Greenplum Database system.

### Synopsis

```
gpstop -m [-d master_data_directory] [-y] [-l logfile_directory] [-v | -q]
gpstop -u [-d master_data_directory] [-l logfile_directory] [-v | -q]
gpstop --host host_name [-d master_data_directory] [-l logfile_directory] [-t timeout_seconds] [-a] [-v | -q]
gpstop --version
```

### Description

The `gpstop` utility is used to stop the database servers that comprise a Greenplum Database system. When you stop a Greenplum Database system, you are actually stopping several `postgres` database server processes at once (the master and all of the segment instances). The `gpstop` utility handles the shutdown of the individual instances. Each instance is shutdown in parallel. The default shutdown mode (`-M smart`) waits for current client connections to finish before completing the shutdown. If any connections remain open after the timeout period, or if you interrupt with CTRL-C, `gpstop` lists the open connections and prompts whether to continue waiting for connections to finish, or to perform a fast or immediate shutdown. The default timeout period is 120 seconds and can be changed with the `-t timeout_seconds` option.

Specify the `-M fast` shutdown mode to roll back all in-progress transactions and terminate any connections before shutting down.
With the -u option, the utility uploads changes made to the master `pg_hba.conf` file or to runtime configuration parameters in the master `postgresql.conf` file without interruption of service. Note that any active sessions will not pickup the changes until they reconnect to the database.

**Options**

- **-a**
  Do not prompt the user for confirmation.

- **-B parallel_processes**
  The number of segments to stop in parallel. If not specified, the utility will start up to 64 parallel processes depending on how many segment instances it needs to stop.

- **-d master_data_directory**
  Optional. The master host data directory. If not specified, the value set for `$MASTER_DATA_DIRECTORY` will be used.

- **--host host_name**
  The utility shuts down the Greenplum Database segment instances on the specified host to allow maintenance on the host. Each primary segment instance on the host is shut down and the associated mirror segment instance is promoted to a primary segment if the mirror segment is on another host. Mirror segment instances on the host are shut down.

  The segment instances are not shut down and the utility returns an error in these cases:
  
  - Segment mirroring is not enabled for the system.
  - The master or standby master is on the host.
  - Both a primary segment instance and its mirror are on the host.

  This option cannot be specified with the -m, -r, -u, or -y options.

  _Note:_ The `gprecoverseg` utility restores segment instances. Run `gprecoverseg` commands to start the segments as mirrors and then to return the segments to their preferred role (primary segments).

- **-l logfile_directory**
  The directory to write the log file. Defaults to `~/gpAdminLogs`.

- **-m**
  Optional. Shuts down a Greenplum master instance that was started in maintenance mode.

- **-M fast**
  Fast shut down. Any transactions in progress are interrupted and rolled back.

- **-M immediate**
  Immediate shut down. Any transactions in progress are aborted.

  This mode kills all `postgres` processes without allowing the database server to complete transaction processing or clean up any temporary or in-process work files.

- **-M smart**
  Smart shut down. This is the default shutdown mode. `gpstop` waits for active user connections to disconnect and then proceeds with the shutdown. If any user connections remain open after the timeout period (or if you interrupt by pressing CTRL-C) `gpstop` lists the open user connections and prompts whether to continue waiting for connections to finish, or to perform a fast or immediate shutdown.

- **-q**
  Run in quiet mode. Command output is not displayed on the screen, but is still written to the log file.
-r
  Restart after shutdown is complete.

-\texttt{t} \ \texttt{timeout\_seconds}
  Specifies a timeout threshold (in seconds) to wait for a segment instance to shutdown.
  If a segment instance does not shutdown in the specified number of seconds, \texttt{gpstop}
  displays a message indicating that one or more segments are still in the process of
  shutting down and that you cannot restart Greenplum Database until the segment
  instance(s) are stopped. This option is useful in situations where \texttt{gpstop} is executed and
  there are very large transactions that need to rollback. These large transactions can take
  over a minute to rollback and surpass the default timeout period of 120 seconds.

-\texttt{u}
  This option reloads the \texttt{pg\_hba.conf} files of the master and segments and the runtime
  parameters of the \texttt{postgresql.conf} files but does not shutdown the Greenplum
  Database array. Use this option to make new configuration settings active after editing
  \texttt{postgresql.conf} or \texttt{pg\_hba.conf}. Note that this only applies to configuration
  parameters that are designated as \textit{runtime} parameters.

-\texttt{v}
  Displays detailed status, progress and error messages output by the utility.

-\texttt{y}
  Do not stop the standby master process. The default is to stop the standby master.

-? | -h | --help
  Displays the online help.

--version
  Displays the version of this utility.

\textbf{Examples}

Stop a Greenplum Database system in smart mode:

\begin{verbatim}
gpstop
\end{verbatim}

Stop a Greenplum Database system in fast mode:

\begin{verbatim}
gpstop -M fast
\end{verbatim}

Stop all segment instances and then restart the system:

\begin{verbatim}
gpstop -r
\end{verbatim}

Stop a master instance that was started in maintenance mode:

\begin{verbatim}
gpstop -m
\end{verbatim}

Reload the \texttt{postgresql.conf} and \texttt{pg\_hba.conf} files after making configuration changes but do not
shutdown the Greenplum Database array:

\begin{verbatim}
gpstop -u
\end{verbatim}

\textbf{See Also}

\begin{verbatim}
gpstart
\end{verbatim}
**gpsys1**

Displays information about your operating system.

**Synopsis**

```bash
gpsys1 [ -a | -m | -p ]
gpsys1 -?
gpsys1 --version
```

**Description**

`gpsys1` displays the platform and installed memory (in bytes) of the current host. For example:

```
linux 1073741824
```

**Options**

- `-a` *(show all)*
  
  Shows both platform and memory information for the current host. This is the default.

- `-m` *(show memory only)*
  
  Shows system memory installed in bytes.

- `-p` *(show platform only)*
  
  Shows the OS platform. Platform can be `linux`, `darwin` or `sunos5`.

- `-?` *(help)*
  
  Displays the online help.

- `--version`
  
  Displays the version of this utility.

**Examples**

Show information about the current host operating system:

```
gpsys1
```

**See Also**

`gpcheckperf`

**pg_config**

Retrieves information about the installed version of Greenplum Database.

**Synopsis**

```bash
pg_config [option ...]
pg_config -? | --help
pg_config --version
```
**Description**

The `pg_config` utility prints configuration parameters of the currently installed version of Greenplum Database. It is intended, for example, to be used by software packages that want to interface to Greenplum Database to facilitate finding the required header files and libraries. Note that information printed out by `pg_config` is for the Greenplum Database master only.

If more than one option is given, the information is printed in that order, one item per line. If no options are given, all available information is printed, with labels.

**Options**

--bindir

Print the location of user executables. Use this, for example, to find the `psql` program. This is normally also the location where the `pg_config` program resides.

--docdir

Print the location of documentation files.

--includedir

Print the location of C header files of the client interfaces.

--pkgincludedir

Print the location of other C header files.

--includedir-server

Print the location of C header files for server programming.

--libdir

Print the location of object code libraries.

--pkglibdir

Print the location of dynamically loadable modules, or where the server would search for them. (Other architecture-dependent data files may also be installed in this directory.)

--localedir

Print the location of locale support files.

--mandir

Print the location of manual pages.

--sharedir

Print the location of architecture-independent support files.

--sysconfdir

Print the location of system-wide configuration files.

--pgxs

Print the location of extension makefiles.

--configure

Print the options that were given to the configure script when Greenplum Database was configured for building.

--cc

Print the value of the CC variable that was used for building Greenplum Database. This shows the C compiler used.

--cppflags

Print the value of the `CPPFLAGS` variable that was used for building Greenplum Database. This shows C compiler switches needed at preprocessing time.

--cflags
Print the value of the `CFLAGS` variable that was used for building Greenplum Database. This shows C compiler switches.

`--cflags_sl`
Print the value of the `CFLAGS_SL` variable that was used for building Greenplum Database. This shows extra C compiler switches used for building shared libraries.

`--ldflags`
Print the value of the `LDFLAGS` variable that was used for building Greenplum Database. This shows linker switches.

`--ldflags_ex`
Print the value of the `LDFLAGS_EX` variable that was used for building Greenplum Database. This shows linker switches that were used for building executables only.

`--ldflags_sl`
Print the value of the `LDFLAGS_SL` variable that was used for building Greenplum Database. This shows linker switches used for building shared libraries only.

`--libs`
Print the value of the `LIBS` variable that was used for building Greenplum Database. This normally contains `-l` switches for external libraries linked into Greenplum Database.

`--version`
Print the version of Greenplum Database.

**Examples**
To reproduce the build configuration of the current Greenplum Database installation, run the following command:

```
 eval ./configure 'pg_config --configure'
```

The output of `pg_config --configure` contains shell quotation marks so arguments with spaces are represented correctly. Therefore, using `eval` is required for proper results.

**pg_dump**
Extracts a database into a single script file or other archive file.

**Synopsis**

```
pg_dump [connection-option ...] [dump_option ...] [dbname]
pg_dump -? | --help
pg_dump -V | --version
```

**Description**
`pg_dump` is a standard PostgreSQL utility for backing up a database, and is also supported in Greenplum Database. It creates a single (non-parallel) dump file. For routine backups of Greenplum Database, it is better to use the Greenplum Database backup utility, `gpbackup`, for the best performance.

Use `pg_dump` if you are migrating your data to another database vendor's system, or to another Greenplum Database system with a different segment configuration (for example, if the system you are migrating to has greater or fewer segment instances). To restore, you must use the corresponding `pg_restore` utility (if the dump file is in archive format), or you can use a client program such as `psql` (if the dump file is in plain text format).
Since `pg_dump` is compatible with regular PostgreSQL, it can be used to migrate data into Greenplum Database. The `pg_dump` utility in Greenplum Database is very similar to the PostgreSQL `pg_dump` utility, with the following exceptions and limitations:

- If using `pg_dump` to backup a Greenplum Database database, keep in mind that the dump operation can take a long time (several hours) for very large databases. Also, you must make sure you have sufficient disk space to create the dump file.
- If you are migrating data from one Greenplum Database system to another, use the `--gp-syntax` command-line option to include the `DISTRIBUTED BY` clause in `CREATE TABLE` statements. This ensures that Greenplum Database table data is distributed with the correct distribution key columns upon restore.

`pg_dump` makes consistent backups even if the database is being used concurrently. `pg_dump` does not block other users accessing the database (readers or writers).

When used with one of the archive file formats and combined with `pg_restore`, `pg_dump` provides a flexible archival and transfer mechanism. `pg_dump` can be used to backup an entire database, then `pg_restore` can be used to examine the archive and/or select which parts of the database are to be restored. The most flexible output file formats are the `custom` format (`-Fc`) and the `directory` format (`-Fd`). They allow for selection and reordering of all archived items, support parallel restoration, and are compressed by default. The `directory` format is the only format that supports parallel dumps.

### Options

**dbname**

Specifies the name of the database to be dumped. If this is not specified, the environment variable `PGDATABASE` is used. If that is not set, the user name specified for the connection is used.

**Dump Options**

- `-a | --data-only`

  Dump only the data, not the schema (data definitions). Table data and sequence values are dumped.

  This option is similar to, but for historical reasons not identical to, specifying `--section=data`.

- `-b | --blobs`

  Include large objects in the dump. This is the default behavior except when `--schema`, `--table`, or `--schema-only` is specified. The `-b` switch is only useful add large objects to dumps where a specific schema or table has been requested. Note that blobs are considered data and therefore will be included when `--data-only` is used, but not when `--schema-only` is.

  **Note:** Greenplum Database does not support the PostgreSQL large object facility for streaming user data that is stored in large-object structures.

- `-c | --clean`

  Adds commands to the text output file to clean (drop) database objects prior to outputting the commands for creating them. (Restore might generate some harmless error messages, if any objects were not present in the destination database.) Note that objects are not dropped before the dump operation begins, but `DROP` commands are added to the DDL dump output files so that when you use those files to do a restore, the `DROP` commands are run prior to the `CREATE` commands. This option is only meaningful for the plain-text format. For the archive formats, you may specify the option when you call `pg_restore`.

- `-C | --create`

  Begin the output with a command to create the database itself and reconnect to the created database. (With a script of this form, it doesn't matter which database in the destination installation you connect to before running the script.) If `--clean` is also
specified, the script drops and recreates the target database before reconnecting to it. This option is only meaningful for the plain-text format. For the archive formats, you may specify the option when you call `pg_restore`.

```bash
-E encoding | --encoding=encoding
```

Create the dump in the specified character set encoding. By default, the dump is created in the database encoding. (Another way to get the same result is to set the `PGCLIENTENCODING` environment variable to the desired dump encoding.)

```bash
-f file | --file=file
```

Send output to the specified file. This parameter can be omitted for file-based output formats, in which case the standard output is used. It must be given for the directory output format however, where it specifies the target directory instead of a file. In this case the directory is created by `pg_dump` and must not exist before.

```bash
-F p|c|d|t | --format=plain|custom|directory|tar
```

Selects the format of the output. format can be one of the following:

- `p` | plain — Output a plain-text SQL script file (the default).
- `c` | custom — Output a custom archive suitable for input into `pg_restore`. Together with the directory output format, this is the most flexible output format in that it allows manual selection and reordering of archived items during restore. This format is compressed by default and also supports parallel dumps.
- `d` | directory — Output a directory-format archive suitable for input into `pg_restore`. This will create a directory with one file for each table and blob being dumped, plus a so-called Table of Contents file describing the dumped objects in a machine-readable format that `pg_restore` can read. A directory format archive can be manipulated with standard Unix tools; for example, files in an uncompressed archive can be compressed with the `gzip` tool. This format is compressed by default.
- `t` | tar — Output a tar-format archive suitable for input into `pg_restore`. The tar format is compatible with the directory format; extracting a tar-format archive produces a valid directory-format archive. However, the tar format does not support compression. Also, when using tar format the relative order of table data items cannot be changed during restore.

```bash
-j njobs | --jobs=njobs
```

Run the dump in parallel by dumping `njobs` tables simultaneously. This option reduces the time of the dump but it also increases the load on the database server. You can only use this option with the directory output format because this is the only output format where multiple processes can write their data at the same time.

**Note:** Parallel dumps using `pg_dump` are parallelized only on the query dispatcher (master) node, not across the query executor (segment) nodes as is the case when you use `gpbackup`.

`pg_dump` will open `njobs` + 1 connections to the database, so make sure your `max_connections` setting is high enough to accommodate all connections.

Requesting exclusive locks on database objects while running a parallel dump could cause the dump to fail. The reason is that the `pg_dump` master process requests shared locks on the objects that the worker processes are going to dump later in order to make sure that nobody deletes them and makes them go away while the dump is running. If another client then requests an exclusive lock on a table, that lock will not be granted but will be queued waiting for the shared lock of the master process to be released. Consequently, any other access to the table will not be granted either and will queue after the exclusive lock request. This includes the worker process trying to dump the table. Without any precautions this would be a classic deadlock situation. To detect this conflict, the `pg_dump` worker process requests another shared lock using the `NOWAIT` option. If the worker
process is not granted this shared lock, somebody else must have requested an exclusive lock in the meantime and there is no way to continue with the dump, so *pg_dump* has no choice but to abort the dump.

For a consistent backup, the database server needs to support synchronized snapshots, a feature that was introduced in Greenplum Database 6.0. With this feature, database clients can ensure they see the same data set even though they use different connections. *pg_dump* -j uses multiple database connections; it connects to the database once with the master process and once again for each worker job. Without the synchronized snapshot feature, the different worker jobs wouldn't be guaranteed to see the same data in each connection, which could lead to an inconsistent backup.

If you want to run a parallel dump of a pre-6.0 server, you need to make sure that the database content doesn't change from between the time the master connects to the database until the last worker job has connected to the database. The easiest way to do this is to halt any data modifying processes (DDL and DML) accessing the database before starting the backup. You also need to specify the *--no-synchronized-snapshots* parameter when running *pg_dump* -j against a pre-6.0 Greenplum Database server.

`-n schema | --schema=schema`
Dump only schemas matching the schema pattern; this selects both the schema itself, and all its contained objects. When this option is not specified, all non-system schemas in the target database will be dumped. Multiple schemas can be selected by writing multiple -n switches. Also, the schema parameter is interpreted as a pattern according to the same rules used by *psql*'s `\d` commands, so multiple schemas can also be selected by writing wildcard characters in the pattern. When using wildcards, be careful to quote the pattern if needed to prevent the shell from expanding the wildcards.

Note: When -n is specified, *pg_dump* makes no attempt to dump any other database objects that the selected schema(s) may depend upon. Therefore, there is no guarantee that the results of a specific-schema dump can be successfully restored by themselves into a clean database.

**Note:** Non-schema objects such as blobs are not dumped when -n is specified. You can add blobs back to the dump with the *--blobs* switch.

`-N schema | --exclude-schema=schema`
Do not dump any schemas matching the schema pattern. The pattern is interpreted according to the same rules as for -n. -N can be given more than once to exclude schemas matching any of several patterns. When both -n and -N are given, the behavior is to dump just the schemas that match at least one -n switch but no -N switches. If -N appears without -n, then schemas matching -N are excluded from what is otherwise a normal dump.

`-o | --oids`
Dump object identifiers (OIDs) as part of the data for every table. Use of this option is not recommended for files that are intended to be restored into Greenplum Database.

`-O | --no-owner`
Do not output commands to set ownership of objects to match the original database. By default, *pg_dump* issues ALTER OWNER or SET SESSION AUTHORIZATION statements to set ownership of created database objects. These statements will fail when the script is run unless it is started by a superuser (or the same user that owns all of the objects in the script). To make a script that can be restored by any user, but will give that user ownership of all the objects, specify -O. This option is only meaningful for the plain-text format. For the archive formats, you may specify the option when you call *pg_restore*.

`-s | --schema-only`
Dump only the object definitions (schema), not data.
This option is the inverse of --data-only. It is similar to, but for historical reasons not identical to, specifying "--section=pre-data --section=post-data."

(Do not confuse this with the --schema option, which uses the word "schema" in a different meaning.)

To exclude table data for only a subset of tables in the database, see --exclude-table-data.

-S username | --superuser=username

Specify the superuser user name to use when disabling triggers. This is relevant only if --disable-triggers is used. It is better to leave this out, and instead start the resulting script as a superuser.

Note: Greenplum Database does not support user-defined triggers.

-t table | --table=table

Dump only tables (or views or sequences or foreign tables) matching the table pattern. Specify the table in the format schema.table.

Multiple tables can be selected by writing multiple -t switches. Also, the table parameter is interpreted as a pattern according to the same rules used by psql's \d commands, so multiple tables can also be selected by writing wildcard characters in the pattern.

When using wildcards, be careful to quote the pattern if needed to prevent the shell from expanding the wildcards. The -n and -N switches have no effect when -t is used, because tables selected by -t will be dumped regardless of those switches, and non-table objects will not be dumped.

Note: When -t is specified, pg_dump makes no attempt to dump any other database objects that the selected table(s) may depend upon. Therefore, there is no guarantee that the results of a specific-table dump can be successfully restored by themselves into a clean database.

Also, -t cannot be used to specify a child table partition. To dump a partitioned table, you must specify the parent table name.

-T table | --exclude-table=table

Do not dump any tables matching the table pattern. The pattern is interpreted according to the same rules as for -t. -T can be given more than once to exclude tables matching any of several patterns. When both -t and -T are given, the behavior is to dump just the tables that match at least one -t switch but no -T switches. If -T appears without -t, then tables matching -T are excluded from what is otherwise a normal dump.

-v | --verbose

Specifies verbose mode. This will cause pg_dump to output detailed object comments and start/stop times to the dump file, and progress messages to standard error.

-V | --version

Print the pg_dump version and exit.

-x | --no-privileges | --no-acl

Prevent dumping of access privileges (GRANT/REVOKE commands).

-Z 0..9 | --compress=0..9

Specify the compression level to use. Zero means no compression. For the custom archive format, this specifies compression of individual table-data segments, and the default is to compress at a moderate level.

For plain text output, setting a non-zero compression level causes the entire output file to be compressed, as though it had been fed through gzip; but the default is not to compress. The tar archive format currently does not support compression at all.

--binary-upgrade
This option is for use by in-place upgrade utilities. Its use for other purposes is not recommended or supported. The behavior of the option may change in future releases without notice.

**--column-inserts | --attribute-inserts**

Dump data as `INSERT` commands with explicit column names (``INSERT INTO table(column, ... ) VALUES ...``). This will make restoration very slow; it is mainly useful for making dumps that can be loaded into non-PostgreSQL-based databases. However, since this option generates a separate command for each row, an error in reloading a row causes only that row to be lost rather than the entire table contents.

**--disable-dollar-quoting**

This option disables the use of dollar quoting for function bodies, and forces them to be quoted using SQL standard string syntax.

**--disable-triggers**

This option is relevant only when creating a data-only dump. It instructs `pg_dump` to include commands to temporarily disable triggers on the target tables while the data is reloaded. Use this if you have triggers on the tables that you do not want to invoke during data reload. The commands emitted for `--disable-triggers` must be done as superuser. So, you should also specify a superuser name with `-S`, or preferably be careful to start the resulting script as a superuser. This option is only meaningful for the plain-text format. For the archive formats, you may specify the option when you call `pg_restore`.

**Note:** Greenplum Database does not support user-defined triggers.

**--exclude-table-data=table**

Do not dump data for any tables matching the `table` pattern. The pattern is interpreted according to the same rules as for `-t`. `--exclude-table-data` can be given more than once to exclude tables matching any of several patterns. This option is useful when you need the definition of a particular table even though you do not need the data in it.

To exclude data for all tables in the database, see `--schema-only`.

**--if-exists**

Use conditional commands (i.e. add an `IF EXISTS` clause) when cleaning database objects. This option is not valid unless `--clean` is also specified.

**--inserts**

Dump data as `INSERT` commands (rather than `COPY`). This will make restoration very slow; it is mainly useful for making dumps that can be loaded into non-PostgreSQL-based databases. However, since this option generates a separate command for each row, an error in reloading a row causes only that row to be lost rather than the entire table contents. Note that the restore may fail altogether if you have rearranged column order. The `--column-inserts` option is safe against column order changes, though even slower.

**--lock-wait-timeout=timeout**

Do not wait forever to acquire shared table locks at the beginning of the dump. Instead, fail if unable to lock a table within the specified `timeout`. Specify `timeout` as a number of milliseconds.

**--no-security-labels**

Do not dump security labels.

**--no-synchronized-snapshots**

This option allows running `pg_dump -j` against a pre-6.0 Greenplum Database server; see the documentation of the `-j` parameter for more details.

**--no-tablespaces**
Do not output commands to select tablespaces. With this option, all objects will be created in whichever tablespace is the default during restore.

This option is only meaningful for the plain-text format. For the archive formats, you can specify the option when you call `pg_restore`.

--no-unlogged-table-data
Do not dump the contents of unlogged tables. This option has no effect on whether or not the table definitions (schema) are dumped; it only suppresses dumping the table data. Data in unlogged tables is always excluded when dumping from a standby server.

--quote-all-identifiers
Force quoting of all identifiers. This option is recommended when dumping a database from a server whose Greenplum Database major version is different from `pg_dump`'s, or when the output is intended to be loaded into a server of a different major version. By default, `pg_dump` quotes only identifiers that are reserved words in its own major version. This sometimes results in compatibility issues when dealing with servers of other versions that may have slightly different sets of reserved words. Using `--quote-all-identifiers` prevents such issues, at the price of a harder-to-read dump script.

--section=sectionname
Only dump the named section. The section name can be `pre-data`, `data`, or `post-data`. This option can be specified more than once to select multiple sections. The default is to dump all sections.

The `data` section contains actual table data and sequence values. `post-data` items include definitions of indexes, triggers, rules, and constraints other than validated check constraints. `pre-data` items include all other data definition items.

--serialized-deferrable
Use a serializable transaction for the dump, to ensure that the snapshot used is consistent with later database states; but do this by waiting for a point in the transaction stream at which no anomalies can be present, so that there isn't a risk of the dump failing or causing other transactions to roll back with a serialization_failure.

This option is not beneficial for a dump which is intended only for disaster recovery. It could be useful for a dump used to load a copy of the database for reporting or other read-only load sharing while the original database continues to be updated. Without it the dump may reflect a state which is not consistent with any serial execution of the transactions eventually committed. For example, if batch processing techniques are used, a batch may show as closed in the dump without all of the items which are in the batch appearing.

This option will make no difference if there are no read-write transactions active when `pg_dump` is started. If read-write transactions are active, the start of the dump may be delayed for an indeterminate length of time. Once running, performance with or without the switch is the same.

Note: Because Greenplum Database does not support serializable transactions, the `--serialized-deferrable` option has no effect in Greenplum Database.

--use-set-session-authorization
Output SQL-standard `SET SESSION AUTHORIZATION` commands instead of `ALTER OWNER` commands to determine object ownership. This makes the dump more standards-compatible, but depending on the history of the objects in the dump, may not restore properly. A dump using `SET SESSION AUTHORIZATION` will require superuser privileges to restore correctly, whereas `ALTER OWNER` requires lesser privileges.

--gp-syntax | --no-gp-syntax
Use `--gp-syntax` to dump Greenplum Database syntax in the `CREATE TABLE` statements. This allows the distribution policy (DISTRIBUTED BY or DISTRIBUTED
RANDOMLY clauses) of a Greenplum Database table to be dumped, which is useful for restoring into other Greenplum Database systems. The default is to include Greenplum Database syntax when connected to a Greenplum Database system, and to exclude it when connected to a regular PostgreSQL system.

--function-oids oids
Dump the function(s) specified in the oids list of object identifiers.

Note: This option is provided solely for use by other administration utilities; its use for any other purpose is not recommended or supported. The behaviour of the option may change in future releases without notice.

--relation-oids oids
Dump the relation(s) specified in the oids list of object identifiers.

Note: This option is provided solely for use by other administration utilities; its use for any other purpose is not recommended or supported. The behaviour of the option may change in future releases without notice.

--function-oids oids
--relation-oids oids

-? | --help
Show help about pg_dump command line arguments, and exit.

Connection Options
-d dbname | --dbname=dbname
Specifies the name of the database to connect to. This is equivalent to specifying dbname as the first non-option argument on the command line.

If this parameter contains an = sign or starts with a valid URI prefix (postgresql:// or postgres://), it is treated as a conninfo string. See Connection Strings in the PostgreSQL documentation for more information.

-h host | --host=host
The host name of the machine on which the Greenplum Database master database server is running. If not specified, reads from the environment variable PGHOST or defaults to localhost.

-p port | --port=port
The TCP port on which the Greenplum Database master database server is listening for connections. If not specified, reads from the environment variable PGPORT or defaults to 5432.

-U username | --username=username
The database role name to connect as. If not specified, reads from the environment variable PGUSER or defaults to the current system role name.

-W | --password
Force a password prompt.

-w | --no-password
Never issue a password prompt. If the server requires password authentication and a password is not available by other means such as a .pgpass file the connection attempt will fail. This option can be useful in batch jobs and scripts where no user is present to enter a password.

--role=rolename
Specifies a role name to be used to create the dump. This option causes pg_dump to issue a SET ROLE rolename command after connecting to the database. It is useful when the authenticated user (specified by -U) lacks privileges needed by pg_dump, but can switch to a role with the required rights. Some installations have a policy against logging in directly as a superuser, and use of this option allows dumps to be made without violating the policy.
Notes

When a data-only dump is chosen and the option `--disable-triggers` is used, `pg_dump` emits commands to disable triggers on user tables before inserting the data and commands to re-enable them after the data has been inserted. If the restore is stopped in the middle, the system catalogs may be left in the wrong state.

The dump file produced by `pg_dump` does not contain the statistics used by the optimizer to make query planning decisions. Therefore, it is wise to run `ANALYZE` after restoring from a dump file to ensure optimal performance.

The database activity of `pg_dump` is normally collected by the statistics collector. If this is undesirable, you can set parameter `track_counts` to false via `PGOPTIONS` or the `ALTER USER` command.

Because `pg_dump` may be used to transfer data to newer versions of Greenplum Database, the output of `pg_dump` can be expected to load into Greenplum Database versions newer than `pg_dump`'s version. `pg_dump` can also dump from Greenplum Database versions older than its own version. However, `pg_dump` cannot dump from Greenplum Database versions newer than its own major version; it will refuse to even try, rather than risk making an invalid dump. Also, it is not guaranteed that `pg_dump`'s output can be loaded into a server of an older major version — not even if the dump was taken from a server of that version. Loading a dump file into an older server may require manual editing of the dump file to remove syntax not understood by the older server. Use of the `--quote-all-identifiers` option is recommended in cross-version cases, as it can prevent problems arising from varying reserved-word lists in different Greenplum Database versions.

Examples

Dump a database called `mydb` into a SQL-script file:

```
pg_dump mydb > db.sql
```

To reload such a script into a (freshly created) database named `newdb`:

```
psql -d newdb -f db.sql
```

Dump a Greenplum Database in tar file format and include distribution policy information:

```
pg_dump -Ft --gp-syntax mydb > db.tar
```

To dump a database into a custom-format archive file:

```
pg_dump -Fc mydb > db.dump
```

To dump a database into a directory-format archive:

```
pg_dump -Fd mydb -f dumpdir
```

To dump a database into a directory-format archive in parallel with 5 worker jobs:

```
pg_dump -Fd mydb -j 5 -f dumpdir
```

To reload an archive file into a (freshly created) database named `newdb`:

```
pg_restore -d newdb db.dump
```

To dump a single table named `mytab`:

```
pg_dump -t mytab mydb > db.sql
```
To specify an upper-case or mixed-case name in `-t` and related switches, you need to double-quote the name; else it will be folded to lower case. But double quotes are special to the shell, so in turn they must be quoted. Thus, to dump a single table with a mixed-case name, you need something like:

```bash
pg_dump -t "'MixedCaseName'" mydb > mytab.sql
```

`pg_dumpall`, `pg_restore`, `psql`

### pg_dumpall

Extracts all databases in a Greenplum Database system to a single script file or other archive file.

#### Synopsis

```
pg_dumpall [connection-option ...] [dump_option ...]
pd_dumpall -? | --help
pg_dumpall -V | --version
```

#### Description

`pg_dumpall` is a standard PostgreSQL utility for backing up all databases in a Greenplum Database (or PostgreSQL) instance, and is also supported in Greenplum Database. It creates a single (non-parallel) dump file. For routine backups of Greenplum Database it is better to use the Greenplum Database backup utility, `gpbackup`, for the best performance.

`pg_dumpall` creates a single script file that contains SQL commands that can be used as input to `psql` to restore the databases. It does this by calling `pg_dump` for each database. `pg_dumpall` also dumps global objects that are common to all databases. (`pg_dump` does not save these objects.) This currently includes information about database users and groups, and access permissions that apply to databases as a whole.

Since `pg_dumpall` reads tables from all databases you will most likely have to connect as a database superuser in order to produce a complete dump. Also you will need superuser privileges to execute the saved script in order to be allowed to add users and groups, and to create databases.

The SQL script will be written to the standard output. Use the `[-f | --file]` option or shell operators to redirect it into a file.

`pg_dumpall` needs to connect several times to the Greenplum Database master server (once per database). If you use password authentication it is likely to ask for a password each time. It is convenient to have a `~/.pgpass` file in such cases.

#### Options

**Dump Options**

- `-a | --data-only`
  
  Dump only the data, not the schema (data definitions). This option is only meaningful for the plain-text format. For the archive formats, you may specify the option when you call `pg_restore`.

- `-c | --clean`
  
  Output commands to clean (drop) database objects prior to (the commands for) creating them. This option is only meaningful for the plain-text format. For the archive formats, you may specify the option when you call `pg_restore`.

- `-f filename | --file=filename`
Send output to the specified file.

-g | --globals-only
   Dump only global objects (roles and tablespaces), no databases.

-o | --oids
   Dump object identifiers (OIDs) as part of the data for every table. Use of this option is not recommended for files that are intended to be restored into Greenplum Database.

-O | --no-owner
   Do not output commands to set ownership of objects to match the original database. By default, `pg_dump` issues `ALTER OWNER` or `SET SESSION AUTHORIZATION` statements to set ownership of created database objects. These statements will fail when the script is run unless it is started by a superuser (or the same user that owns all of the objects in the script). To make a script that can be restored by any user, but will give that user ownership of all the objects, specify `-O`. This option is only meaningful for the plain-text format. For the archive formats, you may specify the option when you call `pg_restore`.

-r | --roles-only
   Dump only roles, not databases or tablespaces.

-s | --schema-only
   Dump only the object definitions (schema), not data.

-S username | --superuser=username
   Specify the superuser user name to use when disabling triggers. This is relevant only if `--disable-triggers` is used. It is better to leave this out, and instead start the resulting script as a superuser.

   Note: Greenplum Database does not support user-defined triggers.

-t | --tablespaces-only
   Dump only tablespaces, not databases or roles.

-v | --verbose
   Specifies verbose mode. This will cause `pg_dump` to output detailed object comments and start/stop times to the dump file, and progress messages to standard error.

-V | --version
   Print the `pg_dumpall` version and exit.

-x | --no-privileges | --no-acl
   Prevent dumping of access privileges (GRANT/REVOKE commands).

--binary-upgrade
   This option is for use by in-place upgrade utilities. Its use for other purposes is not recommended or supported. The behavior of the option may change in future releases without notice.

--column-inserts | --attribute-inserts
   Dump data as `INSERT` commands with explicit column names (`INSERT INTO table (column, ...) VALUES ...`). This will make restoration very slow; it is mainly useful for making dumps that can be loaded into non-PostgreSQL-based databases. Also, since this option generates a separate command for each row, an error in reloading a row causes only that row to be lost rather than the entire table contents.

--disable-dollar-quoting
   This option disables the use of dollar quoting for function bodies, and forces them to be quoted using SQL standard string syntax.

--disable-triggers
This option is relevant only when creating a data-only dump. It instructs `pg_dumpall` to include commands to temporarily disable triggers on the target tables while the data is reloaded. Use this if you have triggers on the tables that you do not want to invoke during data reload. The commands emitted for `--disable-triggers` must be done as superuser. So, you should also specify a superuser name with `-S`, or preferably be careful to start the resulting script as a superuser.

**Note:** Greenplum Database does not support user-defined triggers.

`--inserts`
Dump data as `INSERT` commands (rather than `COPY`). This will make restoration very slow; it is mainly useful for making dumps that can be loaded into non-PostgreSQL-based databases. Also, since this option generates a separate command for each row, an error in reloading a row causes only that row to be lost rather than the entire table contents. Note that the restore may fail altogether if you have rearranged column order. The `--column-inserts` option is safe against column order changes, though even slower.

`--lock-wait-timeout=timeout`
Do not wait forever to acquire shared table locks at the beginning of the dump. Instead, fail if unable to lock a table within the specified `timeout`. The timeout may be specified in any of the formats accepted by `SET statement_timeout`. Allowed values vary depending on the server version you are dumping from, but an integer number of milliseconds is accepted by all Greenplum Database versions.

`--no-security-labels`
Do not dump security labels.

`--no-tablespaces`
Do not output commands to select tablespaces. With this option, all objects will be created in whichever tablespace is the default during restore.

`--no-unlogged-table-data`
Do not dump the contents of unlogged tables. This option has no effect on whether or not the table definitions (schema) are dumped; it only suppresses dumping the table data.

`--quote-all-identifiers`
Force quoting of all identifiers. This option is recommended when dumping a database from a server whose Greenplum Database major version is different from `pg_dumpall`'s, or when the output is intended to be loaded into a server of a different major version. By default, `pg_dumpall` quotes only identifiers that are reserved words in its own major version. This sometimes results in compatibility issues when dealing with servers of other versions that may have slightly different sets of reserved words. Using `--quote-all-identifiers` prevents such issues, at the price of a harder-to-read dump script.

`--resource-queues`
Dump resource queue definitions.

`--resource-groups`
Dump resource group definitions.

`--use-set-session-authorization`
Output SQL-standard `SET SESSION AUTHORIZATION` commands instead of `ALTER OWNER` commands to determine object ownership. This makes the dump more standards compatible, but depending on the history of the objects in the dump, may not restore properly. A dump using `SET SESSION AUTHORIZATION` will require superuser privileges to restore correctly, whereas `ALTER OWNER` requires lesser privileges.

`--gp-syntax`
Output Greenplum Database syntax in the `CREATE TABLE` statements. This allows the distribution policy (`DISTRIBUTED BY` or `DISTRIBUTED RANDOMLY` clauses) of
a Greenplum Database table to be dumped, which is useful for restoring into other
Greenplum Database systems.

--no-gp-syntax
Do not output the table distribution clauses in the CREATE TABLE statements.

-? | --help
Show help about pg_dumpall command line arguments, and exit.

Connection Options

-d connstr | --dbname=connstr
Specifies parameters used to connect to the server, as a connection string. See
Connection Strings in the PostgreSQL documentation for more information.

The option is called --dbname for consistency with other client applications, but because
pg_dumpall needs to connect to many databases, the database name in the connection
string will be ignored. Use the -l option to specify the name of the database used to dump
global objects and to discover what other databases should be dumped.

-h host | --host=host
The host name of the machine on which the Greenplum master database server is
running. If not specified, reads from the environment variable PGHOST or defaults to
localhost.

-l dbname | --database=dbname
Specifies the name of the database in which to connect to dump global objects. If not
specified, the postgres database is used. If the postgres database does not exist, the
template1 database is used.

-p port | --port=port
The TCP port on which the Greenplum master database server is listening for connections.
If not specified, reads from the environment variable PGPORT or defaults to 5432.

-U username | --username= username
The database role name to connect as. If not specified, reads from the environment
variable PGUSER or defaults to the current system role name.

-w | --no-password
Never issue a password prompt. If the server requires password authentication and a
password is not available by other means such as a .pgpass file the connection attempt
will fail. This option can be useful in batch jobs and scripts where no user is present to
enter a password.

-W | --password
Force a password prompt.

--role=rolename
Specifies a role name to be used to create the dump. This option causes pg_dumpall
to issue a SET ROLE rolename command after connecting to the database. It is useful
when the authenticated user (specified by -U) lacks privileges needed by pg_dumpall,
but can switch to a role with the required rights. Some installations have a policy against
logging in directly as a superuser, and use of this option allows dumps to be made without
violating the policy.

Notes
Since pg_dumpall calls pg_dump internally, some diagnostic messages will refer to pg_dump.

Once restored, it is wise to run ANALYZE on each database so the query planner has useful statistics. You
can also run vacuumdb -a -z to analyze all databases.
pg_dumpall requires all needed tablespace directories to exist before the restore; otherwise, database creation will fail for databases in non-default locations.

Examples
To dump all databases:

```bash
pg_dumpall > db.out
```
To reload database(s) from this file, you can use:

```bash
psql template1 -f db.out
```
To dump only global objects (including resource queues):

```bash
pg_dumpall -g --resource-queues
```

See Also

`pg_dump`

**pg_restore**

Restores a database from an archive file created by `pg_dump`.

Synopsis

```bash
pg_restore [connection-option ...] [restore_option ...] filename
pg_restore -? | --help
pg_restore -V | --version
```

Description

`pg_restore` is a utility for restoring a database from an archive created by `pg_dump` in one of the non-plain-text formats. It will issue the commands necessary to reconstruct the database to the state it was in at the time it was saved. The archive files also allow `pg_restore` to be selective about what is restored, or even to reorder the items prior to being restored.

`pg_restore` can operate in two modes. If a database name is specified, the archive is restored directly into the database. Otherwise, a script containing the SQL commands necessary to rebuild the database is created and written to a file or standard output. The script output is equivalent to the plain text output format of `pg_dump`. Some of the options controlling the output are therefore analogous to `pg_dump` options.

`pg_restore` cannot restore information that is not present in the archive file. For instance, if the archive was made using the "dump data as INSERT commands" option, `pg_restore` will not be able to load the data using `COPY` statements.

Options

**filename**

Specifies the location of the archive file (or directory, for a directory-format archive) to be restored. If not specified, the standard input is used.

**Restore Options**

- `-a` | `--data-only`
Restore only the data, not the schema (data definitions). Table data and sequence values are restored, if present in the archive.

This option is similar to, but for historical reasons not identical to, specifying --
section=data.

- c  | --clean
Clean (drop) database objects before recreating them. (This might generate some harmless error messages, if any objects were not present in the destination database.)

- C  | --create
Create the database before restoring into it. If --clean is also specified, drop and recreate the target database before connecting to it.

When this option is used, the database named with -d is used only to issue the initial DROP DATABASE and CREATE DATABASE commands. All data is restored into the database name that appears in the archive.

- d dbname  | --dbname=dbname
Connect to this database and restore directly into this database. This utility, like most other Greenplum Database utilities, also uses the environment variables supported by libpq. However it does not read PGDATABASE when a database name is not supplied.

- e  | --exit-on-error
Exit if an error is encountered while sending SQL commands to the database. The default is to continue and to display a count of errors at the end of the restoration.

- f outfilename  | --file=outfilename
Specify output file for generated script, or for the listing when used with -1. Default is the standard output.

- F c|d|t  | --format={custom | directory | tar}
The format of the archive produced by pg_dump. It is not necessary to specify the format, since pg_restore will determine the format automatically. Format can be custom, directory, or tar.

- I index  | --index=index
Restore definition of named index only.

- j  | --number-of-jobs | --jobs=number-of-jobs
Run the most time-consuming parts of pg_restore — those which load data, create indexes, or create constraints — using multiple concurrent jobs. This option can dramatically reduce the time to restore a large database to a server running on a multiprocessor machine.

Each job is one process or one thread, depending on the operating system, and uses a separate connection to the server.

The optimal value for this option depends on the hardware setup of the server, of the client, and of the network. Factors include the number of CPU cores and the disk setup. A good place to start is the number of CPU cores on the server, but values larger than that can also lead to faster restore times in many cases. Of course, values that are too high will lead to decreased performance because of thrashing.

Only the custom archive format is supported with this option. The input file must be a regular file (not, for example, a pipe). This option is ignored when emitting a script rather than connecting directly to a database server. Also, multiple jobs cannot be used together with the option --single-transaction.

- l  | --list
List the contents of the archive. The output of this operation can be used with the -l option to restrict and reorder the items that are restored.
-L list-file | --use-list=list-file
  Restore elements in the list-file only, and in the order they appear in the file. Note that if filtering switches such as -n or -t are used with -L, they will further restrict the items restored.

  list-file is normally created by editing the output of a previous -l operation. Lines can be moved or removed, and can also be commented out by placing a semicolon (;) at the start of the line. See below for examples.

-n schema | --schema=schema
  Restore only objects that are in the named schema. This can be combined with the -t option to restore just a specific table.

-O | --no-owner
  Do not output commands to set ownership of objects to match the original database. By default, pg_restore issues ALTER OWNER or SET SESSION AUTHORIZATION statements to set ownership of created schema elements. These statements will fail unless the initial connection to the database is made by a superuser (or the same user that owns all of the objects in the script). With -O, any user name can be used for the initial connection, and this user will own all the created objects.

-P 'function-name(argtype [, ...])' | --function='function-name(argtype [, ...])'
  Restore the named function only. The function name must be enclosed in quotes. Be careful to spell the function name and arguments exactly as they appear in the dump file’s table of contents (as shown by the --list option).

-s | --schema-only
  Restore only the schema (data definitions), not data, to the extent that schema entries are present in the archive.

  This option is the inverse of --data-only. It is similar to, but for historical reasons not identical to, specifying --section=pre-data --section=post-data.

  (Do not confuse this with the --schema option, which uses the word “schema” in a different meaning.)

-S username | --superuser=username
  Specify the superuser user name to use when disabling triggers. This is only relevant if --disable-triggers is used.

  Note: Greenplum Database does not support user-defined triggers.

-t table | --table=table
  Restore definition and/or data of named table only. Multiple tables may be specified with multiple -t switches. This can be combined with the -n option to specify a schema.

-T trigger | --trigger=trigger
  Restore named trigger only.

  Note: Greenplum Database does not support user-defined triggers.

-v | --verbose
  Specifies verbose mode.

-V | --version
  Print the pg_restore version and exit.

-x | --no-privileges | --no-acl
  Prevent restoration of access privileges (GRANT/REVOKE commands).

-1 | --single-transaction
Execute the restore as a single transaction. This ensures that either all the commands complete successfully, or no changes are applied.

`--disable-triggers`

This option is relevant only when performing a data-only restore. It instructs `pg_restore` to execute commands to temporarily disable triggers on the target tables while the data is reloaded. Use this if you have triggers on the tables that you do not want to invoke during data reload. The commands emitted for `--disable-triggers` must be done as superuser. So you should also specify a superuser name with `-S` or, preferably, run `pg_restore` as a superuser.

**Note:** Greenplum Database does not support user-defined triggers.

`--no-data-for-failed-tables`

By default, table data is restored even if the creation command for the table failed (e.g., because it already exists). With this option, data for such a table is skipped. This behavior is useful when the target database may already contain the desired table contents.

Specifying this option prevents duplicate or obsolete data from being loaded. This option is effective only when restoring directly into a database, not when producing SQL script output.

`--no-security-labels`

Do not output commands to restore security labels, even if the archive contains them.

`--no-tablespaces`

Do not output commands to select tablespaces. With this option, all objects will be created in whichever tablespace is the default during restore.

`--section=sectionname`

Only restore the named section. The section name can be `pre-data`, `data`, or `post-data`. This option can be specified more than once to select multiple sections.

The default is to restore all sections.

`--use-set-session-authorization`

Output SQL-standard `SET SESSION AUTHORIZATION` commands instead of `ALTER OWNER` commands to determine object ownership. This makes the dump more standards-compatible, but depending on the history of the objects in the dump, it might not restore properly.

`-? | --help`

Show help about `pg_restore` command line arguments, and exit.

**Connection Options**

`-h host | --host host`

The host name of the machine on which the Greenplum master database server is running. If not specified, reads from the environment variable `PGHOST` or defaults to localhost.

`-p port | --port port`

The TCP port on which the Greenplum Database master database server is listening for connections. If not specified, reads from the environment variable `PGPORT` or defaults to 5432.

`-U username | --username username`

The database role name to connect as. If not specified, reads from the environment variable `PGUSER` or defaults to the current system role name.

`-w | --no-password`

Never issue a password prompt. If the server requires password authentication and a password is not available by other means such as a `.pgpass` file the connection attempt
will fail. This option can be useful in batch jobs and scripts where no user is present to enter a password.

-\texttt{W} | \texttt{--password}

Force a password prompt.

\texttt{--role=rolename}

Specifies a role name to be used to perform the restore. This option causes \texttt{pg_restore} to issue a SET ROLE \texttt{rolename} command after connecting to the database. It is useful when the authenticated user (specified by \texttt{-U}) lacks privileges needed by \texttt{pg_restore}, but can switch to a role with the required rights. Some installations have a policy against logging in directly as a superuser, and use of this option allows restores to be performed without violating the policy.

**Notes**

If your installation has any local additions to the \texttt{template1} database, be careful to load the output of \texttt{pg_restore} into a truly empty database; otherwise you are likely to get errors due to duplicate definitions of the added objects. To make an empty database without any local additions, copy from \texttt{template0} not \texttt{template1}, for example:

```
CREATE DATABASE foo WITH TEMPLATE template0;
```

When restoring data to a pre-existing table and the option \texttt{--disable-triggers} is used, \texttt{pg_restore} emits commands to disable triggers on user tables before inserting the data, then emits commands to re-enable them after the data has been inserted. If the restore is stopped in the middle, the system catalogs may be left in the wrong state.

See also the \texttt{pg_dump} documentation for details on limitations of \texttt{pg_dump}.

Once restored, it is wise to run \texttt{ANALYZE} on each restored table so the query planner has useful statistics.

**Examples**

Assume we have dumped a database called \texttt{mydb} into a custom-format dump file:

```
pg_dump -Fc mydb > db.dump
```

To drop the database and recreate it from the dump:

```
dropdb mydb
go_restore -C -d template1 db.dump
```

To reload the dump into a new database called \texttt{newdb}. Notice there is no \texttt{--disable-triggers} is used, \texttt{pg_restore} emits commands to disable triggers on user tables before inserting the data, then emits commands to re-enable them after the data has been inserted. If the restore is stopped in the middle, the system catalogs may be left in the wrong state.

```
createdb -T template0 newdb
go_restore -d newdb db.dump
```

To reorder database items, it is first necessary to dump the table of contents of the archive:

```
go_restore -l db.dump > db.list
```

The listing file consists of a header and one line for each item, for example,

```
; Archive created at Mon Sep 14 13:55:39 2009
;   dbname: DBDEMONS
;   TOC Entries: 81
;   Compression: 9
```
Semicolons start a comment, and the numbers at the start of lines refer to the internal archive ID assigned to each item. Lines in the file can be commented out, deleted, and reordered. For example:

```
10; 145433 TABLE map_resolutions postgres
;2; 145344 TABLE species postgres
;4; 145359 TABLE nt_header postgres
6; 145402 TABLE species_records postgres
;8; 145416 TABLE ss_old postgres
```

Could be used as input to `pg_restore` and would only restore items 10 and 6, in that order:

```
pg_restore -L db.list db.dump
```

```

**Description**

PgBouncer is a light-weight connection pool manager for Greenplum and PostgreSQL databases. PgBouncer maintains a pool of connections for each database user and database combination. PgBouncer either creates a new database connection for the client or reuses an existing pooled connection for the same user and database. When the client disconnects, PgBouncer returns the connection to the pool for re-use.
PgBouncer supports the standard connection interface shared by PostgreSQL and Greenplum Database. The Greenplum Database client application (for example, psql) should connect to the host and port on which PgBouncer is running rather than directly to the Greenplum Database master host and port.

You configure PgBouncer and its access to Greenplum Database via a configuration file. You provide the configuration file name, usually pgbouncer.ini, when you run the pgbouncer command. This file provides location information for Greenplum databases. The pgbouncer.ini file also specifies process, connection pool, authorized users, and authentication configuration for PgBouncer, among other configuration options.

By default, the pgbouncer process runs as a foreground process. You can optionally start pgbouncer as a background (daemon) process with the –d option.

The pgbouncer process is owned by the operating system user that starts the process. You can optionally specify a different user name under which to start pgbouncer.

PgBouncer includes a psql-like administration console. Authorized users can connect to a virtual database to monitor and manage PgBouncer. You can manage a PgBouncer daemon process via the admin console. You can also use the console to update and reload the PgBouncer configuration at runtime without stopping and restarting the process.

For additional information about PgBouncer, refer to the PgBouncer FAQ.

**Options**

- **-d | --daemon**
  Run PgBouncer as a daemon (a background process). The default start-up mode is to run as a foreground process.

  When run as a daemon, PgBouncer displays start-up messages to stdout. To suppress the display of these messages, include the –q option when you start PgBouncer.

  To stop a PgBouncer process that was started as a daemon, issue the SHUTDOWN command from the PgBouncer administration console.

- **-R | --restart**
  Restart PgBouncer using the specified command line arguments. Non-TLS connections to databases are maintained during restart; TLS connections are dropped.

  To restart PgBouncer as a daemon, specify the options –Rd.

  Note: Restart is available only if the operating system supports Unix sockets and the PgBouncer unix_socket_dir configuration is not disabled.

- **-q | --quiet**
  Run quietly. Do not display messages to stdout.

- **-v | --verbose**
  Increase message verbosity. Can be specified multiple times.

- **{-u | --user}=username**
  Assume the identity of username on PgBouncer process start-up.

- **-V | --version**
  Show the version and exit.

- **-h | --help**
  Show the command help message and exit.

**See Also**

pgbouncer.ini, pgbouncer-admin
**pgbouncer.ini**

PgBouncer configuration file.

**Synopsis**

```ini
[databases]
db = ...

[pgbouncer]
...

[users]
...
```

**Description**

You specify PgBouncer configuration parameters and identify user-specific configuration parameters in the `pgbouncer.ini` configuration file.

The PgBouncer configuration file (typically named `pgbouncer.ini`) is specified in `.ini` format. Files in `.ini` format are composed of sections, parameters, and values. Section names are enclosed in square brackets, for example, `[section_name]`. Parameters and values are specified in `key=value` format. Lines beginning with a semicolon (`;`) or pound sign (`#`) are considered comment lines and are ignored.

The PgBouncer configuration file can contain `%include` directives, which specify another file to read and process. This enables you to split the configuration file into separate parts. For example:

```
%include filename
```

If the filename provided is not an absolute path, the file system location is taken as relative to the current working directory.

The PgBouncer configuration file includes the following sections, described in detail below:

- **[databases] Section**
- **[pgbouncer] Section**
- **[users] Section**

**[databases] Section**

The `[databases]` section contains `key=value` pairs, where the `key` is a database name and the `value` is a `libpq` connect-string list of `key=value` pairs.

A database name can contain characters `[0-9A-Za-z_.-]` without quoting. Names that contain other characters must be quoted with standard SQL identifier quoting:

- Enclose names in double quotes (`" "`).
- Represent a double-quote within an identifier with two consecutive double quote characters.

The database name `*` is the fallback database. PgBouncer uses the value for this key as a connect string for the requested database. Automatically-created database entries such as these are cleaned up if they remain idle longer than the time specified in `autodb_idle_timeout` parameter.

**Database Connection Parameters**

The following parameters may be included in the `value` to specify the location of the database.

- `dbname`
The destination database name.
Default: the client-specified database name

host
The name or IP address of the Greenplum master host. Host names are resolved at
connect time. If DNS returns several results, they are used in a round-robin manner. The
DNS result is cached and the dns_max_ttl parameter determines when the cache entry
expires.
Default: not set; the connection is made through a Unix socket

port
The Greenplum Database master port.
Default: 5432

user, password
If user= is set, all connections to the destination database are initiated as the specified
user, resulting in a single connection pool for the database.
If the user= parameter is not set, PgBouncer attempts to log in to the destination
database with the user name passed by the client. In this situation, there will be one pool
for each user who connects to the database.

auth_user
If auth_user is set, any user who is not specified in auth_file is authenticated
by querying the pg_shadow database view. PgBouncer performs this query as the
auth_user Greenplum Database user. auth_user's password must be set in the
auth_file.

client_encoding
Ask for specific client_encoding from server.

datestyle
Ask for specific datestyle from server.

timezone
Ask for specific timezone from server.

Pool Configuration
You can use the following parameters for database-specific pool configuration.

pool_size
Set the maximum size of pools for this database. If not set, the default_pool_size is
used.

connect_query
Query to be executed after a connection is established, but before allowing the connection
to be used by any clients. If the query raises errors, they are logged but ignored otherwise.

pool_mode
Set the pool mode for this database. If not set, the default pool_mode is used.

max_db_connections
Set a database-wide maximum number of PgBouncer connections for this database. The
total number of connections for all pools for this database will not exceed this value.
[pgbouncer] Section

**Generic Settings**

**logfile**

The location of the log file. The log file is kept open. After log rotation, execute `kill -HUP pgbouncer` or run the `RELOAD;` command in the PgBouncer Administration Console.

Default: not set

**pidfile**

The name of the pid file. Without a pidfile, you cannot run PgBouncer as a background (daemon) process.

Default: not set

**listen_addr**

A list of interface addresses where PgBouncer listens for TCP connections. You may also use `*`, which means to listen on all interfaces. If not set, only Unix socket connections are allowed.

Specify addresses numerically (IPv4/IPv6) or by name.

Default: not set

**listen_port**

The port PgBouncer listens on. Applies to both TCP and Unix sockets.

Default: 6432

**unix_socket_dir**

Specifies the location for the Unix sockets. Applies to both listening socket and server connections. If set to an empty string, Unix sockets are disabled. Required for online restart (`-R` option) to work.

Default: `/tmp`

**unix_socket_mode**

Filesystem mode for the Unix socket.

Default: 0777

**unix_socket_group**

Group name to use for Unix socket.

Default: not set

**user**

If set, specifies the Unix user to change to after startup. This works only if PgBouncer is started as root or if `user` is the same as the current user.

Default: not set

**auth_file**

The name of the file containing the user names and passwords to load. The file format is the same as the Greenplum Database `pg_auth_file`.

Default: not set

**auth_hba_file**
HBA configuration file to use when auth_type is hba. Refer to the HBA file format discussion in the PgBouncer documentation for information about PgBouncer support of the HBA authentication file format.

Default: not set

auth_type

How to authenticate users.

pam

Use PAM to authenticate users. auth_file is ignored. This method is not compatible with databases using the auth_user option. The service name reported to PAM is "pgbouncer". PAM is not supported in the HBA configuration file.

hba

The actual authentication type is loaded from the auth_hba_file. This setting allows different authentication methods different access paths.

cert

Clients must connect with TLS using a valid client certificate. The client's username is taken from CommonName field in the certificate.

md5

Use MD5-based password check. auth_file may contain both MD5-encrypted or plain-text passwords. This is the default authentication method.

plain

Clear-text password is sent over wire. Deprecated.

trust

No authentication is performed. The username must still exist in the auth_file.

any

Like the trust method, but the username supplied is ignored. Requires that all databases are configured to log in with a specific user. Additionally, the console database allows any user to log in as admin.

auth_query

Query to load a user's password from the database. If a user does not exist in the auth_file and the database entry includes an auth_user, this query is run in the database as auth_user to lookup up the user.

Note that the query is run inside target database, so if a function is used it needs to be installed into each database.

Default: SELECT usename, passwd FROM pg_shadow WHERE usename=$1

auth_user

If auth_user is set, any user who is not specified in auth_file is authenticated through the auth_query query from the pg_shadow database view. PgBouncer performs this query as the auth_user Greenplum Database user. auth_user's password must be set in the auth_file.

Direct access to pg_shadow requires Greenplum Database administrative privileges. It is preferable to use a non-admin user that calls SECURITY DEFINER function instead.

pool_mode

Specifies when a server connection can be reused by other clients.

session

Connection is returned to the pool when the client disconnects. Default.

transaction
Connection is returned to the pool when the transaction finishes.

**statement**

Connection is returned to the pool when the current query finishes. Long transactions with multiple statements are disallowed in this mode.

**max_client_conn**

Maximum number of client connections allowed. When increased, you should also increase the file descriptor limits. The actual number of file descriptors used is more than `max_client_conn`. The theoretical maximum used, when each user connects with its own username to the server is:

```
max_client_conn + (max_pool_size * total_databases * total_users)
```

If a database user is specified in the connect string, all users connect using the same username. Then the theoretical maximum connections is:

```
max_client_conn + (max_pool_size * total_databases)
```

(The theoretical maximum should be never reached, unless someone deliberately crafts a load for it. Still, it means you should set the number of file descriptors to a safely high number. Search for `ulimit` in your operating system documentation.)

Default: 100

**default_pool_size**

The number of server connections to allow per user/database pair. This can be overridden in the per-database configuration.

Default: 20

**min_pool_size**

Add more server connections to the pool when it is lower than this number. This improves behavior when the usual load drops and then returns suddenly after a period of total inactivity.

Default: 0 (disabled)

**reserve_pool_size**

The number of additional connections to allow for a pool. 0 disables.

Default: 0 (disabled)

**reserve_pool_timeout**

If a client has not been serviced in this many seconds, PgBouncer enables use of additional connections from the reserve pool. 0 disables.

Default: 5.0

**max_db_connections**

The maximum number of connections per database. If you hit the limit, closing a client connection to one pool does not immediately allow a server connection to be established for another pool, because the server connection for the first pool is still open. Once the server connection closes (due to idle timeout), a new server connection will be opened for the waiting pool.

Default: unlimited

**max_user_connections**

The maximum number of connections per-user. When you hit the limit, closing a client connection to one pool does not immediately allow a connection to be established for
another pool, because the connection for the first pool is still open. After the connection for
the first pool has closed (due to idle timeout), a new server connection is opened for the
waiting pool.

**server_round_robin**

By default, PgBouncer reuses server connections in LIFO (last-in, first-out) order, so that
a few connections get the most load. This provides the best performance when a single
server serves a database. But if there is TCP round-robin behind a database IP, then it is
better if PgBouncer also uses connections in that manner to achieve uniform load.
Default: 0

**ignore_startup_parameters**

By default, PgBouncer allows only parameters it can keep track of in startup packets:
`client_encoding`, `datestyle`, `timezone`, and `standard_conforming_strings`.

All others parameters raise an error. To allow other parameters, specify them here so that
PgBouncer can ignore them.
Default: empty

**disable_pqexec**

Disable Simple Query protocol (PQexec). Unlike Extended Query protocol, Simple Query
protocol allows multiple queries in one packet, which allows some classes of SQL-injection
attacks. Disabling it can improve security. This means that only clients that exclusively use
Extended Query protocol will work.
Default: 0

**application_name_add_host**

Add the client host address and port to the application name setting set on connection
start. This helps in identifying the source of bad queries. The setting is overwritten without
detection if the application executes `SET application_name` after connecting.
Default: 0

**conffile**

Show location of the current configuration file. Changing this parameter will result in
PgBouncer using another config file for next RELOAD / SIGHUP.
Default: file from command line

**service_name**

Used during win32 service registration.
Default: pgbouncer

**job_name**

Alias for `service_name`.

**Log Settings**

**syslog**

Toggles syslog on and off.
Default: 0

**syslog_ident**

Under what name to send logs to syslog.
Default: pgbouncer

**syslog_facility**
Under what facility to send logs to syslog. Some possibilities are: auth, authpriv, daemon, user, local0-7

Default: daemon

**log_connections**
Log successful logins.
Default: 1
